## INTRODUCTION

In 1987, the Arizona Game and Fish Department (AGFD) began to monitor fish in the Little Colorado River (LCR) to assess the population trends and status of endangered humpback chub (*Gila cypha*)(HBC) (Robinson and Clarkson 1992). Annual standardized hoop net sampling is conducted for 30 – 40 days to capture humpback chub during the spring spawning period (Table 1). This program was discontinued in 2000 but then reinstated in 2002 at the advice of the Grand Canyon Monitoring and Research Center Protocol Evaluation Panel (Anders et al. 2001). Catch-per-unit-effort (CPUE) indices derived from this monitoring program are useful as independent validation for mark-recapture population models of humpback chub developed by Coggins and Walters (2001). With the exception of the period 2000-2001, the lower 1200 meter sampling represents one of the most consistent, long-term sampling methods in use for Grand Canyon fishes.

## STUDY SITE

The study site is the lower LCR, 1200 m upstream from its confluence with the Colorado River. The LCR in the study area is a deeply entrenched channel located in a vertical-walled canyon that in places narrows to less than 50 m. The LCR channel contains runs, riffles, deep pools and small rapids. Substrates are primarily silt and sand with scattered large boulders. The LCR is the primary spawning site for endangered HBC in Grand Canyon. It is the only known HBC aggregate in the Colorado River Ecosystem (CRE) from which fish are recruited into the adult population (Valdez and Ryel 1995; Coggins and Walters 2001). Other native fishes, bluehead sucker (*Catostomus discobolus*), flannelmouth sucker (*Catostomus latipinnis*), and speckled dace (*Rhinichthys osculus*) spawn in the LCR (Robinson et al. 1998) as do exotic species including channel catfish (*Ictalurus punctatus*), fathead minnow (*Pimephales promelas*), red shiner (*Cyprinella lutrensis*), and common carp (*Cyprinus carpio*).

## METHODS

Thirteen standardized AGFD hoop nets were fished continuously from April 13 to May 5, 2003, and checked once daily. Hoop nets measured 5 m long and 1m diameter with 6.3 mm mesh, 7 hoops and two throats. Nets were set at 100, 119, 137, 165, 420, 480, 500, 577, 675, 1045, 1110, 1160, and 1195 m upstream from the confluence. Net locations were set as close as possible to those used in previous sampling efforts (Brouder and Hoffnagle 1998). Catch per unit effort was calculated as number of fish caught per hour or 24 hours.

All fish caught (1,999) were handled following protocols in Ward (2002). All fish collected were identified to species and measured for total length (TL; mm). Fork length was also measured for humpback chub, flannelmouth sucker, and bluehead sucker. Weights were not measured because scales did not yield accurate weights in high winds common during the study period. Native fish were sexed when possible based on extrudable gametes and sexual condition (not ripe, ripe, spent) was recorded. Examination of sexual characteristics (none, color, tuberculate) were also noted. Number and type of external parasites were recorded. Native fish  $\geq$  100 mm TL were scanned for the presence of a PIT tag with both new 134.2 KHz tag reader and an old 400 KHz tag reader to evaluate the new PIT tag readers and verify that no tags were missed. If a tag was not found and the fish was  $\geq$  150 mm TL, a 134.2 KHz PIT tag was inserted into the abdominal cavity. Tag presence or absence and PIT tag number were recorded. Fish were also checked for fin clips. PIT tag information was downloaded to electronically and checked for errors. Flannelmouth and bluehead sucker over 150 mm TL were injected with a pink elastomer dye in the head. These marks were used to evaluate the use of injectible elastomer dye as a secondary mark to estimate tag loss.

## RESULTS

A total of 1,999 fish representing 11 species were captured in the LCR during standardized monitoring in 2003. Native species dominated the catch and comprised more than 90% of total fish caught (Table 2). Flannelmouth sucker, speckled dace, bluehead sucker and humpback chub were the predominant species caught (Table 2 & 3). Catch rates of native fishes were generally higher than those seen during the previous three years of sampling efforts (1997-2002) (Table 4 & 5).

The LCR was above base flow during the 2003 sampling until May 1<sup>st</sup> after which it returned to base flow (approximately 222 cfs, Robinson et al. 1998) and remained there for the duration of the sampling period. Turbidity was over 500 NTU's at the beginning of the sampling and gradually decreased to less than 10 NTU's. Turbidity did not appear related to overall CPUE in 2003 (Figure 2). Water temperature ranged from 15 – 18 °C during the sampling period (Figure 4).

## **Native species**

### *Humpback chub*

A total of 322 humpback chub were collected in standardized hoop net sets during the spring monitoring period. Approximately half of the fish were juveniles (< 150 mm TL) (Tables 3 & 7). Large chub appeared to be mostly spent adults.

We examined 247 humpback chub  $\geq$  100 mm TL for the presence of a PIT tag. No fish between 100 and 150 mm TL had tags. We examined 172 humpback chub  $\geq$  150 mm TL for presence of a PIT tag and 91 (53%) were PIT tag recaptures (Table 3).

Forty-seven young-of-the-year humpback chub (<100 mm) were caught; the smallest was 31 mm TL. We found one ripe male HBC, one tuberculate HBC and one HBC reported with color. No ripe female chub were observed (Table 8). Four HBC had a single parasite *Lernea*. Average total length of HBC with *Lernea* was 176.8 mm. *Lernea* was found in only one other fish (SPD) in 2003.

### *Flannelmouth sucker*

Flannelmouth sucker were the most abundant species captured (590, 29.5%) in 2003 (Table 2). Flannelmouth sucker caught in 2003 had a mean length of 263 mm and ranged in size from 65 to 581 mm TL (Table 7). Most flannelmouth suckers were presumed to be Age II fish (Figure 1). A total of 522 flannelmouth suckers were scanned for the presence of a PIT tag and 184 (35%) were recaptured fish (Table 3). The number of flannelmouth suckers recaptured in 2003 was more than double the number of flannelmouth suckers recaptured in 2002. The percent of recaptures did not change. This may be because of additional tagging efforts taking place in the mainstem Colorado River in conjunction with trout removal projects near the LCR. Two ripe male flannelmouth suckers were captured, 6 tuberculate fish, and 3 recorded as females “with color” (Tables 8-9). Many small flannelmouth suckers were observed at the end of the sampling period which were too small to be captured with the mesh size of the nets. Based on the abundance of larval and post larval juveniles seen in shallow near-shore areas, we assume that flannelmouth sucker had spawned in late March or early April in 2003.

### *Bluehead sucker*

Bluehead suckers caught in 2003 had a mean TL of 97 mm and ranged in size from 45 to 379 mm (Table 7). Bluehead suckers captured were primarily comprised of fish presumed to be Age-0 (Figure 2). A total of 64 bluehead suckers were scanned for presence of a PIT tag, only

one was a recapture. This fish was initially tagged during the 2002 sampling effort and grew 41 mm in 1 year (Appendix).

Five ripe male bluehead suckers were collected between 13 April and 5 May (Table 8). One ripe female was recorded and young-of-the-year (< 80 mm) bluehead sucker were common in catches (Figure 1, Table 7). We assume bluehead suckers spawned prior to our sampling in 2003, likely in February or March.

#### *Speckled dace*

Five hundred and twenty speckled dace were caught in 2003 and were the second most abundant species caught (Table 2). Ten ripe females were collected toward the end of the sampling period indicating speckled dace spawn in the LCR in late April and early May (Table 8).

#### **Nonnative species**

Nonnative species made up only 8 % of the total catch in 2003 with fathead minnow and red shiner being the most abundant species caught (Table 2 & Figure 3). Adult fathead minnows between 54 – 82 mm were relatively common in catches and fish were near spawning condition. Stomachs from 9 large bodied predators were examined. Four stomachs were empty, 4 contained fish remains, and one contained invertebrates (Table 6).

## **DISCUSSION**

#### **Native species**

In 2003, mean CPUE of flannelmouth sucker and bluehead sucker  $\geq 150$  mm TL were the highest recorded since monitoring began in 1987 (Figure 5). Large numbers of age 2 and 3 flannelmouth suckers were caught indicating survival and recruitment was high in 2000 (Figure 1). High recruitment of flannelmouth suckers may have been caused by the low summer steady flows in 2000 which increased mainstem water temperature by approximately 2 °C in the lower river. Subsequent warmer mainstem water temperatures caused by drought conditions and lowered water levels in Lake Powell (Susan Hueftle, USGS unpublished data) may have also led to increase survival of suckers. Flannelmouth suckers recaptured in 2003 in the LCR were originally tagged in areas very distant from the Little Colorado River. One flannelmouth sucker was originally tagged at RMI (-2.5 mile) in the Lee's Ferry area and two other fish were originally tagged in the Paria River. Flannelmouth suckers were also recaptured from as far

downstream as RMI 192.4 with several others originally being tagged in Havasu Creek and Kanab Creek (Appendix).

Mean CPUE of humpback chub  $\geq 150$  mm in 2003 was also higher than any observed since 1990 (Figure 5). High catch rates of humpback chub appear to be comprised largely of fish previously tagged in 2001 (Figure 9). Recaptures of HBC are exclusively from fish initially tagged in or near (within 5 miles) the LCR confluence (Appendix). HBC recaptured ranged from 1-14 years of age (Appendix) with most of the recaptured fish tagged in 1991 – 1995 or in 2002 (Figure 9). Catch of SPD is highly variable among years with no significant trends in CPUE of SPD from 1987 to 2003 (Figure 5).

### **Nonnative species**

There is some indication that the number of fathead minnows in the system has increased since 1994 although differences are not statistically significant (Figure 6). Catch rate of red shiner also appears to have increased since 1996 (Figure 6). Black bullhead have shown higher variability in catch since 1995 (Figure 6). Channel catfish show no significant increase in CPUE since monitoring began in 1987 (Figure 6). No trends are evident in catch rate of common carp although 1997 and 2003 catch rates appear to be higher than in previous years (Figure 6). There is some indication that catch of small-bodied exotic fishes is correlated with low spring (April and May) stream flow in the LCR (Figures 6, 7). The percentage of nonnative fish in the catch, although low, appears to be increasing since monitoring began in 1987 (Figure 3).

### **Trends in LCR spring stream flow**

The Palmer Drought Severity Index indicates much of Arizona and the watershed of the Little Colorado River is in a period of extreme drought (Figure 8). Since 1979 there has been a decline in the mean stream flow of the LCR during the months of April and May (Figure 7). Reduced peak stream flow in April and May could have long-term consequences for the survival of humpback chub in the Little Colorado River. In the Verde River, CPUE of age-1 roundtail chub were found to increase following large floods in late winter or early spring of the previous year (Brouder 2001). We speculate that the scouring effects of a large spring flood, while destructive to successful recruitment in that year, may create conditions that favor survival of fish in the following year. If large spring flood events are important to the survival and recruitment of strong cohorts of humpback chub, then the reduction in the frequency and magnitude of spring flood events since 1979 in the LCR may have detrimental impacts on the

long-term survival of humpback chub. There are only 4 years of record for the stream gauge located near the mouth of the LCR (USGS gauge 09402300) so evaluation of long term changes in LCR base flow and how they may impact humpback chub can not be done at this time.

### **Elastomer dye evaluation**

Many flannelmouth and bluehead suckers marked in the head with elastomer dye were recaptured a short time later during the same trip (40/142) and marks were highly visible. Initial assessment indicates that this tagging method can be done in the field with adequate preparation but does require additional handling of fish. Long-term assessment of mark retention is needed. Recent information from elastomer tag recoveries in humpback chub translocated above Chute Falls indicate these marks may fade and become undetectable as fish grow (Stone and Sponholtz 2003). Two flannelmouth suckers with elastomer marks were recaptured without PIT tags (5%). This PIT tag loss rate is similar to that observed in laboratory tag retention studies using bonytail chub during a 30-day period (4 %) (Childs 2002).

### **Evaluation of new 134.2 KHz PIT tag readers**

Both the old (400 KHz) and new (134.2 KHz) pit tag readers were used to scan all native fish over 150 mm TL. There were 19 fish out of a total of 192 old (400 KHz) tags scanned that the new scanner would not pick up but the old scanner did, indicating a failure rate of 9.8 % for the new scanners. The problem may be because of fish with multiple 400 KHz tags in them. Trials with two 400 KHz tags indicate that two 400 KHz tags in a fish with the same orientation confuse the new scanners. This appears to be a problem caused by the unreliability of the old scanners that may be perpetuated by the new scanners. Both scanner types must continue to be used to avoid these errors.

### **Value of long-term catch trends**

Catch-per-unit-effort (CPUE) indices derived from the lower 1200-meter monitoring show dramatic declines in CPUE of adult humpback chub and validate mark-recapture population estimates. This index of catch rate is also valuable as an independent method to confirm output of age structured mark recapture (ASMR) open population models and demonstrates the importance of long-term monitoring programs. Standardized monitoring should be continued to compare catch rate data with population estimates from the USFWS and validate ASMR stock assessment models produced by GCMRC.
