When GCWCD was formed, the district immediately began work to develop the Mill Creek Project – a water storage system that includes constructing a dam to divert water from Mill Creek into a reservoir at Ken's Lake, and the lake's delivery system that now provides irrigation water to shareholders within the district.

To accomplish this massive project, the district needed financing. The State of Utah's Division of Water Resources agreed to provide a low-interest loan to pay for the project, but in order to receive financing, the GCWCD first had to acquire water rights, which they purchased from the Moab Irrigation Company, to be held by the state as partial collateral for the loan.

The district's initial 1979 agreement with the state estimated the cost of the Mill Creek Project at about \$3.7 million, but construction delays, and the county's economic downturn in the early 1980s –largely a result of the demise of the uranium business – forced the district to seek an additional \$900,000 in funding over a period of several years.

To recoup part of the cost, the district elected to sell irrigation shares to valley farmers and ranchers. Today, about 125 individuals and corporations purchase irrigation water shares in Ken's Lake water, and the annual proceeds from the sale of those shares helps cover the annual loan payment to the state.

The district initially believed it could also generated revenue through the sale of industrial water to mining and other business entities. But as the mining industry went bust, those hopes dried up, said James Walker, president of the Moab Irrigation Company, and a current member of the GCWCD board.

Unfortunately, the water shares owned by GCWCD were strictly irrigation water, so in 1979, the district entered into an exchange agreement with local farmer George White that provided the district with a minimum of 625 acre feet of culinary quality water from White's numerous wells, in exchange for an equal amount of irrigation water from Ken's Lake. The district set about constructing a storage system and pipes to transport the water from White's wells to a storage tank that would eventually provide culinary water to Spanish Valley residents.

Delivering Culinary Water and Sewer Services: The creation of Spanish Valley Water and Sewer Improvement District

Because state law prohibits water conservancy districts from operating a sanitary sewer system, the county commission, in 1974, created the Spanish Valley Water and Sewer Improvement District. The district's boundaries were tightly drawn to encompass only Spanish Valley, and then, only that portion of the valley located within Grand County.

SVWSID is charged with the responsibility of building and operating a culinary water distribution system, storm drainage, and a sewer collection system to service Spanish Valley residents.

The district's five-member board, appointed by the Grand County Council, consists of individuals residing within the district's boundaries.

Since its formation, SVWSID has systematically built infrastructure to deliver culinary water, and sanitary sewer services to Spanish Valley, including the recent \$5.4 million

expansion project that extended those services to outlying areas of the valley and created additional culinary water storage tanks that will hold water generated from new wells recently approved for partial development by the state.

Under the original agreement, SVWSID purchased culinary water at wholesale prices from GCWCD, then provided the water at retail cost to customers. Rather than incur the expense of building and maintaining a sewer treatment plant, SVWSID contracts with the city of Moab for sewer treatment, and recoups the cost through user fees.

Currently, SVWSID revenues pay a portion of three separate bonds incurred to cover costs of water delivery systems and development of culinary water and sewer services.

Financing: Creating the Grand County Special Service Water District

Developing water services and storage facilities is an expensive business. In Grand County, financing the host of projects dating to the original Mill Creek Project was a challenge that, like many other Utah counties, commissioners resolved by proposing creation of a special service water district. The Grand County Special Service Water District, approved by Grand County voters in 1977, possesses specific powers to raise funds through taxes and bonds – powers not bestowed upon GCWCD and SVWSID. The GCSSWD may also raise funds through various federal and state granting agencies.

The creation of GCSSWD enabled Grand County to acquire additional funding – through taxes and bonds – needed for the construction of the Mill Creek Project, as well as monies required for building a culinary water and sewer delivery system in Spanish Valley. The agency is an independent district but is governed by Grand County, which appoints the district's five board members.

Primarily a financing agency, GWSSA works in tandem with the Grand County Water Conservancy District, and with Spanish Valley Water and Sewer Improvement District, to secure funding and make payment on outstanding loans and bonds for Grand County water and sewer projects, said Grand County water planning administrator, Lance Christie.

Combining Resources: Creation of the Grand Water and Sewer Service Agency

As all three water-related agencies worked to develop their joint and individual projects, the issue of managing Grand County's water systems surfaced as a significant problem. From the beginning, the boards of GCWCD and GCSSWD met jointly and shared the same chairman and vice-chairman. The two districts were bound by an agreement, signed in 1979, that gave GCSSWD authority to act as the conservancy district's agent for construction of the Mill Creek Project, and making payments on the project loans.

In 1980, SVWSID and GCWCD agreed to share staff and office space. The conservancy district hired staff, and SVWSID paid a percentage of staff salaries and benefits through reimbursements to GCWCD. These districts were also bound through an agreement by which GCWCD leased culinary water and storage to SVWSID, which then distributed the water to Spanish Valley customers.

These confusing arrangements were, perhaps, not ideal, but as Christie points out, they were likely necessary.

"This complicated mess of agencies was required because of the limitations and powers in the Utah State Code which are extended to Water Conservancy Districts, Special Service Districts, and Water and Sewer Improvement Districts," Christie has said. "It may be a mess, but it's the best mess we could come up with."

In an effort to simplify matters, the three districts agreed in 1998 to create one management agency that would oversee the daily operations and ongoing financial management of Grand County's water projects.

The Grand Water and Sewer Service Agency has, perhaps, become the most contentious part of the county water puzzle. Many find the agency's organization difficult to understand, and some question whether it gives each individual district equal representation at the table.

But the agency's structure is fairly simple. The GWSSA board consists of all members of each of the individual district boards, and board members have equal voting power. However, the agency also has a seven-member operating committee, charged with overseeing the agency's day-to-day business. That committee, consisting of three members each from the boards of the GCWCD and SVWSID, and one member from the GCSSWD board, has no power to set budgets, and may not conduct elections, but the committee is empowered to approve agency expenditures up to \$10,000. The operating committee appears to hold no clear power over the agency's full board because any member of the agency's full board may vote on issues brought before the operating committee.

GWSSA manager Dale Pierson is empowered through the interlocal agreement signed by all three districts, to "perform and carry out the functions, activities, and responsibilities of improvement districts," and to act as the financial agent, disbursing debt payments and collecting annual revenues for the individual districts. Under the agreement, the individual districts retain ownership of all property, and resources, and they also remain responsible for any outstanding district debts.

Is GWSSA Here to Stay?

Those who support the GWSSA structure say it saves all the districts money by streamlining staff and operations, and has improved communications between districts that sometimes in the past appeared to be working at cross purposes.

But critics charge that GWSSA staff, originally hired by GCWCD, rarely has the interests of SVWSID users at heart. To illustrate, SVWSID board member Barb Morra points to the fact that the titles to culinary water rights purchased through the agency are always held by the conservancy district. Spanish Valley Improvement District, she said, has never been offered the chance to own water rights even though it has the largest and only culinary water customer base.

Resolving these issues may be the greatest challenge confronting GWSSA staff, and the boards of Grand County's individual water districts. In the next several weeks, the Times-Independent will examine in-depth the inner-workings of GWSSA, and water issues facing Grand County's water districts.

Editor's Note: This is the first detailed installment of a series, a heavily researched series on how things operate in Spanish Valley's complex water and sewer agencies. The situation is critical to the future of Grand County, and needs to be understood. Though controversial, we believe it is essential.

Umbrella agency may be causing confusion, conflict (part two)

Times-Independent
Moab, UT
by Lisa Church
contributing writer

When Grand County's three water districts agreed in 1998 to create an umbrella agency to oversee operations and management of culinary and irrigation water systems the plan was touted as a cost-saving measure for all water users in Spanish Valley.

Today, some Spanish Valley water users believe the arrangement has created an unwieldy financial structure that forces culinary water users to unfairly subsidize about 125 irrigation water users.

The plan to combine the districts seemed logical at the time, past board members have said. The three districts – Spanish Valley Water and Sewer Improvement District (SVWSID), Grand County Water Conservancy District (GCWCD), and Grand County Special Service Water District (GCSSWD) – already shared staff and office space, and the culinary and irrigation systems were dependent on one another because the Conservancy District, which built the Mill Creek Project and Ken's Lake Reservoir, owned the culinary water rights, storage tank and tank delivery systems and sold culinary water to the Improvement District, which provided drinking water to Spanish Valley customers but did not own substantial culinary water rights or storage facilities. The Conservancy District paid staff, then billed the Improvement District for the time staff logged working on Improvement District projects.

By creating the agency, many argued, districts had little to lose and everything to gain. Districts would still own all their property and resources, but revenues, except those from property taxes, would be billed by and paid directly to the Grand Water and Sewer Service Agency (GWSSA), and the agency, in turn, would issue payments for outstanding revenue bonds and other ongoing agency expenses. GWSSA staff would continue to oversee the daily operations of the culinary water and sewer system, and

the Ken's Lake irrigation system, but could focus all their attention on work rather than spending valuable time tracking daily hours by project so the Improvement District could be billed separately.

"Some days I felt like I was spending more time writing down what I was doing than I actually spent doing the work," GWSSA manager Dale Pierson said. "Now, we can focus completely on our jobs."

Improvement District board member Barb Morra is not convinced.

"We don't know how their time is spent now. The Improvement District contributes four times the revenue of the Conservancy District, but are we getting four times the work? I don't know. And [agency staff] has no documentation," Morra said.

Pierson said the staff "probably spends that much more time" doing work for the Improvement District because maintaining culinary water and sanitary sewer systems is far more costly, both in time and money, than maintaining the Conservancy's irrigation system. In addition, he said, the Improvement District has grown, and the agency employs a staff member whose time is largely spent handling monthly billing for water and sewer service customers.

"The Improvement District is our primary focus," Pierson said. "There's health and human welfare involved there. If we have two jobs to do, and one is irrigation and the other is drinking water or sewer, the drinking water or sewer job takes top priority. It's that simple."

For critics, on-site staff accountability is but one of several problems with the agency arrangement. Morra says. In 2002, the Improvement District contributed more than \$1 million in revenues to the agency, compared to \$362,000 contributed by the Conservancy District. The agency budget shows that Improvement District Costs totaled \$910,000 – a gross profit of about \$100,000 – while the Conservancy District had \$360,000 in expenses.

"The whole thing about the agency is every time you try to figure out something fiscal, it's like trying to hit a moving target," Morra said. "We're contributing 90 percent to the agency while the other districts are contributing 10 percent. Where is our money going? I'd like to know specifically."

Spanish Valley resident Bill Love believes he knows. The agency, he charges, is using Improvement District revenues to "subsidize" the 125 irrigators who annually purchase Ken's Lake water.

In a detailed written statement to the Times-Independent, Love argues that the agency regularly uses Improvement District revenues to pay for work and maintenance of the irrigation water system and Ken's Lake Reservoir.

Love rightly points out that state-backed loans for the Mill Creek Project which created Ken's Lake are annually paid through property taxes charged to all Grand County taxpayers. That bond was approved by taxpayers in 1980, and will be completely paid in

2018. Love argues that through those property taxes, all Grand County residents are "subsidizing" the irrigation water users of Ken's Lake.

And it is true that the lake would likely not exist without the tax revenues. But Pierson points out that voters approved the bond, in part, because Ken's Lake is also a recreation area that is open to the public.

"A lot of people use Ken's Lake every year. A lot of people here see it as an amenity," Pierson said. "The lake isn't just for irrigators."

Love also believes recent water fees from Spanish Valley customers are being used by the agency to pay Conservancy District expenses.

"The fees from the culinary users and irrigation users are co-mingled to pay expenses of \$490,477 for the operations and maintenance of the irrigation system, the culinary water system, and debts. GWSSA claims that they are unable to identify which fee is used to pay which bill without extensive analysis," Love wrote.

And he charges that the water rate structure of Spanish Valley – a conservation-oriented structure that charges increased fees for higher water consumption – are unfair, compared to the rate structure for irrigation customers whose fees per acre-foot of water decrease with higher consumption. Irrigators pay between \$21 and about \$35 per acre foot, depending on use, Pierson said.

"The culinary water users are now completely unprotected from GWSSA using their fees to subsidize the 125 irrigation Ken Lake and the golf course," Love said.

Pierson said the rate structure for irrigation users is "typical" for Utah.

"There are a very few number of irrigation customers who actually try to make a living from farming," Pierson said. "We don't want the water to be so expensive we put them out of business."

Lance Christie, the water planning administrator for Grand County, said it is not uncommon in the West for drinking water customers to subsidize irrigators. But in many parts of the state, he said, the culinary water users pay much higher fees.

"It's a common practice. But from my research, the people in Spanish Valley are subsidizing at a much lower rate than in most other places," Christie said.

A 2001 report by the state's Division of Drinking Water backs up Christie's claim. According to that report, culinary water agencies in Utah charge, on average, \$1.39 per 1,000 gallons of water. In Spanish Valley, customers pay between \$.50 and \$1.25 per 1,000 gallons depending on how much water they use. The state report shows that the average Utah home customer pays \$33.89 per month for drinking water. Bills in Spanish Valley average about \$24 per month, GWSSA staff said. Sewer charges are billed separately.

For critics of GWSSA, the monthly cost of water is less important than whether the agency is properly managing the financial resources of the Spanish Valley Improvement

District. Agency staff now view revenues from all districts – except tax revenues, which are kept in separate accounts – as agency revenues, not separate revenues from individual districts. And supporters of the agency say the arrangement works to the advantage of all districts because all three are interconnected through the complex network of culinary and irrigation water supply lines and storage facilities.

"It may not be perfect, but things work a lot better now," said Conservancy District board member James L. Walker. "The idea here is for all the districts to work together. We all have the best interests of Grand County at heart."

Pierson puts it another way. "One district wouldn't exist without the other," he said. "It's that simple." Morra believes otherwise.

"I think the Improvement District would be better off as a separate district," Morra said. "The agency isn't doing us any favors."

Next week, this Times-Independent series will examine arguments for and against an agency plan to purchase wells and property that they currently lease, and which district should own the water rights if the purchase is completed.

How district got culinary water rights (part three)

Moab Times Independent by Lisa Church contributing writer

From their inception in the 1970s, Grand County's two main water districts have struggled with a serious dilemma – both had authority to provide culinary water to Spanish Valley, but neither district owned any culinary water rights.

Because the state had placed a moratorium on further water exploration in the valley more than a decade before, the county could only secure culinary water by purchasing or leasing existing water rights. In 1979, the Grand Water Conservancy District solved this massive problem by striking a deal with local rancher George White. In exchange

for a maximum of 625 acre feet of irrigation water from Ken's Lake, White agreed to provide the district with an equal amount of culinary water from his wells.

That 50-year agreement between White and the Conservancy District enabled the district to provide wholesale culinary water to the Spanish Valley Water and Sewer Improvement District, which delivered the water at retail prices to customers in Spanish Valley. For some, the pact also marks the beginning of a water monopoly in the valley.

In recent years, district and county officials have mulled, with increasing concern, the county's prospects for securing culinary water rights beyond 2029 when the exchange agreement with White is set to expire. So when a pair of those wells came up for sale, board members of the Grand Water and Sewer Service Agency – an umbrella agency created by the districts in 1998 to oversee daily management of Grand County water projects – jumped at the chance to own them outright.

With the board's near unanimous blessing – two members opposed the purchase – GWSSA in February began efforts to secure a purchase agreement with White, and the financing needed to seal the deal. The sales price will remain undisclosed until final negotiations are completed, but Dale Pierson, GWSSA manager, has said the agency hopes to recoup much of the cost by selling land – about 130 acres – that is also included in the deal.

The plan approved by board members gives the agency staff authority to pursue the purchase, and places ownership of the White water rights and land in the hands of the Grand Water Conservancy District. That decision, some charge, gives the Conservancy District a monopoly on valley water, and forces Spanish Valley water users to remain forever dependent on the Conservancy District for its culinary water supply.

"There's no reason the [Spanish Valley Improvement] district should not own that water," said SVWSID board member Barb Morra. "If we purchase the water, we can become independent of the Conservancy District. But they don't want that to happen. Basically, we're allowing the Ken's Lake water users to control the agency, and that means they control where the water is going and how much Spanish Valley users pay."

For Spanish Valley resident Bill Love, the plan represents a "boondoggle" that gives the Conservancy District total control over Spanish Valley water users. Love said the agency should hold a public hearing before making a final decision about the purchase.

"This water is for the use of the culinary rate payers in Spanish Valley. The negotiations are controlled by the irrigators' board members," Love said in a letter to the Times-Independent. "The irrigators, per a June 6, 1979 agreement, can charge the culinary rate payers any fee they 'fixed from time to time' for the culinary water. If the new culinary water is given to the irrigators, they will have the ability to charge the culinary users any fee they decide is sufficient to pay all their expenses."

Morra points to the fact that agency board chairman, Gary Wilson, is "one of the largest users of irrigation water in the district," as evidence that the members of the Conservancy District control the GWSSA board.

Wilson and other board members take issue with Morra's characterization.

"To me, the whole purpose of this agency is for us all to work together," Rex Tanner said at a recent meeting. Tanner, a Grand County Council member and a GCWCD board member, dismissed Morra's allegations as "paranoia."

"It's not us against them here. It's one pool that we're working from," Tanner said. "We started down this road to purchase this water because of the long-term goal to better serve the community. This seems like a good business deal to me, and I hope we go through with it."

During several board meetings, Morra and Love have also repeatedly questioned why the Improvement District has not been given the option to purchase the White wells. Pierson said the decision is purely financial – banks view the Conservancy District as a "better risk" than the Improvement District because GCWCD has fewer outstanding debts.

Currently, SVWSID makes annual payments on eight outstanding revenue bonds totaling almost \$5 million– most associated with a recent system expansion – and one general obligation bond, paid through property taxes collected from Spanish Valley residents, totaling \$126,000 that will be paid off in 2006. The revenue bonds have payoff dates ranging from 2006 to 2040, depending on the specific bond, Pierson said.

The Conservancy District has one outstanding bond, Pierson said. That bond, a \$1.5 million general obligation bond paid through annual property taxes assessed all county property owners, will be paid off in 2018, he said.

"Either district could purchase the White property and wells. But from what our attorneys and the bank tell me, the Conservancy District is in a better position to borrow the funds," Pierson said. "Banks want to be at or near the top as lien holders. In the case of the Improvement District, that just isn't possible because they already have several outstanding revenue bonds."

But Morra said that simply is not true.

"I've had conversations with the bank, and they've said we can buy the property," she said. "I just don't see what the problem is here."

Pierson said bank representatives "prefer" making the loan to the Conservancy District for reasons stated earlier.

"The Improvement District may be able to secure financing, but it would be much more difficult, if it's even possible," Pierson said.

Some agency board members fear that the ongoing debate will derail the White purchase, leaving Grand County vulnerable in future years should the Whites sell the wells to someone else.

"Barb has some good points to make, but I think we need to move on this," said James Walker, Conservancy District board member. "No one has ulterior motives with this

purchase. But proven wells like this don't come along often. We need to buy them while we can."

The agency has yet to finalize a contract for the White well purchase, but Pierson said an agreement is "close." So far, the board has not responded to Love's call for a public hearing on the issue.

Next week, in the final installment of this series, the Times-Independent will explore the effectiveness of the GWSSA agreement, and examine arguments for and against dissolving the agency.

Letter to LR 05/02/03

Response from BuRec: Glen Canyon Dam's Adaptive Management

United States Department of the Interior
Bureau of Reclamation
Washington, D.C. 20240
In Reply Refer To: ADM - 2.00

Ms. Lisa Force
Program Director
Living Rivers
P.O. Box 1589
Scottsdale, AZ 85252

[Letter to Gabaldon \(January, 2002\)](http://www.livingrivers2.org/archives/article.cfm?NewsID=234)

<http://www.livingrivers2.org/archives/article.cfm?NewsID=234>

Dear Ms. Force:

Thank you for your participation as a member of the public in meetings of the Glen Canyon Dam Adaptive Management Work Group (AMWG). The AMWG was formed as a Federal Advisory Committee to make recommendations to the Secretary of the Interior on the operation of Glen Canyon Dam and the use of other management authorities to achieve the resource protection objectives of the Grand Canyon Protection Act and the Glen Canyon Dam Environmental Impact Statement (GCDEIS) Record of Decision (ROD). You have raised concern for many of the important resources downstream of Glen Canyon Dam, and have encouraged the AMWG to take action to protect these resources. We have integrated your specific comments into the areas of endangered species protection, sediment conservation, administrative activities, and public outreach.

Endangered Species

Protection of endangered species is one of the paramount mandates of all Federal agencies, and the AMWG strategic plan is framed from that perspective. Many recent discussions within the Adaptive Management Program (AMP) have addressed the apparent decline in juvenile recruitment and adult population estimates of the humpback chub. The cause of this decline is unknown, but may be related to non-native competition and predation, parasitic infestation, habitat conditions, or adverse effects from handling and sampling. It is the current opinion of the Grand Canyon Monitoring and Research Center (GCMRC) that negative effects from non-native fish predation and competition overshadow other factors.

Collecting and addressing this type of new information and hypotheses is one of the strengths of adaptive management. At its January 2002 meeting, the AMWG passed the following motion calling for the control of non-native fish:

"In support of goal 2 (of the Strategic Plan), the AMWG recommends the following actions subject to environmental compliance to include assessing recreational use, Endangered Species Act (ESA), in consultation with the tribes and other affected state agencies.

1. evaluate methods to remove non-native fish, except rainbow trout, from Bright Angel Creek in 2002,
2. evaluate methods to remove non-native fish from the LCR in 2002,
3. gather public input and conduct public education and environmental compliance on long-term removals in #1 and 2 above,
4. establish a Technical Work Group (TWG) ad hoc committee to develop a 2002 - 2006 research monitoring and management work plan for meeting MO 2.5 and 2.6 of the August 17, 2001, Draft of the AMP Strategic Plan. The TWG will report back to the AMWG at the next meeting,
5. using data from #1 - 4 above to make recommendations on future removal."

Through a combination of National Park Service and Bureau of Reclamation funding, appropriate environmental compliance, and approval by the Secretary of the Interior, these nonnative fish control efforts began this year. The authority and responsibility for these non-native control actions rest with appropriate Federal and State agencies, the National Park Service for the Glen Canyon National Recreation Area and Grand Canyon National Park and the Arizona Game and Fish Department for the State of Arizona. Results from initial evaluations will guide future decisions about management actions and dam operations.

Testing experimental dam releases to benefit the humpback chub is also an important part of the Biological Opinion (BO) on the Operation of the GCDEIS. The BO discusses implementing these test releases in low release years of approximately 8.23 million acre-feet (maf). Reclamation has agreed to implement such experiments through the AMP. Several years ago, GCMRC coordinated the preparation of a program of experimental flows to address this requirement. The resultant work product called for

the establishment of baseline conditions, followed by a steady release with moderately high spring flows and low flows the remainder of the year. In fiscal year 2000, we tested these steady spring and summer flows, even though the annual water year release was greater than 8.23 maf. In water years 2001 and 2002, the dam made releases according to the GCDEIS ROD, and baseline data was collected. This baseline data will be compared with data from future experiments, the nature of which is still evolving among native fish experts through the AMP.

As described in more detail below, GCMRC followed this initial experimental design with a 2003-2004 experiment designed to benefit humpback chub and conserve sediment inputs. In all these adaptive management actions, the U.S. Fish and Wildlife Service (Service) has actively participated, and Reclamation has continually discussed with the Service the resulting effects to ensure that sufficient progress is being made toward removing jeopardy from the humpback chub and achieving the recently published U.S. Fish and Wildlife Service Recovery Goals for the humpback chub.

Sediment Conservation

The 1996 Beach Habitat Building Flow (BHBF) was highly successful in depositing sand above the normal maximum discharge stage. Subsequent wind and water erosion of these deposits was expected, as was the need for periodic redeposition of sediment. Since that time, additional research has indicated that the previous assumption of interannual sediment conservation of tributary sediment inputs is likely incorrect, indicating a relatively short residence time for the finer fractions of tributary inputs. As a result, the AMWG passed the following motion at the January meeting relating to further testing of BHBFs:

"In concert with Reasonable Prudent Alternative flows for native fish, during 2002-2003 request that the GCMRC, in consultation with the TWG, design an experimental flow sequence that tests hypotheses for conservation of sediment. Report to AMWG in April 2002 on the proposed flow sequence."

In response to this motion, GCMRC proposed an integrated experiment in February 2002, addressing specific assumptions and hypotheses for the humpback chub and sediment conservation. To counter the short residence time of fall tributary sediment inputs, this experiment tests two strategies to preserve these inputs until high flow tests can be conducted the following January. The fall flows of these tests are hypothesized to benefit the humpback chub and would complement the results of the 2000 Low Steady Summer Flow experiment. Nonnative fish control efforts during 2003-2004 are also expected to reduce the deaths of humpback chub from predation and competition. This experiment is now underway. In addition, GCMRC and the AMWG are now working to develop an overall program of experimentation that addresses the ecosystem as a whole, including all the resources considered by the AMP.

Administrative Actions

During the past 2 years, the AMP has succeeded in developing a strategic plan, the completion of which has represented a significant increase in the ability of stakeholders

to work together on common goals. We recognize that some reject the concepts of collaboration and consensus, but we believe that these approaches will produce more effective resource protection results than litigation and conflict. In addition to completing the strategic plan, the AMP has sequenced the strategic plan research information needs, which will guide future scientific work.

Reclamation and the GCMRC have restructured their websites to facilitate public access of AMP documents such as the GCMRC State of the Natural and Cultural Resources in the Colorado River Ecosystem report and the annual report to Congress required by the Grand Canyon Protection Act. These reports include results from the monitoring and research activities conducted as part of the AMP. The AMWG meeting minutes also contain scientific presentations at technical and management meetings on the status of resources.

Public Outreach

Public involvement is a key part of the AMP. Stakeholder membership on the AMWG was carefully selected to provide representation of public interests. It is important to note that any AMWG recommendation to the Secretary of the Interior is implemented only after completing appropriate National Environmental Policy Act (NEPA) compliance with applicable federal law (e.g., NEPA), a step that ensures additional public participation. In addition to inviting the public to AMP meetings, we have attempted to keep all information about the program visible and accessible. We recognize that to date, few outside public comments have been given at our meetings, and that the AMWG's response to your comments has been less than you desired. In future meetings, we will encourage AMWG members to continue their discussion after public comments are received to ensure understanding, prior to voting on recommendations. It would also likely be more effective for public comments to be received prior to any meeting to allow AMWG members time to consider comments. Since most of the issues addressed during the AMWG meetings are first discussed by technical and ad hoc groups, we would encourage you to become involved in the technical presentations and discussions which form the basis for AMWG recommendations.

In conclusion, we believe the AMP is a successful example of a collaborative, multi-stakeholder process. Moreover, we believe that this critical program is fulfilling the role envisioned by the Grand Canyon Protection Act, the 1996 Glen Canyon Dam EIS, and the Federal Advisory Committee Act. The Department of the Interior is taking action to address resource concerns revealed by scientific monitoring and have enlisted prominent scientific advisors and other forms of peer review to enhance the quality of analysis in this process. We appreciate your comments and welcome your continued involvement in all our meetings.

Sincerely,

Michael R. Gabaldon

Lake Powell's 'new marina' another Park Service fumble

May 17, 2003 12:00 AM

Arizona Republic

Letter to the Editor

The May 5 article "New marina at Lake Powell 30 years in making" omitted two significant facts:

- Low reservoir levels make the marina unusable.
- The Diné will receive only low-level jobs, while profits go to non-Diné developers.

The Diné Medicinemens Association, along with Living Rivers and others, asked for a proper environmental impact statement. The concerns were disavowed by the National Park Service, which determined that this \$75 million project on virgin Diné land would have "no significant impact" on the human or natural environment.

The Diné leaders asked the Park Service to consider dedicating this spiritually significant site as a place for their people to be educated in the traditional ways of their cultural heritage. This alternative deserves a respectful response by the National Park Service.

The Park Service wants to provide economic opportunities for the Diné, yet it refused to study Living Rivers' proposal to allow the Diné to become the concessionaire at Wahweap Marina. Living Rivers also stressed that building another marina when visitation has been declining does indeed impact humans and the environment.

Antelope Point is perched on top of a canyon wall. To operate this facility the reservoir must be nearly full. Currently the reservoir is down 95 feet and the public boat ramp ends at the cliff's edge. Current high demands for an already over-allocated Colorado River, compounded by a present and future drought cycles, makes Antelope Point a boondoggle.

How can a facility that must face the hardships of natural topography and drought during a period of decreased visitation be considered without a study? The Park Service should be delighted to provide taxpayers with a thoughtful process, especially if it will demonstrate true benefit to the Diné.

Secretary Gale Norton's 2025 Water Plan--propaganda to mask reality

Colorado River water users should prepare for the worst

Contact:

Owen Lammers (435) 259-1063

On Friday, June 6, Denver will play host to Interior Secretary Gale Norton and one of the greatest public relations charades in the history of western river management. At a time when many Western states are experiencing major problems with water allocation, the Department of Interior is selling the public "band-aids for gun-shot wounds," says the Colorado River advocacy group Living Rivers.

Secretary Norton's initiative "Water 2025 Plan: Preventing Crisis and Conflict in the West," is little more than a repackaging of management strategies Interior is already implementing combined with a heightened push for desalinization technology. It contains no proposals for how to substantively address major water shortages, such as those looming in the Colorado River watershed.

"Minor efficiency gains and conservation measures as Secretary Norton prescribes will bring about some savings, but these are merely drops in the bucket given that the Colorado River is providing barely half the water the Department of Interior is contracted to deliver," says Owen Lammers, Executive Director of Living Rivers.

Abundant historical evidence reveals that the present drought in the Colorado watershed is far from unprecedented, and warnings from the United States Geological Survey one year ago urged water managers to be prepared for several decades of below average precipitation. Lammers notes, "Water 2025 demonstrates that the Department of Interior is ignoring this responsibility."

- The Plan emphasizes Interior's long-standing tradition of acquiescing to the states for resolving disputes. However, as eighty years of conflict reveals, cooperation is rare, even in the best of times. Moreover, as California recently demonstrated, reaching agreement amongst Colorado River water users within

states is problematic. This internal dispute forced federal action in January to reduce Colorado River flows into California.

- The Plan's market-driven water banks and transfers from farmers to municipalities during times of shortages are laudable on a small scale, but there is no discussion of what will happen when the real crisis hits. Certainly, the 25 million people reliant on Colorado River water will not be deprived, but what will it cost? Farmers are becoming increasingly reluctant to make water transfers, as San Diego has recently experienced. Without strict federal guidelines and policies, municipalities like Los Angeles, Phoenix, Los Vegas and Salt Lake City will be forced into a cost environment not unlike what California energy utilities faced three years ago.
- Crop substitutions, which represent the greatest opportunities for water savings are completely ignored by the Plan. Nearly half of Colorado River water is used to grow water-intensive alfalfa and other forms of cattle feed. Much of this water could be saved by growing crops for human consumption.
- The Plan relegates environmental stewardship as merely aspects of conflict, not as an integral part of what society now demands of its river managers. Despite the fact that all the water referred to in the Plan comes from rivers integral to this continent's natural heritage, the Plan does not even mention or use the word river, other than when using place names. In describing its "Five Realities" the Plan completely ignores the reality that the riverine ecology throughout the watershed, such as in Grand Canyon National Park, Dinosaur National Monument and the Colorado River delta, has been dramatically altered, while the public is becoming increasingly vocal about reversing the damage.
- The Plan advocates maintaining and enhancing existing infrastructure. However, much of this infrastructure is responsible for the loss of up to 20 percent of the Colorado River's flow due to evaporation and seepage amongst its reservoirs. The draining of Lake Powell reservoir, for example, will eliminate enough water loss to service the municipal water needs of the state of Arizona.
- Not until the 25-page report's last 100 words does the term "drought" receive much attention. This should be Interior's main focus at this time. Questions Interior needs to be asking include: outlining specific federal management tactics it may employ; how farmers will be enticed or forced to release their water to preserve municipal economies, and will Interior enforce strict conservation strategies and efficiency standards?

"This report is all about carrots with no federal stick," adds Lammers. "Interior must begin developing water use standards and practices, as well as allocation strategies to be implemented as this drought situation worsens. Absent this, crisis is inevitable, despite Secretary Norton's report and marketing strategy titled to prevent it."

A River, Saved: Wild Yampa and Green nearly went the way of Glen Canyon

A River, Saved: Wild Yampa and Green nearly went the way of Glen Canyon

By Judy Fahys The Salt Lake Tribune

THE YAMPA RIVER, Colo. -- This wild place might have been entirely different were it not for a fateful boat trip a half-century ago. Fifty years ago this month, David Brower fell in love with the Yampa, and the Green and the Colorado rivers downstream. In the years that followed, a time before the word "environmentalist" existed, the activist rallied the nation against two dams planned for canyons just below the Yampa, dams that would have forever changed the landscape into vast lakes. This history was unknown to Salt Lake City resident Bob Hausser when he signed up for a white-water rafting adventure this month. In fact, the retired Kennecott engineer wore his "Lake Powell" T-shirt as Brower's one-time aides talked about the significance of Brower's fight for wild rivers and urged listeners to follow the example of his spirit.

Hausser's trip leader was John Weisheit, who sipped all day from a plastic coffee mug that proclaims, "Just Drain It!" referring, of course, to the same Lake Powell beloved by Hausser. Weisheit is director of the Moab-based environmental group Living Rivers, which through its Colorado Riverkeeper project organized the 50-year anniversary raft trip.

"We have things to do," Weisheit said at the outset. "We're going to get going again."

"Going," in this case, means reviving the broad-based conservation ethic that made it possible for activists such as Brower to help shape the modern West.

Brower, who died in 2000, took his trip in the U.S. Bureau of Reclamation's heyday, when it had more than 140 dams on its project list. And, after he drifted through Dinosaur National Monument's scenic redrock canyons, he made a career of harnessing American outrage over the destruction of national treasures for water and electricity intended to profit the bureau alone.

Two of the proposed dams would have braced against canyon walls visited on this month's Riverkeeper trip.

The bureau proposed one for below Echo Park, at the confluence of the Yampa and the Green. The other would have been more than 20 miles below at Split Mountain on the Green. If they had been built, the dams would have inundated 140 miles of canyon, up to Flaming Gorge on the Green and to Deerlodge Park on the Yampa.

"What happened here 50 years ago changed the world," said Rod Nash, the noted wilderness historian who joined the Brower commemorative trip in his dory, Canyon Dancer.

Brower fought dams with statistics that showed they would not conserve as much water, nor provide as much power, as the Bureau of Reclamation projected. When the bureau had finished building its Colorado River Basin dams, the two Dinosaur dams were not among them. "We have a living river here -- the Yampa is undammed," Nash told the 20 commemorative trip clients in one after-dinner talk. "It's a miracle in the American West." The guide: What might have been lost can be seen by anyone floating the rivers with Dee Holiday. He has been guiding for about 42 years, much of it with his wife, Sue, co-owner of their Holiday Expeditions, which hosted the commemorative trip.

Tall and wiry, Holiday probably knows the Yampa as well as a human can after spending roughly 2,000 days of his life on it.

He is the naturalist who can point out a chokecherry forest on the trail and tell about a woman named Josie whose chokecherry wine was the county's best. He is the oarsman who can pull a fast-moving raft away from the dangerous waves and dips of a rapid.

He is the historian who knows the story behind Pat Lynch, the hermit whose initials are chipped into canyon and cave walls. He can point out an unusual wild, desert orchid, rare spawning grounds for endangered fish and secret sea fossils captured in canyon stone.

Holiday is also the hiking guide who asks visitors to be respectful inside a cavern that holds ancient American Indian ruins.

"It's a real special place to me," he says, nearly whispering. "But it's sacred to the Native Americans."

The song and feel of rivers has always gripped Holiday, and its hold has only tightened with time.

"When you are younger, you do rivers for the experience," he said. "The longer you do it -- that's when I started to love the river." Slack water: To the activists, loving Western rivers means, in many cases, trying to undo the damage wrought by mankind. Where dam advocates point to the electricity Colorado Basin dams provide to 9 million people and the water they deliver to 30 million people, the activists see environmental havoc.

Wherever dams have been constructed, the surrounding ecology has fundamentally changed, usually harming the plants and animals around it. A good example is Glen Canyon, which was filled with water behind a dam built just outside the boundaries of Grand Canyon National Park, a dam Brower didn't fight but always wished he had.

Its riverbed spawning grounds for endangered fish species have been ruined by the dam flow's unnatural currents. And the trophy trout planted in the cold water below the dam are blamed for making meals of the federally protected humpback chub, flannelmouth sucker and the bluehead sucker.

More recently, the Bureau of Reclamation's renewed efforts to desalt the lower Colorado River have environmentalists worried about the fate of species-rich wetlands near the river's end, in Mexico and California.

Meanwhile, a near-war continues between the Grand Canyon's commercial rafting outfitters, who insist on using motorized boats to speed clients downriver, and wilderness advocates who say the Colorado, by law, should be motor-free in the park.

Weisheit's group has spearheaded the 4-year-old campaign to remove Glen Canyon Dam, which forms Lake Powell. Living Rivers charges that, besides imperiling or wiping out seven fish species, weak canyon walls and pressure from silt buildup will someday make the dam fail.

While dam supporters have laughed at the idea, Weisheit remains confident the dam will be removed and Lake Powell will be drained. "We can do it, and we can do it soon."

Kim Crumbo, a retired Grand Canyon river ranger and wilderness advocate, takes a starker, more ominous view.

"The victories are ephemeral," he says. "The defeats are forever." To dam or not to dam: Heady as the debates and history lessons might have been for the 20 paying customers on this trip, it was the wild Yampa that swayed their hearts.

Ranging in age from 7 to 70-something, they came from Portland, Ore., and Scottsdale, Ariz., and the nation's capital to run the Yampa and sections of the Green.

They saw how, because there is no dam, the Yampa's water is brown with silt and carries a forest of tree-size snags on its boisterous current. They observed migrating pelicans and browsing deer. They might have seen small rabbits, snakes or the fossil remains of prehistoric life.

Still, they didn't always agree with the activist-leaders.

For instance, Denise Dion, a Maryland-based regulatory consultant and rafting enthusiast, agrees that motors should be restricted in the Grand Canyon, but not banned, because motorized rafts make the place much more accessible to the public.

"I want to go to pristine areas," she said. "But my aunt, she wants to see them, too. She's 70," and cannot get around easily without the help of paved paths and motorized conveyances.

Dion called the push for a motor ban "elitist."

"You have to think about how you can serve many masters," she said.

A retired political science professor on the trip commented: "For most people, wilderness is not having a flush toilet and a motel."

Hausser, meanwhile, has not lost any affection for his Lake Powell houseboat, although he did gain a new appreciation for conserving water and efforts to block future dams. He says activists are "unrealistic" about decommissioning Glen Canyon Dam.

"I love the idealism of the people on the trip," he said, "but they are not going to be able to take back what is done." "Don't give up": Some activists are optimistic that this, the latest effort to engage the public in the debate in the fight for the West's rivers, will succeed. Others have doubts.

Lisa Force, a project director for Living Rivers, predicts that the movement will not gain broad public support until society has a crisis, perhaps a fit of guilt over its wasteful use of the Colorado River and the ecological damage that is being left for future generations.

"The hope is we'll recognize humans are part of the Earth community," said Force, who serves on the Sierra Club's board of national directors.

Jeff Ingram, another speaker on the trip, reminded the group that Americans deeply value the places they have set aside in parks, wilderness and preserves such as the wild Yampa. Ingram is a mathematician and Grand Canyon advocate who has been described by Cadillac Desert author Marc Riesner as Brower's secret weapon in the fight against dams proposed for the Grand Canyon.

Recalling Brower's seemingly futile efforts to protect wild, Western rivers, he pressed listeners to hold fast to their ideals, think independently and pursue those ideals even in the face of what seems like hopeless odds.

Parks, wilderness and wild places are something that all Americans cherish, he said.

"You may get defeated, but don't give up."

Water: BuRec to alter flows at Utah's Flaming Gorge Dam to protect endangered fish

April Reese

Land Letter Colorado correspondent

The Bureau of Reclamation is putting the finishing touches on a proposal to change the way it operates Flaming Gorge Dam on the Green River in Utah to help recover endangered fish downstream, agency officials say. While federal biologists say the new flow regime will go a long way to meet recovery goals, some environmentalists contend that decommissioning the dam is the only way to help the fish over the long run.

The forthcoming draft environmental impact statement, over three years in the making, will likely call for releasing more water from the dam in the spring, said Beverly Heffernan, environmental protection specialist in the BuRec's Provo, Utah office. Providing peak spring flows will bring sediment downstream, where it forms sandbars and replenishes beaches -- important nursery habitat for endangered fish.

"The proposed action is to change the way we operate the dam so it more closely resembles a natural river flow," Heffernan said.

The draft EIS, initially scheduled to be released this spring, is now expected to be issued in October. The delay is necessary to give the agency a chance to incorporate new water temperature data into the document, Heffernan said.

The dam, authorized by Congress as part of the Colorado River Storage project in 1956 and completed in 1964, was primarily built to create a 91-mile-long reservoir that would store water promised to users in the Upper Colorado River Basin as part of the Colorado River Compact. The dam -- the largest on the Green River, a major tributary of the Colorado -- also provides hydropower: The Flaming Gorge power plant's net generation in 2002 was about 217 million kilowatt hours (kWh).

But in the 1980s, federal wildlife biologists began to suspect that the dam was harming native fish downstream in Dinosaur National Monument. In 1992, FWS issued a biological opinion that found the dam was contributing to the decline of four species of endangered fish in the Green River: the razorback sucker, Colorado pikeminnow, humpback chub and bonytail.

That prompted BuRec, which operates the dam, to study how changing the operation of the dam might help the fish. The resulting flow recommendations, completed in 2000, provided the basis for the new proposal, Heffernan said.

Under the new plan, BuRec would allow as much as 11,900 cubic feet per second (cfs) of water to flow over the dam in the spring. Currently, flows below the dam fluctuate between 830 cfs and 4,000 cfs, peaking in summer and winter, when electricity demand

is greatest. But operating the dam to simulate natural flows will not have a significant effect on power generation, Heffernan said.

Larry Crist, a fisheries biologist with FWS who helped develop the 2000 flow recommendations in his previous position with BuRec, said that while altering the operation of the dam is "a big step forward," it's only part of the solution. "It's an important element, but it's not the only element in recovering these fish," he said. "You'll have to do that in conjunction with dealing with non-native species and reintroducing native fish in places where they're no longer found."

The Moab, Utah-based environmental group Living Rivers says altering flows is not enough to recover the fish. It has urged BuRec to consider decommissioning the dam, and hoped the agency would include dismantling as an alternative in the draft EIS. But Heffernan said taking out the dam is not an option. "We can protect fish while maintaining other functions of the dam," she said.

John Weisheit, conservation director for the group Living Rivers, is skeptical.

"It's not going to work, in my opinion," he said. "They're applying band-aids to stay out of court, to show they're trying to keep the fish alive. But as long as that dam is there, affecting temperature and sediment, recovery of those fish is not going to happen."

Crist acknowledged that a natural system would be "the most ideal situation," but he said the new flow regime is "a good compromise" considering the realities of demands for power, irrigation and recreation.

"When you deal with the Endangered Species Act and you deal with recovery, it doesn't mean returning all the way to natural conditions," he said. "I think endangered fish can tolerate a certain amount of development."

And with snowmelt still below average in some watersheds, Lake Flaming Gorge provides an important source of water for a growing population, Heffernan said.

"The current drought we're in shows the value of these reservoirs, for both water storage and endangered species. It provides a source of water for everybody in a period where there wouldn't be water otherwise," she said.

"Unless we can get everybody to not move to the state of Utah, (the dam) will continue to figure in our water needs substantially."

Complicating recovery efforts is the presence of an economically important blue-ribbon trout fishery below the dam. While the endangered razorback sucker, Colorado pikeminnow, humpback chub and bonytail require warm water, trout need cool water.

Crist said the new flow regime will create temperatures agreeable to both endangered fish and trout. But Weisheit sees that scenario as overly optimistic. "You can't manage for both endangered native fish and exotic fish in the same system," he said.

Letter to LR 06/17/03

Commissioner Keys responds to LR letter

United States Department of the Interior
Bureau of Reclamation
Washington, D. C. 20240
In Reply Refer To:
W-6333 June 17, 2003
ADM-13.00

Mr. Owen T. Lammers
Executive Director, Living Waters [Rivers]
P.O. Box 466
Moab, Utah 84532

Dear Mr. Lammers:

Thank you for your [letter to Secretary of the Interior Gale A. Norton dated March 14, 2003](#), regarding Colorado River issues. The Secretary has asked that I respond to you on her behalf. Similar to other Western rivers, the Colorado River Basin has experienced four dry years, some of which having been among the driest on record. With such a significant part of the nation dependent on water supplies from the Colorado River, it is truly fortunate that we continue to enjoy the benefits of our existing water supply facilities that help to mitigate to make up for these tough years of insufficient moisture.

As you point out in your letter, these issues are complex and sometimes contentious, and it gives me a perfect opportunity to mention the Secretary's new initiative, entitled Water 2025: Preventing Crises and Conflict in the West. Water 2025 recognizes the realities we face in dealing with water issues, such as explosive population growth, increasing needs for water for environmental and recreational uses, and the national importance of food and fiber production from Western irrigated agriculture. Water 2025 sets forth a strategic plan to facilitate a vigorous and educated public discussion in key Western communities, including those that rely on the Colorado River, where the likelihood for conflict and crises over water exists or can be predicted to occur by the year 2025. I invite you to attend and participate in any of the eight regional consulting sessions hosted by the Bureau of Reclamation. The information on these sessions is located on our website, www.doi.gov/water2025.

Again, thank you for your comments and concerns about Colorado River issues. The Colorado River has been and will continue to be a top priority for our agency, and I look forward to working with you and your organization in the constructive and positive manner set forth in Water 2025.

Sincerely,

John W. Keys, III
Commissioner

Colorado River basin unprepared for shrinking reservoir capacity

April Reese, Land Letter Colorado correspondent

PAONIA, Colo. -- The intricate plumbing system that has turned the arid Colorado River basin into a patchwork of irrigated fields and fast-growing cities is at risk of running dry if water managers do not focus more effort on keeping sediment from building up behind the river's dams, some water experts and river advocates warn.

The Colorado River stretches 1,450 miles from the Rocky Mountains to the Gulf of California and the Sea of Cortez, draining a 244,000-square mile basin. More than 30 million people in seven states depend on water stored in the basin's reservoirs to provide a steady and reliable supply for irrigation, hydropower and municipal water use. But while the dams allow large volumes of water to be stored and distributed, they also intercept sediment that would otherwise be carried downstream in the silt-heavy river. Sediment is slowing accumulating in the system's reservoirs, and eventually will render their usefulness for water storage obsolete, water experts say.

"If we allow those reservoirs to fill up with sediment, we'll have severe water shortages, and we will not be able to meet our water needs," said Ron Christensen, an independent water engineer based in Salt Lake City.

Scientists say siltation is affecting areas downstream as well: Reservoirs are collecting sediment that in a natural river system would flow downstream and replenish sandbars and riverbanks, resulting in erosion and a deepening of the river channel.

Barry Wirth, who handles communications for the Bureau of Reclamation's Upper Colorado River Basin office, said sedimentation "will present some challenges," but not until "many years down the road."

Wirth said it will take centuries for silt to have a major impact on water storage capacity in the basin's reservoirs. As an example, he cited Lake Powell, the reservoir created by Glen Canyon Dam in Arizona and one of the Colorado's largest. It will not silt up for another 500 to 700 years, he said, adding that that estimate is based "somewhat on conjecture."

But some water experts say that is an overly optimistic scenario that fails to take into account the vagaries of weather, climate change, water demand and other variables.

Christensen said capacity can shrink dramatically long before silt reaches the top of a dam.

For instance, "Lake Powell has gone from full to half empty," because of the current drought, he said. "If the reservoir was half full with sediment [when the drought hit], you'd be done today, basically. All the water you'd have is what's coming down the river

- there would be nothing in storage." Glen Canyon Dam and Lake Powell. Photo courtesy of BuRec.

John Weisheit, conservation director for the Moab, Utah-based group Living Rivers, said that BuRec's wait-and-see approach could backfire.

"It puts the entire system in jeopardy, and it's going to be embarrassing for them," he said. "They're in denial. They knew this was going to happen when the dams were built."

All of the dams -- including the massive Hoover Dam, built in the 1930s -- were constructed with extra storage capacity to account for sedimentation buildup, said Bob Walsh, Wirth's counterpart in BuRec's Lower Colorado River Basin office. Dam engineers estimated how much sediment was likely to build up behind the dam and expanded the reservoir's depth accordingly, Walsh said. For example, of Lake Mead's 32 million acre-feet capacity, 2.5 million acre-feet were set aside for sediment. (One acre-foot is the amount of water needed to cover an acre of land in one foot of water.)

"Some of the organizations that would like to see the dams removed would like to tell people the dams are going to silt up and be useless. But we've never seen anything that provides hard evidence of that," Walsh said. "The engineers that planned and built these dams knew the Colorado was a silty river and they took special precautions for that. These dams were built to handle sedimentation."

It's too soon to come up with solutions to a problem that isn't likely to surface for centuries, Walsh said. And when that day comes, "there will be ways to remove the sediment, if that's necessary," he said.

Wirth added that with the water supply for 30 million people -- and counting -- hanging in the balance, BuRec would not hesitate to address the sediment problem if the agency felt it was a pressing concern.

"It's to our advantage to do as thorough a job as we can, because it's in our best interest," he said. "We want to ensure the water is there to be allocated."

In the meantime, BuRec faces more immediate challenges, such as meeting the water needs of the current generation, Wirth said. "I just don't think in the year 2003, we can make an allocation decision for the people who will be here in 500 years. But we can do that for people who will be here in 2030," Wirth said. "Those dams were built according to what society wanted in those years. Now that we have 30 million people in the basin, how do we best utilize those resources?"

But as far back as the early 20th Century, before the dams were built, federal officials were expressing concern about sedimentation. In 1910, F. H. Newell of the Geological Survey, who later became the first Director of the Reclamation Service (now BuRec) wrote: "The upper ends of all reservoirs are rapidly filled with silt and it becomes an important question to the projectors of storage works as to how many years will elapse before the value of the reservoir is practically destroyed and whether its use can be restored in part by subsequent removal of some of this material."

Wirth said that as far as he knows, none of the reservoirs in the basin have plans for handling sediment buildup.

"I think that there are ways to wash the sediment out or stop it before it gets into the reservoirs. But no one's doing anything about it," Christensen said. "I think they ought to do it sooner rather than later because we need the water storage that we're losing to sediment," Christensen said. "We ought to be maintaining our storage capacity rather than letting it fill up."

As Colorado River-dependent cities like Tuscon, Salt Lake City and San Diego continue to grow, and demands on limited water supplies increase, maintaining full storage capacity in the system's reservoirs is becoming more crucial.

"Everybody's worried about how to get more water. Not nearly as many are worried about their reservoirs filling up with sediment," Christensen added. "And they're not going to worry about it until it becomes a problem."

Although BuRec and environmental groups have completed a handful of sedimentation studies of reservoirs in the basin, many are outdated or flawed, and "very little research is being done," Christensen said.

Water experts say the little research that has been done suggests that sediment is expensive to remove or control and difficult to dispose of.

But Weisheit said taking on the problem now, while it's still in the early stages, is preferable to waiting until diversion pipes are clogged with silt.

"A sediment survey for the whole Colorado River basin is an appropriate thing to ask for and accomplish," he said. "The longer they wait, the greater the amount of sediment they will have to deal with and the more it will cost to mitigate."

Water: Growing demand, dwindling supply

Shaun McKinnon The Arizona Republic Jul. 6, 2003

Lesson No. 1 about water in the West: There's never enough to go around, and no one's making any more.

Competition for what there is has intensified as growth and drought tighten the supply. The struggle threatens everything from economic development and tourism to agriculture and municipal water supplies.

Courts are deciding who can use the water and who can't. Cities are preparing to buy or lease from farmers or Indian tribes for 10 times the current cost.

If you go Phoenix will host the first of eight regional meetings to discuss issues raised by "Water 2025," Interior Secretary Gale Norton's blueprint for reventing water crises and conflict.

The half-day conference will be held from 1 to 5 p.m. Tuesday at the downtown Hyatt Regency Hotel.

Two sessions are scheduled, one to talk about specific Arizona issues and the other focusing on resolving conflicts. Participants include Herb Guenther, director of the state Department of Water Resources; Sid Wilson, general manager of the Central Arizona Project; Douglas Nelson of the Arizona Rural Water Association; and representatives from Indian tribes, environmental groups and local governments.

Additional sessions are scheduled throughout the summer in Las Vegas; Sacramento; Salt Lake City; Boise, Idaho; Billings, Mont.; Albuquerque and Austin.

Input from the sessions could help shape Water 2025 as well as other Interior Department water policies.

The Phoenix sessions are open to the public, but advance registration is required. Information is available by logging on to www.doi.gov/water2025/az/main.cfm.

And on the eve of a series of meetings aimed at quelling some of the unrest, the federal government lobbed its own bomb, ruling on Thursday that farmers in California's Imperial Valley are wasting water and will receive less beginning next year. Furious farmers are already preparing a legal challenge that will likely drag on for months and could eventually draw in Arizona and other states.

The escalating battles pushed Interior Secretary Gale Norton to step in and try to negotiate a truce. She introduced "Water 2025" in May as blueprint for preventing crisis and conflict and planned to begin discussing it with regional water leaders beginning Tuesday in Phoenix.

"When water crises and conflict pit neighbor against neighbor, species against species and business against recreation, when they threaten your way of life, we cannot afford to stand on the sideline," Norton said last month from Denver. "The consequences . . . are just too severe."

Critics have already dismissed Norton's plan as, among other things, "Band-Aids for gunshot wounds," as the environmental group Living Rivers called it. State and local water managers bemoan its puny budget, fearing more unfunded federal mandates. But some water experts believe it's a reasonable approach to a nearly unreasonable situation.

"The water supply is finite, and the demands are growing," said University of Arizona law Professor Robert Glennon, an authority on Western water issues. "There will be no new Central Arizona Project, no second era of dam building. That's just not going to happen. What the West is looking at is the fastest-growing section of the country, a population boom that's going on unabated. The question is, What's going to give?"

Among the issues that fuel the fiercest fights:

*Growth. More than 25 million people rely on the Colorado River, which is now controlled by dams and reservoirs for much of its 1,400-mile length. Nevada has exhausted its legal allocation of the river and is now searching for alternatives. Colorado lawmakers recently approved a plan to build a new pipeline that will carry more of that state's share of the river to its most populous cities east of the Rockies.

Related links

- * Saving Southwestern willow flycatcher
- * Special report: A long, dry streak

The story is similar on other rivers, which strain to serve growing populations. "Almost every major river in the West is overappropriated," said John Keyes, commissioner of the Bureau of Reclamation, the agency that operates most of the region's water delivery systems. In Arizona, the groundwater supply is at greater risk of depletion, especially in rural areas.

*Environment. Courts are increasingly siding with environmental groups who want water set aside for wildlife and natural habitat. Salt River Project must spend \$20 million to create and maintain a habitat for the Southwestern willow flycatcher, an endangered bird that moved into the drought-stricken edges of Roosevelt Lake. Another court ordered the Army to reduce its pumping near Sierra Vista, ruling that growth there was endangering the San Pedro River.

Just last month, a New Mexico court ruled that Albuquerque must take less water from the Rio Grande to accommodate the endangered silvery minnow. That decision is "huge," said Lisa Force, Arizona program director for Living Rivers. "It has the potential of impacting Western water law."

* Politics. Few issues have fueled the kind of political battles that water has in the West. And it has rarely been more evident than the past year in California, where the powerful Imperial Irrigation District has dug in to protect its huge water supply from San Diego, Los Angeles and the U.S. government.

Federal officials said Thursday that the district is wasting some of its allocation and will lose up to 9 percent of its water next year. Imperial holds the rights to more water than any single user on the river, more than the entire states of Nevada, Wyoming and New Mexico.

In Arizona, tribal water claims are crawling through Congress, the Legislature and the courts. The Navajo Nation earlier this year filed suit to force action on its claim to the Colorado and Little Colorado rivers, a move that could set off new skirmishes over who must give up water to satisfy any settlement.

If the tribes decide to lease water back to urban providers, they could demand premium costs. Valley cities that now pay roughly \$30 to \$100 per acre-foot could find bills topping \$1,000 per acre-foot, according to water experts. (An acre-foot equals 325,851 gallons.)

* Agriculture. Despite the urban growth explosion, farmers still use more water than anyone else in the West. The Imperial Irrigation District in southern California holds the largest single allocation on the Colorado River, larger even than all of Arizona's. That gives farmers power, but in many cases, it also gives cities a source of water for new growth. The battles will focus on how farmers will reduce their consumption and how much cities will have to pay them to do so.

* Drought and climate. The one pressure point out of anyone's direct control, drought has reshaped many of the arguments in recent years simply by reducing the amount of water available. Both the Colorado River and the Salt and Gila rivers in Arizona produced record-low runoff last year, forcing cities to draw heavily on reservoirs. Lake Powell is now at half-capacity, and Lake Mead dropped low enough to trigger limits on some states.

Drought cycle

University of Arizona hydrologist Julio Betancourt predicts the Southwest is headed into a long-term drought cycle that would choke the water supply for years or even decades. But that may be just the beginning, according to Tim Barnett, a researcher at Scripps Institution of Oceanography who is studying abrupt climate change.

Warming seasonal temperatures will shorten the snow-melting season in the West's high country and will reduce runoff by 17 percent to one-third on the Colorado River and other systems, leaving them unable to meet demands for the foreseeable future, Barnett asserts.

Those pressure points form much of the foundation for Norton's Water 2025 initiative, which begins with what she calls "the five realities:" growth, existing water shortages, conflicts caused by those shortages, aging water delivery and treatment systems, and ineffective crisis management.

From there, she proposes four tools to help stave off future crisis and conflict: improving water management through conservation, efficiency and water markets, such as Arizona's water bank; collaboration among cities, farmers, environmental groups and others who have a stake in the West's water; boosting supplies with technology such as desalinization of water that otherwise would be wasted; and adjusting policy and even law to more efficiently use existing supplies.

The proposal included an \$11 million appropriation for the first year, an amount reclamation chief Keyes acknowledges would barely address issues in Phoenix but still "money to get things started." The Interior Department will encourage state and local leaders to develop ideas and plans suitable for their specific situations.

Water experts say the plan falls short of addressing some of the most critical conflicts still looming. One potentially blockbuster showdown is brewing just over the border in Mexico, where environmental groups in that country and this one are trying to force their governments to restore the Colorado River Delta. That once lush riparian area most years now receives no water from the overtaxed river.

Restoring it would cost tens of millions of dollars and billions of gallons of water, which someone would have to give up at such a significant cost that few U.S. leaders will even consider it. Some delta advocates have tried instead to focus on minor successes that could lead to a long-term approach.

One such example is a tiny edge of the delta just south of Yuma, where runoff from farms has created a new riparian habitat that supports birds and other wildlife.

"The big lesson is that it is possible on very small water budgets to finally incorporate wildlife and the river itself into the way we manage the river," said Charles Bergman, whose book *Red Delta* chronicles the transformation.

The one hitch: The water that runs into the marshes is the same water that some officials want to treat and desalt, making more efficient use of it.

The only way around such conflicts is to settle feuds, set aside differences and cooperate, said Patricia Mulroy, general manager of the Southern Nevada Water Authority.

'This is all political'

"The consequences of not cooperating are very real and very immediate," Mulroy said. "If this drought continues, there is no way, given the current separatist approach of the lower basin states, that we can all make it through. This is all political. The hydrology of the river has made those politics more acute."

She said Arizona's willingness to bank water for Nevada is one sign that politics aren't forever. Norton actually cited the water bank in her initiative as an example of what should happen throughout the West.

"Long-lasting solutions will come from the people who must live with or learn to live without the water they need," Norton said.

"Doing nothing is an option, but only if we are willing to accept the drastic consequences that follow."

Thirsty Colorado Is Proposing to Stick a 'Big Straw' Into Its Namesake River

July 12, 2003 LA Times Headlines

By Bettina Boxall, Times Staff Writer

GRAND JUNCTION, Colo. - It's an audacious - some say absurd - scheme: Take Colorado River water just before it slips over the Utah border, pump it east more than 200 miles, lift it 5,000 feet over the Rocky Mountains and deliver it to the state's burgeoning Front Range communities.

Nicknamed the "Big Straw," it is a big, old-fashioned kind of idea, reminiscent of the mega-water projects that greened the West in the 20th century. Estimates of its cost start at \$2.5 billion and climb. Opponents call it a giant boondoggle in the making that would suck water from some of Utah's most popular rafting spots and deplete flows needed by endangered fish.

The Big Straw's grand scope underscores Colorado's keen desire to protect its full share of the 1,400-mile-long river that cleaves the Southwest like a rusty saw. Downstream in California, the plan is seen as a harbinger of the future, when the rising demands of other states along the Colorado will inevitably staunch the bounteous surplus on which the Golden State has long depended.

The water hog of the Colorado, California has no choice but to stand by while other states move to tap their full entitlements meted out by Congress and a multi-state compact in the 1920s and '40s. "They have a right to develop their apportionment," said Dennis Underwood, vice president of the giant Metropolitan Water District of Southern California.

California's prodigious thirst looms large in Western water policy and is helping drive the Big Straw proposal. Politicians see it as a way to keep Colorado water in Colorado - and out of the swimming pools and sprinkler systems of Southern California.

"While Coloradans are carefully considering which day they are allowed to turn their home sprinklers on, California lawns are lush and green, thanks to Colorado's water," Gov. Bill Owens lamented during a water policy discussion this spring.

The Big Straw proposal is still in the earliest stages of review. A \$500,000 study, due out in the fall, will determine only if the project is worth pursuing, not whether it will be built.

Nobody can say at this point how much electrical power it would take to transport the water, how much the project would cost, who would pay for it, what the route of the pipeline would be, or how much treatment the water would require. Nor can anyone say precisely who would use the water, which is coveted more for the Front Range's future growth than current consumption.

But Grand Junction water attorney and Big Straw backer Gregory Hoskin believes there is a ready market, even if the water proves expensive.

"This is the desert. People can't stand the desert. They need trees. They need green," insisted Hoskin, a member of the Colorado Water Conservation Board. "I don't know what people will pay for water. But I know people with money will pay anything to water their lawn."

Were it not for a mismatch of geography, Coloradans would probably already be using their full share of the river. But the Colorado, like most of the state's water, is on the western side of the Rockies, while most of its people - and growth - are on the eastern side in a stretch of development that runs from Colorado Springs to Denver and beyond.

Starting in the 1930s, the state and the federal Bureau of Reclamation developed a complex system of reservoirs, aqueducts and mountain tunnels to ship water to the eastern side of the Continental Divide. The Big Straw would reach farther, pulling water through a 10-foot-wide pipe all the way from Colorado's westernmost border. The pipeline would climb 4,000 to 5,600 feet over the Rockies, higher than California's most grandiose projects. Although the State Water Project in California sends water a greater distance - 600 miles south to Los Angeles from the Sacramento-San Joaquin Delta - its rise across the Tehachapi Mountains is no more than 2,000 feet.

By waiting to tap the river after western Colorado has used what it wants, the Big Straw would avoid many messy in-state water brawls. But removing at least several hundred thousand acre-feet of water annually - an acre-foot would supply two Southern California households for a year - could change the nature of the river in the downstream states.

There would be much less flow for the river's four endangered fish species, for the huge reservoirs that store water for the Lower Basin, and for the rafting outfitters who play a significant role in Utah's recreation economy.

"We think it's horrible. It could put the river-running industry at risk," warned John Weisheit, conservation director of Living Rivers in Moab, Utah, and a member of several river outfitter boards. "It is going to be a huge burden to the taxpayer, when the more reasonable alternative is conservation."

The proposal has its critics in Colorado as well. "I don't think average, everyday Coloradans want to pay through the nose for a project like this," said state Sen. Terry Phillips, a Democrat from the Denver suburb of Louisville who scoffed at the Big Straw as an extravagant fantasy when the Legislature appropriated funding for the preliminary study. "It's ridiculous."

At the Colorado Canyons National Conservation Area, manager Greg Gnesios fears the pipeline's massive infrastructure could blight the scenic red rock canyons of the 123,000-acre tract bordering the river at the state's western edge.

"It's almost like putting it through the national park," Gnesios said. "That could create some problems for the Big Straw folks."

Dan Luecke, a hydrologist who works for several Colorado environmental groups, doubts that the scheme will survive close scrutiny.

"I think an evenhanded study will drive a stake in its heart," he said. "It's a bad idea. It will be enormously expensive. It will require an enormous amount of energy to pump that water. It will have incredible water quality problems."

Born amid the 13,000-foot peaks of Rocky Mountain National Park, the Colorado is far from pristine when it hits the Utah border. Often it resembles a giant, murky irrigation ditch.

On its course down the western slope of the Rockies, the river picks up salts and selenium from the riverbed and farm runoff, as well as urban effluent. The river's salinity levels at the Utah border are 10 times greater than they are at its headwaters. Selenium levels at times exceed state standards. If pumped untreated to high-country reservoirs on its way to the Front Range, the border water would be warmer and dirtier than the supplies into which it is piped, lowering overall water quality.

"From our standpoint, that is the biggest concern," David Nickum, executive director of the Colorado Council of Trout Unlimited, said as he stood near a mountain reservoir that flows into a trout-fishing river. "If you envision taking a large amount of water out of the Colorado and bringing it up here, it's hard to imagine the magnitude of the change [in quality] or the magnitude of treatment."

Using more water in the Colorado's Upper Basin also means that less water would reach the Lower Basin, where California has been sucking more than its share from the river for nearly half a century.

It could do so because the other six Western states that draw from the Colorado didn't need their full allocations. But as the West grows, that is changing. Arizona and Nevada have both begun to use their full river entitlements in the last three years.

"Now the reason there are surpluses is because the Upper Basin states have not developed their allocations," observed Jerry Zimmerman, executive director of the Colorado River Board of California. "In the future, there will not be surpluses nearly as frequently."

Nor is there as much water in the Colorado as everybody thought when the river's flow was divvied up between the Upper and Lower basins in a 1922 interstate compact.

Hydrologists had figured that 18 million acre-feet of water a year spilled down the river's rock-walled canyons to the Gulf of Mexico. But that estimate, based on a wet period, turned out to be too high by about 3 million acre-feet a year. The average river flow is in fact less than the total legally allotted to the seven basin states and Mexico.

"If you have a river overcommitted, then the chances of getting shortages are there. That's why you need to look at more effective ways of doing things," said the MWD's Underwood.

Ironically, the Big Straw idea grew out of love of another river. Ralph Clark III, a private environmental planner, first proposed it in the late 1980s as a way of protecting the headwaters of the Gunnison River in western Colorado. Better, he thought, to take water from the Colorado at the state border than divert the upper reaches of his beloved Gunnison to the east side of the Rockies.

But even Clark is not yet prepared to endorse its construction. He thinks of the Big Straw, which he more mundanely calls the Colorado Aqueduct Return Project, as a last resort. * Times staff writer Doug Smith contributed to this report.

Reclamation chief won't drain Powell

Arizona Daily Sun

By PAUL FOY

Associated Press Writer

SALT LAKE CITY -- Advocates of draining Lake Powell and allowing the Colorado River to flow freely through southern Utah again pitched their idea Wednesday to the head of the Bureau of Reclamation, but he dismissed it out of hand, declaring: "That's never going to happen."

Reclamation Commissioner John Keys convened the fourth of eight regional conferences on Western water problems Wednesday in Salt Lake City.

Speaking to about 350 government and water district officials, Keys advocated conservation, collaboration and planning. He told officials they shouldn't look to the federal government for money as a solution.

"I didn't come here with a bag of money to solve everyone's water problems," Keys said.

Advocates of draining Lake Powell argued that four years of drought have left the huge reservoir on the Utah-Arizona border only about half full.

John Weisheit, director of the Moab group Living Rivers, said Lake Powell could be sucked dry in eight years if the drought continues. Keys disputed that, saying Lake Powell never would run dry. And he said it would be irresponsible to drain Lake Powell or Lake Mead, the two largest Colorado River reservoirs.

Weisheit said the reservoirs squander huge quantities of water to evaporation and seepage -- a loss Keys dismissed as the "cost of doing business."

Without Lake Powell or Lake Mead, Keys said, the 23 million people who depend on the lower Colorado River basin would have had only 40 percent of their normal water supplies last year.

"It's something that's never going to happen," he said in an interview of the idea of tearing out Glen Canyon Dam. "I won't spend a dollar studying it."

LR Press Release 07/22/03

House votes to destroy Colorado River Delta wetlands

Taxpayer money to be wasted on mothballed desalting plant; Senate yet to act
Contacts:

Owen Lammers, Living Rivers, POB 466 * Moab, UT 84532 * 435-259-1063/fax
259-7612

Lisa Force, Living Rivers, POB 1589 * Scottsdale, AZ 85252 * 303-237-2269/fax

480-990-2662

Kara Gillion, Defenders of Wildlife * 824 Gold SW, Albuquerque * 505-248-0118

The U.S. House of Representatives voted last Friday to retool a defunct desalting plant near Yuma, Arizona. The Bureau of Reclamation (Bureau) estimates the cost of repairing the now obsolete plant technology at \$26 million. The decision was made despite the reality that operating the plant will destroy the majority of wetland habitat in the Colorado River delta region, and that far less costly measures are available to meet US treaty obligations for water delivery to Mexico.

"At a time when federal deficits are skyrocketing, it's unbelievable that Congress would consider throwing away taxpayers dollars to retool this plant, " says Lisa Force, program director for Living Rivers. "This is pork barrel politics at its worst."

The inclusion of the provision in the House report on the 2004 Energy and Water Appropriations bill allows for re-operating the Yuma Desalting Plant, a measure which the Bureau estimates will cost a minimum of \$36 million annually. Completed in 1992 at a cost of \$256 million to clean up brackish wastewater from farms in southern Arizona, the plant was shut down several months later due to extremely high operating costs. The Bureau of Reclamation has downplayed an alternative solution costing 33% to 85 % less--just \$6 million to \$26 million annually--involving paying willing sellers to lease water they presently do not need.

The agricultural wastewater that the plant would process is now funneled into the Cienega de Santa Clara, a 40,000-acre open water ecosystem in the Colorado River delta region. The desalting plant would remove the entire flow from the cienega and return only highly saline brine to the wetlands.

"This provision would destroy an extremely important wetland in Mexico that contains the largest remaining population of Yuma Clapper Rail in the world," says Bill Snape, Defenders of Wildlife Vice President for Law and Litigation. "It will be impossible to replace the value of the Cienega de Santa Clara to the Colorado River ecosystem."

The cienega is the largest remaining wetland in the southwest Americas and is home to fifty-six threatened, endangered and declining species. Several scientific studies funded by the Department of Interior confirm that the wetland would be completely destroyed by desalter operations.

"This is reminiscent of the days of old, when the Bureau wasted tax payer money left and right, leaving renowned habitat laid to waste," says John Weisheit, conservation director of Living Rivers and the designated Colorado Riverkeeper.

"We are disappointed that some members of Congress wish to move forward with such an expensive and destructive proposal. Congress mandated public involvement in Colorado River management but we fear the public is not being heard," says Steve Glazer, Chair of the Sierra Club Colorado River Task Force.

"We're fighting hard to ensure the Senate does not duplicate the folly of the House," adds Lisa Force. The U.S. Senate is expected to vote on the water and energy appropriations bill as early as this week.

LR Press Release 08/11/03

Sediment forces closure of Hite Marina

For immediate release
August 11, 2003

Contact: John Weisheit (435) 259-1063

Sediment makes access to Hite Marina impossible

Glen Canyon Dam hydropower at risk

As predicted two years ago by the environmental group Living Rivers in Moab, Utah, Colorado River sediment at Hite Marina has necessitated the removal of all reservoir conveniences such as the floating store, fuel docks, water and septic lines, boat rentals, and courtesy docks. With the blessing of the National Park Service the concessions operator, ARAMARK, has literally lifted anchor and towed their floating facilities down-reservoir to keep their investment from becoming engulfed in mud.

A "use at your own risk" boat launch currently remains open for the convenience of river runners and small, hard-hull boaters. Because Lake Powell reservoir is dropping fast, this primitive boat ramp will be completely unusable by the first of September, and will force river runners to go another 45 miles down-reservoir to exit instead at Bullfrog Marina.

The land-based facilities at Hite, which includes a store, gasoline, drinking water and a sewer clean-out, will remain open to service the needs of the residents and the traveling public.

In 1986 the Bureau of Reclamation determined that the delta for the Colorado River arm was located at Dark Canyon, which is 15 miles above Hite. The National Park Service and ARAMARK jointly authorized a sediment survey to be conducted by Mussetter Engineering of Denver in 2000. The engineers had determined that the delta advanced from Dark Canyon to the mouth of the Dirty Devil River at a rate of about one-mile per year. At present the delta is just beyond Hite Marina where the original river channel is 245 feet below the full reservoir elevation of 3700 feet.

According to the 2000 survey, reservoir managers were given another 35 years of service at Hite Marina provided the reservoir could be maintained at full pool. "Such a projection is incredibly optimistic," says John Weisheit, conservation director of Living Rivers. "Considering the downstream demand for water, the present drought situation, and how the river erodes into the exposed sediment and feeds the delta, the facilities at Hite are basically history."

By April of 2004, Lake Powell reservoir is predicted to be 106 feet below normal. At this elevation, Bullfrog and Antelope Point marinas will also feel the effects of sustained drought. The boat ramp at Bullfrog is beginning to flatten out and the lack of incline will make it very difficult to load and unload boats--especially longer craft such as a houseboat and the highway department's ferryboat. Because Antelope Point is located on the rim of the original Colorado River canyon, the lowering reservoir level will perch this boat ramp high and dry. Already boat traffic is creating congestion problems at the narrows before Antelope Point and a no-wake designation is now being enforced to minimize hazards to navigation.

During the spring snowmelt, Lake Powell reservoir levels rose a mere 11 feet. Already the reservoir has returned to the levels of the previous winter. With no drought relief in sight, this continuing trend will eventually place power generation at risk too. The minimum storage level to safely produce electricity is set at 6 million acre-feet. Right now the reservoir is storing 12.7 million acre-feet of water at 50% of capacity. Power generation at Glen Canyon Dam could effectively end in two or three years under present drought conditions.

"This drought emphasizes the dubious nature of Lake Powell reservoir. By decommissioning Glen Canyon Dam we could restore five hundred miles of river to its natural habitat, which includes Grand Canyon National Park, while at the same time saving the water that is otherwise lost to evaporation," concludes Weisheit, who is also the designated Colorado Riverkeeper.

LR Letter 08/11/03

Proposed Modification to Mechanical Removal of Non-native Fish from the Colorado River in Grand Canyon Arizona, dated July 25, 2003

August 11, 2003
Mr. Dennis Kubly
Bureau of Reclamation
125 South State Street
Suite 6107
Salt Lake City, UT 84138-1107

Re: Proposed Modification to Mechanical Removal of Non-native Fish from the Colorado River in Grand Canyon Arizona, dated July 25, 2003

Via Fax and E-mail

Dear Mr. Kubly ,

Thank you for the opportunity to submit comments on Proposed Modification to Mechanical Removal of Non-native Fish from the Colorado River in Grand Canyon Arizona, dated July 25, 2003.

Living Rivers finds this proposed action constitutes improper science, thus an inappropriate deviation from the original objective. Living Rivers is also disappointed that this proposed action represents yet another example of how the Adaptive Management Program (AMP) is failing to address the long-term recovery needs for endangered fish, and merely perpetuating a reactive strategy with no demonstrated results.

1) No justification for altering the experiment

As noted in materials for the 13-14 August AMP meeting, it is clear that in-migration is occurring in the existing mechanical fish removal zone. The supplemental EA stated the contrary. (The EA should be re-written to reflect this new information, and released again for public comment.) Since there is no confirmation that the experiment is indeed permanently reducing non-native population to desired levels, there is no reason to contemplate any change in the experiment.

Second, while the experiment is certainly demonstrating that fish are being killed, there is no data to support the experiment is leading to improved Humpback Chub recruitment. It is improper to change the parameters of the experiment until such time as there is a demonstrated rationale to do so. Such is not the case at present, especially, as noted above, with migration now well underway.

Third, there has been no independent review of this proposal, a consistent recommendation by the National Research Council and the National Academy of Sciences of such GCMRC activities.

2) Demonstrated lack of focus on the long term objectives.

The investment of AMP resources in contemplating and studying the alteration of an incomplete, and so far, inconclusive experiment is yet another unfortunate example of poor leadership within GCMRC and the AMP. There is an extensive amount of work that needs to be undertaken to help recover Grand Canyon's native fish, the principle charge of the AMP. After nearly two decades, seven under the direction the AMP, the results have been abysmal. This is in no small part due to wasted resources, such as plans to alter an experiment with insufficient justification to do so.

A more appropriate investment in resources would be to begin studying and implementing mechanisms to address the need to reduce non-native fish with natural, as opposed to mechanical approaches. An objective of the AMP is to reintroduce presently extirpated species, such as the Colorado Pikeminnow or Otter. Both such species would gladly feed on the non-native fish, likely at a much higher rate than the remaining natives.

With movement now by the AMP to address the need to warm the water, habitat conditions may be sufficient to support Pikeminnows. But the AMP need not wait until the temperature issue has been resolved to implement such a reintroduction, as it may petition to so for experimental purposes, despite the fact that it is unlikely that the Pikeminnow can reproduce in the present system. However, if it appears that they are

helping to significantly reduce the non-native population, with minimal impact to the native fish, and thus aiding in Humpback Chub recruitment, this would be cause to accelerate efforts to realize this species recovery as well.

While the Park Service has so far been resistant to Otter reintroduction due to inconclusive evidence regarding which sub-species dominated Grand Canyon habitat, it is clear that the increased interest and assumed need to increase predation on non-native fish, amplifies the call for implementation of a reintroduction plan.

Such nature-based proposals to mimic and rebuild the natural system should be the focus of the AMP, not short-term efforts to modify inconclusive experiments.

Thank you for your attention to these concerns.

Sincerely,

John Weisheit Conservation Director

LR Letter 08/13/03

Concerns regarding Glen Canyon Dam Adaptive Management Program

August 13, 2003

Mr. Michael Gabaldon Deputy Director of Operations U.S. Bureau of Reclamation
Department of Interior 1849 'C' Street, NW Washington, DC 20240

Re:Concerns regarding Glen Canyon Dam Adaptive Management Program

Dear Mr. Gabaldon,

The consistent message emanating from the Glen Canyon Dam Adaptive Management Program (AMP) is that it is failing in achieve its principal objective, the protection and recovery of endangered Humpback Chub (HBC). While the AMP and independent scientists debate how low HBC numbers are, all agree that they have declined considerably since the process began seven years ago. Living Rivers recognizes that AMP efforts are underway in an attempt to remedy this situation, but is very concerned that such efforts are not sufficiently comprehensive, nor do they justify hasty and inappropriate management practices.

Furthermore, Living Rivers believes that more than sufficient "new information" now exists to warrant the immediate undertaking of an entirely new, or supplemental, Environmental Impact Statement (EIS). Additionally, such new information also warrants an EIS be prepared for the planned Temperature Control Device (TCD) or the potential installation of generators on the dam's bypass tubes.

1. Emphasis on HBC numbers insufficient to address recovery needs

The AMP and Grand Canyon Monitoring and Research Center (GCMRC) focuses undue emphasis on yet conclusive approaches of counting of fish, and little to no

resources on understanding their physical condition, nor the biological parameters necessary for their recovery. After nearly seven years of operation, all GCMRC has learned is that HBC populations are declining, but cannot determine by how much. The present estimate has an one hundred percent level of variability of 2,000 to 4,000 fish. Why has GCMRC yet to develop a mechanism to provided reliable fish counts, nor can the scientists within the AMP agree on whether the present counts constitute a crisis as far as the near extirpation of HBC in Grand Canyon?

The AMP's priority should not just be numbers of fish, but knowing their physical condition and what biological parameters must exist for preservation, and, as necessary, recovery. In 2000, Meretsky, et. al., published findings that indicated a possible decline in HBC condition since 1978. If true, such a trend would indicate that factors other than predation are effecting the HBC, and that undue emphasis on predation, as is presently occurring, won't address this problem. So far all reports and analysis by the AMP have focused on HBC numbers, and not their relative condition or health. While some of this data has been collected, there has not yet been any ongoing analysis of HBC condition factors as was recommended by Meretsky. Why?

Additionally, GCMRC has not developed sufficient information on HBC biological parameters. Such understanding is critical for making effective management decisions for the HBC future in Grand Canyon. At minimum, GCMRC should be investigating feeding habits, water quality, and recruitment and migration patterns for all periods of the HBC's lifespan. As the Little Colorado River presently represents the sole refuge for HBC in Grand Canyon, immediate emphasis should be placed on understanding the biological parameters to be persevered in this tributary to ensure this critical habitat is not disrupted.

Lastly, GCMRC must determine the population level, and changes in biological parameters, that would trigger a cessation of handling HBCs so as to avoid placing undue stress on the remaining population.

2. Inappropriate emphasis and approach to alien fish suppression

Scientist's are in agreement that predation by alien fish on HBC is limiting their recruitment, and thus suppression of these predators is warranted. While Living Rivers concurs, we find GCMRC's management choices are over-emphasizing this aspect of the problem, potentially to the detriment of the HBC recovery effort, and the scientific integrity of the AMP process.

First, the non-native fish suppression flows from Glen Canyon Dam represent a significant departure from the spirit of the EIS and the Record of Decision (ROD). While the flow levels themselves are within the ROD, they are being used in an attempt to affect non-native fish, not to directly affect native fish as was contemplated in the EIS. Any departure from the river's natural hydrograph is bound to have negative effects ecosystem-wide, not just the HBC. However, because the AMP has not sufficiently addressed the biological parameters for the HBC, it is not yet qualified to determine if, and to what extent, these alien fish suppression flows are impacting HBC recovery. It is also unclear if these flows have demonstrated any formidable change in trout

populations. Plans to repeat these flows in 2004 are not prudent. Also, how could these increases in daily flows compliment a Beach/Habitat Building Flow planned for January if triggers are met? They seem at odds with each other.

Living Rivers is also concerned with the lack of independent review, and competitive bidding associated with contracts being let for monitoring the results of these experimental flows. When the AMP began seven years ago, it took pride in the independence afforded in the competitive bidding process for its science programs. Now, the vast majority of this work is being moved in house to GCMRC staff. When consultants are being used, as in the case of monitoring for these experimental flows, they are awarded without any competitive bid. This appears particularly suspicious in this case, since a contract was awarded to ECO PLAN Associates, which has been under contract with the Western Area Power Administration (WAPA). As these experimental flows would benefit WAPA and its customers by affording greater flexibility in power generation ramping, and that a variety of other consultants with greater experience in this area were not considered by GCMRC, AMP's appointment of ECO PLAN Associates has the strong appearance of industry bias.

Problems with the lack of independent oversight also appear to be surfacing with the mechanical fish removal program. The recent proposal to alter this program has been prematurely developed and submitted to the AMP without sound justification. The experiment has yet to demonstrate any impact on HBC recruitment, nor that in-migration is indeed not occurring in the target zone. Independent review of such proposals as recommended by the National Research Council should be standard procedure for such modifications to AMP activities to avoid such potential missteps in future.

A more appropriate and economically sustainable plan for non-native fish removal would be to study the reintroduction of natural predators. The management objectives of the AMP are to reintroduce presently extirpated species, such as the Colorado Pikeminnow or River Otter. Both aquatic predators species would gladly feed on the non-native fish, and likely not harm the native fish population.

The AMP could petition the US Fish Wildlife Service for an experimental release of the endangered Pikeminnow, despite the fact that it is unlikely that the Pikeminnow can reproduce in the present ecosystem. Thermal modification of the river could also provide the needed habitat for recruitment of these native predators. This scenario would provide sustainable control of alien fishes in Grand Canyon while providing for the recovery of two native fish.

There has been resistance to studying River Otter reintroduction due to inconclusive evidence regarding which sub-species dominated Grand Canyon habitat. However, it is clear that the increased interest and assumed need to increase predation of alien fish, particularly trout, amplifies the call for a reintroduction plan. Such nature-based proposals to mimic and rebuild the natural system should be the focus of the AMP, not short-term efforts to modify inconclusive experiments.

3. Need for a Supplemental Environmental Impact Statement

The assumed environmental baseline associated with the Glen Canyon Dam EIS, and the launching of the AMP has little bearing on reality. Options allowed under the ROD have been attempted and have proven to be ineffective, leading to continued impairment to all significant downstream resources since the ROD was implemented. This is now placing the AMP in uncharted territory, as evidenced by the implementation of trout suppression flow not contemplated by the EIS or the ROD. Furthermore, the continued drought conditions are effecting reservoir levels, and soon, water temperature and dam operations in a manner not evaluated in the EIS. The AMP is effectively operating without a net, and must advise the Secretary of the Interior to call for a supplemental EIS to guide and inform its future programs.

The most significant changes are in HBC populations and sediment budgets. While the AMP has yet to agree on how bad the current HBC count is, there is no doubt that the population is in significant decline since the program began. Furthermore, there has been no movement on establishing a second population in the mainstem Colorado. Beach building efforts under the ROD have not worked in a sustained manner. The number and size of beaches in the Grand Canyon have experienced a significant decline since the AMP was put into place. Not only has this negatively effected the Canyons recreational experience, but has also impacted the river corridor's cultural resources which are now prone to erosion.

Anticipated upstream impacts associated with reduced elevations of Glen Canyon Reservoir (i.e. increased temperatures, modified nutrient dynamics, etc.) will have significant effects on the downstream resources in the Grand Canyon. As the drought situation persists, these effects will become most pronounced once reservoir levels fall below the elevation of the penstocks.

The key to reinitiating compliance with the National Environmental Policy Act, through a supplemental EIS, is if new data or impacts are recognized. Clearly in the case of Glen Canyon Dam and Grand Canyon National Park, significant new data (biological and sediment) indicate that the ecosystem needs to be reevaluated and assessed. The fact that new data on the HBC, sediment deposits, cultural resources, water quality, and reservoir levels show that decisions made on the original data from the Glen Canyon Environmental Studies is now in need of reassessment.

Thank you for your attention to these matters, and we look forward to your reply.

Sincerely,

John Weisheit Conservation Director

LR Press Release 08/15/03

Draining Update: 50 percent--forcing marina closures.

Marinas left high and dry, power generation next to go.

Contact:

John Weisheit (435-259-1063 or 435-259-8077)

Lake Powell reservoir is down 90 feet from normal, equating to a reservoir that is half full. The National Park Service, which manages marina facilities at Lake Powell, is at the beginning of shutting down marina's because they can no longer accommodate launch vessels. Meanwhile, Glen Canyon Dam is just two years away from no longer being able to generate hydroelectric power.

Now in the fourth year of an anticipated sustained drought, Lake Powell reservoir will soon be empty. Forecasters have informed the Park Service that the reservoir levels will only be getting lower. The reservoir is dropping faster than it can be replenished.

The United States Geological Survey 2002 report on Southwest climate change predicted that the Colorado Plateau would be heading into a 30-year period of below average river flows. Previous estimates by forecasters, on the impacts of such a sustained drought, calculated that Lake Powell would be drained within eight years. It's right on schedule. In July 1999, Lake Powell was at 90 percent. As of August 1, 2003, it was at 50 percent.

If the present drought does not relent, within two years Lake Powell will drain to the level of the penstock tubes that spin the generators at Glen Canyon Dam. According to a model that was published in October of 1995 in the Water Resources Bulletin, if a severe and sustained drought similar to the drought of the late 16th century appears, Lake Powell could stay drained for eight years.

"We're witnessing the end of Lake Powell right now," says Living Rivers' Conservation Director John Weisheit. "This was predicted, and nothing the National Park Service or the marina operators can do will change this."

- Two of Lake Powell's six boat ramps have been closed, and another will be closed by the end of the season. River sediment has brought an end to the marina at Hite at the top of the reservoir. At the other end of the reservoir, near Glen Canyon Dam, Antelope Point's marina facilities will soon be forced to again close because they will be perched atop a cliff being exposed as the reservoir lowers. This, just four years after construction in 1999.
- A \$3 million emergency appropriation was made in January to extend three other boat ramps at Bullfrog, Hall's Crossing and Wahweap marinas. But as the reservoir continues to lower, Bullfrog marina may also see its facilities shut down. Wahweap and Hall's Crossing will probably be able to stay open until the reservoir completely drains.
- A new \$75 million marina facility is supposed to be under construction at Antelope Point, but with a 500-foot cliff being exposed where the launch ramps are proposed, progress has stalled. Calls to Antelope Point Holdings and their

engineers, revealed no comment to the feasibility of the project..

- The fate of the white-water rafting industry, which concludes trips at the top of Lake Powell, is also a major question. With sediment and mud clogging the marina and boat ramp at Hite, rafters will have a very difficult time getting off the water.

"As the drought persists, it is going to be very difficult, if not impossible, to conduct business as normal with the river and reservoir users. This includes the Grand Canyon river runners who will lose the large Glen Canyon Dam releases they need to run their large motorized boats through the canyon only to arrive at the sediment-choked Lake Mead," adds Weisheit.

Lake Powell is not the only problem. The entire Colorado River storage system has dropped from 92 to 60 percent over the past 44 months. "Lack of access to flat water recreation is the least of our worries," concludes Weisheit. "The Southwest plumbing system is headed for complete catastrophe, and the Bureau of Reclamation and the seven states that use Colorado River water have no disaster preparedness."

Colorado River Battle: 100 Years of Water War

Deal: Thirsty California, desperate for water, is willing to pay reluctant farmers billions to get some of their surplus.

By Alec MacGillis

Baltimore Sun National Staff

EL CENTRO, Calif. - Inch by inch, the life's blood of a large swath of the United States - Colorado River water - seeped across the desert. Or rather, across the desert that is now Mike Cox's cotton field.

For Cox, circling the field in his pickup truck to check on the water's progress, soaking his cotton is a routine procedure. Every 10 days during the summer, he uses 7.8 million gallons of water diverted by canals from the Colorado River to irrigate the 70-acre field, just a fraction of the 1,000 acres he farms in California's Imperial Valley.

But for the rest of the Southwest, Cox's routine watering represents something more significant. In this single irrigation of a tiny corner of a broad farming plain, Cox used about as much water as 50 households use in a year - as much as all their showering, toilet-flushing and dish-washing put together.

This is the explosive equation at the heart of the battle that, after gripping the Southwest for years, is now nearing a climax.

With the cities of the western Sun Belt booming, much of the water from the Colorado River, the main water source in a parched region, continues to be used by only a few hundred farmers in the Imperial Valley along the Mexican border.

The valley won the right to the water more than 100 years ago and has guarded it ever since. But in a historic shift, the Southwest is now on the verge of a landmark transfer of Colorado water from the Imperial Valley to San Diego.

The deal, which negotiators hope to seal by next month but which could still collapse, might help resolve a conflict that has been building for a century.

The war over Colorado water has pitted cities against farmers, fomented tensions among seven states, and dominated the attention of Native American tribes, environmentalists, federal officials and Mexico. The water wars have transformed a whole corner of the country, from the construction of vast cities on arid plains to the accidental creation of a sea in the middle of the desert.

For the 25 million Americans who rely on the river as it flows 1,400 miles from the snowpacks of the Rocky Mountains to its delta across the Mexican border, the outcome of the negotiations is nothing less than a matter of their region's survival.

"The big picture is that there are more rights to water from the Colorado than there is reliable water in the river," said Robert Glennon, a law professor at the University of Arizona. "We have a train wreck ahead of us."

Under the deal, San Diego would pay the Imperial Valley \$2.5 billion over 45 years to receive about 7 percent of the valley's share, water made available by more efficient irrigation. The water would compensate for the cutback California faces because of higher usage in Arizona, which now stores river water underground, leaving less for its western neighbor.

The deal, which also includes several smaller transfers within California, looks like a win-win arrangement. San Diego would get a reliable new source of water, while the Imperial Irrigation District would be able to sell water to San Diego at a rate 16 times what its own farmers pay.

But in the kind of twist so common to the water wars, a possible deal-breaker arose last year. Conserving water on Imperial farms, it turns out, would doom the Salton Sea, the giant lake in the middle of the desert at the valley's edge, imperiling millions of birds for which it is a key stop on the Pacific flyway.

Last week, amid the hoopla of the effort to recall Gov. Gray Davis, negotiators spent long days in Sacramento seeking a way to split the cost of protecting the sea and still salvage the transfer.

It is a surreal situation, with all the water machinations of the classic film Chinatown: Because of water being pumped into the Arizona sand, farmers in the California desert are being urged to sell water to a port city but are being held up by the danger of causing a landlocked sea to vanish from the Earth.

A century of change

It seemed simpler when farmer Cox's predecessors in the valley won rights to the water more than 100 years ago. Phoenix was a desert town of 5,000, San Diego a fledgling port city of 17,000 and the river water was the farmers' for the taking.

One century later, the farmers are not about to give up the water easily, no matter how many Beverly Hills lawns or Las Vegas casino gardens need to be kept a luscious green.

"It does take a lot of water, but I get a lot of production out of it," said Cox, 52, as he looked down his cotton furrows to monitor the water, which is drawn from an irrigation ditch by small siphon hoses and flows by gravity across the slightly slanted field. "Why is it OK for [cities] to use it in their fountains and spray it on their sidewalks? I think I have the right to use it for productive purposes."

But to many in the Southwest, such farmers' claims represent an entitlement the region can no longer afford. Phoenix, which has grown 75 percent in 30 years to 1.4 million people, will soon surpass Philadelphia as the fifth-largest U.S. city; Las Vegas, a railroad town of 5,000 in 1930, now has a metropolitan area population of 1.5 million.

This boom has caused the most problems for California, which uses more Colorado water than any other state. For years, California has taken more than its allocated share of the river because other states haven't used their full amount.

Now, with the Southwest growing fast and suffering a long drought, there's less extra water to go around, and California is under strict orders from the federal government to cut back.

The pressure on California is driven most by Arizona, which profoundly altered the region's water equation with the construction, in the 1980s, of a 336-mile aqueduct to carry Colorado water over the mountains and desert as far as Tucson.

This has allowed Arizona to claim its full share of river water, even though it doesn't actually use the full amount. Instead - in a tactic viewed as being unfair by some, brilliant by others - it pumps surplus water into the ground, reserving it for future use and thereby leaving no surplus for California.

Forcing California to cut back to its allocated share of the river would hit hardest in Southern California's sprawling cities, which have the legal right to far less than the state's farms, and therefore have been relying heavily on the leftover water.

That's where the deal comes in. By transferring Imperial water to San Diego, California can gradually wean itself from excessive use of the river.

Imperial Valley leaders were close to signing on to the transfer late last year when they balked, worried that the valley would be liable for the cost of restoring the Salton Sea, estimated to be as much as \$2 billion. The 15-by-35-mile sea, created when floodwaters on the Colorado broke an early canal to the Imperial Valley in 1905, depends on runoff from valley farms as its main water source.

Reducing runoff would rapidly shrink the sea, threatening the birds that, deprived of other wetlands, now rely on it.

As a penalty for pulling out of the deal, Interior Department Secretary Gale A. Norton cut the valley's river allocation by 10 percent last winter, saying that farmers were wasting water.

It was a major step: The Interior Department, which has the authority to withhold water if it's not put to "reasonable and beneficial use," had rarely invoked the right before. The valley sued in protest.

Unlike the backroom water deals in Chinatown, dealing over the transfer has played out in public view. In a region where residents face rising water bills and threats of rationing, water politics is front-page news.

If a deal is reached, it could be the blueprint for future transfers from farms to ever-thirstier cities, possibly spelling the decline of agriculture in the region.

The transfer is "a model for how historic distrust between urban and agricultural water interests can be overcome," said Dennis Cushman, assistant general manager of the San Diego County Water Authority.

But if the deal falls through and Imperial farmers are forced to give up water anyway, they say they'll defend their century-old rights to the end.

"If we have to fight them in the Supreme Court, that's what we'll do," said John Pierre Menvielle, a third-generation farmer who is running for the Imperial Irrigation District board, a paid, five-member panel elected by the voters of 140,000-resident Imperial County. "We got some hard-headed people down here - maybe because we've been in the heat for too long."

The river's journey

Once a raging river, the Colorado now peters out in marshes well short of its outlet in the Gulf of California.

It barely makes it that far. Massive dams halt its flow for storage and power generation, and wide canals carry off its water like so many needles stuck in a blood donor.

Near Parker Dam, one aqueduct heads west carrying about 1.2 million acre-feet of water a year 242 miles to Southern California, while close by another carries 1.5 million acre-feet a year 336 miles east into Arizona. (An acre-foot is the amount of water needed to cover an acre of land at a depth of 1 foot. It is about 326,000 gallons and is roughly equal to what two households use in a year.)

Farther south, near the Mexican border, 3 million acre-feet of water a year are diverted into the All-American Canal, the 82-mile canal built in 1942 to carry water into the Imperial Valley. From the canal, the water flows into a network of smaller canals connected to irrigation ditches.

The broad reach of Colorado River water is extraordinary because it is not a particularly big current to begin with, with an average depth of only about 20 feet and an annual flow that is only 3 percent of the amount of the Mississippi River's.

Indeed, seen from the riverbank at Blythe, Calif., on the border with Arizona, the Colorado looks like any other medium-size river. A few small trees sprout on its bank. Children in life vests are paddled upstream in a canoe. A man on a jet ski roars up and down.

In effect, many say, the Colorado today is less a river than a glorified water main serving seven states - a main that happens to have carved out the Grand Canyon eons ago.

"The river is extremely generous - as a desert river it produces a lot of water," said Lisa Force, a program director for Living Rivers, a group seeking to reduce Colorado River water use. "But it was seen as inexhaustible, and it's not."

Valley of green

The mining of the river began in earnest more than 100 years ago when enterprising farmers made a discovery that would change the Southwest forever: The California desert near Mexico may look bleak, with less than 3 inches of rainfall a year, but sprinkle water on it, and it turns to gold.

The desert adjacent to the river was made of silt carried from the Grand Canyon and elsewhere upstream, deposited in a broad swath by the river's shifts in direction. When irrigated, this soil was extremely fertile. And with the warm climate, farmers had a far-longer growing season than those in the rest of the country.

Cox, who has farmed for 30 years, marvels at the founders' ingenuity every time he drives out of the valley and reaches the point where green fields stop and the brown desert resumes.

"I'm in awe of this valley," he said. "I'm in awe of the people who had the foresight to divert the water from the river."

Backing up the farmers' discovery was the law. When it comes to allocating natural resources, the East operates on riparian rights: You can use water your property abuts, as long as you're not taking from your neighbor's fair share.

Not so out West. Ever since the gold rushes of the mid-19th century, natural resources on the frontier were awarded on a first-come, first-served basis. By diverting water into the desert, farmers not only won themselves newly fertile land, but they also secured the Imperial Valley's place in a series of compacts and court rulings that make up the "law of the river."

In 1922, an interstate compact divided the river's annual flow in two portions: 7.5 million acre-feet to the upper basin states of Utah, Colorado, Wyoming and New Mexico; and 7.5 million to the lower basin states of California, Arizona and Nevada. In a 1944 treaty, Mexico won rights to 1.5 million acre-feet a year.

Shares among the lower basin states were settled by the Supreme Court in 1963: California got 4.4 million acre-feet, Arizona got 2.8 million, and Nevada got 300,000. Within California, the Imperial Valley and some smaller farming districts eventually were allocated 3.85 million acre-feet, while the Metropolitan Water District, which delivers water to 18 million people in Southern California, gets only 550,000.

After all the divvying up, the Imperial Valley receives about 3.1 million acre-feet a year. That's more than all of Arizona, and nearly one-fourth of the river's flow, which has averaged about 13 million acre-feet a year, far less than the 15 million assumed in the original divisions.

This worked well enough for years; California was able to take as many as 800,000 additional acre-feet a year left over by other states. But in the past decade, the arrangement has been badly strained. Not only have Arizona and Nevada started claiming their shares, but a four-year drought has further reduced river flow.

The crop debate

With supplies running short, scrutiny has fallen on the Imperial Valley's \$1 billion farming industry. Most of the valley's 470,000 acres is in water-guzzling field crops, mostly alfalfa and other grasses that feed the West's dairy and beef industries, as well as cotton, wheat and sugar beets.

Only about 55,000 acres are used for vegetables and melons, which use much less water per acre than field crops. The area's long growing season makes it ideal for winter vegetables, and its lettuce, asparagus, broccoli, cauliflower, onions and carrots are its most lucrative crops on a per-acre basis.

But many farmers prefer field crops: Their prices fluctuate less, due partly to federal price supports; they require less labor; and farmers say there is limited demand for vegetables.

"We have a huge amount of water being used in inefficient ways for crops that one might question why they're being grown in this area," said Joseph L. Sax, a law

professor at the University of California, Berkeley who has consulted for the Interior Department. "It's a good place to grow avocados, but why we're growing cotton and alfalfa here is a question a lot of people have been asking for some time."

Meanwhile, having enjoyed a large share of river water for so long, valley farmers have seen little reason to limit use.

The valley's canals are unlined, allowing water to seep through their borders. Irrigating by gravity means that 15 percent of the water used runs out at the end of the field, runoff that goes into the Salton Sea. Some farmers, like Cox, now use pumps to recycle some of the runoff, but the pumps, and more costly conservation tools like drip irrigation systems, are relatively rare.

"They won't admit they're wasting water," said Adan Ortega Jr., vice president of the Metropolitan Water District. "Because they believe they have this God-given right to the water, they don't have any incentive to preserve it."

This kind of talk infuriates Imperial Valley farmers, who say they would use more efficient irrigation if they could afford it. Already, they say, they've spent thousands on tiles placed beneath their fields to keep salt from sinking too far into the soil.

Moreover, they say, it's their thousands of tons of field crops that fuel California's dairy industry (the largest in the country), feed the Southwest's cattle and help maintain America's cotton industry.

"Where's this agriculture going to go? It has to go someplace," said Steven A. Pastor, director of the Imperial County Farm Bureau. "You need your feed grown, your cotton. Do we want to rely on other countries to supply our food and fiber?"

Heidi Kuhn, an activist whose husband owns and runs one of the valley's largest farms, sums up the argument with a simple refrain for what she calls "the person sitting in Starbucks": "We're the latte in your coffee."

"We're not just doing this for our own health. We're doing it because there's a market need for it," she said. "I don't know if growing food is any less beneficial than having 112 golf courses in Palm Springs."

Hard-won success

On a tour of her family's 14,000-acre, 300-employee operation, Kuhn shows just how productive a single Imperial Valley farm can be. After passing field after field of the Kuhns' hay crops, she stops at the vast lot where the grasses are baled, compressed and stacked by the hundreds under long sheds.

Many of the bales, a grass variety called Sudan grass, will be loaded in containers to be transported to California ports by the train line running adjacent to the lot. There, they will be shipped to Japanese ranchers, who prefer Sudan grass for cattle feed but lack room to grow it.

Other bales will go to California dairies, but many stay with the Kuhns, to serve as feed at their own 4,000-cow dairy. The dairy's milk, in turn, goes across the street to a cheese-making plant that produces Muenster and Swiss cheese.

It's a thriving operation, but Kuhn says it's not hugely profitable, given slumping commodity prices and the cost of state labor and environmental regulations. Her family recently moved into her mother-in-law's old house, a three-bedroom rancher with a cracked tennis court. It's one of the nicer houses in El Centro, a struggling town of small bungalows and shuttered stores, but it's no mansion.

Indeed, many valley landowners resent the widespread notion that their big share of Colorado water has made them wildly wealthy.

"They see us driving nice pickups and cars and having a house in San Diego," said John Grizzle, a valley farmer since 1964, sitting in the office of his 7,000-acre operation. "They don't realize the hard work and the risk involved. The return on our investment is not large."

As they fend off critics, the valley's residents also face internal divisions.

There are disagreements about how to divide the \$2.5 billion San Diego would pay for the 200,000 acre-feet a year it would receive under the transfer. As the deal stands, the Imperial Irrigation District would distribute most of the money among the county's roughly 400 farmers, requiring much of it to be used for more efficient irrigation, while some would go toward the larger community.

A large faction of farmers, though, believes that the money, as well as any revenue from future transfers, should go directly to landowners, who in turn would give part of it to the community. This group has sued the irrigation district.

Others view this effort as a naked grab by farmers for the millions in water revenue.

"We better make sure that if the money comes in, it's applied to increasing efficiency, to insulate us against long-term attacks on our water use," said district board member Andy Horne. "If landowners are allowed to take the money and do whatever they want with it, including sticking it in their pocket and not doing anything toward efficiency, then we haven't accomplished that."

Farmers also disagree over whether to reduce their usage by investing in more efficient irrigation or by leaving fields fallow, which would mean lower crop yields and fewer farm jobs but would require less effort and leave more water for the Salton Sea than conservation would.

To valley outsiders, the ambivalence over the transfer is hard to fathom, given how much money is involved. The valley would get \$258 an acre-foot from San Diego for water that costs farmers \$16 an acre-foot.

"What they're not admitting is that these are the first farmers that will be allowed to sell water at market rates," said Ortega, of the Metropolitan Water District. "They're going to create a precedent that a lot of people in the valley can benefit from."

But this is just what alarms many in the valley - including some of the non-landowning Mexican immigrants who see the farms as the biggest source of employment in the county. Once farmers start selling water, they fear, it may be hard to stop; farmers will walk away rich, but the valley will have sold away its livelihood.

One thing unites the county residents: All see themselves as underdogs trying to keep their rights from being pried away by powerful California cities.

"We can see the handwriting on the wall: We have a very large water right, and there is a seemingly unquenchable thirst for this water around the southwestern United States," said district board member Horne. "We're such a small community facing such a huge population that doesn't care what happens to us in the future."

And all in the valley think the same thing when they hear urban critics question the wisdom of desert farming: Why doesn't the same argument apply to the cities of the arid Southwest?

"San Diego is as much of a desert as we are," Kuhn said. "Why is it any more logical for people to live there?"

Growing demand

It's a question that San Diego officials don't have the luxury of asking. Whatever the wisdom of its growth, the city is now the country's seventh largest, it lacks water of its own, and officials need supplies for 3 million area residents and counting.

The transfer deal with the Imperial Valley is the centerpiece of this effort, but it's not the only element. The San Diego County Water Authority is planning a desalination plant that would process enough ocean water, at great cost, to provide 15 percent of the county's demand.

In addition, the authority is about to finish a massive new dam in a box canyon in Olivenhain, 30 minutes north of the city, that will hold more than two months' supply of emergency water. The aqueducts that bring San Diego's water south from Los Angeles, a mix of Colorado River and northern California water, cross major fault lines, and the city's been at risk of running dry after an earthquake.

The new dam is visible proof of water's primacy in the Southwest. At 318 feet high and 250 feet long, it is designed to withstand an earthquake measuring a magnitude of 7.2. The reservoir, a giant cavity that will be filled over the coming year, is 2,552 feet long; 700,000 cubic yards of fill was blasted out of it.

"With the amount of water we have to deliver to people, we just have to build some amazing structures to do it," said project manager Jerry Reed as he oversaw work on a recent morning.

That is what happened hundreds of miles away in Arizona, where two decades ago engineers designed an aqueduct to carry 1.5 million acre-feet a year of Colorado River water as far as Tucson. The \$3.8 billion Central Arizona Project uses six 60,000-horsepower pumps to lift water 824 feet above the river.

Fourteen pumps along its 336-mile route lift the water high enough so it can run downhill to the next pump. At a control room north of Phoenix, two men sitting before a big screen regulate the flow on the 80-foot-wide, 16-foot-deep canal by raising or lowering gates at checkpoints every seven miles.

Things to come

The Arizona aqueduct represents more than just the driving force behind the pressure on California to reduce its river use. The project also offers hints of what might happen in California if the San Diego water deal sets a precedent for future transfers.

That's because in Arizona, transferring water from agriculture to urban use has been the policy for decades. Unlike their counterparts in the Imperial Valley, the cotton and alfalfa growers on the plains of central Arizona lack enshrined rights to the Colorado River, and have long relied on groundwater.

When the state built the aqueduct, it allocated two-thirds of the water to farmers - but with the understanding that their share of the water would decline as farmland was developed for homes, leaving most of the water for urban users. And indeed, large tracts of former farmland around Phoenix are sprouting dense subdivisions.

This sprawl has met with relatively little official resistance. Subdivisions may cause problems, officials reason, but they have one thing going for them: They require about half as much water as the farms they replace.

"We want to sustain agriculture as long as possible, but while making sure we have a sustainable water source" for residential use, said Dennis G. Kimberlin, a state water manager in Pinal County, an agricultural area south of Phoenix that is rapidly being developed.

Those farms that remain, meanwhile, have already taken many of the steps that California farms may face. Because water is at a greater premium in Arizona, costing farmers \$36 an acre-foot - more than double the Imperial Valley rate - there is incentive to conserve.

Dan Thelander, for instance, added an underground drip irrigation system four years ago at his 500-acre cotton field in Pinal County. It cost \$1,500 per acre, but his cotton now uses one acre-foot less per acre.

His neighbor, C.L. "Bill" Scott, long ago leveled many of his fields so that less tailwater runs out at the end. Instead of irrigating his fields at a steady stream for a full day as Cox does in the Imperial Valley, Scott sends a stronger stream across for only two hours, producing a more even level of saturation while using less water.

Scott happens to know the Cox family and isn't about to second-guess their techniques. He chalks up his conservation to market demands: His water costs more, so he must use less.

"There are a lot of things you can do to make better use of water," he said, driving a visitor across his 6,800-acre farm. "It's a matter of economics. It makes you do things that are cheaper."

Future battles

Even if the transfer from the Imperial Valley to San Diego is approved, few expect the deal to settle the water wars for good.

Other demands for water loom: The state of Colorado is discussing building its own version of the Central Arizona Project to carry its share of the river over the Rockies to Denver and other cities. This may be prohibitively expensive, but if it happened, it would remove 400,000 more acre-feet a year from the river, about 3 percent of its flow.

More immediate is a drive by environmentalists to allow more of the river to make it to Mexico, to start restoring the delta, at a cost of 150,000 acre-feet a year. And in Arizona, Native Americans winning rights to hundreds of thousands of acre-feet, forcing cities to buy water from them.

But the biggest fights ahead, many expect, will be continued clashes between cities that will need ever more water and farms that still use most of it.

Regional water officials admit they may eventually push the limits of their supply, even with the transfer. This, they say, will force higher water prices, constraining further growth, and may even raise the once-unthinkable prospect of "toilet-to-tap," treating wastewater for drinking use.

Aware of the growing needs of the cities, Imperial Valley farmers say they are bracing for the federal government, goaded on by the Metropolitan Water District, to return and pressure them to give up even more water. If the valley refuses to sell, they fear, federal officials will again declare it is wasting water and take the water for free.

"It's a slippery slope," said Pastor, the farm bureau director. "A lot of farmers worry this isn't going to end until all the water is shipped to San Diego or Los Angeles."

Valley landowners say they owe it to their forerunners on the land not to let that happen. Their critics may question the wisdom of having created a farming valley in a desert, they say, but the transformation happened, and it can't just be reversed, 100 years later.

"This place is not unworthy of being here. It's families who are proud to be here, who put roots here, who had kids here," said Kuhn, the activist. "It's not as simple as wiping us off the map to have more water for L.A."

River News 08/19/03

PECOS RIVER MANAGEMENT PLAN UPDATE

An Environmental Assessment containing the Pecos Wild and Scenic River Forest Plan Amendment and Management Plan was sent out for public review on April 23, 2003 thirteen years after its declaration as a Wild and Scenic River. The proposed management plan banned all boating in the Wild and Scenic Corridor as it "can only be done in short sections along the river during periods of high water flow, which commonly does not occur. Prohibiting floating would therefore not be expected to displace many users and it would enhance fishing within the corridor."

The Pecos River was declared a Wild and Scenic River in 1990. Above Cowles (mostly in the Pecos Wilderness) is designated wild. From Cowles to Terrero is designated recreational. The section from Cowles past Terrero to Windy Bridge is runnable by kayak, canoe and inflatable kayaks during spring high water each year. This is a period of heavy boating use of other rivers in New Mexico and the Pecos serves as an alternative run for boaters looking for more solitude. Although there is development along the road to Cowles, the sections of the river away from the road retain much of the wilderness characteristics of the surrounding Pecos Wilderness. The run is unique for New Mexico due to the clear water and forested environs that are reminiscent of rivers further north in Colorado and Idaho. Although the area is very popular for fishermen, they generally prefer lower water levels when the river is unrunnable by boaters.

Tom Robey (River Runners for Wilderness) noticed the public comment period for the management plan and Tim Scofield (Adobe Whitewater Club) discovered the prohibition on boating. Enlisting the help of Jason Robertson (American Whitewater Association) they undertook a campaign during Memorial Day weekend to send in comments. An excerpt from the comments submitted by Tom Robey stated:

"...There is no reasonable basis that eliminating boating would enhance fishing. It is evident that there have not been any recreational surveys of boating use on the Pecos River. Have you done any surveys of fishermen about their encounters with boaters? Have you documented any adverse impacts of boaters upon fishing? My experience is that very few fishermen encounter boaters and that encounters between fishermen dwarf any such impacts. As fast as the Pecos is moving during high water (there are few eddys) it is ludicrous to suggest that boaters have any impacts on the fish or fishing. Therefore I suggest that the management plan allow boating and that the Forest Service gather data before even considering any management action regarding boating between Cowles and Terrero."

The first item of the Decision Notice issued July 31st stated:

"Revised the provision to allow floating use. The Standard now reads, 'The use of non-motorized rafts, boats, or other conveyances to float down the river is permitted. No additional facilities (put-ins, parking areas) will be constructed to facilitate floating' ",

The entire decision and other materials should be available at www.fs.fed.us/r3/sfe or upon request from the Pecos/Las Vegas Ranger District, PO Drawer 429, Pecos, NM 87552 (phone 505-757-6121).

Drought drying up boater fun

by Tom Wharton

The Salt Lake Tribune

Prolonged drought in the western United States, particularly Utah, has left boaters high and dry on launches at many major lakes and reservoirs.

At Lake Powell, water levels have dropped below boat ramp and marina access levels, forcing closures, especially in the upper end of the huge reservoir on the Utah-Arizona border. Visitation is down 13 percent from a year ago. And the lake level is expected to drop even farther, perhaps as far as 112 feet below capacity by April. Still, Barry Wirth of the U.S. Bureau of Reclamation said there are still 12.5 million acre-feet of water in the reservoir.

"That is an awful lot of water," he said. "It is important to note that that is a pretty nice half-full body of water."

Char Obergh, of the Glen Canyon National Recreation Area, said boaters have experienced few delays launching despite the closure of Hite Ramp and "use at your own risk" warnings at Stateline and Antelope Point, a precaution to boaters that they could get stuck in the muck, or worse.

She expects some launching delays to occur during the upcoming Labor Day weekend.

"It has been an interesting year," she said. "But there is a lot of lake to enjoy. It's just a different lake. We are asking people to be aware of that. We have done our best to maintain access. As it goes down this winter, we will be faced with additional challenges."

Because of low water at Lake Powell, Defiance House and Three Roof Ruins are no longer accessible by water. The Castle Rock Cut is closed. And vehicle access is not possible at Dirty Devil, Farley, White Canyon, North and South Bullfrog Primitive Camping Area and Crosby Canyon. Stanton Creek may be the best primitive vehicle camping area still available.

On the upper end of the lake, Hite Marina is out of service. The launch ramp there is closed, though river runners floating down from Cataract Canyon on the Colorado River are using a temporary dirt facility. All water-based marina facilities have been relocated downstream.

These developments have not gone unnoticed by environmentalists who would like to drain Lake Powell and decommission its dam.

"This drought emphasizes the dubious nature of Lake Powell reservoir," said John Weisheit of Moab-based Living Rivers in a news release.

"By decommissioning Glen Canyon Dam, we could restore 500 miles of river to its natural habitat, which includes Grand Canyon National Park, while at the same time saving the water that is otherwise lost to evaporation."

Low water apparently has not affected boating safety, either on Lake Powell or other reservoirs across Utah.

"We have had no safety problems out of the ordinary," said Obergh. "We do caution people if they have not been here for a while that it is a different lake and they need to boat with caution."

Ted Woolley, boating coordinator for the Utah Division of Parks and Recreation, said added congestion among boaters has not contributed to safety problems.

"It seems that when you get more people in there, they pay more attention to what is going on," he said.

Visitation has been down at some water-based state parks because of perceptions -- some real, some not -- that the drought is affecting boating. But Woolley said there are plenty of good boating opportunities if you know where to look.

"We have some areas in good shape and some that are in real poor shape," he said.

He listed eastern Utah reservoirs such as Starvation, Red Fleet, Steinaker and Flaming Gorge as good boating alternatives that, in some cases, have been underused this summer.

Closer to the Wasatch Front, Rockport, Jordanelle, East Canyon and the Great Salt Lake are relatively safe for boating.

Perhaps the biggest problem area is Willard Bay, where the south marina has been closed and the north marina is available for personal watercraft and smaller boats. But, Woolley said, boaters should use Willard Bay at their own risk because rescue boats are not available.

Yuba Reservoir has been drained for dam repairs, and Lost Creek Reservoir's ramp is not available. The main ramp at Deer Creek Reservoir State Park is out of the water, but boaters are still launching on the dirt ramp at the Island area. Trailer parking, however, can be a problem there.

Utah Lake's boat ramp has major problems, though some boaters are launching smaller craft. Bear Lake's marina is still OK for motor boats, but some sailboaters are experiencing problems. Echo Reservoir is about 50 percent of capacity but is still in use. Pine View reservoir is also low, but there is adequate water for launching.

River News 08/25/03

Sediment Clogs River Runner Access At Former Hite Marina

Submitted by Tom Robey on Mon, 08/25/2003 - 23:00 August 2003.

Sediment at Hite Marina, the most upstream facility at Powell Reservoir, has necessitated the removal of all reservoir conveniences such as the floating store, fuel docks, water and septic lines, boat rentals, and courtesy docks. The concessions operator, ARAMARK, has towed its floating facilities down-reservoir to keep the facilities from becoming trapped in mud. The land-based facilities at Hite, which includes a store, gasoline, drinking water and a sewer clean-out, remain open to service the needs of the residents and the traveling public.

A primitive "use at your own risk" boat takeout area opposite the former Hite boat ramp can still be used by river runners for inflatable and small, hard-hull boats. Since Powell Reservoir continues to drop rapidly, this site could be completely unusable by September, which will force river runners to go another 45 miles down-reservoir to exit at Bullfrog Marina. Glen Canyon National Recreation Area currently has no plans to accommodate river runners by constructing an alternate ramp, despite spending over \$1 million earlier in the year to temporarily extend ramps for houseboats and power boats. A description of the takeout site is posted at Canyonlands National Park's Cataract Canyon website at <http://www.nps.gov/cany/river/lakepowell.htm>.

According to a sediment survey conducted by Mussetter Engineering of Denver in 2000, the Colorado River delta beginning at Dark Canyon and reaching to the mouth of the Dirty Devil River was advancing at a rate of about one mile per year. At present the delta is just beyond Hite Marina where the original river channel is 245 feet below the full reservoir elevation of 3700 feet. The survey predicted another 35 years of power boat access at Hite Marina provided the reservoir could be maintained at full pool. "Such a projection is incredibly optimistic," says John Weisheit, Conservation Director of Living Rivers. "Considering the downstream demand for water, the present drought situation, and how the river erodes into the exposed sediment and feeds the delta, the facilities at Hite may never again be usable."

By April of 2004, Powell Reservoir is predicted to be 106 feet below normal. At this elevation, Bullfrog and Antelope Point marinas will be affected by the sustained drought. The lack of incline and shallow depth at the Bullfrog Marina boat ramp will make it very difficult to load and unload boats--especially longer craft such as houseboats and the Bullfrog-to-Halls crossing ferryboat--the only method of transporting land vehicles across the 186-mile-long reservoir. Because Antelope Point is located on a cliff at the rim of the original Colorado River canyon, the dropping reservoir level will perch this boat ramp high and dry. During the spring snowmelt, Powell Reservoir levels rose a mere 11 feet and the reservoir has now returned to the levels of the previous winter, about 90 feet down from full-pool. With no drought relief in sight, this continuing trend will eventually place power generation at risk. The minimum storage level to safely produce electricity is set at 6 million acre-feet. Currently the reservoir is at 50% of capacity storing 12.7

million acre-feet of water. Power generation at Glen Canyon Dam could effectively end in two or three years under present drought conditions. "This drought emphasizes the dubious nature of Lake Powell reservoir. By decommissioning Glen Canyon Dam we could restore five hundred miles of river to its natural habitat, which includes Grand Canyon National Park, while at the same time saving the water that is otherwise lost to evaporation" observes Weisheit.

LR in the News 08/28/03

Hite Marina closure leaves Cataract Canyon outfitters high and dry

Times Independent

Moab, Utah

by Lisa Taylor, contributing writer

The end of a Cataract Canyon river trip usually involves motoring or rowing for miles from where Lake Powell effectively absorbs the Colorado River's current to the small marina at Hite. This year, with the lake receding to record lows, some commercial trips are having to motor right on to Hall's Crossing or Bullfrog, 45 miles to the south.

Lake Powell is currently about 100 feet below "full", and is expected to drop another 12 feet by next spring. Dropping water levels and rising sediment have acted as pincers, squeezing away the usable access at the marina on Hite's eastern shore. In July, concessionaire ARAMARK got approval from the National Park Service to move its floating facilities down-lake, and in mid-August towed them completely clear of the area. The facilities include a floating store, fuel docks, water and septic lines, boat rentals, and courtesy docks. Hite's land-based store, gas, water and sewer services are still open.

Commercial and private boaters can use an "at your own risk" launch area, but as water levels continue to drop, the primitive ramp is barely usable, and at least one outfitter, Sheri Griffith River Expeditions, has opted to continue to Hall's Crossing, another 11 hours farther if the weather cooperates.

Tag-a-Long Expeditions president Bob Jones is frustrated that the Park Service didn't heed outfitter warnings about the marina going dry. "They should have been ready, because we met with them in March and outlined almost to the day when they'd have to find a solution. I'm discouraged they're not responding to the public."

Until the Park Service officially deals with the problem, Jones is improvising. "We've opened up another road [the NPS] allowed to the old marina site on the east side, where the water is pretty close. We've simply taken down our Snow-cat, to take people and boats across that dry mud." The dry mud he's referring to is a 150-yard-wide band of compacted silt, webbed with cracks up to two inches across and two feet deep. Vehicles and pedestrians would have trouble with it on a dry day – if it rains, forget it.

Jones says the access he's using won't work for everyone, but argues that it wouldn't cost much to upgrade it, and with the Colorado River's original channel closest to the west side, "we're where the water will always be." Tag-a-Long has about 12 more trips

this season, and Jones isn't interested in bypassing Hite. "The alternative – to go to Bullfrog – is 12 to 14 hours of motoring on a calm day, but if you get into wind and waves, rafts don't go like hard-hull boats, they go all over the place."

As to the environmental impact of restoring river access on the western shore, Jones points out, "We're talking about moving silt that's not supposed to be there anyway. Any environmental assessment will tell you to get rid of it."

An ARAMARK/Park Service sediment survey done in 2000 showed that the Colorado River delta, effectively the "top" of the lake, had crept four miles downstream in four years, and was about 11 miles north of Hite.

The survey allowed the marina 35 years of use provided the reservoir held steady at 3,700 feet, an "incredibly optimistic" projection according to John Weisheit, conservation director of environmental group Living Rivers. "Considering the downstream demand for water, the present drought situation, and how the river erodes into the exposed sediment and feeds the delta, the facilities at Hite are basically history."

Even Jones, with a vested interest in Hite's recovery, guesses it will take at least five years to restore the facilities, provided there's a break in the drought and the reservoir can recharge. In the meantime, a 2003 NPS/ARAMARK survey showed the delta had already crept past Hite, and new dock and pumping-station closures pop up on the official Glen Canyon National Recreation Area website every week. Lake Powell businesses are insistent that there are still unlimited activities on the water – the trouble for the foreseeable future is how to get out there.

LR Press Release 08/28/03

Drought could cause Lake Powell Reservoir to drop as low as 39% next year

For immediate release
August 27, 2003

Contact: John Weisheit (435) 259-1063

Drought could cause Lake Powell Reservoir to drop as low as 39% next year.

Recreation access to be cut substantially.

Federal forecasts for the operation of major dams in the Colorado River system indicate that if drought conditions continue as anticipated, Lake Powell could see another significant drop to as low as 39 percent over the next 12 months. System-wide storage could drop from 57 to 48 percent as water users in the basin continue to use water at pre-drought rates.

Using data from the past 30 years, the Bureau of Reclamation's (BuRec) "2004 Draft Annual Operating Plan" forecasts a range of inflow scenarios for Lake Powell reservoir

from 3.8 to 15.6 million acre feet. This would equate to a range of reservoir levels from 39 to 83 percent.

The lower level would represent a near repeat of 2002, when flows into Lake Powell reservoir were 75 percent below normal. Normal flows as estimated by BuRec are approximately 12 million acre-feet. The upper level would represent flows not seen since 1997.

"As federal scientists continue to forecast that drought conditions will last several decades, water managers and the public should not count on any high flows," says John Weishiet, Conservation Director for Living Rivers. "During the drought of 1942 to 1977, flows were off by 19% percent. Taking into account increased diversions above Lake Powell reservoir since that time, which now are approximately 4.7 million acre-feet per year, it's easy to see why Lake Powell continues to drop."

Over the past four years, inflows into Lake Powell have averaged just 50 percent of normal: 62, 59, 25 and 54 percent respectively from 2000 to 2003. Even last year's forecasted El Niño conditions, which generally result in well above average precipitation, yielded a snowpack of just 84 percent of normal. Due to the significantly dry soil conditions from three straight years of well below average precipitation, Lake Powell received just 54 percent of its average inflow of 12 million acre-feet.

Simulating a significant drought event, as the region is now experiencing, the American Water Resources Association estimated that it could take just eight years of drought for Lake Powell reservoir to be emptied of its store of water. "They're right. It's been four years, and we're half way there," adds Weisheit.

Presently, Lake Powell reservoir is reported to be at 51 percent capacity, down from 59 percent last year and 95 percent at the beginning of 2000. The actual amount of available water is 50 percent, as BuRec is not compensating for 500,000 acre-feet of storage lost to sediment since its last sediment inventory was conducted in 1986.

When full, Lake Powell reservoir can store 24.3 million acre-feet. An acre-foot of water represents 326,000 gallons, or enough for two urban families per year.

If inflows into Lake Powell reservoir continue to average 50 percent of normal, or about six million acre-feet per year, this would result in the reservoir level dropping an additional eight percent next year, to 10.7 million acre-feet, or 44 percent of capacity.

This would bring the reservoir elevation down 140 feet from full. Only two of the reservoirs six marinas would be operational. Commercial and private Colorado River rafting trips, which normally end at Lake Powell reservoir, would have no way to get off the reservoir, short of rowing or motoring their rafts more than fifty miles to the nearest functioning marina.

"This is a multi-million dollar industry that we are about to lose," adds Weisheit. "First they killed the rafting industry through Glen Canyon when they built Glen Canyon Dam, and now they're stopping us from running the rivers upstream too."

In addition to Lake Powell dropping eight percent, the systems other major reservoir, Lake Mead, will also drop. In water year 2003 (October 2002-September 2003) Lake Mead will have dropped from 66 to 60 percent. 2004 will see a repeat of this six percent reduction. Lake Mead's primary input comes from releases from Glen Canyon Dam which are only 8.2 million acre-feet per year. Hoover Dam is scheduled to discharge 9.4 million acre-feet for its users downstream, which combined with evaporation and reservoir withdrawals will draw the reservoir down to 54 percent of capacity next year.

GLEN CANYON DAM UPDATE

Operations

Releases from Glen Canyon Dam will be lower in September than August. Releases in August averaged about 14,600 cubic feet per second (cfs) with a total of 900,000 acre-feet released. In September, releases will average 8,000 cfs with a total of 476,000 acre-feet scheduled to be released. On Mondays through Saturdays (except for Labor Day) in September, daily fluctuations due to load following will likely vary between a low of 5,000 cfs (during late evening and early morning off-peak hours) to a high of 10,000 cfs (during late afternoon and early evening on-peak hours). On Sundays (and on Labor Day), releases will be 5,000 cfs from 7 pm until 7 am, and 8,000 cfs from 7 am until 7 pm.

Releases from Glen Canyon Dam in October and November of 2003 are currently scheduled be 492,000 acre-feet and 476,000 acre-feet respectively, with the same load following pattern as September.

Because of the draw down condition of Lake Powell, releases from Lake Powell in water year 2003 are being scheduled to meet the minimum objective release of 8.23 million acre-feet. This is consistent with the requirements of the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs.

Basin Hydrology

Drought in the Colorado River basin continues. Inflow volumes have been substantially below average this year with water year 2003 being the 4th consecutive year with below average inflow to Lake Powell. April through July unregulated inflow to Lake Powell in 2003 was 3.91 million acre-feet, only 49 percent of the 30 year average. Total unregulated inflow for water year 2003 will likely be about 51 percent of average.

Snow accumulations in water year 2003 were again well below average levels. Additionally, what snowpack there was in the Upper Colorado River basin this year melted earlier than normal, with the runoff for the most part, being completed by late June. This has resulted in very low summer flows. Inflow to Lake Powell in July tallied up to only 350,000 acre-feet or 22 percent of average. Summer thunderstorms can help augment river flows in the summer, but thus far there has been only limited monsoonal precipitation in the Upper Colorado River basin. Unregulated inflow to Lake Powell in August will likely be only 24 percent of average. Inflow to Lake Powell on August 28, 2003 was 4,800 cfs, 50 percent of what is usually seen in late August.

Total unregulated inflow into Lake Powell in water years 2000 and 2001 was 62 and 59 percent of average, respectively, and only 25 percent of average in 2002. Inflow in 2002 was the lowest ever observed since the completion of Glen Canyon Dam in 1963. These low inflows have reduced water storage in Lake Powell. Lake Powell reached a low water surface elevation this spring at 3605 feet (95 feet from full pool) on May 1, 2003. The lake then rose in response to snowmelt-runoff, reaching a peak on June 23, 2003 at 3616.6 feet. The current elevation of Lake Powell is 3,604.8 feet (95.2 feet from full pool). Current storage is approximately 12.2 million acre-feet (50 percent of capacity). The water surface elevation at Lake Powell will likely continue to decrease for the remainder of the year. Under expected inflows, Lake Powell will likely be near elevation 3600 feet on January 1, 2004.

This release courtesy Tom Ryan.

Living Rivers Currents 09/01/03

Water 2025: A Crisis in the Making

Throughout the summer the Department of Interior, through the Bureau of Reclamation (BuRec), has been orchestrating another of its legendary public relations charades. At a time when most Western states are experiencing major problems with water allocation, BuRec is responding with a long-term management plan which completely ignores the problem. It is dubbed "Water 2025: Preventing Crises and Conflict in the West," and is little more than a repackaging of existing management strategies combined with a heightened push for desalinization technology. It contains no proposals for how to substantively address major water

shortages, such as those already manifesting in the Colorado River watershed. "Minor efficiency gains and conservation measures as Secretary Norton prescribes will bring about some savings, but these are merely drops in the bucket given that the Colorado River is providing barely half the water the Department of Interior is contracted to deliver," says Owen Lammers, executive director of Living Rivers.

Abundant historical evidence reveals that the present drought in the Colorado watershed is far from unprecedented, and warnings from the United States Geological Survey one year ago urged water managers to be prepared for several decades of below average precipitation. Lammers notes, "Water 2025 demonstrates that the Department of Interior is ignoring this responsibility."

- * The Plan emphasizes Interior's long-standing tradition of acquiescing to the states for resolving disputes. However, as 80 years of conflict reveals, cooperation is rare, even in the best of times.

- * The Plan's market-driven water banks and transfers from farmers to municipalities during times of shortages are laudable on a small scale, but there is no discussion of what will happen when the real shortages occur. Certainly, the 25 million people reliant on Colorado River water will not be deprived, but what will it cost? Farmers are becoming increasingly reluctant to make water transfers. Without strict federal guidelines and policies, municipalities like Los Angeles, Phoenix, Las Vegas and Salt Lake City will be forced into a cost environment not unlike what California energy utilities faced three years ago.

- * Crop substitutions, which represent the greatest opportunities for water savings, are completely ignored by the Plan. Nearly half of Colorado River water is used to grow water-intensive alfalfa and other forms of cattle feed. Much of this water could be saved by growing crops for human consumption.

- * The Plan advocates maintaining and enhancing existing infrastructure. However, much of this infrastructure is responsible for the loss of up to 20 percent of the Colorado River's flow due to evaporation and seepage amongst its reservoirs, but there are no capital improvements planned to reduce these losses.

Not until the 25-page report's last 100 words does the term "drought" receive much attention. This should be Interior's main focus at this time. Areas that Interior should be addressing include: outlining specific solutions for federal management to employ; how farmers will be enticed or forced to release their water to preserve municipal economies; and how Interior will enforce necessary conservation strategies and efficiency standards.

"This report is all about carrots with no federal stick," adds Lammers. "Interior must begin developing water use standards and practices, as well as allocation strategies to be implemented as this drought situation worsens. Absent this, crises is inevitable, despite Secretary Norton's report and marketing strategy titled to prevent it."

Riverkeeper: On the Yampa, Green and Grand Canyon

From June 2-6, Living Rivers' Colorado Riverkeeper program, in conjunction with Holiday River Expeditions, honored the 50th Anniversary of the first Yampa/Green river trip organized to stop the inundation of Dinosaur National Monument from Echo Park Dam. It's purpose included drawing attention to the slow death of Dinosaur National Monument's river corridor due to the operations of Flaming Gorge Dam upstream. This month the Riverkeeper program will return to the Green River. It will spend nine days in Desolation Canyon, the most remote wilderness- quality river corridor in the continental United States. Like those in Dinosaur National Monument, native fish in this stretch suffer from the impacts of Flaming Gorge Dam. This critical habitat is being ignored by federal researchers developing re-operation plans for the dam.

In October the program will undertake a 12-day science trip down the Colorado River through Grand Canyon National Park. Participants will assist researchers from Northern Arizona University in collecting data to evaluate how the food base of Grand Canyon's river ecosystem has changed due to the operation of Glen Canyon Dam. Federal scientists are considering ceasing financial support for such research, despite its vital role in understanding the steps needed to recover endangered fish species in the Grand Canyon National Park.

Living Rivers Currents 09/01/03

Powell Reservoir: Draining Recreation

The reservoir-draining drought is again revealing canyon walls not seen in 30 years. For example, the National Parks Service's marina facilities at Antelope Point near Glen Canyon Dam will be perched on a cliff's edge this Autumn.

The situation at Hite Marina at the top of Lake Powell reservoir is already disastrous, where a vanishing reservoir has exposed a sediment plug that backs up the Colorado River Arm for 30 miles. Because of the thick, gooey mud, the Hite concessions operator, ARAMARK, has literally pulled anchor and moved their floating docks 50 miles downstream to the marina at Hall's Crossing. Hite Marina is looking like a ghost town of thick mats of non-native weeds and obnoxious tamarisk trees.

Colorado River runners who previously finished their trips at Hite, now have no place to exit. Thoughts of pushing rafts through a choppy reservoir 50 miles further to Bullfrog or Hall's Crossing marinas are not welcomed. Bullfrog's boat ramp is about to become unusable itself, and Hall's Crossing is too small to accommodate all of the visitors now that these other facilities are closing. In desperation, river outfitting companies are attempting to forge a road across the sediment themselves at a location across the reservoir from Hite.

In a letter to the superintendent at Glen Canyon National Recreational Area, Living Rivers has reminded the National Park Service that the money targeted for capital improvements at Hite Marina must immediately be shifted toward mitigating the impacts from sediment on the river running public, who typically have to endure the National Recreation Area's bias to the powerboat industry. In 2003, power boaters have received \$3 million dollars in boat ramp improvements, and river runners have received none.

Living Rivers Currents 09/01/03

LR Drought Watch: No Relief In Sight

Federal forecasts for the operation of major dams on the Colorado River indicate that if drought conditions continue, Lake Powell could see another significant drop to 39 percent in one year. Basin-wide storage could drop from 57 to 48 percent as water users continue to use water at pre-drought rates.

BuRec's "2004 Draft Annual Operating Plan" forecasts a range of inflow scenarios for Lake Powell reservoir from 3.8 to 15.6 million acre-feet. This would equate to a range of reservoir levels from 39 to 83 percent. The lower level would represent a near repeat of

2002, when flows into Powell reservoir were 75 percent below normal. Normal flows estimated by BuRec are approximately 12 million acre-feet, flows not seen since 1997.

"During the drought of 1942 to 1977, flows were off by 19 percent. Taking increased diversions above Lake Powell reservoir since that time, which are now approximately 4.7 million acre-feet per year, it's easy to see why Lake Powell continues to drop, " says John Weishiet, conservation director for Living Rivers.

Since year 2000, inflows into Lake Powell have averaged just 50 percent of normal: 62, 59, 25 and 54 percent respectively. Presently, Lake Powell reservoir is reported to be at 51 percent capacity, down last year from 59 percent. The actual amount of available water is 50 percent, as BuRec is not compensating for .5 million acre-feet of storage lost to sediment since its last inventory was conducted in 1986.

If inflows into Lake Powell reservoir continue to average 50 percent of normal, or about six million acre-feet per year, this would result in the reservoir level dropping an additional eight percent to 10.7 million acre-feet, or 44 percent of capacity. This would bring the reservoir elevation down 140 feet from full. Only two of the reservoirs six marinas would be operational. Commercial and private Colorado River rafting trips, which normally end at Lake Powell reservoir, would have no way to get off the reservoir, short of rowing or motoring their rafts to the nearest functioning marina.

"This is a multi-million dollar industry that we are about to lose," adds Weisheit. "First the Bureau of Reclamation killed the rafting industry through Glen Canyon when they built Glen Canyon Dam, and now they're stopping us from running the rivers upstream too."

Living Rivers Currents 09/01/03

Glen Canyon Dam: LR Demands Supplemental EIS

In a letter submitted this month to Michael Gabaldon, chair of the Adaptive Management Program (AMP) for Glen Canyon Dam, Living Rivers outlined the justification for the Department of Interior initiating a new Environmental Impact Statement (EIS) for Glen Canyon Dam. This would would compel the federal government to examine decommissioning Glen Canyon Dam as a means of recovering endangered species habitat lost in Grand Canyon National Park as a result of the dam's operations. Completed in 1996, the existing EIS for Glen Canyon Dam prescribed a set of operational criteria for the dam in an effort to halt the Bureau of Reclamation's violation of the Endangered Species Act in Grand Canyon. So far, all these efforts have failed.

* The decline of the Humpback Chub population from 8,000 to 2,000 fish, and the inability to establish a second location in the river corridor for Humpback Chub to live.

* The inability to provide enough sediment for the preservation of beach habitat. The number and size of beaches in the Grand Canyon have experienced a significant decline since the AMP began. This negatively effected the Canyon's recreational

experience, but has also impacted the river corridor's cultural resources, which are now prone to erosion.

* Unanticipated impacts resulting from reduced elevations of Glen Canyon Reservoir, such as increased temperatures and modified nutrient dynamics, could have significant effects on the downstream resources in the Grand Canyon. As the drought situation persists, these effects will become more pronounced.

The key to reinstating National Environmental Policy Act compliance, through a supplemental EIS, is if new data or impacts are recognized. Clearly in the case of Glen Canyon Dam, significant new data (biological and sediment) indicate that the system needs re-evaluation.

Living Rivers Currents 09/01/03

Delta Deficit: Wasting Money and Habitat

Congress is about to fund the start-up of a defunct desalting plant on the Colorado River near Yuma, Arizona, dooming critical habitat in the delta region. The Bureau of Reclamation (BuRec), which has recommended that Congress authorize the desalter's repair, is downplaying the results of its own analysis, which reveals far less costly and less environmentally damaging measures to meet US treaty obligations for water delivery to Mexico.

"This is reminiscent of BuRec of the past," says Lisa Force, Living Rivers program director. "At a time when federal deficits are the largest in U.S. history, it's unbelievable that Congress would consider throwing away taxpayers' dollars to prop up this boondoggle." "There are cheaper and less destructive ways to save Colorado River water than running the Yuma Desalting Plant," added Myra Wilensky, regional organizer at the National Wildlife Federation.

BuRec's objective is to produce about 108,000 acre-feet of water from the plant of sufficient quality to help meet its 1.5 million acre-feet annual obligation to Mexico. Taxpayers will be required to pay \$26 million to replace obsolete technology-plus a minimum of \$36 million in annual operating costs for the plant.

Completed in 1992 at a cost of \$256 million (a five-fold increase in projected construction costs) to clean up brackish wastewater from farms in southern Arizona, the plant was shut down several months later due to extremely high operating costs.

Another option ignored by BuRec for the 108,000 acre-feet involves paying willing sellers to lease water they presently do not need, at just 15 percent the cost of starting

the Yuma plant. "The Department of the Interior has already proposed an alternative that could save \$30 million every year. Not only does Interior's alternative have great economic advantages, it will also save enough electricity to supply 25,000 people," says Jennifer Pitt of Environmental Defense.

International water expert and director of the Pacific Institute in Oakland, Dr. Peter Gleick, said "Despite the Department of Interior's much ballyhooed 'Water 2025 Plan' claiming a new era in western water management, the decision to reopen the expensive and environmentally damaging Yuma desalter shows that federal water policy is really business as usual - spending taxpayer money for unsustainable water projects."

The agricultural wastewater that the plant would process now flows into the Cienega de Santa Clara, a 40,000-acre open water ecosystem in the Colorado River delta region. The desalting plant would remove this flow from the Cienega and return only highly saline brine to the wetlands.

"This provision would destroy an extremely important wetland in Mexico that contains the largest remaining breeding population of Yuma Clapper Rail in the world," says Bill Snape, Chief Counsel for Defenders of Wildlife.

"It will be impossible to replace the value of the Cienega de Santa Clara to the Colorado River ecosystem."

The Cienega is the largest remaining wetland in the Southwest and is home to 56 threatened, endangered and declining species. Several scientific studies funded by the Department of Interior confirm that the wetland would be completely destroyed by desalter operations.

MOTOR RIG STRANDED IN UNKAR RAPID

Grand Canyon National Park

A Wilderness River Expeditions 36 foot motorized tour boat ran aground in Unkar Rapid on the Colorado River in Grand Canyon Thursday afternoon. The boat was part of a two-boat trip of 41 people. National Park Service technical rescue personnel used a helicopter to short-haul 6 people off the stranded raft late yesterday afternoon. This type of rescue involves lifting two people at a time off the boat by a 100-foot line from the helicopter. Rescue personnel acknowledge this is the most dangerous type of rescue the park performs. Darkness halted the rescue operation of the remaining boat occupants around 7:00PM. The remaining passengers spent last night on the boat. The short-haul operation resumed this morning.

The river trip was scheduled to exchange passengers at Phantom Ranch before noon today. Concessions passengers hiking into the canyon to join the river trip are being told they can expect the arrival of the boats late this afternoon.

Flows from Glen Canyon Dam have been between 5,000 and 8,000 cubic feet per second. This flow is considered very low for motorized tour boat travel through the park.

During low water flows in 2000, the NPS conducted 3 short-haul operations for motorized tour boats stranded in the rivers rapids. Drought conditions in the Colorado River Basin continue, with Powell Reservoir above Glen Canyon Dam at 50% capacity.

It's been a busy period over the last 30 days for National Park Rescue teams responding to commercial river tip calls for evacuations. There have been two rescues of passengers with broken arms, a number of rescues of passengers with Norwalk Virus-like gastrointestinal distress, and one passenger sustained a de-gloving injury to his hand when he caught his wedding ring on boat rigging as he jumped off the boat into the river.

RRFW Riverwire - USFS TO TRASH WILDERNESS ON MIDDLE FORK

The Salmon Challis National Forest has released a Finalized Environmental Impact Statement (FEIS) which proposes to reduce the number of days that parties can remain on the Middle Fork of the Salmon river. The idea is to reduce the impacts of boaters on the river corridor, while at the same time the analysis would allow for an increase in jetboat numbers on the wilderness mainstem Salmon River.

The boiled down synthesis goes something like this: Public parties of 21-24 members, and commercial parties of 21-30 customers, would be limited to a maximum of 6 days on the river. Parties (both commercial and public) of 11 -20 members would be limited to 7 days on the river. Only those groups of 10 or less would be allowed to remain on the river for the current use limit of 8 days.

Lloyd Knapp, with North West Rafters Association, notes that most commercial trips don't stay on the river for 8 days due to quick turnaround times. This new ruling will not affect commercial outfitters, but it will fall onto the backs of self-outfitted recreational boaters, who typically take longer trips through the area. While the intent of the plan is to reduce the wear and tear on the Frank Church River of No Return Wilderness, Lloyd notes that in doing quick-turnarounds, the commercial outfitters are pouring more people down the river than trips that moving at a slower pace. Knapp notes "I would say that the river is not over-used. It does get a lot of use, but the Summer float season is relatively short. It's not at all like the Gauley in West Virginia, or other rivers that are loved to death."

Knapp also points out that the river also raises a substantial fortune in the contested Recreation Fee Demonstration program. "There is no evidence that the Forest Service has spent a dime of this money on the river. If there is over use in certain areas, then the Fee Demo money should be used for repairs and maintenance."

Jo Johnson, co-director of River Runners For Wilderness, notes there are clear flaws in this management plan. "Increasing motorized use and speeding up river travel through the wilderness do nothing to promote wilderness character. This plan continues the now outdated concept of allocating river use between the public and a small oligopoly of middlemen. This model has outlived its usefulness, especially in light of a continued

growth in public rafting and ongoing declines in demand for guided river running services."

The FEIS has been issued, and the deadline for comments is October 27, 2003. A summary version of the FEIS is available at the website below. This is a Forest Service publication known as Frankly Speaking (a reference to Frank Church).

www.fs.fed.us/r4/sc/recreation/fcronr.htm

Your comments strongly opposing this plan are needed. Quite simply, there is very little justification for this type of wilderness river use. It's discriminatory against public river users, and doesn't do anything about the commercial interests, who carry very large groups of people quickly through while putting most of the use on the wilderness.

PARK AIRLIFTS 17 PEOPLE OFF STUCK RAFT

By Brad Fuqua Editor, Grand Canyon News

A 37-foot motorized raft, operated by Wilderness River Adventures, became pinned on a rock at Unkar Rapid September 11, 2003. Unkar Rapid is at river mile 72.5. "At approximately 2 p.m., the motorized raft experienced engine failure upon entering the rapid," incident commander K.J. Glover said in a report. "It traveled to the left side and got lodged on rocks towards the base of the rapid." For the next three hours, the boatman and crews from two other Wilderness River Adventures' boats attempted to free the raft. The NPS received a satellite call for assistance at 5 p.m., after the self-rescue attempts failed. But SAR [search and rescue] personnel had less than two hours of daylight left for the operation.

Two rangers were inserted onto the boat via short-haul, a technique of moving rescuers utilizing a 100-foot rope attached to the helicopter. Six passengers were evacuated before nightfall, but air operations had to be suspended at dusk due to safety protocols. "Rangers stayed on the boat with the remaining passengers throughout the night," Glover reported. "In the morning the passengers were short-hauled to safety." There

were no reports of injuries. Some of the 17 were able to get onto other river trips and hike out from Phantom Ranch.

Following the helicopter operation, rescuers and boatmen remained on the raft to assist with efforts to free it from the rock. Attempts to free the boat Friday proved unsuccessful. However, the boat was moved with a "Z rig" from the initial point of entrapment to a location 10 feet downstream. The boat also rotated 180 degrees. On Saturday morning, park rangers returned to Unkar Rapid to assist with freeing the boat. The raft finally broke free utilizing engine power. The boat then continued down river without further incident.

A photo of the stranded boat is at <http://www.grandcanyontourguide.com/> click on "Grand Canyon Newspaper".

GRAND CANYON SLIDESHOW TOUR

Tom Martin, Co-Director of River Runners for Wilderness, will be presenting a slideshow on the Colorado River Management Plan and on his book Day Hikes from the River: A Guide to 100 Hikes from Camps on the Colorado River in Grand Canyon National Park. The CRMP-Hikes slideshow will be shown in Grand Junction, Boulder, Denver, Fort Collins and Colorado Springs, Colorado. See beautiful vistas illustrating Grand Canyon hikes you can do from the river and exciting river running shots. Tom will cover the latest news on the controversial Colorado River Management Plan now in progress for Grand Canyon National Park, and how this plan will affect your boating access. Tom will be signing books, the sale of which will benefit River Runners for Wilderness.

Round up your boating buddies, and catch one of these free shows:

Grand Junction Wednesday, October 8th, 7PM - 9PM White Water West 418 South 7th St Hosted by W.A.T.E.R.

Boulder Thursday, October 9th, 7PM - 9PM The Dairy Center 2590 Walnut St. Plenty of free parking in Dairy Center's Walnut St lot

Ft. Collins Tuesday, October 14th, 7PM - 9PM REI 4025 S. College Ave. Hosted by REI

Denver Downtown Wednesday, October 15th, 7PM - 9PM AAA Inflatables 3264 Larimer St. Hosted by High Country River Rafters

Colorado Springs Thursday, October 16th, 7PM - 9PM Sports Page 965 Summer Games Dr. Hosted by Pikes Peak River Rafters

All shows are free and open to the public. For more information or for scheduling a show in your area, contact Jo Johnson at jojohnson@rrfw.org or 303-443-1806.

River News 10/01/03

GLEN CANYON DAM UPDATE

Operations

Releases from Glen Canyon Dam will be nearly identical in October to what they were in September. In October, releases will average 8,000 cfs with a total of 492,000 acre-feet scheduled to be released. On Mondays through Saturdays in October, daily fluctuations due to load following will likely vary between a low of 5,000 cfs (during late evening and early morning off-peak hours) to a high of 10,000 cfs (during late afternoon and early evening on-peak hours). On Sundays, releases will be 5,000 cfs from 7 pm until 7 am, and 8,000 cfs from 7 am until 7 pm.

Releases from Glen Canyon Dam in November of 2003 are currently scheduled be 476,000 acre-feet (an average releases of 8,000 cfs), with the same load following pattern as October.

Because of the draw down condition of Lake Powell, releases from Lake Powell in water year 2003 were scheduled to meet the minimum objective release of 8.23 million acre-feet. This is consistent with the requirements of the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs.

Basin Hydrology

Drought in the Colorado River basin continues. Inflow volumes have been substantially below average this year with water year 2003 being the 4th consecutive year with below average inflow to Lake Powell. April through July unregulated inflow to Lake Powell in 2003 was 3.91 million acre-feet, only 49 percent of the 30 year average. Total unregulated inflow for water year 2003 will be 53 percent of average.

Inflow into Lake Powell picked up somewhat in September, 2003. Significant amounts of precipitation fell in the Colorado River Basin, particularly in the Four Corners region, in the first two weeks of September. Unfortunately, a drying trend followed. There has been almost no precipitation in the Colorado River Basin in the latter part of September. Total unregulated inflow in September will end up at about 453,000 acre-feet, or 95 percent of average. Inflow on September 29, 2003 was 5,600 cfs, about 60 percent of what is usually seen in late September.

Total unregulated inflow into Lake Powell in water years 2000 and 2001 was 62 and 59 percent of average, respectively, and only 25 percent of average in 2002. Inflow in 2002 was the lowest ever observed since the completion of Glen Canyon Dam in 1963. These low inflows have reduced water storage in Lake Powell. Lake Powell reached a peak elevation in 2003 on June 23 at 3616.6 feet. The current elevation of Lake Powell is 3,603.8 feet (96.2 feet from full pool). Current storage is approximately 12.1 million acre-feet (50 percent of capacity). The water surface elevation at Lake Powell will likely continue to decrease for the remainder of the year. Under expected inflows, Lake Powell will likely be near elevation 3600 feet on January 1, 2004.

Experimental Flows

Daily high fluctuating releases from Glen Canyon Dam, as part of the Glen Canyon Dam experimental flows, were completed on March 31, 2003. From January through March 2003 releases ranged between a high of 20,000 cfs to a low of 5,000 cfs each day. These same high fluctuating releases are scheduled to be repeated in January through March of 2004.

The January through March high fluctuating releases were intended to benefit the endangered humpback chub. Scientists have recognized that the humpback chub population has been in general decline since highly fluctuating flows were curtailed in November of 1991. Those flows helped keep the non-native fish, especially the rainbow and brown trout, in check. The trout are thought to prey upon and compete with native fish such as the endangered humpback chub.

The experimental flows from Glen Canyon Dam received environmental clearances in December 2002. The flows were analyzed in an environmental assessment in accordance with the National Environmental Policy Act. The experimental flows are the result of ongoing studies by scientists from the United States Geological Survey and were recommended by the Glen Canyon Dam Adaptive Management Work Group, a Federal advisory committee. The experimental flows address the decline of two key resources in the Grand Canyon: sediment and population viability of endangered humpback chub. The Finding of No Significant Impact on the experimental flows can be found at http://www.uc.usbr.gov/amp/flow_fonsi.pdf.

COLORADO RIVER ECOSYSTEM SYMPOSIUM

The Glen Canyon Dam Adaptive Management Program and the Grand Canyon Monitoring and Research Center will be hosting a symposium on the Colorado River in Grand Canyon. The symposium will be held in Tucson Arizona, October 28-30, 2003, and is open to all interested persons (public and students welcome!). The symposium will address questions such as:

Was the Low Steady Summer Flow in 2000 good for the river? How can conditions for the endangered humpback chub be improved? Are the new flows and experimental removal of non-native fish working? What is the role of experimentation under the Record of Decision?

Registration is free, but please register your attendance online using the website link below so organizers have enough meeting materials and light refreshments available. The program will run from approximately 8:30 a.m. to 5 p.m. each day, with a special poster session the evening of October 28th.

The program and flyer are available at <http://www.gcmrc.gov/symposium/2003/symposium.html> The Symposium will be held at the Sheraton Tucson Hotel and Suites, 5151 E. Grant Road, Tucson, AZ 85712. For further information, contact Serena Mankiller, USGS/BRD, Southwest Biological Science Center, Grand Canyon Monitoring and Research Center, 2255 N. Gemini Dr., Flagstaff, AZ 86001, Ph: 928/556-7094, E-mail: smankiller@usgs.gov

River News 10/06/03

BOULDER, GRAND JUNCTION SLIDESHOW REMINDER

Grand Canyon enthusiasts in Boulder and Grand Junction, Colorado: Don't forget the free upcoming Day Hikes from the River slideshow and CRMP update this week at the following locations.

Grand Junction Wednesday, October 8th, 7PM - 9PM White Water West 418 South 7th St Hosted by W.A.T.E.R.

Boulder Thursday, October 9th, 7PM - 9PM The Dairy Center for the Arts 2590 Walnut St.

If you can't make it to one of those, you have more opportunities in Fort Collins, Denver and Colorado Springs.

Fort Collins Tuesday, October 14th, 7PM - 9PM REI 4025 S. College Ave. Hosted by REI

Denver Downtown Wednesday, October 15th, 7PM - 9PM AAA Inflatables 3264 Larimer St. Hosted by High Country River Rafters

Colorado Springs Thursday, October 16th, 7PM - 9PM Sports Page 965 Summer Games Dr. Hosted by Pikes Peak River Rafters

Additional shows are tentatively scheduled in Colorado for Salida, December 2nd and Durango, December 4th, and in Salt Lake City. For more information on any of the shows, contact jojohnson@rrfw.org or at 303-443-1806.

River News 10/09/03

RIVER RUNNERS WANT LARGER SHARE OF CANYON

By Chris Barge, Boulder Daily Camera Staff Writer

So let's say you're a hard-core paddler who wants to lead your own trip down the Colorado River through the Grand Canyon. Now, pretend you want to do that some time in the next decade. Good luck. Under the current wait-list system, you'd have to buy a Day Planner for the year 2023 before finding a page to pencil in a trip. The wait list for recreational paddlers is about 20 years long. If you want to go this year, cash in those stocks: A spot is waiting for you on a commercial trip with one of the many outfitters that

share 68 percent of the trip allocations. A woman from Boulder and a man who spends most of his time near the Grand Canyon are trying to rally the public behind a movement to change the status quo.

Jo Johnson of Boulder and guide book author Tom Martin co-founded River Runners for Wilderness one year ago. Martin will present a slide show tonight to promote their organization and his updated guidebook, "Day Hikes from the River: 100 Hikes from Camps on the Colorado River in Grand Canyon National Park." The book, an expanded version of his first guide, points out fun side hikes from the river for the 32 percent of river runners who are going it on their own. He says he hopes the book warms people to the idea of joining his and Johnson's cause.

Together, Johnson and Martin are trying to get the public engaged as the National Park Service develops a new Colorado River Management Plan. "There has been 30 years of stagnation down there to the benefit of an oligopoly of concessionaires," Martin said. "Fixed allocations don't work." The Park Service is scheduled to publish a draft environmental impact statement for the plan this fall. It will address the allocation system, as well as whether to continue allowing motorized boats on the river.

Commercial outfits in the canyon like using motor boats because they allow them to offer customers longer river trips over fewer days. Johnson says, in addition to being expensive, fast trips rob visitors of the true immersive psychological experience that the Grand Canyon can provide.

Hooey, says Mark Grisham, executive director of the Grand Canyon River Outfitters Association, which represents the concessionaires. Go to Minneapolis or Dallas and fill an auditorium with people who would seriously consider taking a river trip through the Grand Canyon, he said. Then, ask for a show of hands to these questions: Who wants to book an outfitter for a one- to two-week trip? Now, who wants to round up their own gear, own group and all the time off necessary to do the trip on their own? "We don't think that show of hands would be 50-50," Grisham said. "We think it would be more like 95-five."

Grisham said he and Martin disagree on how many commercial boats should run the river. It's the right mix, Grisham said. It's the antiquated wait-list system that needs to change. He suggests introducing a lottery. Both sides agree that the current method for private boaters to get on the water needs improvement. "That's why people are so pissed off," Grisham said. "They feel like the Park Service has let them down, so we become the for-profit bad guys."

The Grand Canyon River slide show and park plan update will be from 7 to 9 p.m. today at the Dairy Center, 2590 Walnut St., Boulder. For more information, call Johnson at (303) 443-1806. Martin's book is available at www.vishnutemplepress.com. For more information on the Colorado River Management Plan, visit www.nps.gov/grca/crmpl/. River News 10/13/03

RRFW Riverwire – RIVER OF NO RETURN MANAGEMENT PLAN UPDATE

The final environmental impact statement (FEIS) has been released for the Frank Church River of No Return Wilderness Management Plan by the Salmon Challis National Forest. This plan will guide management of the Main and Middle Fork of the Salmon River for years to come. The wild character of this area has degraded significantly in the past 20 years and that trend will actually increase under the new plan. Please take a few minutes to write a letter to the Forest Service asking them to protect the wilderness character of the Frank Church - River of No Return Wilderness. Comments must be submitted by October 27, 2003.

The final plan allows unlimited expansion of aircraft and motorboat use, continued degradation around campsites, lakes, streams and trails, serious impairment of the opportunity for a wilderness experience on the Middle Fork Salmon and Main Salmon rivers, and an unfair quota system that has commercialized much of the access to these rivers. While the draft EIS included 11 alternatives for consideration, the final EIS has been reduced to a final five (A to E). Though none of these alternatives are optimal to preserve Wilderness character and values, Alternative B comes closest. We endorse Alternative B, but only with the following changes:

(1) Managing use on the Middle Fork and Main Salmon rivers: Alternative B is the only alternative that caps use at a level that protects Wilderness character and opportunities for a wilderness experience. However, because this alternative continues an outdated and unfair allocation system (60 percent of use is for commercial trips), and allows for overly large party sizes (19 per group) it unnecessarily limits the number of public boaters who can float these rivers. The Forest Service should cap river use at the level set in Alternative B, but increase the number of trips available to the public by reducing group size limits to 12 per trip, and by allocating a much larger percentage of the launches to the public, rather than commercial users. The opportunity to experience Wilderness should not be based on one's willingness to pay a commercial outfitter.

(a) Jetboats: The plan allows virtually unlimited motorboat use on the Mail Salmon. Jetboat use has grown dramatically since 1978, much of it for "jetback" shuttles, which bring rafters upriver to their cars. Urge the Forest Service to prohibit jetbacks, and to cap motorboat use at 1978 levels.

(b) Painter Bar Road: The Painter Bar road is a primitive route that was used to access a private inholding within the Wilderness and Wild Salmon River corridor. The Forest Service has acquired the inholding. The FEIS proposes to leave this road open to ATVs and 4-wheel drive traffic. The Wilderness Act prohibits permanent roads and the Wild Scenic Rivers Act prohibits roads along Wild Rivers. Urge the FS to close the Painter Road in the final plan.

(2) Aircraft Use: The Forest Service estimates that 5,500 aircraft land on airstrips in the Wilderness each year. Most of the use is not for wilderness dependent activities but part of a new fad where pilots "bag" airstrips to prove their competence, or engage in an airplane version of car camping. All of the alternatives the Forest Service developed

allow aircraft use to increase without restriction. Urge the Forest Service to limit the number of aircraft landings to pre-Wilderness designation levels, and to implement a permit system that allows access for legitimate Wilderness dependent activities only.

In addition, and without agency approval, pilots have converted four Wilderness meadows into landing strips, referred to as the Dewey Moore, Mile-Hi, Simonds, and Vines "landing strips". The Forest Service preferred alternative proposes to maintain these strips for "emergency use," though landing at other times would not be prohibited. Urge the Forest Service to permanently close the Dewey Moore, Mile-Hi, Simonds, and Vines landing strips.

(3) Backcountry: Urge the Forest Service to implement specific management strategies to reduce crowding and on-site physical impacts by reducing group size limits from the current 20 people/20 head of stock, to 10 people/10 head of stock.

(4) Outfitter Camps: The plan would continue the practice of reserving over 80 camps for commercial land-based outfitters. The camps include permanent structures such as corrals, tent logs and fences. All Wilderness users should be required to meet the same rigorous leave-no-trace standards. Urge the Forest Service to require that outfitter camps be temporary and removed at the end of each season.

(5) Livestock grazing, fire control, fish stocking: These three important ecological issues are not addressed in the plan despite the fact that each has a significant effect on natural conditions in the Wilderness. Urge the Forest Service to adopt standards that promote naturally functioning ecosystems. Natural fires should be allowed to burn, stocking non-native species should cease, and strict controls should be incorporated into livestock allotment plans.

Send your comments to: Ken Wotring, FC-RONR Wilderness Coordinator, Forest Supervisor's Office, Salmon-Challis National Forest, 50 Highway 93 South, Salmon, ID 83467. Phone: (208) 756-5131, Fax: (208) 756 - 5151, email: comments-intermtn-salmon-challis@fs.fed.us

RRFW Riverwire - Update on the CRMP Planning Process

To: All Interested Persons From: Planning Team Leader, Colorado River Management Plan

Subject: Update on the CRMP Planning Process Grand Canyon National Park is making considerable progress in developing a Draft Environmental Impact Statement for revising the park's Colorado River Management Plan (CRMP). We have developed a full range of reasonable draft alternatives (including the current situation which is the No

Action alternative), which is now undergoing preliminary impacts analysis. The planning team has carefully considered and addressed input including the following:

- * Extensive comments the park received during the public scoping period in 2002,
- * Input from the stakeholder workshops and expert panels,
- * Consultation with Native American Tribes,
- * Interagency consultation,
- * Provisions of the 2002 lawsuit settlement agreement,
- * Extensive data and other information gathered by the planning team, and
- * Laws, policies, and principles guiding plan development (on the CRMP website at www.nps.gov/grca/crmp).

The next steps in the CRMP planning process will include:

- * Add mitigation measures to the alternatives, as necessary, to address any major impacts identified in the preliminary impacts analysis. The mitigated alternatives will then undergo additional impacts analysis. All of this is scheduled for completion in early November.
- * Review the draft alternatives and draft impacts analysis, make any necessary changes, and select a preferred alternative. The preferred alternative will be the agency's proposal for a revised CRMP; it may be one of the draft alternatives, the No Action alternative, or a new alternative developed during the preferred alternative selection process.
- * Publish a Draft CRMP/EIS for public review and comment (after any additional revisions and analysis).

We will not know the exact timing for publishing and public review of the Draft CRMP/EIS until the preferred alternative selection process has been completed. Once that process is completed, we will announce the schedule in a note to the CRMP email list, and on the CRMP website.

When the Draft CRMP/EIS is published, the park will issue a Notice of Availability in the Federal Register, a press release, and a note to everyone on the CRMP mailing list. We have begun planning for extensive public review opportunities, including public meetings, and we will keep you informed as we develop the details.

Please send any comments or questions concerning this note or the process to grca_crmp@nps.gov (please be sure to use an underscore to make grca_crmp). Thank you for your interest in Grand Canyon National Park and the Colorado River Management Plan. Rick Ernenwein CRMP Planning Team Leader.

NOROVIRUS UPDATE

River trip illnesses down from last year By Brad Fuqua, September 24, 2003 Grand Canyon News Editor

One year after a series of norovirus outbreaks on the Colorado River, things appeared to be pretty much back to normal this summer as river runners made their way through Grand Canyon. Last year, dozens of river trip passengers fell sick to the gastrointestinal illness, the same strain that ran rampant on cruise ships. This summer at Grand Canyon, only one trip reported three or more sick passengers. The infected trip launched from Lee's Ferry on Sept. 1 and a passenger became sick the following day. As a result, there is a theory that the person may have arrived for the trip already carrying the virus.

"The first person got sick on the 2nd, so our wildest guess is that it was brought in," said Michael McGinnis, Grand Canyon National Park river sub-district ranger. "The Coconino County Health Department actually has the toilets ... they took samples and are testing for norovirus. That's what they think it is, they don't know for sure." McGinnis said it appears 13 people got sick from the incident. Two people were flown out and taken to the hospital in an evacuation done above Crystal Rapid. Last year's problems with the illness were traced to discharges from Glen Canyon Dam's water-treatment plant. This year, McGinnis said "they did testing and did not find it," so that problem has seemingly been solved.

In addition, the National Park Service, commercial river runners and public boating groups met in a series of meetings to go over sanitation practices. Out of those meetings came a policy that private or commercial boating groups must report three or more illnesses immediately via satellite phone. That happened just the one time this year.

If fewer than three people become sick with contagious gastrointestinal illness on a river trip, the boaters are not required to report it until the end of the trip. That happened 12 times this summer, including one person who had to be flown out.

According to the Centers for Disease Control, symptoms of norovirus usually include nausea, vomiting, diarrhea and some stomach cramping. Sometimes people additionally have a low-grade fever, chills, headache, muscle aches and a general sense of tiredness. The illness begins suddenly is usually brief, with symptoms lasting only about one or two days, the CDC reports.

UPDATE ON CRMP PLANNING

Released October 21, 2003 To: All Interested Persons From: Planning Team Leader, Colorado River Management Plan Subject: Update on the CRMP Planning Process
Grand Canyon National Park is making considerable progress in developing a Draft Environmental Impact Statement for revising the park's Colorado River Management Plan (CRMP). We have developed a full range of reasonable draft alternatives (including the current situation which is the No Action alternative), which is now undergoing preliminary impacts analysis. The planning team has carefully considered and addressed input including the following:

- * Extensive comments the park received during the public scoping period in 2002,
- * Input from the stakeholder workshops and expert panels,
- * Consultation with Native American Tribes, * Interagency consultation,
- * Provisions of the 2002 lawsuit settlement agreement,
- * Extensive data and other information gathered by the planning team, and
- * Laws, policies, and principles guiding plan development (on the CRMP website at www.nps.gov/grca/crmp). The next steps in the CRMP planning process will include:
 - * Add mitigation measures to the alternatives, as necessary, to address any major impacts identified in the preliminary impacts analysis.

The mitigated alternatives will then undergo additional impacts analysis. All of this is scheduled for completion in early November.

- * Review the draft alternatives and draft impacts analysis, make any necessary changes, and select a preferred alternative. The preferred alternative will be the agency's proposal for a revised CRMP; it may be one of the draft alternatives, the No Action alternative, or a new alternative developed during the preferred alternative selection process.

- * Publish a Draft CRMP/EIS for public review and comment (after any additional revisions and analysis).

We will not know the exact timing for publishing and public review of the Draft CRMP/EIS until the preferred alternative selection process has been completed. Once that process is completed, we will announce the schedule in a note to the CRMP email list, and on the CRMP website.

When the Draft CRMP/EIS is published, the park will issue a Notice of Availability in the Federal Register, a press release, and a note to everyone on the CRMP mailing list. We have begun planning for extensive public review opportunities, including public meetings, and we will keep you informed as we develop the details.

Please send any comments or questions concerning this note or the process to grca_crmp@nps.gov (please be sure to use an underscore to make grca_crmp).

Thank you for your interest in Grand Canyon National Park and the Colorado River Management Plan. Rick Ernenwein CRMP Planning Team Leader

River News 10/25/03

RIVER CONCESSION SALE POSSIBLE

Grand Canyon, AZ

A Grand Canyon river concessionaire has initiated the process of being purchased by another rafting concession, according to park officials. The river concession contract, owned by High Desert Adventures, has two years left on its present contract extension. The purchaser, if approved by the park, will be Arizona Raft Adventures. High Desert Adventures has 3,323 user days, while Arizona Raft Adventures has 10,368. There are currently 16 river concessions contracts today, with one company holding two contracts. If the sale is approved, there will be 16 contracts held by 14 companies. The contract period is now up to 10 years, with three-year extensions allowed beyond the 10-year period. All river concessions are presently operating under an extension that will expire December 31, 2005.

Grand Canyon National Park will be renewing the river concession contracts based on the Colorado River Management Plan (CRMP), now in the midst of an Environmental Impact Statement review. The final management plan will set the stage for river use for another 10 years.

Jo Johnson, River Runners For Wilderness Co-Director, is hoping for a change in the way the park distributes these permits. Johnson notes that 21 businesses become river concessionaires in the fall of 1971, with the initiation of 5-year contracts. At that time, all government agencies were to be following the National Environmental Policy Act, known as NEPA. Though federal law requires public review and scoping of such activities, these have never been conducted, and river concessions contracts have since been awarded based on requirements found in the CRMP. "Today, the split-allocation system has resulted in the do-it-yourself river running public waiting in a projected 20 year backlog of permits for river access while river concessionaires are slashing prices on river trips to assure their river trips fill." Johnson adds "We question the continued usefulness of a split allocation system."

According to Johnson, there are only two ways to shift user-days from the river concessions back to the public. The first is if the CRMP identifies a decreased need for commercial concessionaire services as they are presently offered. "The other way would be for the CRMP to adopt an allocation-free access system like the one at Boundary Waters or at Grand Canyon for backpackers. This completely eliminates the need for concessions to have a fixed allocation base." Johnson points out that de-regulating the concessions would move them from an oligopoly with fixed subsidies to an oligopoly "that could compete for market share. The park could terminate the concessionaire contracts and award any number of qualified Incidental Business Permits for guided river services."

"A number of businesses have been thriving for over a decade servicing the non-commercial river running public without any allocations whatsoever" Johnson noted. "These businesses provide a wide array of great services at low cost to the public. Allocation-free access plans hold the only hope for a contention free future for the river."

Interior Dept. favors more Canyon flooding

By Mitch Tobin ARIZONA DAILY STAR

Tucson, Arizona - Despite initial resistance, the Bush administration favors continued experimental floods meant to restore the Grand Canyon's ecology, a senior official said in Tucson on Tuesday.

Assistant Secretary of the Interior Bennett Raley, the administration's point man on water issues, spoke to 60 scientists at the start of a three-day meeting on how Glen Canyon Dam affects the Colorado River.

Researchers explained how they're using lasers, underwater cameras, century-old photos and experimental flumes in Minneapolis to learn how sand grains and Volkswagen-sized boulders move through the Canyon's rapids and eddies.

Raley urged the scientists not to politicize their work and to remember that "science is not the only input factor for management of the Colorado River."

"If scientists are sloppy and mix advocacy with science, you will end up with the same public perception of integrity that lawyers have," said Raley, a lawyer by training.

Glen Canyon Dam, completed in 1963, dramatically altered the Colorado's flow. Before the dam, the warm, muddy river roared with spring snowmelt. Sediment was lifted onto beaches and sand bars, creating wildlife habitat and backwaters vital to native fish, such as the endangered humpback chub. The beaches are still important campsites for boaters.

After the river was plugged to stabilize the Southwest's water supply, it ran colder and clearer below the dam, which trapped 90 percent of the silt. But dam releases--which often fluctuate with the Sunbelt's electricity demands--have also caused the Colorado's baseline flow to double downstream. As a result, much of the silt and gravel deposited by the Grand Canyon's 740 tributaries gets whisked into Lake Mead downstream.

"It wasn't that we just lost the spring floods, which redeposited sand," U.S. Geological Survey researcher Ted Melis said, "we lost the low-flows the rest of the time, which were low enough to retain those inputs for use during the high-flows. We're getting hit on both ends."

The result is an ecosystem transformed by a dam that helps supply water and power to 25 million people.

Tucson is becoming increasingly dependent on the Colorado, whose water comes here via the Central Arizona Project's 336-mile canal.

After passage of the 1992 Grand Canyon Protection Act, the Clinton administration tried to replicate the river's natural flows. With much fanfare, Interior Secretary Bruce Babbitt opened the dam's floodgates in 1996; another flooding experiment was tried in 2000.

Despite initial claims of success, scientists now say the results were minimal. A lack of sediment in the river made it tough for sandy areas to expand, and many gains were quickly washed away.

Scientists want to create more floods and time them when the Paria River is dumping sediment into the Colorado.

But the drought has caused that tributary, 15 miles below the dam, to deposit less silt in the past three years than any time in recorded history.

Raley said at first he was "deeply, deeply skeptical about the experimental flow program." But, after talks with scientists on a river trip, Raley accepted it was "good science and it was worth taking the political risks to move forward."

"We know when we're being gamed. Had we sensed that, we probably would have slow-walked, ducked, evaded and done everything not to move forward," he said.

John Weisheit, an environmentalist with the group Living Rivers who would like to see Glen Canyon Dam removed, was encouraged by Raley's words. But he said the Interior Department still isn't spending enough money to restore the Grand Canyon.

In the past 30 years, researchers have flip-flopped on whether the Canyon was losing or gaining sediment, said Jack Schmidt of Utah State University. Some thought the lack of

floods created a surplus of silt and there was enough sand in the river to form new beaches.

"What we've learned in the Grand Canyon is, the system may be in sediment deficit all the way to Lake Mead," he said.

RRFW Riverwire - PUBLIC TO BE BYPASSED AGAIN

Grand Canyon National Park October 31, 2003

River Runners for Wilderness has learned that a Recommendation for Wilderness Proposal has been submitted to the park by Representative George Radanovich (R-CA, Chairman, Subcommittee on National Parks, Recreation and Public Lands).

Chairman Radanovich is proposing a wilderness recommendation which excludes the Colorado River. Grand Canyon National Park staff are responding to a request from the NPS Directorate to prepare the necessary documentation. Representative Radanovich and committee staff members intend to introduce this alternative through the congressional process as a wilderness bill.

"Here we go again." commented Tom Martin, Co-Director of River Runners for Wilderness "We are in the middle of a public process dealing with the river-wild, where the public, as it has for over 30 years, is clamoring for preservation of the wilderness character of the river, and in steps Congress to bypass the public. In fact," Martin notes, " we are possibly only two months away from seeing the release of the long awaited preferred alternative for the Colorado River Management Plan Environmental Impact Statement. Just like this spring, the summer of 2001, and in 1980, we're seeing an attempt to muzzle the public process. This recommendation not only shuts down the public process," he continues, " but it flies in the face of a court ordered settlement from two years ago to include a wilderness alternative."

Grand Canyon Superintendent Joe Alston and staff are in the process of producing a map that reflects the Chairman's intent, which excludes the river from Wilderness designation. The park is providing narrative explanation that delineates further exclusions besides the river, as defined in the 1993 Final Wilderness Recommendation. RRFW has also learned that the 1993 recommendation will also be included for reference purposes. These documents will be submitted to the NPS Office of Congressional Affairs for final drafting services. The information is being provided as a service to the Chairman and Subcommittee staff, who will then handle all further liaison activities with the Congressman's office relating to the proposed recommendation.

"The river rafting public has discovered that wilderness rivers are an incredibly unique and scarce resource. This recommendation eliminates 240 miles of the best wilderness river running in the world. There are no motorized boats on the river for three months of

the year, and no jet-boats at all. The loss of wilderness protections will change all that." remarks Jo Johnson, also of River Runners for Wilderness. "Most importantly, allowing 80% of the public river access to be given to park rafting concessionaires, 75% of which use motorized tour boats to run through the canyon, while the do-it-yourself paddler waits in a 20 year backlog for access, is inconsistent with wilderness management. Thirty years of access wars over the character of the river have taught us that outdated fixed allocations are not what wilderness river running is supposed to be all about."

This recommendation will result in a reduction in wilderness acreage at Grand Canyon National Park. The 1993 Final Wilderness Recommendation proposes 1,139,077 acres. By excluding the river, the amount is reduced by 12,190 acres to 1,126,887 acres of wilderness. RRFW has learned that Grand Canyon National Park has taken no position on this recommendation at this time.

All river runners are encouraged to contact the following congressmen and ask to speak with the environmental staffer. Politely request that the Radanovich Grand Canyon Wilderness recommendation not be introduced while a public process to sort these issues out is ongoing. Even if the listed congressmen below are not in your district, you are all encouraged to contact them as this is a National Park, and therefore a national issue.

Rick Renzi 202-225-2315 Mark Udall 202-225-2161 Tom Udall 202-225-6190 Raul Grijalva 202-225-2435 George Radanovich 202-225-4540 John McCain 202-224-2235

River News 11/02/03

RRFW Riverwire - GLEN CANYON DAM UPDATE

Updated October 31, 2003
Operations

Releases from Glen Canyon Dam in November will be nearly identical to what they were in October. In November, releases will average 8,000 cfs with a total of 476,000 acre-feet scheduled to be released. On Mondays through Saturdays in November, daily fluctuations due to load following will likely vary between a low of 5,000 cfs (during late evening and early morning off-peak hours) to a high of 10,000 cfs (during late afternoon and early evening on-peak hours). On Sundays, releases will be 5,000 cfs from 7 pm until 7 am, and 8,000 cfs from 7 am until 7 pm.

Releases from Glen Canyon Dam in December of 2003 will likely be higher than November. The volume releases in December is likely to be 600,000 acre-feet (an average release of about 10,000 cfs).

Because of the draw down condition of Lake Powell, releases from Lake Powell in water year 2004 are being scheduled to meet the minimum objective release of 8.23 million acre-feet. This is consistent with the requirements of the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs.

Basin Hydrology

Severe drought conditions in the Colorado River Basin continue. As we move into a new water year there are no signals of the drought easing. Water year 2004 began on October 1, 2003 and the first month of our new water year was much warmer and drier than average. Basinwide precipitation in October was only about 30 percent of average. Soil moisture levels throughout the basin are very low, and as we move into winter it appears likely that the snowpack will be building upon these very dry soils. The scenario is not favorable for next spring's runoff, as much of the melting snow will be absorbed by the dry soil. Reclamation is estimating that with average snowpack conditions this winter, runoff next spring would be about 75 percent of average.

The Colorado River Basin is now in its 5th year of drought. Inflow volumes have been below average for 4 consecutive years. Unregulated inflow in water year 2003 was only 53 percent of average. Unregulated inflow in 2000, 2001 and 2002 was 62, 59, and 25 percent of average, respectively. Inflow in 2002 was the lowest ever observed since the completion of Glen Canyon Dam in 1963.

The trend of low inflow continues. Unregulated inflow in October, 2003 will end up being only 55 percent of average. As of October 31, 2003 observed inflow to Lake Powell is about 6,000 cfs, about 58 percent of what is usually seen in late October.

Low inflows have reduced water storage in Lake Powell. The current elevation of Lake Powell is 3,602.0 feet (98.0 feet from full pool). Current storage is approximately 11.9 million acre-feet (49 percent of capacity). The good news is that even after 4 years of severe drought, Lake Powell is still storing a large volume of water (nearly 12 million acre-feet).

Experimental Flows

Daily high fluctuating releases from Glen Canyon Dam, as part of the Glen Canyon Dam experimental flows, were completed on March 31, 2003. From January through March 2003 releases ranged between a high of 20,000 cfs to a low of 5,000 cfs each day. These same high fluctuating releases are scheduled to be repeated in January through March of 2004.

The January through March high fluctuating releases were intended to benefit the endangered humpback chub. Scientists have recognized that the humpback chub population has been in general decline since highly fluctuating flows were curtailed in November of 1991. Those flows helped keep the non-native fish, especially the rainbow

and brown trout, in check. The trout are thought to prey upon and compete with native fish such as the endangered humpback chub.

The experimental flows from Glen Canyon Dam received environmental clearances in December 2002. The flows were analyzed in an environmental assessment in accordance with the National Environmental Policy Act. The experimental flows are the result of ongoing studies by scientists from the United States Geological Survey and were recommended by the Glen Canyon Dam Adaptive Management Work Group, a Federal advisory committee. The experimental flows address the decline of two key resources in the Grand Canyon: sediment and population viability of endangered humpback chub. The Finding of No Significant Impact on the experimental flows can be found at http://www.uc.usbr.gov/amp/flow_fonsi.pdf.

Endangered Species: Interior mulls warming Colorado River to help humpback chub

April Reese, Land Letter Southwest correspondent

This story is the first of a series on management of natural resources in the Grand Canyon.

GRAND CANYON NATIONAL PARK, Ariz. -- Almost 40 years after Glen Canyon Dam plugged the Colorado River, one of the river's oldest inhabitants is struggling for survival. But as the debate swirls over recovering the endangered humpback chub while meeting human water demands, the river's federal caretakers have devised a new solution: warm up the river.

The chub, which ranges in size from 5 to 20 inches and can live up to 30 years, evolved in the Colorado River basin 3 million to 5 million years ago. Once numbering in the millions throughout the watershed, the fish has been reduced to a couple thousand, although scientists disagree over just how many remain. While small groups of the fish persist in the upper Colorado River basin, the only surviving lower basin population is in the Little Colorado River, near its confluence with the mainstem in Grand Canyon National Park.

[The largest known population of humpback chub is in the Little Colorado River in the Grand Canyon, where there may be up to 10,000 fish. Photo courtesy of the Fish and Wildlife Service/John Rinne.]

Scientists attribute the species' decline primarily to Glen Canyon Dam, built in 1963 to provide water and power to the interior West. While many credit the dam and its reservoir, Lake Powell, with turning the arid region into a land of verdant farms and booming cities, the project also has drastically changed the ecosystem downstream. The Colorado River, which historically ran muddy and warm, turned clear and cool with the closing of the floodgates.

As incoming water pools behind the dam, its sediment load settles, and the water released through the dam's penstocks is drawn from the cool depths of the reservoir. Water temperatures that once fluctuated seasonally from about 80 degrees in summer to almost freezing in winter now average 46 degrees year-round, according to the Bureau of Reclamation. Biologists suspect the chub and other native fish that have disappeared from the river altogether have difficulty tolerating the cool, clear waters that now flow through the Grand Canyon.

[The picture on the left shows the clear-running Colorado River in the Grand Canyon above the confluence with the Little Colorado River; the other picture shows the murky Little Colorado. Photos by April Reese.]

On a recent data-gathering trip funded by the U.S. Geological Survey, Joe Shannon, a Northern Arizona University-based aquatic ecologist who has been monitoring the Grand Canyon ecosystem for 15 years, pointed out the contrast between the murky Little Colorado and the mainstem river. A recent storm had loaded the Little Colorado with sediment, and its milk-chocolate flow muddied the crystalline main stem where the two rivers meet in Grand Canyon National Park, about 75 miles downstream from the dam.

"That's how the Colorado should look," he said, pointing to the river, which has grown murky under the influence of its temporarily muddy tributary. "It's not supposed to be clear."

It was a rare glimpse of the river as the humpback chub saw it for millions of years, before the construction of the dam 40 years ago. But a quick splash of the hand in the cloudy waters is a reminder that this is still a "designer ecosystem," as Shannon calls it. The water is cool -- too cool for humpback chub to reproduce.

Warming the river

The Bureau of Reclamation, which owns and operates the dam, hopes to improve those conditions by using a "temperature control device" (TCD) to release warmer water into the river. Dennis Kubly of BuRec's Environmental Resources Division said the agency wants to send water from the reservoir's warm surface layer downstream instead of drawing from the deep, cold waters of the lake.

The impetus for the project was a biological opinion issued by the Fish and Wildlife Service in 1994. The agency recommended that BuRec investigate using temperature control technology, which up to that point had only been used to enhance conditions for game fish, to help recover the humpback chub.

In August, the proposal received an endorsement from the Glen Canyon Dam Adaptive Management Work Group, comprised of 25 stakeholders representing the park service, BuRec, FWS, power interests, environmental groups and others. This week, the group formally asked Interior Secretary Gale Norton to give BuRec the green light to go forward with the project. Norton is expected to make a decision on the proposal within the next few weeks.

But several biologists question whether the water drawn from the top of the reservoir will be warm enough to significantly benefit the chub. While BuRec's proposal to increase water temperatures in the river is partly in response to FWS' recommendations, some biologists are concerned that warming the river could benefit non-native fish that prey on the chub as well. For instance, channel catfish -- one of several species, including striped bass and carp, introduced to the Colorado River by fishery managers -- respond to increases in water temperature by speeding up their metabolism, which causes them to eat more food, including chub, Shannon said.

"Right now, those fish may be suppressed by cold water temperatures," said Sam Spiller, Lower Colorado River coordinator for the Fish and Wildlife Service. "There might be more damage if we warm the water." Even so, the increase in temperature could help control cold water species like trout, he added.

Even if the TCD succeeds in boosting chub numbers, it's likely to fall short of federal recovery goals for the species, said David Haskell, a former director of Grand Canyon National Park's Science Center. "The recovery plan calls for [establishing] another major, viable population," he said. "The TCD would not do that."

Shannon was more optimistic. "I think the TCD can work, but only if there's a total reworking of dam operations," so that water releases would more closely mimic historic fluctuations in flows, Shannon said. "Recovery efforts have to be on a big scale, because the dam and its impacts are so big."

If the project goes forward, Kubly said it will probably be implemented in small steps so federal managers can monitor the effects on both native and non-native fish and adjust the plan accordingly.

"In a sense, it's a one-arm-behind-your-back approach," he said. "Not everyone trusts one another, so this makes sure we don't move too far too fast."

It also costs less to go slow, Kubly noted. The initial two-penstock plan will cost about \$25 million; to alter all eight, the cost would be about \$100 million, he said.

The agency has used temperature control devices with some success on other dams, including Shasta on California's Sacramento River, Hungry Horse on Montana's Flathead River and Flaming Gorge on Utah's Green River, Kubly added.

"There aren't any known disasters out there," he said. "By and large, the system responses have either been positive or neutral."

Recovering the chub

But Haskell, who was also a ranger at Glen Canyon National Recreation Area in the 1970s, said the only way to restore native fish -- and the rest of the ecosystem -- is to decommission the dam. He compared the TCD project to "tinkering while Rome is burning."

"If there wasn't a dam, the trout would be dead real quick, because they can't take a lot of this," said Haskell, gesturing toward the murky water.

According to the Fish and Wildlife Service, the chub will be considered for removal from the endangered species list "when five viable, self-sustaining populations have been restored ... and when the fish's habitat has been protected."

With one of the river system's biggest dams just upstream from the largest population of the chub, that's a tall order, say Haskell and other decommissioning advocates.

In addition to the TCD proposal, federal managers have launched a program aimed at killing non-native fish. But that effort, too, is fraught with uncertainty. Some biologists are worried that reducing the numbers will only give the remaining non-native fish more room -- and more resources -- to thrive. The question, Shannon said, is, "How do you kill all the bad fish and grow the good fish?"

Complicating recovery efforts are conflicting management objectives in the same ecosystem, Shannon added. "The park is killing non-native fish, but [state managers] are still stocking them upstream," he said.

Debbie Felker, a spokeswoman for FWS' Upper Colorado River endangered fish recovery program, said the agency is working with state game and fish officials to scale back stocking programs that conflict with endangered species recovery.

The challenge of recovering the humpback chub is part of a larger debate over how to protect the park's resources while meeting water delivery mandates.

Lake Powell is one of several reservoirs that are part of the Colorado River Storage Project, which provides water for seven states: Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming. About 85 percent of the water is used for irrigation; the rest is allocated for residential, commercial and industrial use. Balancing those demands with the protection of an extensively altered river ecosystem is a daunting task, observers say.

Meanwhile, the stakes are becoming increasingly higher for the chub in the Grand Canyon, Shannon said. "If we lose the base flow of the Little Colorado River because of drought, it's all over," he said. "We're talking at most another 20 years."

River News 11/06/03

RRFW Riverwire CONDOR CHICK FLIES!

Grand Canyon National Park

Biologists from Grand Canyon National Park and The Peregrine Fund have confirmed the fledging of the first California Condor nestling in Arizona in perhaps over a century. The flight was observed at 1:30 p.m. on Wednesday, November 5. The chick jumped out looking like it wanted to land but there was nothing there. It ungracefully circled and landed 500 - 600 feet below its cave in a remote canyon. The California Condor was included on the first Federal Endangered Species List in 1967.

"It was spectacular!" announced an excited Sophie Osborn, Field Manager of The Peregrine Fund. "It was not the graceful flight we had envisioned, more like a controlled fall and our hearts were in our throats as it dropped 500 to 600 feet below the nest cave. Minutes after the chick landed it started to explore its environment, tugging on a yucca plant and hopping from boulder to boulder. We waited and hoped so long for this to happen that being part of it was indescribable!" she added.

"Our biggest worry after the chick left the cave was how long it would take for the parents to find it," remarked Chad Olson, Raptor Technician for the National Park Service. "Both parents were away from the area when the chick fledged. To our great relief, female 127 flew to the nest about two hours after the chick fledged, realized the chick was not in the nest cave, immediately found it, and dropped down to feed it. Since fledging is such a dangerous time for the chick it is tremendous to be past this and on to another exciting phase." Olson said.

The chick is healthy and alert to its surroundings. Biologists are planning to attach telemetry equipment and assess overall health issues. The bird will be closely monitored.

"A fledgling condor chick spreads its wings and flies into the wild, and not just the parents share in the pride. The partners who have worked for decades to rescue this species from the brink of extinction see it as a great cause for hope," observed Interior Secretary Gale Norton.

"I have watched adult condors soaring above the spectacular beauty of the Grand Canyon. The birth and flight of this young condor creates optimism that condors will flourish in the Canyon for many generations to come," Norton added.

Biologists first suspected that Condors 123 and 127 were incubating an egg in March 2003. Daily observations were made, with assistance from a group of "Nestwatch" volunteers. The parents became very attentive to the nest in early May. The existence of the chick was confirmed on August 18 after biologists made an arduous 24-mile hike in 100 degree heat down to below the nesting cave. Daily monitoring continued.

"We are very pleased about this new step in the recovery of the California Condor species," stated Joseph Alston, Superintendent of Grand Canyon National Park. "We are proud to be a part of this highly anticipated and monumental event for both the park and the Colorado Plateau. We look forward to working with our partners in order to ensure the well-being of this new arrival to the condor population and to ensure continued success in the program."

Three pairs of California Condors produced eggs in Arizona in 2003 (one in BLM's Vermilion Cliffs National Monument and two in Grand Canyon National Park). Two of the eggs did not hatch, which is not uncommon for California Condors during their early breeding years. In fact, this was the second egg laid by Condor 127 and the third laid by Condor 119. In California this year, one egg was laid and hatched in early May, but, unfortunately, the chick did not survive.

As Roger Taylor, Arizona Strip Field Manager for the Bureau of Land Management (BLM) states, "We have been anxiously awaiting this bird's first flight. With the good condor viewing opportunities that are typically available along the Vermilion Cliffs, perhaps the public will have an opportunity to view the young condor this winter."

"The significance of the first wild-hatched condor in Arizona is tremendous. While captive-bred condors have exceeded our expectations, it is this chick and others like it in the future that ensure condor recovery in Arizona," says Arizona Game and Fish Director Duane Shroufe.

"The partners have watched this chick prepare to fledge with as much anticipation as any natural parent might," said H. Dale Hall, Southwest Regional Director of the U.S. Fish and Wildlife Service. "We all wish the best for this fledgling and look forward to further successes."

The historic Arizona reintroduction is a joint project among the U.S. Fish and Wildlife Service, the National Park Service, The Peregrine Fund, the Arizona Game and Fish Department, the Bureau of Land Management, Southern Utah's Coalition of Resources and Economics, and others. Funding for the project is being provided by The Peregrine Fund, U.S. Fish and Wildlife Service, Arizona Game and Fish Department, Peter Pfendler, National Fish and Wildlife Foundation, Nina Mason Pulliam Charitable Trust, Disney Wildlife Conservation Fund Awards, Steve Martin/Natural Encounters, Grand Canyon National Park Foundation, Bureau of Land Management, Grand Canyon National Park, Kearney Alliance, Grand Canyon Trust, Patagonia, Turner Foundation, Globe Foundation, Earth Friends, Arizona Public Service, Wallace Research Foundation, Mattie Wattis Harris Foundation, Arizona Community Foundation, and Oracle Corporation Grand Canyon Conservation Fund, and others.

Images and other information may be obtained from the following websites:

The Peregrine Fund: www.peregrinefund.org/press/condor_chick_fledges_2003.html

The Grand Canyon National Park Foundation: www.gcnpf.org, Grand Canyon National Park: www.nps.gov/grca

The California Condors are being released as a "non-essential/experimental population" under section 10(j) of the Endangered Species Act. Section 10(j) provides that the species can be released in an area without impacting current or future land use planning. However, in Grand Canyon National Park condors are provided full protection as federally protected threatened species. This authority has been spelled out further in an innovative agreement between the U.S. Fish and Wildlife Service and local

governments. This "Implementation Agreement" spells out a positive working relationship between the Federal government and the various local governments.

Study: Global warming to 'substantially affect' California in 20 years

Associated Press

Sacramento, Calif.

Global warming will substantially affect California in about 20 years, experts say, warning that the state is more vulnerable because of its coastline, its climate and its dependence on Sierra Nevada snowpack for water and hydroelectricity.

"It's going to affect all of us," said Robert Wilkinson of the University of California, Santa Barbara, School of Environmental Science and Management, who wrote a 432-page treatise on the impact on California.

It means a shorter ski season in the Sierra, and poorer habitat for endangered salmon in lower streams. It may mean more wildfires and more floods. Extreme heat waves, easier spread of diseases and increased air pollution all could imperil health.

Oceans that rose 4 inches to 8 inches over the last century could rise up to 3 feet this century, swamping San Francisco Bay estuaries and endangering pumps sending freshwater from the Sacramento-San Joaquin River Delta to the Bay Area, San Joaquin Valley and Southern California.

It will mean more fights over water throughout the West.

"Climate change is upon us. In 20 to 25 years, we really will be working with a different climate," said Michael Dettinger, a U.S. Geological Survey research biologist and researcher with the Climate Research Division at Scripps Institution of Oceanography.

Every scientific model predicts warmer temperatures, with the bulk projecting an increase in the range of 3 degrees to 6 degrees by 2100. But the computer models split on whether California will become wetter or drier.

Either way, warmer temperatures mean a shift in California's water cycle.

The Sierra snowpack that functions as the state's largest reservoir could shrink by a third by 2060 and to half its historic size by 2090. Runoff that fills reservoirs will start in midwinter, not spring. And rain falling on snow will trigger more flooding, scientists said Thursday at a seminar hosted by the Water Education Foundation.

Models projecting a drier California predict a sharp increase in critically dry periods, said Alan Hamlet, a water resources engineer with the University of Washington.

"We're going to have exacerbated conflicts over water, both in California and the Colorado Basin" that also supplies six upstream states, he said. Fortunately for California, it is rare -- but not unheard of -- for the Sierra and the Rockies to have a simultaneous drought, so usually there is substantial water for Southern California from one or the other.

The trends are already in play.

Spring temperatures have increased 2 degrees to 3 degrees since 1950, peak spring snowmelt comes two to three weeks sooner, and vegetation blooms one to three weeks earlier and stays green longer, scientists earlier told a state Assembly committee on water and climate change.

While more dams and reservoirs could capture vital runoff and control flooding, there are substantial questions where or if to build them given the uncertain long-range weather pattern forecasts. Experts predicted the state will have to rely more on conserving and reusing water, desalinization, groundwater storage, and water trades and transfers between regions.

As with the ebb and flow of the Ice Age, warmer temperatures mean grass and oak woodlands and chaparral will grow higher into the mountains over the next 100 years, while conifer forests can grow above the current tree line, said Susan Ustin, an environmental and resource science professor at the University of California, Davis.

But 100 years is a blink in geologic time, and the relatively quick change will disrupt ecosystems that need millennia to adapt, she said. Invasive species that already threaten native plants and animals may be quick to fill that void.

Earlier snowmelt means less spring runoff for salmon, and water could get too warm for them to spawn. Already, runoff into the Sacramento River has dropped 11 percent over the last century.

But warmer weather means longer growing seasons, which could help agriculture -- as long as there's enough water for irrigation, said Rick Snyder, a biometeorologist at UC Davis. While many of California's crops could benefit, its famed wine grapes need a precise combination of temperatures and could suffer, said Snyder and Wilkinson.

The effect could come down to "if you're talking white wine or red wine," said Wilkinson. "Is that a great research project, or what?"

Dry state will fight to restart desalter

Shaun McKinnon

The Arizona Republic
Nov. 7, 2003 12:01 AM

YUMA - Down along the final, gasping miles of the Colorado River, on the edge of a desert too dry to notice the drought, an unusual skirmish has erupted over a plan to squeeze more water from the West's already over-tapped supply.

The battleground is a water desalination plant on this city's west side, a \$280 million white elephant that operated for all of nine months a decade ago, before floods and design flaws forced it into hibernation. The plant was designed to recycle agricultural runoff water that was otherwise too polluted and salty.

Now Arizona wants to restart the desalination plant as a hedge against the drought and has asked the federal government to spend \$30 million to bring it back on line and an additional \$24 million to \$30 million a year to keep it running. Without the plant, Arizona officials say, Phoenix and Tucson could someday face crippling water shortages.

Critics question that claim and say the desalter is a failure best left idle. Even other Colorado River states, sympathetic to Arizona's effort to reclaim the lost water, shy away from the plant's enormous cost and the relatively meager return, about 25 billion gallons of desalted water a year, or roughly 0.6 percent of the Colorado River's total flow. But the fiercest opposition comes from environmentalists, who say that operating the desalter would destroy a thriving Mexican wetland and spoil the first real success story in the struggle to restore the Colorado River Delta. That argument frames a larger one, not about who should use the water or how, but whether it should be used at all.

'Very perplexing'

"There are tough issues," admits Herb Guenther, director of the Arizona Department of Water Resources. "It could be quite a tug of war down there. But if we don't operate the plant, there is a potential for water shortages and Arizona is the one to feel the impact. . . . This is a very perplexing problem."

Perplexing barely begins to describe what's happening here. This is, after all, a story about a desalination plant in the middle of the desert. And it asks a sort of chicken-and-egg question of whether the government should take water from a wetland that was the unintentional creation of that plant in the first place. Racing through it all is a gnarly tangle of issues: the environment, border politics, public money and, gnarliest of all in the West, water and how it should be managed.

"There is a taxpayer issue and an environmental-impact issue," said Lisa Force, Arizona program director for the advocacy group Living Rivers. "But the bigger issue is about the Bureau of Reclamation continuing to operate in an old-fashioned way. Re-operating the desalination plant is more of the same old pork-barrel politics, continuing to throw away taxpayer dollars on unsustainable water projects. "There are so many other options to create new water."

30 years of history

As odd as it sounds here at the end of the mighty Colorado, creating new water - or at least wringing every last drop from the water that already exists - is where this story started three decades ago when Mexico complained that the water flowing out of Arizona was too salty.

Mexico is entitled to 1.5 million acre-feet per year from the Colorado, about 489 billion gallons. Because Mexico is last on the river, it sometimes has had to settle for the dregs, often irrigation runoff from farms around Yuma and across the border in California.

Mexico finally complained that the water it was receiving was too salty, unfit to irrigate crops. Although the Colorado River originates half a continent from an ocean, it's one of the saltiest freshwater rivers in the country. It picks up minerals along its rugged 1,400-mile route, along with runoff from thousands of acres of irrigated farmland. In all, the river carries 9 million tons of salt a year, the equivalent of nearly 250 full railroad cars a day. To reduce the salinity of the river as it crossed the border, the United States decided to build a desalination plant at Yuma. The plant would take heavily polluted water from farms in the Wellton and Mohawk valleys to the northeast - water that had been running back into the Colorado and down to Mexico - treat it and return it to the river, in effect using it twice by recycling it.

"The plant is just a tool for salinity on the Colorado river," said Jim Cherry, who oversees the desalination plant as Yuma-area director for the Bureau of Reclamation. "It's just one of the tools. It won't change the salinity of the river significantly - it's almost like running a hose into the swimming pool - but it's a good amount of water we save (by recycling)."

The bureau fired up the plant in late 1992 at one-third capacity. It operated for about nine months, then shut down after a flood on the Gila River washed out one of the delivery canals. A chain of frustrating design flaws kept the plant inactive and a series of wet years in effect rendered the plant unnecessary. Enough water was flowing down the Colorado to fill Mexico's orders.

That changed this year. The drought sucked up all the surplus water and forced the Bureau of Reclamation to draw about 35 billion gallons of water from Lake Mead.

Although the reservoirs are nowhere near running out of water, many scientists predict that drought conditions will persist for years. Both Utah and Colorado are considering plans to use more of their river allocations. If the river can't deliver enough water, Arizona - specifically the Central Arizona Project, which supplies Phoenix and Tucson - is the first to have its flow halted.

Water shortage risks

"The desalter is important to Arizona because it reduces our long-term risk for shortages," said Tom Carr, who oversees Colorado River issues for the state Water Resources Department. "Reducing the water in storage on the river is a significant

issue." So is time, Carr said. Fixing the remaining design flaws and preparing the desalination plant for full-scale operation would take four to five years. An environmental-impact study could stretch that timetable. Congress will have to appropriate up to \$30 million just to fix the design flaws and prepare the plant to operate.

State officials worry that the price tag could hold up their request. The annual operating budget would likely top \$29 million, about \$311 per acre-foot delivered to Mexico, or about 30 times what Yuma farmers pay. But they say a long-term water shortage in Arizona could run up damages of more than \$300 million in lost crops and money spent to find alternate sources.

Shifting money to the desalter would probably mean taking it from other uses, said Bob Johnson, regional director for the Bureau of Reclamation in Boulder City, Nev. Although the agency is moving ahead with an environmental-impact study and repairs to the desalination plant, officials also are exploring other ideas.

Most often mentioned is leasing water from farmers along the river or paying them to leave croplands unplanted. "My guess is if you packed something correctly, you could probably get some water out of there at a lesser cost and with less of an environmental impact than operating the plant," Johnson said. Other states along the Colorado have expressed limited support for Arizona, but they also suggest there may be better alternatives.

"It's been in storage a long time and the technology has changed tremendously. We need to know if it is cost-effective to upgrade it," said Kay Brothers, deputy general manager of the Southern Nevada Water Authority in Las Vegas.

Arizona officials say the other options are even more expensive. Leasing water or paying farmers to fallow land could cost nearly \$54 million a year, the state estimates. A plan to bank surplus water underground to allow more water to flow down the river could cost nearly \$40 million.

Water leases or purchases are equally troublesome, said Carr of the Water Resources Department. If an irrigation district, for example, agrees to give up some of its water, other users on the river, such as California or the CAP, could claim the water first, leaving the state and the bureau no better off than before.

"Arizona pays the price no matter what," said Larry Dozier, deputy general manager of the Central Arizona Project. "It's pretty apparent if there is land fallowed, it would be in Arizona. And if they use system water, well, we're on the short end of the stick, so if you give up system water, you give up CAP water."

Dozier said if the bureau would upgrade the desalter's technology, it could increase output and feed more water into the system.

Far more troublesome for Arizona and the bureau are the claims raised by environmental groups that the desalter would destroy the Cienaga de Santa Clara, a

wetland about 50 miles south of Yuma in Mexico that supports hundreds of species of birds, fish and other wildlife.

The wetland is, in a way, a byproduct of the desalter. While the plant was under construction, the agricultural runoff it would someday treat was diverted south toward what was then a mostly dry corner of the Colorado River Delta.

Because the plant only operated for nine months, the water continued to flow into Mexico. Over the years, it formed the wetland, in effect restoring a sliver of the delta. It is home to dozens of endangered species.

"The delta is coming back by itself," said Michael Cohen, a senior associate for the Pacific Institute, a water research and advocacy group. "They added water and it came back. Vegetation springs up in response to water. It's pretty clear-cut. There are studies that show when they took the water out in the '90s, it dried up. Here's a benefit that has occurred just because people added water."

Three strikes?

If the government restarts the desalting plant, that water will be taken away again. Using existing technology, the desalter can recover as much as 75 percent of what it treats. The remaining 25 percent would be returned to the diversion canal and sent south to the wetland, but it would be up to six times saltier than before.

"They reduce the amount of water, that's strike one," said Steve Cornelius, a Colorado delta specialist for the Tucson-based Sonoran Institute. "The water that does get there will be higher in salinity. That's strike two. The cattails there are pretty resilient, but they're not going to be able to survive that change."

Arizona officials concede that the wetland could suffer some damage if the desalination plant is restarted and the flow of runoff water is altered. But they say the plant's construction was responsible for the wetland's almost accidental creation, an accident that was never meant to happen.

"The original environmental study acknowledged there would be a temporary wetland down there," said the CAP's Dozier. "It would evolve into something different once the plant was started." The fact that the marsh grew over the years is unfortunate, Dozier said, but doesn't alter the original assessment.

Contentious times

That argument peeves conservation advocates: "They did create the wetland area by mistake, but in order to do that they had to destroy it first," said Force, with Living Rivers. "That was a much more biodiverse area before. It did have wetlands, and it also had riparian corridors, estuaries and much more complex ecosystem that died when they filled the reservoirs."

Instead of trying to drain the river dry with a recycling plant, water managers should confront the issue of whether cities and farms should claim every drop of water in the

river, Cornelius said. "The river itself needs water," he said, enough to restore flow all the way to the Gulf of California. Returning the freshwater mix to the gulf would not only benefit wildlife habitat, but fisheries along the coast that have been devastated by the loss of the delta.

"It was fortuitous that the cienaga became what it was today," he said. "We ought to be looking at this as a positive thing instead of a mistake."

Both the state and the environmental groups are preparing for a contentious study period. Carr plans to meet with a conservation advocates in the coming weeks and pledged to listen to their concerns and their ideas. He'll get an earfu

"When you take on anybody on water in the West, it's tough," Force said. "Everybody's very protective of the old way of doing things. But we have a diverse group this time, taxpayer groups, environmental groups, even farmers who want to lease water. It's going to be a tough battle, but it's going to be worth it."

RRFW Riverwire - WILDERNESS UPDATE AND THANK YOU!

Thanks to all the folks who called into your elected officials about Representative Radanovich's (R-CA) river-less "wilderness" proposal. The wilderness documents, with the Colorado River omitted, were requested from Grand Canyon National Park by the representative's office. RRFW has learned that these documents are being forwarded to his staff, but the representative has not yet submitted a bill based on this material. Your congressional leaders heard you loud and clear, and it helped! It turns out many congressional members do not take kindly to this sort of back door approach to wilderness management, especially at a place like Grand Canyon National Park. Indications are that a member of congress will submit a counter bill with the river included. This will be done in the event a bad river-less wilderness bill is introduced, to stop the bad bill so that the public process is allowed to continue.

The Radanovich spurn-the-river proposal would circumvent the public management plan that has already generated over 50,000 comments. The clear signal from congress is that the on-going Colorado River Management Plan should be allowed to run its course without pressure from the park's own river concessionaires to bypass the public process. "There is no doubt we will need to keep up the pressure with more phone calls in the future" notes Jo Johnson, River Runners for Wilderness co-director. "We are grateful to Grand Canyon lovers who have been responsive to this issue. Circumventing the process allows the nightmare of fixed allocations to continue while trashing park wilderness values."

RRFW will continue to keep you informed of developments as they happen.

Eco Fighting for Rivers: Living Rivers keeps David Brower's legend alive

Paddler Magazine

By Matt Hansen

November/December 2003

It's a warm June morning on the Yampa River and 66-year-old river guide Dee Holladay stands in the shade of Mantle Cove, a magnificent alcove of sandstone in Dinosaur National Monument that harbors ruins from the ancient Fremont civilization. While his guests quietly peruse the alcove, Holladay watches swifts dart back and forth among the high cliffs. The birds are making a ruckus but only a few others notice them. "Look," he says, using his stained coffee mug as a pointer, "they're fighting."

The same could be said about many of Holladay's floatmates this week--although they're not fighting each other, they're fighting for rivers. The nonprofit Living Rivers--an environmental group primarily focused on draining Lake Powell--has gathered river and wilderness advocates to float the canyons of the Yampa and Green with Holladay's Holiday River Expeditions. The trip's purpose is to celebrate the life of David Brower, who first floated through Dinosaur in 1953 as the head of the Sierra Club. Afterward he singlehandedly defeated two dams that had been proposed for the monument. In doing so, he launched the modern conservation era but forsook Glen Canyon, which now sits below the motor-heavy waters of Lake Powell. It was a decision that haunted Brower the rest of his life. A cunning fighter for wilderness, he died in 2000 at the age of 88, but his fight presses on through Living Rivers, which he helped found just before his death.

Those floating with Holladay in June included Roderick Nash, whose 1967 book *Wilderness and the American Mind* has been noted as one of the most definitive pieces ever written on wilderness; Jeffrey Ingram, an activist characterized in Marc Reisner's book *Cadillac Desert* as Brower's "most valuable" asset in successfully fighting off dams proposed for the Grand Canyon in the 1960s; Kim Crumbo, former Grand Canyon river guide and activist with the Arizona Wilderness Coalition; and former river guide John Weisheit, who serves as Living Rivers' conservation director. They're all fighting for more responsible water usage, specifically fewer dams and eliminating motorized vessels on the Colorado in the Grand Canyon. "This is not a happy river," says Ingram of the Colorado. "Outfitters spend hundreds of thousands of dollars to defend themselves against outside interests. Private floaters are angry because of the grievances they go through to get on the river and because they're discriminated against. And people like me have been angry for 30 years because we think it should be wilderness."

Among those present, the 49-year-old Weisheit is these days the one most often tangling with the Bureau of Reclamation and Western politicians. The Los Angeles native first met Brower in the early 1990s, when he told Brower that he hated him for not fighting Glen Canyon Dam. Brower responded by asking for forgiveness, and for help. So that's what Weisheit did. And it's Glen Canyon Dam that he has in the crosshairs, although there are others on his agenda (see sidebar). "We can't manage our rivers this way," he says. "We have sacrificed our natural heritage for short-term gain."

But for these activists, going after Glen Canyon Dam is akin to a mosquito trying to suck a bison dry. The Glen Canyon National Recreation Area and Lake Powell are visited by more than 2 million people annually--making it one of the National Park Service's most popular sites. The Bureau of Reclamation says the reservoir ensures water for millions of Southwest residents. Perhaps more important, however, the Bureau sees Glen Canyon Dam as a symbol of its ability to fundamentally change the desert landscape. Giving up Lake Powell would require the Bureau to turn its back on nearly a century of dogmatic belief that the Colorado River must be harnessed in order to make it valuable. Indeed, this summer Bureau Commissioner John Keys was quoted by The Associated Press as saying the decommissioning of Glen Canyon Dam "is something that's never going to happen. I won't spend a dollar studying it."

Barry Wirth, public affairs officer for the Bureau's Upper Colorado Office in Salt Lake City, says furthermore that if Glen Canyon were drained, there would have to be someplace else for that water to be stored. That reservoir, he says, is simply too important to the well-being of the seven states that depend on the Colorado River. "The current drought has clearly driven home the importance of Glen Canyon Dam," he says, adding that the Bureau's focus is how to balance the needs of agricultural and industrial interests, the public and conservation groups.

Given such statements, Ingram, 66, says being an activist is like "banging your head against a 710-foot concrete wall," which, incidentally, is the height of Glen Canyon Dam. But Weisheit, like Brower before him, doesn't belch anger despite his fanatical belief that Glen Canyon Dam wastes water and is killing the Grand Canyon. He speaks softly and fluidly, smiling often. He sees children as his inspiration, hoping to give them the chance to visit the former Glen Canyon with their own children.

Despite the enormous task, Weisheit believes he will see Glen Canyon drained. "Congress built these dams and said we'd worry about the problems later" he says. "Well, later is now, and the public needs to know there are alternatives." One of Lake Powell's primary problems is the loss of water due to sediment buildup, seepage and evaporation. According to Scott Miller's 2000 report titled "Undamming Glen Canyon," published in the Stanford Environmental Law Journal, some 65 million tons of sediment fills Lake Powell each year, reducing storage capacity. Evaporation accounts for the second highest consumptive use of Lake Powell's waters, behind only irrigation. Bank seepage accounts for 350,000 acre-feet of water being lost each year. The hydropower produced by the dam provides electricity for only 3 percent of the region, according to Miller. And the cold, clear water being sent through the Grand Canyon harms endemic fish that have evolved over millennia in warm, silty water. "These systems are going to

fail before our mortgages are paid," says Weisheit. "And I don't want to pass our poor planning on to future generations. It's unacceptable and it's embarrassing."

Weisheit also points out that this year Lake Powell was only half full due to the drought. He says if the current drought persists, the reservoir will be empty in two years, rendering the dam useless for water storage and power generation. Of removing the dam, he says, "people are beginning to believe that it's not impossible."

On the day that Holladay and his group float into Echo Park, the confluence of the Yampa and Green and approximate site of one of the two proposed dams Brower defeated, he asks everyone to stay silent, allowing their senses to take in the canyon's immensity and the power of two rivers becoming one. Overhead a turkey vulture rides a thermal, floating gently among the 500 foot high canyon walls. Cliff swallows dart back and forth looking for insects. On the bank a lone deer grazes quietly. The sun is warm and the Yampa's muddy waters sparkle beneath an unspeakably blue sky. Other than the sound of the oars plying the river, it is silent. As Roderick Nash floats his dory through these spared canyon walls, he reflects on the significance of Brower's fight. "The only reason why we're not on a lakeshore right now," he says, "is because somebody cared."

Sidebar

Glen Canyon Dam isn't the only bull's-eye being targeted by Living Rivers. The several-hundred-member-strong group promotes large-scale river restoration, habitat preservation and responsible water use. Among the many issues on its agenda, the group has asked the Bureau of Reclamation to decommission Flaming Gorge Dam in northeast Utah. Flowing cold and gin clear from the dam, the Green River here is the best tailwater trout fishery in the country, but Living Rivers contends that the cold water coming from the reservoir is killing the warm-water-loving and endangered humpback chubs as well as the riparian habitat downriver in Dinosaur National Monument. Living Rivers is also trying to preserve a permanent water flow into the Colorado River Delta in Mexico's Gulf of California. In addition, the group opposes the Big Straw, a proposal to siphon water from the Colorado River near the Utah-Colorado border and pump it back to the Front Range of the Rockies to fuel urban growth. "As these depletions continue, we'll find fewer rivers to run because we can't seem to lose our addiction for irresponsible water use," says Living Rivers' John Weisheit.

River News 11/14/03

RRFW Riverwire - Interior Dept. Favors More Canyon Flooding

By Mitch Tobin, ARIZONA DAILY STAR

Despite initial resistance, the Bush administration favors continued experimental floods meant to restore the Grand Canyon's ecology, a senior official said in Tucson on Tuesday.

Assistant secretary of the Interior Bennett Raley, the administration's point man on water issues, spoke to 60 scientists at the start of a three-day meeting on how Glen Canyon Dam affects the Colorado River.

Researchers explained how they're using lasers, underwater cameras, century-old photos and experimental flumes in Minneapolis to learn how sand grains and Volkswagen-sized boulders move through the Canyon's rapids and eddies.

Raley urged the scientists not to politicize their work and to remember that "science is not the only input factor for management of the Colorado River."

"If scientists are sloppy and mix advocacy with science, you will end up with the same public perception of integrity that lawyers have," said Raley, a lawyer by training.

Glen Canyon Dam, completed in 1963, dramatically altered the Colorado's flow. Before the dam, the warm, muddy river roared with spring snowmelt. Sediment was lifted onto beaches and sand bars, creating wildlife habitat and backwaters vital to native fish, such as the endangered humpback chub. The beaches are still important campsites for boaters.

After the river was plugged to stabilize the Southwest's water supply, it ran colder and clearer below the dam, which trapped 90 percent of the silt. But dam releases - which often fluctuate with the Sunbelt's electricity demands - have also caused the Colorado's baseline flow to double downstream. As a result, much of the silt and gravel deposited by the Grand Canyon's 740 tributaries gets whisked into Lake Mead downstream.

"It wasn't that we just lost the spring floods, which redeposited sand," U.S. Geological Survey researcher Ted Melis said, "we lost the low-flows the rest of the time, which were low enough to retain those inputs for use during the high-flows. We're getting hit on both ends."

The result is an ecosystem transformed by a dam that helps supply water and power to 25 million people. Tucson is becoming increasingly dependent on the Colorado, whose water comes here via the Central Arizona Project's 336-mile canal.

After passage of the 1992 Grand Canyon Protection Act, the Clinton administration tried to replicate the river's natural flows. With much fanfare, Interior Secretary Bruce Babbitt opened the dam's floodgates in 1996; another flooding experiment was tried in 2000. Despite initial claims of success, scientists now say the results were minimal. A lack of sediment in the river made it tough for sandy areas to expand, and many gains were quickly washed away.

Scientists want to create more floods and time them when the Paria River is dumping sediment into the Colorado. But the drought has caused that tributary, 15 miles below the dam, to deposit less silt in the past three years than any time in recorded history.

Raley said at first he was "deeply, deeply skeptical about the experimental flow program." But, after talks with scientists on a river trip, Raley accepted it was "good science and it was worth taking the political risks to move forward."

"We know when we're being gamed. Had we sensed that, we probably would have slow-walked, ducked, evaded and done everything not to move forward," he said.

John Weisheit, an environmentalist with the group Living Rivers who would like to see Glen Canyon Dam removed, was encouraged by Raley's words. But he said the Interior Department still isn't spending enough money to restore the Grand Canyon.

In the past 30 years, researchers have flip-flopped on whether the Canyon was losing or gaining sediment, said Jack Schmidt of Utah State University. Some thought the lack of floods created a surplus of silt and there was enough sand in the river to form new beaches.

"What we've learned in the Grand Canyon is, the system may be in sediment deficit all the way to Lake Mead," he said.

RRFW Riverwire - Free Grand Canyon Slideshow Comes To Durango

Author Tom Martin will be in Durango at the Abbey Theater at 6:30 p.m., Nov. 30, to update local boaters on the controversial Colorado River Management Plan (CRMP) now in progress for Grand Canyon National Park, and how this plan will affect the boating public. Tom will illustrate his talk with a slide show on the Grand Canyon based on his book, *Day Hikes From The River: A Guide to 100 Hikes from Camps on the Colorado River in Grand Canyon National Park*.

The highly controversial CRMP, which was stopped by the Park in 2000, was restarted as part of a settlement agreement in a lawsuit filed by river running groups and individuals. The public comment period during the past summer gathered over 50,000 comments. "The wait for do-it-yourself river runners is so long, those at the bottom of the list will wait an incredible 20 years to get permission to run the river" said Martin, who notes that "you can book a commercial trip tomorrow for next summer, if you can afford it. This process is of vital interest to all Colorado boaters, as more Coloradoans are waiting for a permit to boat the Colorado River in Grand Canyon than river runners from any other state."

The free slide show will be open to the public and features beautiful vistas illustrating Grand Canyon hikes you can do from the river and exciting river running shots. Tom will

be signing books, the sale of which will benefit River Runners for Wilderness, a non-profit group which is sponsoring the event. RRFW represents the interests of the boating public. Taxpayers for the Animas River and the Weminuche Group of the Sierra Club are co-sponsoring the event locally.

Following the slide show, there will be an 8:30 p.m. screening of the movie, "The Same River Twice." This award winning independent film is about a group of friends who re-ran Grand Canyon 25 years after their first trip. There will be an admission charge for the movie.

Feds gear up for new round of test flows to aid Grand Canyon

April Reese, Land Letter Southwest correspondent

GRAND CANYON NATIONAL PARK, Ariz. -- Seven years after releasing a torrent of water from behind Glen Canyon Dam to provide a much-needed ecological boost to the Grand Canyon, federal water managers are preparing to try it again. But while the dam's gatekeepers hope this experimental flood will bring back some of the river's wild characteristics, some scientists and river advocates say those good intentions may not be enough.

The Colorado River once raged and whimpered through the Grand Canyon in accordance with the seasons, swelling during the monsoons and laying low during dry periods. Those changeable flows alternately carried huge amounts of sediment into the canyon and deposited it in the river channel and on the banks, creating sandbars and beaches. The muddy river also provided prime habitat for several species of native fish (Land Letter, Oct. 30).

Glen Canyon Dam, completed in 1963, drastically altered the historic flow regime and reduced the amount of water -- and sediment -- transported downstream. According to federal estimates, about 90 percent of the sand and silt carried by the upper Colorado River now settles in Lake Powell, the reservoir created by the dam.

The result has been a sediment-starved canyon with fewer and smaller sandbars and beaches, less backwater habitat for native fish and a clearer river that is alien to native fish accustomed to murky water.

Now, the Bureau of Reclamation is poised to open the floodgates in an attempt to deliver some of the sediment that is so crucial to the ecosystem -- and to boaters who camp on the canyon's beaches.

BuRec spokesman Barry Wirth said the agency, which operates the dam, plans to release water from the dam at a rate of about 45,000 cubic feet per second for two days. The volume of water will be about the same as it was in the 1996 flood, but the tap will be shut off six days earlier this time. Scientists and managers monitoring the earlier flood found that continuing the high flows after two days brought no additional benefit, said Bob Hart, a hydrologist with the U.S. Geological Survey in Flagstaff, Ariz.

"Within the first couple of days, the goal was reached," Hart said.

Building the beaches

But the biggest change this time around will be in the timing, Wirth said. The surge of water will be released after the Paria River, a tributary of the Colorado just downstream of the dam and above the park, is running high and thick with sediment. The hope is that timing the rush of water from the dam to coincide with high sediment loads in the Paria will bring more sand and silt into the canyon, where it will build sandbars and beaches and muddy up the river for the endangered humpback chub.

With the dam trapping most of the Colorado's sediment, the Paria River is crucial for delivering what little sediment the canyon receives, said Utah State University professor Jack Schmidt. "The Paria River is the only major source of sediment for the first 60 miles of the Grand Canyon," Schmidt said. "So it's the only significant natural source that the canyon has. It's everything."

A USGS study found that an August 1992 flood of the Paria River delivered 544,000 tons of sediment -- primarily sand -- into the Colorado in less than 24 hours. Typically, flows of that size occur on the Paria about every two years, according to USGS. In all, the Paria dumps about 1 million tons of sediment downstream during the monsoon season in late summer and early fall.

But this year is not a typical precipitation year. BuRec, the National Park Service and USGS have signed off on the necessary environmental studies for the project, and it has the blessing of the Bush administration. The only thing missing is rain.

"We're just not getting the floods during the monsoon season that we need," Wirth said. "The big key is having enough sediment flowing out of the Paria River to justify having the experiment." Without a roiling Paria, there cannot be experimental flows, he said.

A sense of urgency

Nikolai Ramsey of the Grand Canyon Trust said he is supportive of the test flows, but cautioned the canyon may not be able to wait for the drought to recede. "If the weather helps us, we're in good shape for an experiment. If it doesn't, we're still stuck with a sediment-starved system," Ramsey said.

A more timely idea, Ramsey said, is to move the sediment that is building up behind the dam -- at a rate of 6 centimeters annually, by some estimates -- downstream. While that solution may come with its own set of issues--including the potential for carrying heavy metals into the canyon and a price tag of up to \$500 million--it would guarantee a

dependable supply of sediment to the canyon, he said. That, in turn, would head off difficult questions about whether to decommission the dam, Ramsey added.

"The ecosystem in the Grand Canyon would recover, and power and water supplies would be secure," Ramsey said.

Wirth said that option is not on the table. "It's never been studied from a scientific viewpoint," he said. "Maybe some day. Right now we're focused on that which is probably more realistic."

The experimental flows come at a crucial time because there simply is not much sediment left to manipulate, Schmidt said. "We're losing the beaches in the Grand Canyon and continue to do so. Either this will work, or we'll know it's impossible."

If it does not work, federal managers could be left with some tough choices, he added. "Basically, we'll either have to come up with a radical new solution, or announce to the public that we've raised the bar too high--that the price paid for the construction and operation of Glen Canyon Dam is the progressive deterioration of the ecosystem of Grand Canyon National Park," Schmidt said.

John Weisheit, conservation director for the advocacy group Living Rivers, supports decommissioning the dam as the only long-term solution. "These experiments are going to show that the dam does need to come down because the sediment the canyon needs is above Glen Canyon Dam," Weisheit said.

"They're going to have a sediment deficit as long as the dam is there."

But decommissioning is highly controversial and would involve major changes in how water tagged for downstream states is stored and distributed. Lake Powell is one of several reservoirs in the Colorado River Storage Project, which provides water for Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming. About 85 percent of the water is used for irrigation; the rest is allocated for residential, commercial and industrial use. Removing the dam would also eliminate a power source for Southwest cities, critics add.

For now, federal water managers are waiting to open the floodgates and see what happens when the sediment-rich water pulses through the Grand Canyon.

"We're ready to do it," Wirth said. "I think we're going to show, over time, some positive results."

RRFW Riverwire - THE NEXT GENERATION GRAND CANYON RIVER GUIDEBOOK

River Runners For Wilderness is pleased to announce the imminent release of a "next generation" Grand Canyon guidebook written by boaters for boaters! Preview copies

have gotten rave reviews for the wealth of information presented in a easy-to-use format. It's been called the definitive Grand Canyon river guide.

Tom Martin, author of Day Hikes from the River, & Duwain Whitis, publisher of RiverMaps map books, have teamed up to write a new guidebook titled Guide To The Colorado River In The Grand Canyon - Lees Ferry to South Cove. This is the only guidebook to the canyon with USGS topographic map backgrounds, printed at their original scale, with additional map detail added in an easy-to-read format. In addition, it is the only guide with maps extending to South Cove in Lake Mead. Each map shows campsite locations, rapids, scout points, river miles and other points of interest. The accompanying mile-by-mile text describes all campsites on the park inventory (and some not on the inventory), with campsite pull-in information, geological, botanical and historical points of interest. All of the significant hikes, rapids and scouting points are also described, with color photographs on almost every text page. The Guide is 8.5" X 14" spiral-bound to lay flat. The 108 pages are printed on tough water proof and tear resistant synthetic paper. Published by Vishnu Temple Press.

RRFW is pleased to be able to take advance orders for titled Guide To The Colorado River In The Grand Canyon - Lees Ferry to South Cove. The cost of this river guide is \$29.00 (\$25.00 each, plus \$4.00 shipping and handling per Guide), with a tentative shipping date of February 27, 2003. Checks or money orders only please. Advance guidebook sales will benefit River Runners For Wilderness, a not-for-profit organization seeking equitable access to a wilderness river running experience in Grand Canyon. Please send your order to:

River Runners For Wilderness PO Box 17301 Boulder, CO, 80308-0301

If you'd like to place an order for that special Christmas someone, just let us know with your order and we'll send an announcement card before Christmas, letting them know they will be receiving a gift from you soon.

For additional guidebook information and dealer inquiries, contact: Vishnu Temple Press, PO Box 30821, Flagstaff, AZ 86003-0821 Info@vishnutemplepress.com

WAPA Blues: Hydro Not Missed

The ongoing drought is seriously effecting hydroelectric power production on the Colorado River. Colorado River Storage Project (CRSP) dams are experiencing an overall reduction of 25% from normal. The Western Area Power Administration (WAPA),

the agency which distributes federal hydropower, must now purchase electricity from private sources to meet their long-term obligations to their customers.

The Bureau of Reclamation has emphatically stated that the region could not survive without power from Glen Canyon Dam. The drought has demonstrated this to be untrue, with surplus power from non-federal projects easily making up the shortfall. Should the pattern of drought continue for another two years, Lake Powell reservoir will lower to the point where Glen Canyon Dam's powerplant will become inoperational.

This situation will effect US taxpayers. Congress mandated that hydropower revenues must repay the loans used to build CRSP projects. Lower reservoir levels mean less power and less revenue to meet these loan obligations. Additionally, power purchased by WAPA to replace the difference comes at premium price, further effecting loan payments which are scheduled for full payment in about fifty years.

According to WAPA spokesperson LaVerne Kriss, this is not yet a problem. "When we have cash flow problems, we use a pool called the Colorado River Basin Fund to float us through times of shortage, and we make up the difference when the reservoirs recharge and surplus water becomes available again."

"Not true," says Living Rivers' conservation director John Weisheit. "That fund has been near zero for some time, and with persistent drought it's not going to be replenished anytime soon."

This will also cause further strains for WAPA-supported recovery programs, which are designed to mitigate the negative impacts from CRSP operations on the critical habitat of endangered species. The failure of these recovery programs will only drive the budget up further and will undermine WAPA's payback schedule over time. "WAPA will never break even. In fifty more years they will be forced to mitigate other impacts such as sediment removal from the reservoirs. When this occurs the taxpayers will have to contribute to unprecedented subsidies to keep these projects operational," concludes Weisheit.

Science Performs: Management Ignores

Scientists meeting in Tucson this past October were criticized by the Department of the Interior for expressing little confidence in federal efforts to mitigate the downstream impacts of Glen Canyon Dam operations on the Colorado River ecosystem in Grand Canyon National Park.

“Advocacy positions belong to lawyers,” said assistant Secretary of the Interior, Bennett Raley, to the assembled scientists, many who have expressed frustration that their research is being ignored.

Dr. Jack Schmidt, a geologist who’s worked in Grand Canyon for 15 years, stressed that scientists have done their jobs well in reporting accurately to Interior’s Adaptive Management Working Group (AMWG) and then asked, “When is AMWG going to act upon this knowledge?”

Raley stated that Interior could “drag it’s feet” if it did not like what was being recommended. Raley, a water attorney by profession, who has asked Congress to repeal the Endangered Species Act, openly advocated to the scientists the concerns of water and power suppliers, and that these interests maintain superior political and legal positions as compared to environmental interests. He argued that the Grand Canyon Protection Act should be subservient to prior Colorado River laws, and river management policy should therefore follow such a doctrine. Nonetheless, scientists should “continue to support” the adaptive management process.

Dr. Richard Valdez, a senior researcher of endangered fish, gave strong recommendations to AMWG concerning the endangered Humpback Chub by saying, “If you are not going to address the threats to their critical habitat, then you will continue to have endangered species in Grand Canyon.” Humpback Chub populations have declined 75% to just 2,000 adult fish over the past eight years.

Although this gathering was organized specifically for AMWG, very few of its members actually attended. The program is presently facing increased criticism as it was established to recover endangered species in Grand Canyon, but native species diversity has actually declined under their management.

Hydrologist William Vernieu reported on the impacts of drought on Lake Powell reservoir and the downstream implications for Grand Canyon’s water chemistry, which has so far been ignored by AMWG. The reservoir is currently experiencing a decrease in available oxygen along with increases in phosphorus, nitrates and salt. Such changes in water quality will exacerbate the decline in the river’s native food base for endangered fish.

The meeting illustrated that the political situation regarding Grand Canyon's management is deteriorating as rapidly as its ecology. Several scientists admitted privately that absent some form of litigation, there will be little chance of recovering the natural and cultural heritage of Grand Canyon before these resources are lost forever as a result of operations at Glen Canyon Dam.

Living Rivers Currents 12/01/03

Grand Canyon Management: Stepping Backwards

In 1986 the Department of the Interior requested that the National Academy of Sciences review their science program for the Glen Canyon [Dam] Environmental Studies (GCES). While many of the Academy's recommendations were applied by science managers in the Grand Canyon, and continued by subsequent program managers, politics and budget considerations are once again compromising the integrity of science. The National Research Council of the Academy encouraged the GCES to "solicit scientific talent for the work based on a research plan [through a peer-reviewed request for proposals]," and to "use merit competition to select researchers, including a peer-review system outside the agency or agencies conducting the study."

David Wegner, former director of science for the Bureau of Reclamation, informed Living Rivers that, "The advice the Academy gave GCES was very helpful to the science community. We are very proud of the programs that later developed, which continued on through the EIS process of the early 1990s." Even after the Environmental Impact Statement this attitude prevailed during the research and monitoring phase under the auspices of the Grand Canyon Research and Monitoring Center (GCMRC), which is administered by the US Geological Survey in Flagstaff, Arizona.

Living Rivers has recently cautioned members of the Adaptive Management Program (AMP) that research programs are reverting back to old ways. This turn of events is gaining the attention of scientists who are fearful that heavy administrative costs will hinder their results. Additionally, a lack of competitive bidding and sufficient peer review will also detract from the quality and quantity of the monitoring undertaken.

For example, GCMRC recently decided to use in-house staff to undertake mechanical removal of trout in Grand Canyon. Bruce Taubert of Arizona Game and Fish Department (AGFD) pointed out to AMP members that "GCMRC may do this at a cost of \$500,000, while AGFD could hire a consultant to do the same work for \$365,000. There would be a savings of \$135,000 that would return money back to the science programs in Grand Canyon."

Living Rivers Currents 12/01/03

Drought Forecast: Situation Unchanged

A barrage of reports and media advisories continue to come forth from scientists about the persistent drought in the Colorado River basin. The public has been reminded that the region experienced droughts of similar intensity before, notably 1901-1904 and 1953-1956. However, the year of 2002 was singled out as the driest year ever in recent history.

While common forecasting techniques allow for predictions of 3 to 6 months, scientists are beginning to observe two patterns of sea surface temperatures that provide a degree of confidence in predicting long-term droughts, notably the warming of the North Atlantic ocean with the cooling of the tropical Pacific ocean.

By obtaining tree ring data, scientists have reconstructed the climate of past centuries with tested credibility. The analyses of both instrumental and tree ring precipitation records should allow scientists to project drought conditions beyond a mere seasonal forecast. By comparing the data sets, the analyses demonstrate that a drought can persist for one or two decades and, in a few cases, even longer. Additionally, the data can be linked with the aforementioned ocean temperatures and thus provide the indicators necessary to forecast a persistent drought.

In 1998 observers were prompted to anticipate the current drought situation and the conditions remain unchanged and will likely persist into the coming decade. "In the context of shifting ocean climate, the current drought should give water and other resource managers in the Rockies and Southwest little cause for optimism about the drought ending any time soon," said Julio Betancourt of the US Geological Survey.

In a recent report Betancourt and others stated the implications, "It is always prudent to be conservative about water and other resources vulnerable to drought; it is particularly prudent now. ...Societal demands on surface water are on the increase. ...Clearly, the context for long-term drought is different now than it has been in the past."

Colorado Riverkeeper: All Hands on Grand Canyon

In October, Living Rivers' Colorado Riverkeeper undertook a 12-day science trip through Grand Canyon National Park. Our assignment was to aid in documenting the status of the river's food supply for endangered native fish. Ten volunteers witnessed first hand how the river ecosystem is affected due to climate change.

"Because Lake Powell's reservoir capacity has been reduced by 52%, the chemical and temperature output from the dam is further altering the food web in ways that we have never observed before," said the Colorado Riverkeeper, John Weisheit. Given this recent turn of events in Grand Canyon, Living Rivers and the Colorado Riverkeeper are now devoting the majority of their resources toward mobilizing national support to save what's left of the canyon's native ecosystem. "If the public can't support protection of this world heritage site, there's probably little hope for the rest of the river," concludes Weisheit.

The first obvious observation was a warmer than usual Colorado River. The volunteers knew from experience that the discharge from Glen Canyon Dam normally originates from the chilly depths of the reservoir. While sampling, the volunteers were amazed with the abundant zooplankton found. This indicates that the water used to generate power is coming from the warmer water zone near the reservoir surface, an area containing many exotic life forms, including pathogens and parasites. "It's only a matter of time before these exotic species from Lake Powell become competitors for the available food that endangered native fish must have to survive. This new condition will become a serious issue for the stakeholders of Grand Canyon," said volunteer David Haskell, retired science director of Grand Canyon National Park.

Tatiana Lawson, a river guide from Moab, was intrigued with the organisms now existing in the river. "A flatworm is something I expect to see in my biology class at school," said Lawson, "not in the Colorado River system. But these newly introduced New Zealand Mud Snails are especially worrisome for me. Tiny as they are, by the millions they are effectively over-grazing the river bottom and depleting the food supply."

Joe Shannon, a Northern Arizona University aquatic ecologist who has studied the river's food base for 14 years, supervised the volunteers and staff. "The ecosystem here has changed since I first arrived," remarked Shannon. "This river was loaded with algae called Cladophora and an invertebrate called Gammarus. Now there is another suite of algal types and Gammarus numbers have declined. The flows from Glen Canyon Dam are not managed consistently and consequently the food web is in constant flux." Shannon laments how managers continue to be unresponsive to the sound

recommendations of his fellow scientists who support flows that mimic the natural flows of the Colorado River. "They continue to manage the dam for hydropower revenues first, with the management mandates of our National Park coming last," adds Shannon.

"It's unbelievable how bad things are down here in the Grand Canyon," remarked Michelle Harrington, coordinator for the Center for Biological Diversity. "The river ecosystem here has completely changed from its unique and natural condition because of Glen Canyon Dam. If the public was fully aware of this condition, I think they would respond in the same way as they have for protecting the Arctic National Wildlife Refuge, and would demand river management alternatives that include the decommissioning of Glen Canyon Dam."

Living Rivers Currents 12/01/03

Access Denied: No Release of Inundation Maps

The public has no right to know who might be in the flood path should Glen Canyon or Hoover Dam fail. Using national security risks as their trump card, the Bureau of Reclamation was able to convince Judge Tena Campbell to deny Living Rivers' appeal for their inundation maps, effectively ending the 18 month effort to obtain this information.

If Glen Canyon Dam fails an estimated 500-foot wall of water would race through the narrow parts of the Grand Canyon toward Hoover Dam. Even if Hoover Dam withstood the initial impact of the flood, a waterfall over the top would last 11 days and would destroy the water delivery infrastructure and communities downstream.

"The funny thing about all this, is that some of this information is already in circulation, we had just hoped to obtain it through official channels," says Living Rivers' executive director, Owen Lammers.

Until the trial the Bureau's arguments for withholding the information had nothing to do with national security. They now claim this information is exempt from disclosure based on things like arrest procedures, or the design of the President's limousine; something that aids criminals in completing a crime. This is certainly not the case with inundation maps.

Since the 9/11 political scene, the government is using national security as a means to keep information from environmental groups. Living Rivers has been told that this case is being used to equip federal attorneys in fighting Freedom of Information requests. In

this political climate Living Rivers does not feel it likely that an appeal would overturn the verdict and is not pursuing the matter further.

'Securing' the Public With Secrets

The News Media and the Law

Published by the Reporters Committee for Freedom of the Press

By Rebecca Daugherty

Judicial deference to the government's widespread claims of national security is keeping unclassified records from public view

Wanting to know what would happen if the Glen Canyon Dam in Arizona burst, a small environmental group filed a freedom of Information Act request in September 2001 for the federal government's projections as to where the renegade waters would go. If the dam should falter, its downstream flow would not only jeopardize the nearby Hoover Dam but waterworks beyond, flooding or destroying communities along the way.

But the Bureau of Reclamation, which creates the "inundation maps" projecting what might happen, denied the request. And in March, the federal district court in Salt Lake City upheld the denial.

Judge Tena Campbell ruled that the government could withhold the unclassified maps under an exemption to the FOI Act for "law enforcement" records because terrorists might make use of the information. One arm of the law enforcement exemption protects against release of information that might help anyone circumvent the law, which Campbell said applied here.

That decision is one of three since the events of Sept. 11, 2001, that defer to the government's pleadings that "national security" interests excuse agencies from giving out records--even when they cannot use the exemption to the FOI Act that is specifically designed to protect national security, or the other far-reaching protection for national security information, a law that protects intelligence sources and methods.

The first FOI Act exemption only covers records that are properly classified in the interest of national security or foreign policy. To classify records, the exemption requires agencies to follow a set of formal procedures laid out in an executive order.

Yet in these three cases the government has used a "national security" excuse to invoke the law enforcement exemption to the FOI Act, denying information that would have likely been released if the government had not played the "terrorist" card to justify use of the exemptions.

Together they demonstrate the breadth of denials in which national security trumps government transparency due to the tenor of the times. With no end in sight to the war on terrorism, the judiciary's deference to administrative secrecy could conceivably trouble FOI requesters for some time to come.

Photo caption: Unclassified information about what would happen if the Glen Canyon Dam in Arizona burst can be withheld from the public based on the government's claims of national security interests, a federal court in Salt Lake City ruled in March.

Examining the U.S. Customs Service

In 1998, Coastal Delivery Corp. successfully sued a warehouse for breaking a contract that made the trucking company the exclusive carrier of its cargo which had to be delivered to a U.S. Customs Service examination station at the Los Angeles/Long Beach port. But in order to recover damages, Coastal Delivery needed to know how often the agency's contraband enforcement team examined containers.

The company asked for the records in October 2001 for use in its complaint, but never got them. Coastal Delivery brought suit against the Customs Service, and again walked away empty-handed.

Coastal Delivery could not have the information, U.S. District Court Judge Matthew Byrne in Los Angeles wrote in March, because "terrorists and others could use the information to discover the rate of inspection and then direct their containers to vulnerable ports." Knowing where the government is lax in its examinations, Byrne reasoned, might tell terrorists how vulnerable some seaports are.

The parties in Coastal Delivery Corp. v. U.S. Customs Service agreed that the purpose of the request made no difference in determining whether information would be available. A reporter hoping to evaluate how thoroughly the Customs Service checked containers would also not be able to see the records under this decision, which was not appealed.

Secretly Detained

Twenty-one public interest and human rights groups have petitioned the U.S. Supreme Court to hear arguments that the government should be required to release the names of hundreds of detainees jailed after Sept. 11, 2001.

The Center for National Security Studies, an advocacy and research group in Washington, D.C., has taken the legal lead on behalf of the organizations, including The Reporters Committee for Freedom of the Press, that are suing the government for the records.

In its request for review, the groups wrote the purpose was "to make clear that a national security crisis is no justification for courts allowing the Government to evade so easily its responsibilities under FOIA--and that courts cannot ignore the vital countervailing interests at stake such as the individual rights petitioners here seek to enforce."

For the divided appeals panel in *Center for National Security Studies v. Department of Justice*, decided in June 2003, Judge David Sentelle wrote that the judiciary would defer to the government's expertise in a "national security" probe. The Justice Department is in a better position than the court to know what should be withheld in a terrorism investigation, the judge wrote, in reversing a lower court. His opinion triggered a lengthy and pointed dissent by judge David Tatel.

The majority's approach "drastically diminishes, if not eliminates" the judiciary's role in FOI cases involving national security, Tatel said.

Fighting an Upstream Battle

"If we had gone forward on this prior to 9/11 it would have been a slam dunk," said Owen Lammers, executive director of the environmental group Living Rivers in Utah and Arizona.

What public interest groups throughout the nation are quickly learning, however, is that policies resulting from the never-ending war on terrorism have done significant damage to the idea of public accountability.

Lammers says his organization wanted copies of the Bureau of Reclamation's inundation maps because it hoped to show the value of decommissioning certain dams in Arizona. The structures are inherently unsafe, he said, and they are far more expensive to maintain than to decommission.

To highlight his point, Lammers says the Glen Canyon dam nearly failed in 1983, as rainfall almost caused the reservoirs to top off and spillways were damaged. Because there are a number of dams along the Colorado River, catastrophic failure of one can affect others. Water from a breached Glen Canyon Dam could flow downstream, flood Lake Mead and possibly breach the Hoover Dam, which holds back the lake.

"It would be quite a scene," Lammers said.

But the government had little interest in allowing Living Rivers to make the projections public. In *Living Rivers v. the Bureau of Reclamation*, the court deferred to the government's claim of national security interests in not releasing the unclassified material. Living Rivers did not appeal, but that does not mean the organization agreed with the rationale.

Photo caption: Environmental groups say the Glen Canyon Dam should be decommissioned, but it's difficult to make a compelling case when public records about the dam are withheld.

Lammers says if terrorists succeeded in breaching a dam of the magnitude of Glen Canyon or Hoover, the inundation maps would have made little difference. The maps, Lammers says, do not show how to carry out an attack on the dam.

"We are trying to point out that a couple of these facilities could fail on their own," he said. "Most states require that inundation maps be public. But the federal government says that it doesn't have to give these out."

Furthermore, says Living Rivers attorney Joro Walker, if people knew the risks, they could better equip themselves against future danger. Instead, notes Walker, the government is saying, "You don't have to worry about it, we have a plan."

Sidebar: Petitioning for Supreme Court Review

The petition to the U.S. Supreme Court by the Center for National Security Studies and others asks the high court not only to find that the government has misused the exemptions to the FOI Act to deny information about the hundreds of people detained since Sept. 11, 2001, but that the First Amendment requires the government to make the information available.

The First Amendment prohibits secret arrests and detentions except in the most compelling circumstances, the groups wrote. In *Richmond Newspapers, Inc. v. Virginia*, the high court first examined what was to become a test for a First Amendment right of access: If the information was traditionally open, and openness served a purpose in democracy, then the First Amendment requires public access to the information.

That test should apply here, the petition says. Public scrutiny is vital, as it is the public's only restraint on the government's awesome power to arrest and detain people in these situations.

Sidebar photo caption: Kate Martin, director of the Center for National Security Studies, argued the FOI Act case before the appeals panel.

The Center for National Security Studies, an advocacy and research group in Washington, D.C., has taken the legal lead on behalf of the organizations, including The Reporters Committee for Freedom of the Press, that are suing the government for the records.

In its request for review, the groups wrote the purpose was "to make clear that a national security crisis is no justification for courts allowing the Government to evade so easily its responsibilities under FOIA--and that courts cannot ignore the vital countervailing interests at stake such as the individual rights petitioners here seek to enforce."

For the divided appeals panel in *Center for National Security Studies v. Department of Justice*, decided in June 2003, Judge David Sentelle wrote that the judiciary would defer to the government's expertise in a "national security" probe. The Justice Department is in a better position than the court to know what should be withheld in a terrorism investigation, the judge wrote, in reversing a lower court. His opinion triggered a lengthy and pointed dissent by judge David Tatel.

The majority's approach "drastically diminishes, if not eliminates" the judiciary's role in FOI cases involving national security, Tatel said.

Fighting an Upstream Battle

"If we had gone forward on this prior to 9/11 it would have been a slam dunk," said Owen Lammers, executive director of the environmental group Living Rivers in Utah and Arizona.

What public interest groups throughout the nation are quickly learning, however, is that policies resulting from the never-ending war on terrorism have done significant damage to the idea of public accountability.

Lammers says his organization wanted copies of the Bureau of Reclamation's inundation maps because it hoped to show the value of decommissioning certain dams in Arizona. The structures are inherently unsafe, he said, and they are far more expensive to maintain than to decommission.

To highlight his point, Lammers says the Glen Canyon dam nearly failed in 1983, as rainfall almost caused the reservoirs to top off and spillways were damaged. Because there are a number of dams along the Colorado River, catastrophic failure of one can affect others. Water from a breached Glen Canyon Dam could flow downstream, flood Lake Mead and possibly breach the Hoover Dam, which holds back the lake.

"It would be quite a scene," Lammers said.

But the government had little interest in allowing Living Rivers to make the projections public. In *Living Rivers v. the Bureau of Reclamation*, the court deferred to the government's claim of national security interests in not releasing the unclassified material. Living Rivers did not appeal, but that does not mean the organization agreed with the rationale.

Photo caption: Environmental groups say the Glen Canyon Dam should be decommissioned, but it's difficult to make a compelling case when public records about the dam are withheld.

Lammers says if terrorists succeeded in breaching a dam of the magnitude of Glen Canyon or Hoover, the inundation maps would have made little difference. The maps, Lammers says, do not show how to carry out an attack on the dam.

"We are trying to point out that a couple of these facilities could fail on their own," he said. "Most states require that inundation maps be public. But the federal government says that it doesn't have to give these out."

Furthermore, says Living Rivers attorney Joro Walker, if people knew the risks, they could better equip themselves against future danger. Instead, notes Walker, the government is saying, "You don't have to worry about it, we have a plan."

Sidebar: Petitioning for Supreme Court Review

The petition to the U.S. Supreme Court by the Center for National Security Studies and others asks the high court not only to find that the government has misused the exemptions to the FOI Act to deny information about the hundreds of people detained

since Sept. 11, 2001, but that the First Amendment requires the government to make the information available.

The First Amendment prohibits secret arrests and detentions except in the most compelling circumstances, the groups wrote. In *Richmond Newspapers, Inc. v. Virginia*, the high court first examined what was to become a test for a First Amendment right of access: If the information was traditionally open, and openness served a purpose in democracy, then the First Amendment requires public access to the information.

That test should apply here, the petition says. Public scrutiny is vital, as it is the public's only restraint on the government's awesome power to arrest and detain people in these situations.

Sidebar photo caption: Kate Martin, director of the Center for National Security Studies, argued the FOI Act case before the appeals panel.

RRFW Riverwire - HOW DID WE GET IN THIS MESS?

River Runners For Wilderness is pleased to announce the imminent release of *Hijacking A River, The Political History of the Colorado River in the Grand Canyon*, by Jeff Ingram. *Hijacking A River* tells the whole story of "How did we get in this mess?": A pummeled government agency, intransigent businessmen and their political allies, apathetic environmentalists, and disorganized river runners; these are the characters who have made a mess of Colorado River management in Grand Canyon National Park. From the first steps to usher in a wilderness river to the Goldwater-Garn-Hatch Rider of 1980, Ingram unfolds the activities of such players as Fred Burke, Steve Carothers, Kim Crumbo, Fred Eiseman, Marvin Jensen, John McComb, Joe Munroe, Bo Shelby, Gaylord Staveley, Sam Steiger, Merle Stitt, Morris Udall, and many others. Surprisingly, a number of the players in the 1970s are still active in today's Colorado River Management Plan revision.

The book follows the changes in Grand Canyon river running from the 1960s onward, while answering all those persistent questions river runners have been asking for over a decade. With humor and wit, Jeff Ingram answers questions like "Why is it the public now waits 13 years for a self-guided permit to raft the Colorado River in Grand Canyon?" The book also clearly spells out why there is no congressional Wilderness designation for Grand Canyon National Park to this day. Step by step, year by year,

Ingram tells the "how and why" behind Grand Canyon river concessionaire's seeming lock on river travel in the Canyon.

Colorado River crusader and historian Jeff Ingram has, since 1964, been fighting for the Canyon and the public. David Brower hired Ingram as the first Southwest Representative for the Sierra Club, and together they successfully fought the proposed dams in Grand Canyon in the 1960s. Ingram worked with then-writer/environmentalist Martin Litton for a Grand Canyon National Park Wilderness bill, until Litton turned...but you'll have to read about it in the book! Ingram documented events, meetings, legislative and legal moves and tells us about the on-going battle of protecting the Grand Canyon for the people of the world, with personal interviews and painstaking research from a number of archives.

If you want to truly understand the supercharged issue of Grand Canyon's wilderness designation (the lack thereof), the denial of public boaters access rights to the river in the park, and the politics behind Grand Canyon National Park management, *Hijacking a River* is a must-read.

RRFW is pleased to be able to take advance orders for *Hijacking A River*, 496 pages, including maps, readers guide, and index. The cost of this book is \$20 (\$17.95 each, plus \$2.05 shipping and handling per book), with a tentative shipping date of January 15, 2003. Checks or money orders only please. Advance book sales will benefit River Runners For Wilderness, a not-for-profit organization seeking equitable access to a wilderness river running experience in Grand Canyon. Please send your order to

River Runners For Wilderness PO Box 17301 Boulder, CO, 80308-0301

If you'd like to place an order for that special Christmas someone, just let us know with your order and we'll send an announcement card before Christmas, letting them know they will be receiving a gift from you soon.

For additional book information and dealer inquiries, contact: Vishnu Temple Press, PO Box 30821, Flagstaff, AZ 86003-0821 Info@vishnutemplepress.com ### RIVERWIRE is a free service to the boating community from River Runners for Wilderness. RRFW Riverwire - CRMP STAKEHOLDER WORKSHOP VIDEOS AVAILABLE

Grand Canyon National Park is making available to the public the audiotapes from the general session of the stakeholder workshop in June 2003, and the videotapes from the stakeholder workshop in January 2003. The costs for these products covers the duplicating and shipping cost. It will be \$28 for the videotapes. Audiotape prices are not

yet available. The order form for the videotapes is below. If you are interested, contact Julie Graham at BJ Communications, (602) 277-9530, ext 229, or julie@bjc.com. If you would like to purchase a copy of the expert panel series and/or the stakeholder workshop for the Colorado River Management Plan revision, please fill-out the form below and send it along with a check or money order for the appropriate amount to:

BJ Communications Attention: Julie Graham 340 East Palm Lane, Suite 280 Phoenix, AZ 85004. If you have any questions, don't hesitate to contact Julie at 602-277-9530 ext. 229 or julie@bjc.com.

Name: Organization: Address (where tapes should be mailed): City, State, Zip: Phone: Email: Please check the box to indicate the event/s you would like to purchase.

*****Expert Panel: Carrying Capacity, Group Size and Seasonality Wednesday, January 29, 2003 [] VHS Cost: \$28.00 includes tax and shipping

*****Expert Panel: Allocation of Recreational Use Among User Groups Friday, January 31, 2003 [] VHS Cost: \$28.00 includes tax and shipping

*****Stakeholder Workshop Thursday, January 30, 2003 [] VHS Cost: \$28.00 includes tax and shipping TOTAL COST: \$_____

Thank you for your interest in the Colorado River Management Plan revision process. RRFW Riverwire - PARK FREEZES ADDITIONS TO WAITING LIST!

Grand Canyon National Park News Release
For Immediate Release December 9, 2003 Dawn O'Sickey

Hold Placed on Adding Names to Noncommercial River Permit Waitlist

Grand Canyon, AZ - Grand Canyon National Park is placing a hold on adding new members to the noncommercial river permit waitlist. As part of the current Colorado River Management Plan (CRMP) planning effort, park staff and planners are carefully examining and considering alternatives to the current waitlist permit system. An overwhelming majority of public comments stated the opinion that the permit system should be overhauled. With this in mind, park management does not want to perpetuate the current system while other alternatives are being considered. There are now over 8,000 people on the waitlist, and more than 1,000 are typically added each year. In the event that the current system is selected as part of the final CRMP decision, to be

completed by December 31, 2004, the system for allowing additions to the waitlist would simply be reinstated.

Until a record of decision is made for the CRMP, current waitlist members will be served in the same manner as they have been in the past. They will soon receive the familiar annual letter regarding waitlist procedures, the schedule of release dates, and other topics. The River Permits Office may be contacted at 1-800-959-9164 or 928-638-7843.

Please go to www.nps.gov/grca for more information regarding Grand Canyon National Park. Information about the Colorado River Management Plan may be found at www.nps.gov/grca/crmp.

River News 12/14/03

RRFW Riverwire - LAKE MEAD UPDATE

Lake Mead elevation is currently at 1140 feet, having dropped 14 feet since March, 2003. The lake is forecast to drop to 1129 feet by June, 2004, subject to the winters snowfall and outflow requirements to California, Arizona and Nevada. Lake Mead full pool elevation is 1220 feet.

Colorado River current continues to flow past Boundary Point, as the sediment cone and river channel pushes out into Iceberg Canyon. End of current is now at North Howland Cove, roughly half way through Iceberg Canyon. The channel runs down the west side of Iceberg Canyons western cliffs. The Lake is still 90 feet deep at Devils Cove, just above Sandy Point. The river may be fairly clear at Separation Canyon (River Mile 240), but becomes more turbid by Burnt Spring, so much so that by Columbine Falls the river is brown with moving silt. There are lots of beach areas to camp on below South American Point, downstream of Pearce Ferry. Hydraulics at Lava Point continue but no rapid has formed there yet.

The upper rapid by Pearce Ferry has cut into the right river bank sediments. The run here is to the right, with exposed rock on the left. The lower riffle still has a strong eddy on the right and a strong wave train. A new sandbar has formed on river left below the lower riffle, and river runners will need to go to the right of this sandbar. Pearce Ferry will remain closed to all boating into the foreseeable future due to low reservoir levels.

Sandbar Alley, an area of shallow water with many sandbars, is now extending from just below the Bat Caves upriver to Mile 253, but there are several sandbars above that up to Surprise Canyon. Dry Canyon corner has a large bar on river right that extends all the way down to the Bat Caves. The current is on the left. There are lots of sandbars in the channel near the Oriental Tours boat landing. Just upstream of there, at Burnt Canyon, there is a big bar on the left, and just above that there is a large bar on the right. There

is good access to the Burnt Canyon campsite, with a big sandbar ½ mile above that on the right.

South Cove is not going to be impacted by the draw down this year and remains open. All river runners taking out at South Cove are supposed to use the gravel area on the south side of the concrete ramp. River runners are asked to be patient in the de-rig area as Hualapai, concessions and public rafters are all taking out in the same area. River runners are encouraged to maintain as small a take-out footprint as possible, and try to de-rig as quickly as possible. Early take-outs are recommended in the high use seasons of late spring, summer and early fall, to avoid late afternoon river traffic. Maintenance work on the South Cove asphalt ramp has been completed. Dumpsters at South Cove are not for downriver use at this time per trip permit regulations.

National Park Service Rangers note that no camping is allowed on the South Cove ramp and take-out area, or the public swimming area just north of the concrete ramp. Camping is allowed outside the harbor area, and is available one-quarter mile downstream (south) of the concrete ramp below the rock jetty just downstream of the take out. The Mead View Scat machine is closed for the winter, and will tentatively re-open in March.

River News 12/15/03

RRFW Riverwire - Commercial Bookings Continue as NPS Freezes Public Access

On December 9, 2003, Grand Canyon National Park announced it will no longer allow the public to seek boating permits for the Colorado River. River Runners For Wilderness Co-Director Jo Johnson called the move "shocking and premature. Now people wishing to reserve a future trip are forced to use expensive commercial services as they can no longer add their names to the permit list. The Park Service cites the failure of the current system without offering any remedies for public relief except the option of purchasing access from a park river concessionaire."

Grand Canyon officials noted that an overwhelming majority of public comments requested an overhaul of the present permitting system, and offered this as their reasoning for disallowing new applicants to the non-commercial permit system to float the canyon. "Granted, Grand Canyon National Park has a serious problem with the non-commercial permit system," says Johnson. "Our own review of the public comments has shown that an overwhelming majority of the public would like to see the access methods and allocation between the public and the river concessions changed. There is a backlog of 130,000 people already waiting years to raft the canyon without paying the high concessions fees. So why add fuel to that fire?" says Johnson, who is quick to

point out that "We want the Park to be thinking about changing the access and allocation method to one that reflects real public demand and shows no favoritism."

Johnson brings up another point: "Freezing the waiting list removes an indicator of public demand for river trips, the only indicator NPS has. Now the park has no way of measuring demand at all. Vigorous advertising by commercial operators to fill trips and lack of demand for those same trips-many of which have gone unfilled the last few years-indicates an oversupply in their allocation. This is in stark contrast to the multi-year wait those 130,000 paddlers face.

One solution for the park that would be responsive to public demand is to introduce a Universal Permitting system. The trip leader gets a permit, then uses whatever commercial services they desire once they have a permit. "We look forward to the park's soon-to-be released draft alternatives for the Colorado River Management Plan" says Johnson, who points out that "If the park does not put forward the idea of an allocation free concept along with other possibilities, then this freeze is a signal that the future of access to our National Parks is in serious jeopardy."

"The Park has given no indication of what will replace the waiting list for public access" notes Jeff Ingram. Ingram's new book on the politics of access to the Colorado River in Grand Canyon, titled Hijacking A River, details how the current problem developed. "The Park started with a First-Come, First-Served system after 92% of the river access was assigned to the commercial operators. The public didn't like that, so the Park used a lottery from 1976 to 1980. This also failed. The Park then started the waiting list. It doesn't work, either, but the 20-year stagnated "status quo" of river management has not changed. Given the Park's attempts at various access systems, we are hoping the park releases a robust spectrum of alternatives, including a Universal Permit system, to get a serious public discussion as a basis for a sound access method."

"Trip opportunities are only open to anyone with the thousands of dollars needed to buy seats on commercial trips, but forbidden to anyone wishing to do it on their own." said Tom Martin, also with River Runners for Wilderness. "This commercialization of our parks is a chilling trend we have seen in this administration, with similar moves at Yellowstone National Park toward privatization of access."

Martin notes that allocations, if they exist at all, need valid indicators of demand so that allocations can shift yearly as needed. "We have heard that the river concessions had 18 trips worth of unused allocation this season. While we are glad to hear that the park will be transferring these unused commercial trips to public boaters for use this winter and next spring, we are amazed that the park does not immediately shift some allocation from the 14 river concessions back to the public. Given the public's huge backlog, if this isn't a clear indicator that the current management system is a failure, and not reflecting real demand, I don't know what is."

River News 12/17/03

RRFW Riverwire - Park Turns 18 Unused Concessions Launches Over To The Public

Officials at Grand Canyon National Park confirmed today the release of 18 additional launches to perspective permittees on the Park's non-commercial waiting list. These permits have been made available as a result of the 2002 lawsuit agreement between Grand Canyon Private Boaters Association with others, and Grand Canyon National Park. The settlement stipulates that unused summer commercial allocation will be turned over to non-commercial launches for the following off-peak season. The dates are limited to the spring of 2004 season: March 1, 3, 4, 7, 10, 11, 13, 15, 18, 20, 23, 26, 29, 31 and April 3, 6, 7, 8.

According to the Continuing Interest Newsletter mailed December 16, 2003 to those on the non-commercial waiting list, during the week of January 5, 2004 to January 9, 2004, the River Permits Office will be releasing 18 launch dates through the cancellation line. Those with a waiting list number assignment of 03#00001 to 03#01499 may call in on Monday, January 5, those with numbers from 03#00001 to 03#02999 may call in on Tuesday, January 6, those from 03#00001 to 03#04499 can call on Wednesday, January 7, those with a number of 03#00001 to 03#05999 on Thursday, January 8, and those holding any number may call on Friday, January 9. Call the River Office cancellation line between 8:00 a.m. to 12 noon and 1 p.m. to 5:00 p.m. at (928) 638-7883. Launch dates will be given out on a first call, first served basis to eligible callers.

The letter goes on to note that many winter launch dates released in past years were not claimed until the very last call-in day. Provided this trend continues, callers who are eligible to call in the first few days should have a good choice of available dates.

The newsletter assures current waiters on the list that their position on the list is not affected by the recently announced hold on new additions to the non-commercial permit waiting list.

Park officials also noted that self guided trip scheduling during the normal year has included a 12% overbooking of non-commercial river trips. This overbooking has all but eliminated the need to release additional launches to the cancellation line, while assuring self guided river trips used all the available user days each season.

Our thanks to Steve Sullivan, Grand Canyon National Park, for this information.

RRFW Riverwire - GLEN CANYON DAM UPDATE

Basin Hydrology

Severe drought conditions in the Colorado River Basin continue. As we move into mid-winter, there are no clear signals that the drought is easing. While much of Utah was slammed with a major winter storm the last week of December, snowpack in the Colorado River Basin remains near average. The bulk of the moisture from the Utah storm was in the Wasatch Mountains, west of the Colorado River Basin. As of December 30, 2003, snowpack in the Colorado River Basin is 101 percent of average. Because of the extended drought, the snowpack lies atop a mantle of very dry soil. This scenario is not favorable for next springs runoff, as much of the melting snow will be absorbed by the soil. Reclamation is estimating that with average snowpack conditions this winter, runoff next spring would be about 75 percent of average. The National Weather Service will issue an April through July inflow forecast for Lake Powell on January 5, 2004.

The Colorado River Basin is now in its 5th year of drought. Inflow volumes have been below average for 4 consecutive years. Unregulated inflow in water year 2003 was only 53 percent of average. Unregulated inflow in 2000, 2001 and 2002 was 62, 59, and 25 percent of average, respectively. Inflow in 2002 was the lowest ever observed since the completion of Glen Canyon Dam in 1963.

The trend of low inflow continues. Unregulated inflow in November, 2003 was 64 percent of average and Decembers will likely end up at about 65 percent of average. On December 29, 2003 observed inflow to Lake Powell was 5,000 cfs, about 60 percent of what is usually seen in late December.

Low inflows have reduced water storage in Lake Powell. On December 5, 2003, the elevation of Lake Powell dropped below 3600 feet. The last time the water surface elevation was this low was in 1973. The current elevation (as of December 30, 2003) of Lake Powell is 3,597 feet (103 feet from full pool). Current storage is 11.5 million acre-feet (47 percent of capacity). The good news is that even after 4 years of severe drought Lake Powell is still storing a large volume of water.

Operations Experimental Flows

Daily high fluctuating releases from Glen Canyon Dam, as part of the Glen Canyon Dam experimental flows, will be implemented from January through March 2003. Releases will range between a high of 20,000 cubic feet per second (cfs) to a low of 5,000 cfs each day. The 20,000 cfs releases will be maintained for about 9 hours each day (from about 11:00 am until about 8:00 pm), while the 5,000 cfs releases will be maintained for about 8 hours (from about 1:00 am until about 9:00 am). The remainder of the hours will be transition releases where releases will be between the daily high and the daily low. This pattern will be maintained for 7 days a week during the January through March

time period. It should be noted that due to real-time power considerations and regulation to stabilize the power system, actual releases may deviate somewhat from this pattern

The January through March high fluctuating releases are intended to benefit the endangered humpback chub. Scientists have recognized that the humpback chub population has been in general decline since highly fluctuating flows were curtailed in November of 1991. Those flows helped keep the non-native fish, especially the rainbow and brown trout, in check. The trout are thought to prey upon and compete with native fish such as the endangered humpback chub. This is the second year of high fluctuating releases as part of the experimental flows. High fluctuating releases were first implemented in January through March of 2003.

Monthly release volumes in January, February, and March 2003 are scheduled to be 788, 737, and 788 thousand acre-feet, respectively, which averages out to 12,800 cfs per day. Because of the draw down condition of Lake Powell, releases from Lake Powell in water year 2004 are being scheduled to meet the minimum release objective of 8.23 million acre-feet. This is consistent with the requirements of the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs. The experimental flows will not change the total volume of water to be released from Lake Powell in water year 2004.

The experimental flows from Glen Canyon Dam received environmental clearances in December 2002. The flows were analyzed in an environmental assessment in accordance with the National Environmental Policy Act. The experimental flows are the result of ongoing studies by scientists from the United States Geological Survey and were recommended by the Glen Canyon Dam Adaptive Management Work Group, a Federal advisory committee. The experimental flows address the decline of two key resources in the Grand Canyon: sediment and population viability of endangered humpback chub. The Finding of No Significant Impact on the experimental flows can be found at http://www.uc.usbr.gov/amp/flow_fonsi.pdf

The experimental flows from Glen Canyon Dam received environmental clearances in December 2002. The flows were analyzed in an environmental assessment in accordance with the National Environmental Policy Act. The experimental flows are the result of ongoing studies by scientists from the United States Geological Survey and were recommended by the Glen Canyon Dam Adaptive Management Work Group, a Federal advisory committee. The experimental flows address the decline of two key resources in the Grand Canyon: sediment and population viability of endangered humpback chub. The Finding of No Significant Impact on the experimental flows can be found at http://www.uc.usbr.gov/amp/flow_fonsi.pdf

Persistent Drought in the Colorado River Basin

THE CONFLUENCE: Journal of Colorado Plateau River Guides
Issue #27, December 2003

Part One: Introduction

Scientists have studied tree-ring records that span the last seven centuries for five regions of the United States, including the Colorado River basin. These records have been used to examine both wet and dry cycles of climate that can sometimes last for many decades, or multidecadal. For example, droughts of 30-70 years persisted from the late 1500s until the mid-1800s in two of the five regions, and wet/dry cycles were synchronous at some sites until the drought of the 1950s. The pattern of severe drought in the late 1500s, followed by unusually wet conditions of the early 1600s, resembled the drought of 1942-1977 and the subsequent wet period from 1978-1998.

The megadrought of the late 1500s may have resulted from a cooling phase in the tropical Pacific Ocean with a warming phase in the subtropical North Atlantic Ocean, and marked a substantial shift for the climate of the Rocky Mountain region. In 1998, scientists recognized similar sea surface temperatures and forecasted the present drought situation we now find ourselves in, and the present indicators offer little hope for improvement in the next few years. It is unknown if the current drought will become multidecadal, but such a situation seems likely at some point in time, as do other extremes that include massive flooding, and higher sediment transport regimes.

Tree-Ring Chronologies

The identification of ocean oscillations from past centuries has been accomplished by scientists who have sampled tree-rings from, for example, logs from archeology sites (dwellings), and then comparing them with modern-day precipitation records. By modeling the climate records of the past by this method, there is a high degree of confidence within the science community that significant ocean oscillations in the future can be identified in order for communities to better prepare and manage the impacts of drought and floods.

Scientists have also refined the data for greater accuracy by examining more closely the chronologies from different tree species and geographic areas back to 1400 A.D. such as the central and southern Rocky Mountains. Although these two regions have different precipitation variables, historically they have suffered prolonged catastrophic droughts at similar times, such as the drought of the 1950s.

The results of refining the measurements from other tree-ring chronologies and from different regional areas mark both dry and wet periods that alternate for many

successive decades, sometimes even four decades and more. However, the frequency and strength of these periods do vary in time spans and among the various regions. In other words, climate cycles do not necessarily impact all regions at the same time. For example, chronologies from Yellowstone and the southwest Rocky Mountains have a strong moisture signal in a band from 30-70 years around 1250-1400 A.D., but these signals are absent from other regions. Additionally, the Bighorn Basin (northern Wyoming) chronology shows significant energy for an even longer wet period that lasted 128 years around 1300-1400 AD.

A significant oscillation was observed during a severe and prolonged drought throughout much of North America from roughly 1575-1595 AD, which was followed by an unusually wet period in the central and southern Rockies from 1600-1625 AD.

Multidecadal precipitation modes at 30-60 years do not persist after 1650 AD in either Yellowstone or the Colorado Plateau and remains so until the drought of the 1950s. However, the drought of the 1950s, though significant, did not resemble the severity of the drought that occurred in the late 1500s.

Discussion of Sea Surface Temperatures

In the North Pacific, much of the sea surface temperature variance occurs within a time scale of 15-25 years, and is accompanied by the strength and position of the Aleutian Low in winter. These variations have been defined as the North Pacific Oscillation (NPO) when referring to anomalies of the North Pacific, or Pacific Decadal Oscillation (PDO) if they extend into the tropics. The positive, warm phase of the PDO is associated with greater precipitation in all seasons throughout the central and southern Rockies (El Niño or wet). The 1900s were marked by two full +PDO cycles. The warm or positive +PDO regime prevailed from 1925-1946 and from 1977-1998. The cool or negative -PDO (La Niña or dry) regime prevailed from 1890-1924 and 1947-1976. In 1998, scientists noted the tropical Pacific Ocean was cooling (-PDO).

Warmer sea temperatures in the North Atlantic exhibit a 65-80 year cycle termed the Atlantic Multidecadal Oscillation (+AMO). Warm phases occurred during 1860-1880 and 1930-1960 and cold phases during 1905-1925 and 1970-1990. The AMO shifted to its warm phase around 1995, coincident with the apparent recent shift to the negative, cool phase of the PDO. During the warm phase of the AMO, the central U.S., including the central and southern Rockies, receives less than normal rainfall, particularly in summer.

By 1998 scientists were confident that having a warm North Atlantic and a cool tropical Pacific would spell out a persistent drought for the United States. They were right, for the last five years have substantiated the prediction with water year 2002 being the driest ever in the history of documentation by modern instruments.

This phenomenon is also identified by dry springs (February-April) over most of the western states and were succeeded in the central and southern Rockies by failures in both the early summer (May-June) and late summer (July-August) monsoon moisture that originates in the Gulf of Mexico.

What the scientists envision is a similar pattern of intraseasonal drought for the megadrought of the late 1500s, which affected most of North America from northwestern Canada to the Valley of Mexico and the Atlantic Coast. Like the 1950s drought, the megadrought of the late 1500s was followed by an unusual wet period in the early 1600s, and both events were associated with intense and prolonged La Niña episodes typical of southwestern U.S. and Great Plains droughts. Such continental-scale droughts may be symptomatic of major reorganizations in both Pacific and Atlantic climate.

Long-term forecasting remains limited

There is considerable discussion about the steady state vs. chaotic behavior of multidecadal variables in climate, and thus about its predictability. An optimistic view is that knowledge about the present phase of the long-term -PDO or +AMO modes can be used to forecast climate more than a year in advance. Some recent forecasts are already taking into account the possible regime shift in both the Pacific and Atlantic sea surface temperatures during 1995-1998, which could signal prolonged drought in the central and southern Rockies.

Although there is plenty of multidecadal persistence in western North America climate, the instabilities argue against extending the forecasting window much beyond 2-3 years. At the very least, however, recent shifts to the cool phase of the -PDO and the warm

phase of the +AMO provide little reason for optimism about ongoing drought in the Rockies.

It is probable that multidecadal variations in North American climate, specifically the occurrence of prolonged, continental-scale drought, involve complex interactions between the Atlantic and Pacific Oceans. Unraveling these relationships will require further development of multi-century, annually-resolved sea surface temperature analyses from the Atlantic and Pacific basins.

Part Two

The Future Hydrology of the Colorado River

The purpose of this next article is to demonstrate that the Colorado River can supply the water

required by humans and the environment, and is available right now and at little cost. This can be achieved by reducing consumption through management policies to increase efficiency. Otherwise the eventuality for all residents in these arid lands, as dictated by its present course in history, is to become another failed hydrosociety. If we simply reduced our water consumption to the national average, Lake Powell would not be needed and the ecosystems of the Grand Canyon and the Colorado River delta in Mexico can be restored.

The other alternative is invasive and economically burdensome, which includes financing and constructing: 1) massive power plants to provide energy; 2) large-scale wastewater and desalinization plants; 3) pipelines to deliver water to the users. These alternatives will increase our dependence on finite natural resources, such as petroleum and nuclear fuels. These fuels are very inappropriate considering: 1) our degraded atmosphere; 2) the expense and dangers associated with nuclear technology and waste; 3) our penchant as a country to generate unproductive relationships with other countries to support our rampant consumptive life style.

Another consideration includes the potential for water to become a commodity controlled by corporations, rather than managed as a public trust.

According to law, the water allocations of the seven states and Mexico is 16.5 million acre-feet. The real time average supply of the Colorado River is, at best, 14 million acre-feet. The total loss due to evaporation and leakage throughout the whole system is currently 3 million acre-feet, which is nearly the complete allocation for the state of Arizona (2.8 million acre-feet). Any objective financial analyst would be shocked at the poor performance of this business venture. Congress is fully aware of this poor performance because they continue to approve Band-Aid fixes and subsidies every year to maintain it.

When the persistent drought appeared in the middle 1900s, nobody really noticed the shortfall because the supply still exceeded the demand-leaks, evaporation and all. Afterwards, when the metropolitan building booms began, nobody noticed either, because the Colorado River over-produced and filled the reservoirs despite the development. Building so-called metropolitan dreams on luck is called greed, not business.

Things are different now that the swimming pools are dug and the golf courses seeded. The demand has almost peaked and the supply continues to wax and wane at the whim of climate. The drought situation at present is very similar to the 35 years of reduced supply that occurred between 1942 and 1977 when El Niños took a long nap and a negative Pacific Decadal Oscillation locked in for an extended stay (see previous article).

The total storage of the Colorado River system right now is below 50%. It took four years to get there. If the drought persists for another four more years, the trend will instead become a long reality and will completely drain Lake Powell reservoir. Obviously the drought will break-they always do. But what is the next climate regime going to bring our way? Will extreme flooding occur and bring the associated shuddering at Glen

Canyon Dam-as occurred in 1983 when the spillways choked at only 20% of capacity? Will the four-hundred fold sediment loads of the early 20th century return? The answer to these questions are-yes.

Models have been generated by hydrologists and resource economists with results posted on the web. Visit: . The diagram presented in this article is based on 400 years of tree-ring data and simulates a drought of the late 16th century (1570-1598). That severe and sustained drought had a 30 percent reduction in stream flow on average in a 19 year period.

How will a drained reservoir effect our river running? Our Colorado River trips will have to take out at the old ferry roads at Hall's Crossing.

Clay Hills Crossing on the San Juan River will continue to be impacted by sediment. The river incising into the sediment may leave the boat ramp perched above a down cutting river. Channel meandering may place the river on the opposite shore. Trips on the San Juan River may have to locate alternate sites to exit the river as well.

RRFW Riverwire - 'Hijacking' A World's Wonder

A New Book From A Flagstaff Publisher Tackles The Commercialization Of The Colorado River In The Grand Canyon

By SETH MULLER Arizona Daily Sun Staff Reporter January 4, 2004
www.azdailysun.com

Advocates for noncommercial boat trips in the Grand Canyon are approaching this year with the same trepidation as a series of class VI, boulder-strewn rapids. By Dec. 31, 2004, the National Park Service must complete a Colorado River management plan for the waterway's Grand Canyon stretch before renewing or augmenting the concessionaire contracts for the 14 commercial raft companies.

The Park Service also will have to figure out how to deal with the growing demand for private permits to run the river-- the waiting list is more than 8,000 permits long and up to 20 years. Some private boaters have organized as River Runners for Wilderness, they will start the year by adding a significant tome to their argument that the river has become too commercialized. This week, the organization will release "Hijacking a River: A Political History of the Colorado River in the Grand Canyon" through the Flagstaff-based Vishnu Temple Press.

The 500-page book by Jeff Ingram of Tucson is a detailed, multi-sourced account of how river running, the idea of wilderness and federal management have had impacts on the Colorado in the Grand Canyon through the late 1960s, 1970s and early 1980s. Tom Martin of River Runners hopes "Hijacking" will give people an opportunity to learn about

how the river came to be managed like it is, with long waiting lists, continued motorized watercraft and bureaucratic resistance to wilderness designation. "When it comes to all the stuff we're dealing with today, Ingram has already been there," Martin said. "He knows the history, and this thing has been going on a long time."

Ingram became the first Southwest representative of the Sierra Club, a position given to him by then-president David Brower. In his work with the Sierra Club, Ingram found himself gaining intimate knowledge of the political landscape and how its changes affect management of the actual landscape. "Back in the 1970s, there was a number of things going on, with the proposed expansion of the park and river as wilderness," Ingram said. "I started collecting materials and saving files with the thought that I would write a history of Grand Canyon National Park and all of the things that have happened to it. Then, life got in the way, but modern history happened when the whole business of planning for the river started in late '90s."

Ingram met with Martin, and Martin asked him to write the book as a way to make more information public on how the past determined the present. "Today, the river runners haven't had a clue as to why we have to pack our solid wastes. They don't know how the commercial river companies become concessionaires," Martin said. "There's nothing else out there like ('Hijacking'). It's opening up a whole new realm of literature."

Martin and members of the River Runners contend that those who want to run private trips down the river are not getting much consideration. In December, park management decided to stop taking names for the private permit waiting list, noting that the list had grown too long. Reports from the Park Service show that they want to reduce the list's numbers as they are unsure of how the management plan will work. "I am just astonished," said Jo Johnson of River Runners, in an earlier interview. "I'm surprised they would do this, and it's not a nice surprise. There is already such a disenfranchisement of private boaters."

Martin said that, meanwhile, the Park Service has not put any restrictions on the commercial outfitters, which could conceivably book trips into 2005 and beyond. Martin is concerned that the park might be leaning toward a plan that penalizes private boaters, but he is optimistic that the Park Service has fully involved the public in the process. For river runners or environmentalists, Ingram has some advice based on his experiences with the Grand Canyon and the politics that affect it. "After 40 years in environmental matters, it's clear to me the most important thing is stamina," Ingram said. "It's possible that we could get a Democratic president and a Democratic Congress, and all of the sudden the political landscape changes."

Reporter Seth Muller can be reached at 928-913-8607 or smuller@azdailysun.com

The book is in! Advance orders are already in the mail (thank you!). RRFW is pleased to be able to take orders for *Hijacking A River*, 496 pages, including maps, readers guide, and index. The cost of this book is \$20 (\$17.95 each, plus \$2.05 shipping and handling per book). Checks or money orders only please. Book sales will benefit River Runners For Wilderness, a not-for-profit organization seeking equitable access to a wilderness river running experience in Grand Canyon. Please send your order to

River Runners For Wilderness PO Box 17301 Boulder, CO, 80308-0301

For additional book information and dealer inquiries, contact: Vishnu Temple Press, PO Box 30821, Flagstaff, AZ 86003-0821 www.vishnutemplepress.com

River News 01/05/04

RRFW Riverwire - Economic Study of Canyon River Runners Gets Low Marks

A recent masters thesis titled "Regional Economic Impacts of Grand Canyon River Runners", by Northern Arizona School of Forestry Masters student Evan Hjerpe, has received low marks. This according to Stephen Fullam, who runs a consulting firm for environmental groups and is a recipient of the prestigious Public Service Fellowship while at the Kennedy School of Government, Harvard University. Mr. Fullam notes "the study examines an issue that compares Macintosh apples (non-commercial river trips) with Granny Smiths (concessions river trips), but the data is so corrupt he's managed to compare apples and oranges." Hjerpe's analysis examines a very contentious, political issue - commercial vs. non-commercial use of a public wilderness area, in this case the Colorado River in Grand Canyon National Park, and the regional economic benefit river runners have on the local economy.

Fullam expressed concern in how data for the study was gathered. A survey was mailed to a large spectrum of non-commercial river runners, while in contrast, all economic data about commercial river running was provided by one source, the commercial river running trade association. "The analysis allows an industry trade group to report economic expenditures for their customers. Given the potential for upward bias, this data collection technique is flawed and should be questioned. Commercial river trip participants surely could have filled out a similar survey as non-commercial boaters. Furthermore, the study does not provide an example of the survey instrument used by commercial firms. These flaws bias any comparison and raise serious questions about the validity of results for the commercial sector" noted Fullam.

Tom Martin, co-director of River Runners for Wilderness, was also not impressed with the study. "We suspected the same thing" said Martin. "Highly detailed economic data from a large number of non-commercial river runners is compared to a lump sum figure reported by an industry trade group whose political motivations are crystal clear. Warning bells and whistles should be going off, but it doesn't even appear to raise the eyebrows of the study's author. I hope the Park Service distances itself from the results of this study."

The analysis not only allows this bias, but makes no effort to alleviate it in reporting from the commercial sector. In fact, Martin argues, commercial interests are more likely to report economic results with an upward bias since they are already organized as a political and economic entity on Grand Canyon wilderness and access issues. "The Grand Canyon River Outfitters Trade Association (GCROA) provided all the commercial data, and I'm sure they understand the political value of such a study" notes Martin. "The other group in this study, the general public who floats the river without using concessions services, are a scattered group of individual households with varying degrees of understanding of the issues. There is little or no expectation that do-it-yourself boaters in a single permit year would organize to over-report expenditures and potentially introduce upward bias."

Mr. Fullam points out other discrepancies with the study, such as the lack of appropriate distinctions between non-commercial user-days and commercial concessions user-days. "It is not clear whether commercial guide user-days are being counted. The omission of these days would inflate economic results since the total number of user-days would be under-reported for commercial firms. It is hard to believe that Hjerpe found that commercial boaters spend \$161 per day on regional expenditures and non-commercials only \$45. These figures should be less divergent and their divergence should have raised alarms for the author, especially about upward bias from commercial reports and possible downward bias from non-commercial reports" says Fullam.

Yet another flaw in the study, according to Fullam, is the lack of differentiation between commercial firms that run motorized trips verses those that run non-motorized trips. According to Fullam, "The majority of motorized trips make use of the Whitmore helipad and fly clients to Las Vegas. Clients flown to Las Vegas have left the regional economic zone defined by Hjerpe, which does not include Las Vegas. The lack of analysis of this negative economic impact raises more questions about the validity of commercial results. If a commercial customer starts and ends their trip in Las Vegas, then a substantial portion of their trip expenditures was never made in the regional economic zone of northern Arizona. It reflects the potential for additional upward bias or omission bias in reporting by commercial firms, especially motorized concessionaires."

The potential for capital flight by owners of river running concessions is also ignored in the study, according to Fullam. "Although warehouses may be located in the regional economic zone, it is not established to what degree the commercial firms leave revenues in the area."

Other deficiencies in the study have Fullam concerned. There is no consideration in the study of wholesale concessions orders of food, gear, and other services coming from outside the economic zone, which could greatly reduce the multiplier effects of the study. In contrast, non-commercial river runners reported on a case-by-case basis whether they purchased food, gear and other supplies within the economic area or not. Non-commercial trips are more likely to purchase all or most of their groceries, ice, and drinks at retail prices in the regional economic zone, while commercial outfitters can buy wholesale goods and have them transported from outside the economic zone. Fullam also points out that non-commercial trips are 2 to 3 times longer than commercial trips,

hence overall food expenditures can be expected to be 2 to 3 times higher on a per trip basis for non-commercial trips, especially factoring in the difference between retail and wholesale prices.

Fullam points out one last discrepancy. Despite the reporting on an aggregate basis and acknowledgment by Hjerpe that only 8 of the 16 firms even have bases within the economic zone, the analysis still states overly confident findings about economic impacts of commercial firms. Fullam says "confidence should be low given these conditions." Combine this with a lack of solid positive information, and Fullam rejects the study as a useful tool for Park Service decision-making. "Open-door methodology simply allows too many opportunities for bias in the economics of the commercial boaters. An economic comparison of the regional impacts from non-commercial and commercial boating would be a useful study, but it needs a more academically strict methodology and independent data collection applied coherently and equally to both groups," Fullam concludes.

The study can be read in its entirety at <https://www.rrfw.org/programs/rrfw/pdfs/RiverRunnerImpacts.pdf>

RRFW Riverwire - ARKANSAS RIVER MEETINGS SCHEDULED

By Colorado State Parks

Arkansas Headwaters Recreation Area Integrated Concept Plan Meetings Scheduled

SALIDA--The Arkansas Headwaters Recreation Area (AHRA) will hold four public meetings to discuss the proposals of the Integrated Concept Plan (ICP).

CONTACT: Gary Thorson 1313 Sherman St Room 618, Denver, CO, 80203 . Office: (303) 866-3203 ext. 337

For immediate release January 12, 2004

Arkansas Headwaters Recreation Area Integrated Concept Plan Meetings Scheduled

SALIDA--The Arkansas Headwaters Recreation Area (AHRA) will hold four public meetings to discuss the proposals of the Integrated Concept Plan (ICP). This plan was developed to provide assistance in resolving a number of Private Boat and Commercial Special Use Agreement issues that have been brought to the attention of Colorado

State Parks and the Bureau of Land Management (BLM). Adoption of the ICP could lead to modifications of the 2001 Arkansas River Recreation Management Plan.

All meetings will be held from 6 pm until 8 pm on the following dates and locations:

Tuesday, Jan. 20, Annex Meeting Room, Lake County Public Library, 1115 Harrison Avenue, Leadville;

Thursday, Jan. 22, Public Room, Community First Bank, 146 G Street, Salida;

Friday, Jan. 27, BLM Field Office Conference Room, 3170 East Main Street (Hwy 50), Canon City;

Monday, Feb. 9, REI Flagship Store, 1416 Platte Street, Denver.

All interested parties are encouraged to attend. For more information, please contact the AHRA office at (719) 539-7289.

RRFW Riverwire - Free Grand Canyon Slideshows In Salida and Portland

Author Tom Martin will update local boaters on the controversial Colorado River Management Plan (CRMP) now in progress for Grand Canyon National Park, and how this plan will affect the boating public. Tom will illustrate his talk with a slide show on the Grand Canyon based on his book, *Day Hikes From The River: A Guide to 100 Hikes from Camps on the Colorado River in Grand Canyon National Park*. The show will be in Salida, Colorado, at Bongo Billy's Coffee House, 300 W. 2nd St., at 8:00 p.m., Sunday, Feb. 8, and at Lewis and Clark College in Portland, Oregon on Tuesday, February 17, in the Templeton Student Center (Council Chambers) at 7:00 p.m.

The highly controversial CRMP, which was stopped by the Park in 2000, was restarted as part of a settlement agreement in a lawsuit filed by river running groups and individuals. The public comment period during the past summer gathered over 50,000 comments. "The wait for do-it-yourself river runners is so long, those at the bottom of the list will wait an incredible 20 years to get permission to run the river" said Martin, who notes that "you can book a commercial trip tomorrow for next summer, if you can afford it. This process is of vital interest to any canyon lover hoping to visit the Colorado River in Grand Canyon."

The free slide shows will be open to the public and feature beautiful vistas illustrating Grand Canyon hikes you can do from the river and exciting river running shots. Tom will

be signing his book, and copies of the new Grand Canyon book "Hijacking A River, A Political History of the Colorado River in the Grand Canyon", by Jeff Ingram, will also be available. Book sales will benefit River Runners for Wilderness, a non-profit group which is sponsoring the events. RRFW represents the interests of the boating public.

Look for upcoming shows in California and Washington in mid-February, times and locations to be announced.

River News 01/19/04

RRFW Riverwire - Annual Outfitters Meeting Held With Park

On November 4, 2003, river concessions owners, their spouses, warehouse personnel, river guides, Hualapai Tribal members, representatives from the river outfitters trade association and National Park Service employees met at Albright Training Academy for the annual NPS-river concessions meeting. Nick Hardigg, Chief of Concessions Management, Grand Canyon National Park, advised the group of 54 that the park had received two requests from non-concessioner representatives to observe the meeting. RRFW was formally denied attendance at the November, 2002 and was turned away from the November 2003 meeting.

According to Grand Canyon historian and author Jeff Ingram, non-participatory public observers were once allowed to attend these meetings. That they are now excluded bothers public advocacy group River Runners for Wilderness. "We have asked to observe for the past two years, and have been denied." said Tom Martin, River Runners Co-Director. "We are amazed that the park would exclude the interested public, as the issues discussed directly affect all river runners. Excluding the public is a disservice to all river runners. Spouses, trade association representatives, river guides, warehouse managers and Native American tribal representatives are all allowed to participate, but the public is turned away."

RRFW has learned that the November topics discussed included a review of river accidents, including Norovirus illnesses, increases in river concessions rates, patrol trip contacts and frequency, availability of rescue helicopters, along with appropriate ways to contact the NPS during river incidents. Other topics included a Phantom Ranch Update on duffel service for river passengers and other Ranch improvements, cultural resource issues presentation, Colorado River Fund project review, and a review of the Cooperative Resource Conservation Program. This program uses river concessions to provide access to the canyon for scientists via chartered commercial river trips.

The group was informed the NPS would not discuss the Colorado River Management Plan, and one attendee was noted to say "We're not going to ask questions, since they cannot be answered." Park Service staff did read material aloud that is posted on the Park web site.

Representatives of the Hualapai Nation reviewed an incident between a concessions guide and non-concessions Hualapai guides at Diamond Creek. This incident resulted in the closure of the Diamond Creek take-out to all non-Hualapai activities between the hours of 7:00 am and 10:00 am daily. When asked by a concessioner whether there was the potential to coordinate use rather than have such a large daily prohibition of use, Hualapai representatives were optimistic that some sort of agreement could be scheduled between the concessionaires and the tribe. "It would be great if the non-commercial river runners could schedule with the Hualapai as well" noted Martin. "We will continue to seek cooperative ways to work with Grand Canyon National Park so that in the future the interested public will be able to attend these important meetings.

A Colorado River Sediment Inventory

THE CONFLUENCE
Journal of Colorado Plateau River Guides
Issue #27, December 2003

Updated Report

The presentation cited below is a compilation of scientific data from reports written by government scientists.

Included in this presentation are reports to Congress by Authur Powell Davis and Frank Weymouth from the Bureau of Reclamation.

A very comprehensive study on sediment in Lake Mead reservoir was conducted by the USGS in 1948-49 and published in 1960 as Professional Paper #295. This paper set the standard for the study of sedimentation in large reservoirs that has yet to be repeated.

Subsequent studies, but limited in scope, have been accomplished such as the 1986 Lake Powell Survey by the Bureau of Reclamation, and an excellent report was written by Edmund D. Andrews of the USGS, Sediment Transport in the Colorado River Basin,

which was published in 1991 by the National Academy of Sciences. Unfortunately, the collection of data for sediment was discontinued by the USGS in 1989.

Two points of climate history must be considered when reviewing this data: 1) sediment loads vary considerably due to changes in climate regimes; 2) since the construction of Hoover Dam, additional reservoirs have been added to the plumbing system, which are collecting sediment independently throughout the entire basin. Incidentally, all river sections between dams have had their sediment loads reduced.

The government scientists who studied the sedimentation of Lake Mead in 1948 were actually alarmed at the rapid accumulation of sediment in that reservoir. To mitigate the problem, and to their chagrin, they recommended the building of upper basin dams. Though this provided more longevity for Lake Mead, it essentially spread the sediment problem to more than one place and effectively increased future mitigation costs substantially. This demonstrates the mismanagement of water resources in the Colorado River basin, which can be summarized best as stealing the future to gain the present.

What the studies indicate is that sediment transport in the main stem of the Colorado River has been significantly reduced since 1942 because of a noticeable change in climate that demonstrates a waning of flash flood activity in the basin.

This does not necessarily mean that natural erosion on the Colorado Plateau is at rest. More likely, sediment is being stored in the arroyos of the basin and waiting for threshold events to transport their loads into the Colorado River, and subsequently into mainstem reservoirs such as Mead and Powell.

For example, a flood with a peak discharge of 140,000 cfs roared through San Juan Canyon below Mexican Hat, Utah in October 1911. It is just a matter of time before similar flood events mobilize many decades worth of sediment from arroyos and send huge plugs of sediment into Lake Powell.

A sediment management plan must be conducted in the very near future by the Bureau of Reclamation. This study must not only evaluate the sediment of all the mainstem reservoirs of the Colorado River and its tributaries, but it must also evaluate the storage of sediment in all the ephemeral arroyos, especially where soft Mesozoic rocks dominate the landscape such as the basins of the San Juan and Little Colorado rivers.

It must also determine the effects that sediment will have on dam safety, power generation, water storage, recreation, and the management of endangered species.

How Much Sediment Are We Talking About?

According to E. D. Andrews' very reasonable estimate, which was published in 1990, there are 44,400,000 tons of sediment arriving into Lake Powell reservoir on a yearly basis under the current climate regime. A truck pulling a street legal load has a carrying capacity of 22 tons. In one year, it would require 2.018 million truck loads to remove the annual sediment load of Lake Powell. That is 5,529 truck loads per day; 230 loads per hour; 4 loads per minute.

This scenario demonstrates very well the costs and impacts involved in solving the sediment problem of reservoirs. It also destroys the myth that federal dams are cost-effective and that hydropower is a renewable resource.

Water Resources: As the West Goes Dry

By Robert F. Service

In a region already prone to water shortages, researchers now forecast that rising temperatures threaten the American West's hidden reservoir: mountain snow

MOUNT BACHELOR, OREGON-- Under the dome of a concrete-gray sky, Stan Fox assembles four pieces of aluminum tubing into a 3-meter-long hollow pipe. After standing it on end, he plunges it through more than 2 meters of snow at Dutchman Flat, an alpine meadow perched on the shoulder of this 3000-meter mountain. Fox, who heads the Oregon snow-survey program for the U.S. Department of Agriculture's Natural Resources Conservation Service (NRCS), removes the tube and reads the snowpack depth, a measurement that has been tracked at nearby sites monthly since the 1930s. Today the snow is 250 centimeters deep, and by comparing the weights of the tube both filled and empty, Fox and a colleague determine that the snow contains about 30% liquid water. If all the snow were instantly liquefied, the water would be nearly 1 meter deep. Not too bad. In a region prone to spikes in precipitation, Dutchman Flat is more than 15% above its 30-year average. "The snow in these mountains is a virtual reservoir," Fox says. As the snow melts in the spring and summer, it will slowly release that water, filling streams and reservoirs, which provide lifeblood to the region during the normally bone-dry summer months.

But indications are that this age-old cycle is beginning to change. New assessments of decades' worth of snowpack measurements show that snowpack levels have dropped considerably throughout the American West in response to a 0.8°C warming since the 1950s. Even more sobering, new studies reveal that if even the most moderate regional warming predictions over the next 50 years come true, this will reduce western snowpacks by up to 60% in some regions, such as the Cascade Mountains of Oregon and Washington. That in turn is expected to reduce summertime stream flows by 20% to 50%. "Snow is our water storage in the West," says Philip Mote, a climatologist at the University of Washington (UW), Seattle, who leads a team that has produced much of the new work. "When you remove that much storage, there is simply no way to make up for it."

The impacts could be profound. In the parched summer months, less water will likely be available for everything from agriculture and hydropower production to sustaining fish habitats. Combined with rising temperatures, the dwindling summertime water could also spell a sharp increase in catastrophic fires in forests throughout the West. With much of the current precipitation headed downstream earlier in the winter and spring, the change is also likely to exacerbate the risk of floods.

For resource managers already struggling to apportion limited water supplies throughout the West, the predictions are grave. "If that's true, it would have a huge impact," says Christopher Furey, a policy analyst with the Bonneville Power Administration in Portland, Oregon, which markets electricity from over a dozen power-generating dams in the Columbia River Basin that provide power to millions of people. In a region where farmers, fishers, recreationalists, and municipalities already compete for water, climate change may be setting the stage for an entirely new round of conflicts. "We think of the water wars in the past," says Fox, referring to the epic battles over rerouting western waters in the early 20th century. "In the future they will probably be more peaceful but much more prevalent."

Too Wet, Too Soon

The root of the problem is easy to state: The semiarid West has too little water, spread too unevenly throughout the year. Most of Montana sees less than 46 centimeters of precipitation a year. Even rainy Portland receives only about one-tenth of its annual 91 centimeters of precipitation during the summer. For most of California the fraction is even smaller. Philadelphia, by contrast, typically receives 102 centimeters of annual precipitation, 30% of which comes in the summer.

Thanks to massive dam-building in the first half of the 20th century, more than 60 million people--roughly one-fifth of the U.S. population--now live in the Pacific and Intermountain West. Those tens of millions of people are dependent not just on water, but on snow. Snowmelt makes up 75% of all water in streams throughout the West. If that snow falls as rain or melts too early, there will be little water left in the virtual reservoir come late summer and fall. Unfortunately, that is just what appears to be happening.

Back down the mountain in a conference room at a small ski resort outside Bend, Fox and a collection of about 50 water experts from the Northwest settle in to listen to Mote describe some of his group's latest data on western snowpacks. Perhaps fittingly, outside the temperature has warmed up on this mid-January day to about 5°C. Icicles encircling the roof drip steadily.

Mote describes work published last year in *Geophysical Research Letters*, in which he took a detailed look at the trend in snowpack accumulations throughout the Pacific Northwest over the last half of the 20th century. Mote reviewed federal records of snow water equivalents (SWE)--the amount of water in a given depth of snow--on 1 April, typically the peak of the season's snowpack. Of the 230 sites where SWEs were measured back to the 1950s, Mote found that nearly all showed negative trends, even as precipitation increased in most places. The hardest hit: areas in the Cascade

Mountains in Oregon and Washington, which saw as much as 60% declines in total snow accumulation. The most likely explanation, Mote says, was the region's temperature rise. When he plotted the snowpack declines against the elevation of the snow-tracking sites, he found that the biggest decreases occurred at the lowest elevations, suggesting that the moderate warming throughout the region was raising the freezing level.

That's just the beginning. In work presented last month at the American Meteorological Society meeting in Seattle, Washington, Mote teamed up with UW Seattle colleague Alan Hamlet and University of Colorado, Boulder, hydroclimatologist Martyn Clark to expand his initial analysis to look at historical snowpack levels throughout the West (see righthand figure). The news was better, but not much. Snowpacks decreased at 85% of the nearly 600 snow-measurement sites throughout the West. The biggest decreases hit the Northwest, where the mountains are smaller and the temperatures warmer, thanks to their proximity to the Pacific Ocean. Declines in the northern Rockies were mostly in the range of 15% to 30%. In these inland areas, Clark points out, winter temperatures are typically far lower than in the Pacific Northwest, so a rise of a few degrees still does not push the mercury above freezing. "In the interior regions all the winter precipitation falls as snow," Clark says. And some regions in the Southwest even witnessed large SWE increases, thanks primarily to a rise in precipitation.

Other clues also suggest that the West's snowpack is changing. The biggest: Snow is melting earlier in the spring. "There has been a fairly broad tendency in snowmelt basins to exhibit advances in runoff timing," says Daniel Cayan, a climate researcher at the Scripps Institution of Oceanography in La Jolla, California. Last month, Cayan, postdoctoral assistant Iris Stewart, and Michael Dettinger, a hydroclimatologist with the U.S. Geological Survey (USGS) in San Diego, reported in *Climatic Change* that the peak of the annual spring runoff in streams throughout California's Sierra Nevada now comes as much as 3 weeks earlier than it did in 1948 (see lower figure). Again, the effect was most pronounced in streams adjacent to lower elevation snow that is more sensitive to temperature increases. "This is very consistent with the evidence Phil [Mote] and company have seen with the snowpack," Cayan says. In a paper now under review at the *Journal of Climate*, Clark and colleagues at the University of Colorado recently found much the same shift for streams in the Northwest. "There is definitely something happening," Clark says.

That evidence is further bolstered, Cayan points out, by records that track the first springtime blooms of flowers such as honeysuckle and lilac, which show a similar 1- to 2-week advance. "This is a totally independent measure and one that is quite strongly related to temperatures in the springtime," Cayan says.

Not everyone is yet ready to believe that these trends will continue. George Taylor, the state of Oregon climatologist and a climate researcher at Oregon State University in Corvallis, for example, argues that broad trends in temperature and snow accumulation over the past century are most likely due to natural multi-decade swings as the climate oscillates between periods of relative warm and cold temperatures. "There was significant warming in the 1920s, '30s, and '40s, cooling in the '50s and '60s, and

warming again from the 1970s through '90s," Taylor says. "In my opinion, the effects of human-induced global warming are small compared to the multi-decadal cycles."

Greg Johnson, a climatologist with NRCS in Portland, also points out that Mote typically starts his analysis of snowpack trends at the beginning of the 1950s, which saw some of the largest snow accumulations over the past century. "If you use those numbers, you will show large decreases," he says. Decadal swings in climate caused by El Niño and the Pacific Decadal Oscillation, he adds, further muddy the numbers.

"I'm not saying it's a nonissue, just that we need to keep watching it closely," Johnson says. "The point is, if you look at the historical record, we've seen some warming and drops in low-elevation snowpack. The question is what can we tie it to. But from a planning standpoint, I think people have to be concerned about this."

Mote agrees that the trend data may be skewed to some degree by the high-snow years of the early 1950s. However, he says, before the 1950s there were so few snow measurement sites that earlier data are suspect. Furthermore, he says, the snow loss is still best explained by the region's modest warming. "The thing that really stands out is that the largest losses are at the lowest elevations, which can only be explained by warming," Mote says. As for whether this warming is best explained by the decade-long climate swings, Mote defers to the latest work by the Intergovernmental Panel on Climate Change (IPCC), the global body of hundreds of scientists that has assembled the "standard model" of climate change. Although IPCC's latest report does show that both natural and human-induced factors explain portions of the last century's global temperature record, climate models that take both into account do the best job at reproducing the complete temperature record.

Dry Times Ahead?

No matter what the historical picture, Mote, Cayan, and others argue that the picture for western snowpacks looks far more bleak when the anticipated future warming is taken into account. Here, too, several teams have been working to understand how events are likely to unfold. All agree there is considerable uncertainty. Precipitation trends, for example, "are all over the map" in different climate models, because precipitation can vary drastically over a short distance, Mote says. However, Mote, Cayan, and others agree that climate models generally do a far better job of estimating temperature, because temperature differences drive winds that tend to reduce those differences. Regional climate models suggest that over the next 100 years, western temperatures are likely to rise between 2° and 7°C, depending on—among other factors—the rate of increase of greenhouse gases in the atmosphere. And unlike the precipitation forecasts, the models all show an increase in temperature.

Modelers then feed these temperature data and other variables into another set of computer programs called hydrology models that compute the effects of changing climate on snowpack and stream runoff. And these hydrology models consistently show that even low-end temperature changes produce big effects. As part of a study described in last month's issue of *Climatic Change*, for example, UW Seattle hydrologist Dennis Lettenmaier and colleagues used a global climate model to compute

how the western snowpack would respond to modest temperature increases. They found that a temperature rise of 1.5°C by 2050 resulted in a loss of nearly 60% of the 1 April snowpack in the Oregon and Washington Cascades, and a 3°C rise by 2090 reduced those snowpacks by 72% (see figure). "That's the best-case scenario," Mote says. "By the 2090s with a warm scenario, you would have essentially no snow left in Oregon by April 1st." When the Pacific Northwest is taken as a whole, the picture is only a bit better, showing a 35% loss in 1 April snowpack by the 2050s and 47% loss by the 2090s.

In a *Geophysical Research Letters* paper last year, Cayan and former postdoc Noah Knowles--now with USGS in Menlo Park, California--computed a similar analysis for the watersheds that make up the western drainage of California's Sierra Nevada Mountains. They found that a predicted temperature rise of about 2.1°C over the next century would reduce the Sierra snowpack by one-third by 2060, primarily at mid to low elevations, and would halve it by 2090. A separate analysis by L. Ruby Leung and colleagues at the Pacific Northwest National Laboratory in Richland, Washington, together with researchers from the National Center for Atmospheric Research in Boulder, Colorado, and Scripps reached similar conclusions when they looked at the effect of climate throughout the West. The one notable difference: In the Rockies, the colder wintertime temperatures are expected to limit the losses to 30%. Without putting too much faith in the exact amount of losses, Mote says, "it's nearly inescapable that we're going to continue losing snowpack."

"Enormous Impacts"

"It doesn't mean we've lost water," Cayan hastens to point out. "It means the water is coming off earlier." Rather than sticking around as snow into the late spring and summer, western snowpacks will wash down mountainsides in the winter and spring. Simply stated, the upshot is wetter winters and drier summers.

In the Sierras, for example, Knowles and Cayan's models predict that the portion of water that flows through the watershed's rivers from April through July each year will decline from 36% today to 26% by 2030. "This represents over 3 km [3 billion cubic meters] of runoff shifting from post-April 1 to pre-April 1 flows," the authors write. That figure nearly doubles by 2090. Other studies show that parts of the Columbia River Basin are likely to fare worse, whereas the Colorado River watershed, with smaller anticipated declines in snowpack and generally colder temperatures, is likely to emerge comparatively unscathed. Overall, however, a steady temperature climb will likely affect tens of millions of people. "There are enormous impacts from this potential change," Cayan says. "Water management in the West has been to use the snowpack as a natural reservoir. This reservoir is really important. It's water that will come later when a lot of the water demand is heaviest." Without that water "people will need to make some difficult choices," adds Todd Reeve, who directs watershed restoration programs for the Bonneville Environmental Foundation in Portland.

That's particularly true in the Pacific Northwest and California. Reservoirs in the Columbia River Basin capture only about 30% of the region's annual runoff, whereas

California's reservoirs hold slightly more. The typical pattern is to fill these reservoirs with late spring runoff and use that water throughout the summer and fall for irrigation and then in the early winter for power generation. An earlier snowmelt means that the water must be spread over a longer dry season when irrigation, recreation, and municipal demand peaks. "You're losing natural storage and taxing built storage. Something has to give," Lettenmaier says. (Here too, Lettenmaier says, the Colorado River Basin is unique, because reservoirs there can store four times the region's annual precipitation.)

With less summertime water, one of the hardest hit areas is likely to be agriculture. Today, farmers in California use about 75% of the state's water. Earlier this month, agricultural economists Wolfram Schlenker of the University of California, San Diego, and W. Michael Hanemann and Anthony Fisher of UC Berkeley presented a preliminary study at the American Economic Association meeting in San Diego of the likely impacts of climate change on California agriculture. Using a range of hypothetical climate and stream-flow scenarios in line with published modeling results, the researchers forecast that snowpack losses could lower farmland values by more than 15%. If that pattern holds for the state's 3.84 million hectares of irrigated farmland, the loss to the state's agriculture economy would be measured in the billions of dollars.

What is more, Fisher says, because access to irrigation water in California depends on the historical system of first-come, first-served water rights, those losses will likely be absorbed primarily by the farmers lowest on the water-rights totem pole, driving many out of business. That same pattern is likely to hold true in the Northwest, particularly in the dry lands east of the Cascades. "It's not going to be feasible to have the irrigated acreage we have now," Mote says--fighting words in a region long wedded to an agricultural way of life.

Forests are also likely to suffer, according to Anthony Westerling, a climate researcher at Scripps. Westerling recently fed data from Cayan and Knowles's climate and hydrology models of the Sierras into a model of his own that attempts to forecast changes in wildfires. Westerling says his preliminary results show that fire danger will soar. "The mean area burned more than doubled by 2090" relative to the present, Westerling says.

Although less easily quantified, low summertime stream flows are also expected to exacerbate problems with declining fish runs, crimp water supplies for recreation and cities, and increase the likelihood of winter and springtime flooding throughout the Northwest and California. But not all the impacts are sure to be bad. Last year, John Fazio, a river flow analyst with the Northwest Power and Conservation Council in Portland, plugged some of the UW group's hydrology forecasts into his Columbia River flow models and found that a warmer Northwest may actually benefit Northwest electricity consumers. Warmer winters, Fazio says, will likely lower the need for electricity during the region's peak demand period, and an expected small increase in wintertime precipitation could churn generators to the tune of an extra 1900 megawatts of power--nearly enough to power two cities the size of Seattle. Of course, if

precipitation swings toward the dry side, it could wind up costing rate payers hundreds of millions of dollars, he says.

No matter how the climate evolves, water managers will face uncomfortable tradeoffs between providing water for agriculture, hydropower, and recreation, and keeping it in streams to support fish runs. In their current Climatic Change paper, for example, Lettenmaier and colleagues show that to keep summertime flow levels in the Columbia River high enough to support endangered-fish recovery plans, water managers will likely have to sacrifice 10% to 20% of the river's wintertime hydropower generating capacity, because it will force water managers to draw down their reservoirs in the summer. "Even with these reductions in power, late-summer minimum flows would still be lower than at present," the authors write.

More Big Dams?

In a region prone to water shortages, talk of such tradeoffs doesn't go down easy. "We already have a problem with shortages," says Maury Roos, chief hydrologist for the state of California. And coming up with the water to deal with population growth throughout the region is already an acute problem, he adds. "This will certainly make the problem worse."

In hopes of heading off some of those problems, Roos and other water officials are beginning to incorporate climate change into their regional water plans. California's latest draft water plan, for example, discusses climate change, although it doesn't yet recommend changing California's infrastructure. Portland, Seattle, and other cities have begun studying the issue in detail to see whether they need to change their water-management plans.

Initial rumblings are also being heard among advocates for building new dams throughout the West. That comes as something of a surprise to many, because during the Clinton Administration, then-Secretary of the Interior Bruce Babbitt claimed that the era of big dam building was over, due to their adverse impacts on fish and wildlife. Already, for example, California is considering building several new dams as part of a joint state and federal effort to provide water for threatened ecosystems while keeping water available for farmers. Washington too is flirting with building a dam at a cost of more than \$1 billion in the eastern part of the state to provide irrigation water for farmers near Yakima. And Idaho water managers say that climate change may force them to build new reservoirs to prevent winter floods along the Boise River, where one-third of the state's inhabitants currently live.

But due to their high dollar and environmental costs, many water experts doubt whether such projects will go forward. "Dams are tough fights and so expensive," says Hal Anderson, planning chief for the Idaho Department of Water Resources. And even if built, they will only soften the blow. With the amount of spring snow expected to be lost due to climate change, "there is no way we're going to build that many dams to capture it all," Mote says.

Other strategies may help. Most water officials agree that there is much that can be done to conserve water, particularly by lining irrigation canals and making other improvements to irrigation. As well, a handful of new programs have sprung up recently to buy or lease water rights from farmers and then keep the water in stream during the low-flow months to improve habitat for fish. Last year, for example, one umbrella effort called the Columbia Basin Water Transactions Program sponsored 32 such deals to keep 28.4 million cubic meters of water in tributaries where it's needed most. That amount of water pales in comparison to what stands to be lost. But for now, water planners still have some time to act before climate change alters the American West in a way humans have never witnessed.

Take Action 02/20/04

Demand New Study on Glen Canyon Dam Operations To Save Grand Canyon, Again!

On March 3-4, the Department of Interior will convene a meeting in Phoenix of the Glen Canyon Dam Adaptive Management Working Group. Open to the public, the agenda will be to discuss the future operating plans for Glen Canyon Dam so as to mitigate the dam's impacts on the Colorado River in Grand Canyon National Park.

Unfortunately, like its 15 previous gatherings over the past eight years, this meeting may accomplish little more than pandering to hydropower interests, while endangered fish in Grand Canyon's famed river ecosystem continue to go extinct. Please join Living Rivers in attending and helping to reverse this.

Top on their agenda is a plan to launch an Environmental Assessment for the installation of proposed temperature control devices on Glen Canyon Dam's water intake structure. Since completion, Glen Canyon Dam has been releasing water into Grand Canyon that is consistently about 48 degrees. Grand Canyon's native fish, however, are used to varying water temperatures that often approached 80 degrees. While a mechanism to warm the water is critical to recovering Grand Canyon's native fish, this device may not be the best choice, and its operation could actually bring remaining native fish species closer to extinction by promoting the proliferation of alien fish that feed on young native fish.

Living Rivers and others will be arguing that a full Environmental Impact Statement (EIS), as opposed to the much narrower and fast-tracked Environmental Assessment must be prepared. This EIS should investigate all potential alternatives to warming the water, including decommissioning the dam. Living Rivers will also argue that this EIS must address a range of "new" information not known when Glen Canyon dam's first EIS was completed in 1996, as is called for by the National Environmental Policy Act when programs such as the AMP demonstrate failure.

Glen Canyon Dam has ravaged Grand Canyon's river corridor, rendering it devoid of much of the life that frequented it when the Park was established. No longer can otters

or muskrats be found. Four of eight native fish are gone, as are all native insects. The dam's cold water releases, trapping of 95 percent of the sediment and nutrients that fed the ecosystem, and unnatural flow regime have made it increasingly difficult for the Canyon's native species to survive.

The AMP was charged with reversing this, but during its tenure the Razorback Sucker has become the fourth endangered fish species to disappear from the Canyon and another, the Humpback Chub, is now headed to be the fifth.

Forty years ago the public rose up and stopped the construction of two proposed dams in Grand Canyon to help preserve this natural wonder. It's now time to save this famed river ecosystem again.

Join us: Wednesday, March 3, 9:30 am – 5:00 pm Thursday, March 4, 8:00 am - noon

Moab Groundwater Report

On March 8, 2004, 7 p.m., Kip Solomon and Phil Gardner of the University of Utah presented their findings on the hydrology of the Matheson Preserve shallow and deep aquifers, the underlying strata revealed by cores from wells drilled 150 feet deep, and water consumption. These findings, detailed below, oblige us to call into question two geohydrological models upon which governmental decision-making is being based:

1. The geohydrological model used by the Department of Energy in evaluating the environmental impacts of the Atlas uranium tailings pile reclamation options. In summary, Solomon and Gardner's data indicate that (A) a highly saline head of water is coming under the Atlas tailings, crossing under the river, and moving well under the Matheson in a deep aquifer flowing through alluvial gravel which is still present at the maximum depth of 150 feet cores were taken; (B) in these gravels next to the portal, at a depth of 24 feet carbon materials test as less than 100 years old and at 35' as 900 years old; (C) below the top 15-18 feet of silty river alluvial deposits, indicating slow water movement, the next 135' of gravels are all flood-scoured with no silty lenses, indicating recurring flood velocities capable of carrying rocks up to fifteen inches in diameter. It is physically impossible to have a bedrock "choke" at the portal and also have these flood velocities immediately upstream of it where current DOE models predict a stillwater lake forming during flood events.

2. The Downs & Kovacs water budget model for the Glen Canyon Group pristine groundwater aquifer: the assumption in that model that the production of the Glen Canyon Group aquifer is 13,300 acre-feet per annum and 9,530 acre-feet of that production is flowing underground down Spanish Valley and discharging into either the

Matheson Wetlands or the Colorado River. In summary, Solomon and Gardner's data indicate that (A) they can account for only about 3,204 acre-feet of groundwater consumed in the Matheson by vegetation and evaporation; (B) they cannot find any outflow into the Colorado River through the Matheson from Spanish Valley in the shallow aquifer; (C) the chemical signature on the water in the Matheson does not match that of the Glen Canyon sandstone aquifer discharge, but instead appears to be "young" water from surface precipitation, irrigation outflow, and shallow flow from Mill and Pack Creeks. At most, 1,000 acre-feet of the Matheson water budget seems to come from the Glen Canyon aquifer, and its location indicates it is from Watercress and Skakel Springs behind the Grand Old Ranch House. (D) the flow in the deep aquifer under the Matheson preserve south of the Colorado River is highly saline water flowing under the river from the north; the center of the plume of saline water corresponds to the Moab Wash and Moab Fault orientation north of the river. In short, of the 9,530 acre feet of Glen Canyon aquifer outflow which is supposed to be flowing into or under the Matheson Preserve from the Spanish Valley valley fill aquifer, 8,530 acre-feet of it cannot be found. There are only two possible explanations for this:

Hypothesis 1: There is a deep gravel "drain" below 150 feet depth which is carrying water out of the Spanish Valley valley-fill aquifer under the Matheson and then beneath the surface water of the Colorado through the portal. There are currently no monitoring wells of sufficient depth to detect this "drain" if it exists.

Hypothesis 2: The water budget for the Glen Canyon sandstone aquifer is around 4770 acre-feet per annum, not 13,300 acre-feet per annum. If this is true, we are close to diverting the entire available output of this aquifer with the existing permitted water rights for the City of Moab and Grand Water Conservancy District culinary wells, and cannot develop more production from this aquifer to support future development.

I will discuss more detail of Solomon and Gardner's findings, and what we need to do in light of them, below.

In addition to Solomon and Gardner, attending the meeting were Sue Bellagamba of the Nature Conservancy; Jeff Freethey and Pat Lambert of the USGS; Laura Kamala of the Grand Canyon Trust; Barbara Morra of the Spanish Valley Water and Sewer Improvement District Board; Richard Lance Christie, Grand County Water Planning Administrator; and Dr. LaRue Christie.

In the Downs and Kovacs water budget (2000), sources of water into the Spanish Valley aquifer system were 13,300 acre-feet outflow from the Glen Canyon sandstone aquifer, 730 acre-feet from precipitation in Spanish Valley, and 3,300 acre-feet leakage from Ken's Lake (this figure includes aquifer recharge from Pack Creek flow). This inflow was accounted for by 6,400 acre-feet diverted and consumed by culinary and irrigation uses; 1,400 acre-feet surface stream flow and vegetative evapotranspiration in Mill and Pack Creeks; and 9,530 acre-feet discharge into the Matheson/Colorado River at the foot of the valley. The 13,300 and 9,530 acre-feet numbers were estimates of low reliability; the other numbers are relatively certain.

In other regional water studies, reliable water budgets have only been established through accurate measurement of discharge from an aquifer system. For a variety of technical reasons, it is very difficult and expensive to accurately measure inputs into aquifers.

The Glen Canyon Group sandstone aquifer water has a geochemical "fingerprint" - low in tritium (<1), R/Ra helium isotope ratio <1 , and stable isotope content indicating the water went into the aquifer at high elevations under cold conditions. The water in the Matheson wetlands in the shallow aquifer is high in tritium (3.1, 2.6, 15, 5.9, 4.7 were typical values in various test wells), has a high R/RA ratio, and does not contain the stable isotopes indicating high elevation, cold conditions at entry into the ground. There is a "plume" of water more like the Glen Canyon water on the NE side of the Matheson which I observe corresponds to the outflow of the Watercress and Skakel spring discharge.

Diane Pataki studied sap flow in cottonwoods in the Matheson under various salinity conditions. They ended up mapping five salinity zones in the Matheson: unhealthy Tamarisk (extremely saline), healthy Tamarisk, unhealthy native, healthy native vegetation, and open water/water vegetation. Evapotranspiration rates were calculated for each zone based on the vegetation there and the sap flow data. Saline conditions across the zones ranged from <1000 microSeimens/cm to over 3,000 average. Evapotranspiration is half that in 3,000 than in 1,000 saline. Total evapotranspiration/evaporation calculated was 3,204 acre-feet per annum.

The wells drilled to 150 feet depth encountered 15-18 feet of silty alluvium (indicating deposition by slow water) followed by cobbles and boulders to the 150 foot depth. There is a sharp transition between the top silty alluvium layer and the cobbles and boulders layer. There are no silty lenses in the cobbles and boulders, which can only have been deposited by swift-flowing current capable of carrying boulders to 15" size routinely. Wood was recovered from cores at 24 feet and 30 feet depth in the BL14 well just upstream of the portal and well back from the current edge of the river. The 24' sample was less than 100 years old and the 30' sample was 900 years old. This tells us that the river has repeatedly flooded at high velocity through an area 1.5 kilometers wide above the portal, and that the current has been swift enough to move 15"+ boulders as well as smaller cobbles, while carrying away anything smaller than about one inch in diameter. This flood cobble zone extends under the Atlas tailings and most of the Matheson. These floods have repeatedly occurred within the last thousand years - in other words, within historic times, and during them the river was scouring to at least 30 feet below today's surface. Since the same flood cobble and boulder formation extends to at least 150 feet depth, this means that the river was scouring at least 150 feet below its current bottom THROUGH THE PORTAL. If the portal had a bedrock sill, as the DOE hydrological models maintain, then the river could not scour below the top of this sill because the sill would slow down the flow of floodwater below the plane of the sill.

Re capping the Atlas tailings in place, with rip-rap armor to protect the cap against erosion from river flood, this kind of water velocity and scouring would make such armoring useless. Why? Because the river cuts down during flood events, and would

undermine the armor and the tailings themselves, causing them to slough into the spate. It would make no difference if the rip-rap was composed of cement-filled greyhound buses; they would still roll off into the flood undercut. Kip Solomon said in light of these findings, leaving the tailings in place "should not even be on the table." As Moab mining engineer Mel Swanson said in 1989, the decision to cap the tailings in place is a decision to put the tailings into the Colorado River; Swanson said it would be cheaper and more honest to shove the tailings into the Colorado with bulldozers for eight years during high water. The environmental effect would be the same as capping in the long run. Solomon's findings confirm Swanson's observation.

The flow of water towards the Colorado is shallow. In the deeper hydraulic system in these cobbles, the water is highly saline, and the head is coming from the north (Moab Wash and Fault align with the center of the saline plume) under the river. As it comes under the Atlas tailings, the uranium concentration rises in a tongue which extends across the river in this saline water. The saline plume is fairly stagnant, so the uranium picked up from Atlas leachate is limited in its extent south of the river so far. Oxygen isotope "fingerprinting" of this water indicates it is not originally derived from either Mill Creek surface or Glen Canyon aquifer waters.

These findings underscore (1) the unfeasibility of a capping-in-place alternative for the Atlas tailings remediation. I've been dealing with this issue since 1989, and every bit of the geohydrology used by Atlas, the NRC, and now the DOE has turned out to be dead wrong. This appears to be yet another chapter in this sorry history. (2) the need to get a good study of the water budget of the Glen Canyon sandstone aquifer done so we know how much water can be supplied to culinary use by it.

LR Letter 03/01/04

Aspinall Unit/Gunnison River EIS Scoping Comments

March 12, 2004
Mr. Ed Warner
Bureau of Reclamation
Western Colorado Area Office
2764 Compass Drive, Suite 106
Grand Junction, CO 81506

RE: Scoping Comments for Environmental Impact Statement for the Aspinall Unit of the Gunnison River

Dear Mr. Warner:

Living Rivers and the Colorado Riverkeeper appreciate this opportunity to submit the following scoping comments on the proposed Environmental Impact Statement (EIS) for

the Aspinall Unit. Our organization collectively represents thousands of individuals from across the United States with an interest in the future of the endangered native fish species and ecological communities of the Colorado River basin, which includes the Gunnison River.

We wish to thank the Bureau of Reclamation (Bureau) for recognizing the seriousness of the plight of the four endangered native fish of the Colorado River basin: the Colorado pikeminnow (*Ptychocheilus lucius*), razorback sucker (*Xyrauchen texanus*), bonytail chub (*Gila elegans*), and humpback chub (*Gila cypha*).

There is wide agreement within the scientific community that dams in the Colorado River basin, including the Aspinall Unit on the Gunnison River, contribute significantly to the degradation of riverine habitat necessary for the survival and flourishing of these species. As builder and operator of many of these structures, the Bureau has a special responsibility to address issues related to the decline and potential extinction of these four federally listed species.

We understand that the Bureau is undertaking this EIS in response to proposed flow criteria established by the Upper Colorado River Endangered Fish Recovery Program (UCREFRP) pursuant to consultation with the US Fish & Wildlife Service under Section 7 of the Endangered Species Act (ESA). The Bureau is required to consider in an EIS, under the National Environmental Policy Act (NEPA), a range of alternatives that reasonably and practically fulfill the purpose and need of the proposed government action.

In our comments below we address some of the considerations necessary for a comprehensive EIS, including:

- o Issues pertaining to the current operation of Aspinall Unit and reservoirs;
- o Critical areas of analysis, including the need to incorporate decommissioning as a potential alternative; and
- o Issues demonstrating the need for the Bureau to undertake a programmatic EIS for endangered species recovery for its activities throughout the Colorado River watershed.

I. ASPINALL UNIT OPERATIONAL ISSUES

A. Endangered Fish

The operation of Aspinall Unit has been known for many years to cause harm to native fish. The introduction of a successful fishery for non-native trout in the tail waters of the Aspinall Unit is testament to the conditions existing downstream that make the river inhospitable for native species which require warmer water for successful spawning and survival. The reservoirs trap vital sediments and woody material (carbon for the food web) behind the dams, thereby preventing replenishment of the silt, sand and nutrients. The dams form reservoirs, which have no fish passage structures and are also managed as a recreational sport fishery for several non-native species known to prey

on endangered natives. Conditions are marginal at best for endangered fish survival in the reservoirs and downstream environments created by the Aspinall Unit.

B. Water Supply

Aspinall Unit is operated as a water storage facility, part of the Colorado River Storage Project which includes Glen Canyon Dam on the Colorado River in Arizona, Navajo Dam on the San Juan River in New Mexico, the Flaming Gorge Dam on the Green River, and others. The Upper Colorado River Endangered Fish Recovery Program goals, as stated, include providing for "future water development." Reservoir evaporation can be significant, especially in warmer months, resulting in less water available for downstream uses, including instream flows for endangered fish. Furthermore, water conservation, not development, must become the Bureau's strategy for meeting future supply needs. Also, agriculture must begin to use their water more efficiently and, at the same time, become more productive by growing crops that are less water-intensive, such as alfalfa. These two factors require leadership from the Department of the Interior (DOI), which is presently lacking. Overall, we find Aspinall Unit's role for water supply purposes not sufficiently significant enough relative to the facility's impacts on endangered species and the alternatives available to fulfill water supply for human uses.

C. Hydroelectric Power Generation

Aspinall Unit was designed to produce hydroelectricity incidental to the primary function of water storage and flow regulation. The average output of the Aspinall Unit at 819 GigaWatt hours is but a small portion of the region's overall generating capacity. Any loss of hydropower from the Aspinall Unit would be relatively insignificant and could be made up through implementation of energy conservation policies and developing new technologies that are truly sustainable. In other words, hydropower loss is not as important an issue as is our consumption in lieu of conservation of natural resources, which includes native fish, and our lack of leadership as a nation to find power sources that are truly renewable and environmentally responsible.

It appears unlikely that the Basin Fund will ever fully repay the US Treasury for the loans provided to build the water projects of the Colorado River basin, because costs and losses associated with sediment mitigation alone will eventually exceed the Fund's capacity for repayment. It makes more sense for the Bureau to provide a complete long-term cost analysis of its hydropower production, as it compares to the mitigation costs of the future. We are confident that the cycle of public-supported subsidies related to Colorado River development will never be broken otherwise.

D. Recreation

The dams provide a local recreation industry centered primarily on sportfishing and motorboating. As noted in I.A. above and II.B. below, the introduction of non-native species to support sportfishing has impacted native endangered species. Motorized watercraft can contribute to water quality problems that also need to be taken into account.

E. Aspinall Unit and the Colorado River Basin

As noted in I.B. above, Aspinall Unit is a unit of the Colorado River Storage Project. In addition to the CRSP dams in the upper basin, an extensive system of dams exists in the lower basin, including Hoover Dam on the Nevada-Arizona border, and several smaller yet important water supply dams on the river between California and Arizona. The river exits the United States south of Yuma, Arizona, where the once-vibrant Colorado River delta ecosystem has been decimated, converted into an alkali flat polluted by agricultural pesticide and fertilizer runoff.

Water delivery contracts for the Upper Basin are structured pursuant to the Upper Colorado River Basin Compact. The compact has never been subjected to NEPA analysis.

Contracts for the lower basin are subject to allocation by the Secretary of the Interior, pursuant to the terms of the Colorado River Compact (passed into law as the Boulder Canyon Project Act in 1928), which led to implementation of basin wide water planning and allocation ever since. Thus the operations of Aspinall Unit are integrally connected to the operations of the CRSP, the Upper Basin Compact, and the Colorado River Compact/Boulder Canyon Project Act. Therefore its impacts are also tied to this larger system, and as described in item III. below, must be appropriately addressed.

II. CRITICAL AREAS OF ANALYSIS TO BE ADDRESSED IN THE EIS

A. Effects of Dam Operation on Black Canyon of the Gunnison National Park

The Bureau must consider the effects of Aspinall Unit operations on Black Canyon of the Gunnison National Park. The National Park Service is required by the National Park Service Organic Act to protect the Park's natural features, ecological communities, streams, and native species, and to leave them unimpaired for future generations.

Aspinall Unit has caused many documented negative effects on the Gunnison River ecosystem downstream of the dam and in the Park. For example, the dam's cold water releases have for years impaired the native fish stocks. In addition, the absence of floods and sediment has negatively affected stream morphology characteristics important for native fishes.

Alternatives presented in the EIS must ensure compliance with National Park Service laws and regulations that provide for protecting the Gunnison River ecosystem and its native fish. The Bureau should analyze each alternative in light of expected effects on Black Canyon's natural features and aquatic communities, especially on listed endangered species, sensitive species, and species of special concern. The EIS should explain in detail the impacts of the dam's past and present operations on Black Canyon. It should also show how future operations will impact park resources and natural regimes of sediment transport and distribution, depositional patterns, streamflow, temperature, riparian ecosystems, native plant communities, and native fish populations within the park. Finally, the EIS should explain in detail how operations at the Aspinall

Unit should be managed so as to ensure compliance with the non-impairment provision of the Organic Act.

B. Removal of Non-Native Fish Which Prey on Endangered Fish

For years the state and federal governments have operated Aspinall Unit and other dams in the Colorado River basin to promote and enhance sportfisheries and related recreation activities. In the reservoirs and downstream in the tailwaters, government policies have increased the numbers and habitat conditions suitable for non-native species such as trout which are known to prey in significant numbers on endangered native species. The Bureau must address the detrimental effects on endangered fish species, sensitive species, and species of special concern, caused by non-native species, and provide alternatives in the EIS that eliminates such predation, both in the reservoirs and in the tailwaters.

C. Endangered Species Recovery Goals at the Critical Habitat Level

The extensive system of dams and diversions throughout the Colorado River basin fragments and artificially isolates endangered fish populations. Historically, regulators have responded to declining populations of these species by attempting to formulate management criteria that fail to question the fundamental circumstances contributing to the endangerment in the first place. The US Fish and Wildlife Service and the Bureau have chosen to address endangered fish recovery by first declaring isolated populations to be distinct, then proposing recovery plans which fail to address the factors causing the isolation in the first place.

Some or all of the endangered Colorado River fish species are known to be migratory. In addition, evidence exists that the interruption of fish migration by construction of dams in the basin has had a detrimental effect on fish recovery. Within the EIS, the Bureau must evaluate the potential effects, including genetic health and reproductive success, on recovery of fish, including listed endangered species, sensitive species, and species of special concern, that are no longer isolated between dams.

For example, the single greatest threat to the critical habitat of endangered fish is Glen Canyon Dam because the Colorado, Green and San Juan rivers all terminate into Lake Powell reservoir. The genetic connectivity of the three basins has been effectively eliminated and has also isolated the native fish from their historic diversity of habitat; habitat that native fish require for both spawning and the rearing of their young according to their natural heritage. This includes reaches of river habitat that provide floodplains, gravel bars, sandbars, deep pools, massive eddies, and etc. These types of diverse habitats have been largely removed from the basin's ecosystem. Glen Canyon Dam has negatively impacted over 500 miles of diverse habitat, including Cataract Canyon, Narrow Canyon, San Juan Canyon, Glen Canyon, Marble Canyon and Grand Canyon. Glen Canyon Dam also diminishes the ability to have a productive food web in these river reaches because nutrients and woody material is now stored uselessly in the sediment deposits of Lake Powell reservoir.

Therefore, a programmatic EIS that analyzes the dysfunction of the critical habitat in the entire basin is a more productive means to recover critical habitat than a piece-meal approach to reaches immediately downstream of the Aspinall Unit, Navajo Dam, Flaming Gorge Dam and Glen Canyon Dam.

D. Water Quality and Recreational Impacts

In recent years, a rapid rise in recreational use of motorized has resulted in increases of petroleum effluent in reservoirs and streams, such as Curecanti National Recreation Area. The EIS must quantify current and future trends in petroleum discharges from recreational watercraft, and address the potential impacts of these compounds on native endangered fish species. The EIS should analyze one or more alternatives that consider the effects of declining water quality on listed endangered species, sensitive species, and species of special concern. Finally, the EIS should consider alternatives, which implement greater restrictions or outright prohibitions on motorized watercraft, and other polluting machinery.

E. Dam Decommissioning Alternative

The Bureau must incorporate into its EIS alternatives which evaluate the potential for decommissioning (e.g., breaching, removing, or disabling) Aspinall Unit and allowing the Gunnison River to flow freely once again. Decommissioning is the most ecologically effective and economically efficient alternative for addressing the purpose and need of the EIS, namely recovering endangered native fish species. Most environmental impacts of dams cannot be adequately mitigated, e.g. loss of sediment deposition and nutrient composition downstream of the dam, and reduction of frequency and intensity of flood events. And as attempts to do so become more costly, complicated and ineffective, agencies such as the Federal Energy Regulatory Commission and the Army Corps of Engineers are now turning to decommissioning as a preferred alternative for habitat restoration and species recovery. The Bureau should also consider decommissioning alternatives amongst its recovery options.

The Bureau is obliged to consider a decommissioning alternative even if the implementation of such an alternative would be beyond the scope of the agency's discretion, so long as it is reasonable and practical.

36 CFR 219.12(f)(5). Reasonable alternatives which may require a change in existing law or policy to implement shall be formulated if necessary to address a major public issue, management concern, or resource opportunity identified during the planning process.

40 CFR 1502.14(a-c). Alternatives including the proposed action. This section is the heart of the environmental impact statement. ... In this section agencies shall:

(a) Rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated.

(b) Devote substantial treatment to each alternative considered in detail including the proposed action so that reviewers may evaluate their comparative merits.

(c) Include reasonable alternatives not within the jurisdiction of the lead agency. ...

The Council on Environmental Quality (CEQ) addresses this question in the following excerpt from its "Forty Most Asked Questions Concerning CEQ's NEPA Regulations, 23 March 1981":

Question 2a. Alternatives Outside the Capability of Applicant or Jurisdiction of Agency. If an EIS is prepared in connection with an application for a permit or other federal approval, must the EIS rigorously analyze and discuss alternatives that are outside the capability of the applicant or can it be limited to reasonable alternatives that can be carried out by the applicant?

Answer. Section 1502.14 requires the EIS to examine all reasonable alternatives to the proposal. In determining the scope of alternatives to be considered, the emphasis is on what is "reasonable" rather than on whether the proponent or applicant likes or is itself capable of carrying out a particular alternative. Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using common sense, rather than simply desirable from the standpoint of the applicant.

Question 2b. Must the EIS analyze alternatives outside the jurisdiction or capability of the agency or beyond what Congress has authorized?

Answer. An alternative that is outside the legal jurisdiction of the lead agency must still be analyzed in the EIS if it is reasonable. A potential conflict with local or federal law does not necessarily render an alternative unreasonable, although such conflicts must be considered. Section 1506.2(d). Alternatives that are outside the scope of what Congress has approved or funded must still be evaluated in the EIS if they are reasonable, because the EIS may serve as the basis for modifying the Congressional approval or funding in light of NEPA's goals and policies. Section 1500.1(a).

Given the increasing attention other federal and state agencies are not only paying to the examination of decommissioning alternatives, but selecting them as the preferred alternative, such an alternative in the case of Aspinnall Unit does meet the definition of "reasonable" and "practical" under NEPA.

III. PERFORM A PROGRAMMATIC EIS ON COLORADO RIVER BASIN DAM OPERATIONS AND WATER MANAGEMENT

Problems facing endangered fish on the Gunnison River and elsewhere in the basin are not likely to be solved solely by addressing impacts associated with Aspinnall Unit. Federal policy has too often chosen to view isolated, remnant populations of endangered fish as if they were and always will be isolated, ignoring the purpose and goals of the ESA—to restore viable, healthy populations throughout the species' range. The problems that lead to fish endangerment are not easily resolved at the micro level and must also be addressed from a watershed perspective.

The Bureau is currently engaged in a number of projects, studies, and current and potential litigation that collectively have and will continue to have a significant cumulative impact on these endangered species, including the following examples but not limited to:

1. Lower Colorado River Multiple Species Conservation Plan (LCRMSCP) for endangered fish and wildlife;
2. Adaptive Management Program for Glen Canyon Dam operations pursuant to the Grand Canyon Protection Act;
3. Upper Colorado River Endangered Fish Recovery Program for endangered fish;
4. San Juan River Basin Recovery Implementation Program
4. EIS for Navajo Dam (San Juan River) operations;
5. EIS for Central Arizona Project water allocations;
7. San Juan-Chama Diversion Project (recovery of the silvery minnow);
8. EIS for Flaming Gorge Dam (Green River) operations;
9. Proposals for new pipelines which would withdraw water from Navajo Reservoir and Lake Powell Reservoir;
10. Litigation by Indian tribes, seeking additional water rights or quantification of existing rights.
11. State of Colorado proposed water projects: AB Lateral, Dominguez Dam, and the Colorado Return Aqueduct Project ("Big Straw")

Council on Environmental Quality regulations require the Bureau to address those ongoing agency actions that relate to the proposed action. Since there are numerous NEPA actions underway within the Colorado River watershed which affect water use and allocation and endangered species management, the Bureau must therefore discuss and consider in the context of the Aspinall Unit EIS these other actions. 40 CFR 1501.7(a)(5). Furthermore, even if the impacts of each of these actions are to be analyzed separately, they still must be tiered to a larger programmatic EIS. 40 CFR 1508.28, 1502.20.

It is unclear whether the Bureau can adequately address long-term needs of the fish throughout the basin in the context of these individual projects. It is also unclear how the Bureau will ensure that the cumulative impacts of all these efforts will work together to guarantee, and not impede, recovery.

The Upper Colorado River Basin Compact has had a profound effect on the management, use, and allocation of water in the upper basin, including the Gunnison River. The compact controls all river operations, facility operations, and contracts. In the context of this EIS, the Bureau must look at alternative ways to implement the compact

in order to minimize effects on aquatic ecosystems, including endangered native fish species, sensitive species, and species of special concern, and to ensure compliance with water quality regulations under the Clean Water Act. Given the constraints of the compact, the Bureau must also consider modifications or changes to the compact that would contribute to the recovery of the affected endangered species, other sensitive species and species of concern, and achieve the purpose and need of the proposed action. As discussed in II.E. above, the Bureau is not constrained by existing laws or contracts in formulating and evaluating alternatives.

Given the extensive amount of federal activity within the Colorado River watershed, much of which directly addresses and/or affects endangered species, a comprehensive programmatic EIS covering the entire basin is not only warranted but also sorely needed. Historically, such an approach is not unprecedented for the Bureau to consider. A programmatic EIS for the Colorado River basin would provide for the multitude of issues affecting endangered species to be addressed in a comprehensive fashion. And as outlined in II.E above, such an EIS must evaluate dam decommissioning as an alternative.

The Bureau's operations of its dam and water diversion systems on the Colorado River have had massive and far-reaching environmental impacts, yet have never been the subject of an EIS. Were such an EIS to exist, it would inform the Bureau, other federal agencies, states, tribes, and the public on all aspects of the Bureau's operations and its "off-river" impacts from the continuing urbanization in the basin states that is able to occur only because of the continued supply of water, or at least the expectation of a continued supply of water, from the Colorado River.

While the construction of the dam system predated the passage of NEPA, the operations and management of the river have changed dramatically since Aspinall Unit and other dams were built—substantial activity, which can no longer be considered "grandfathered in" under NEPA. Such actions include the transfer of water from Imperial Irrigation District (IID) to San Diego, the development of off-stream banking, major increases in water consumption, additional water diversions, and the uses of the water diversions and supplies. These changes have altered the character and impact of river management to the extent that now any Bureau activities must trigger a NEPA process. "[When] an ongoing project undergoes changes which themselves amount to "major federal actions, the operating agency must prepare an EIS." *Upper Snake River v. Hodel*, 921 F.2d 232, 235 (9th Cir. 1990); see *Andrus v. Sierra Club*, 442 US 347, 363 n.21 (1979).

As a result, the present NEPA analysis will need to be much more comprehensive in order to compensate for the lack of pre-existing NEPA analysis and baseline information. Note here that the environmental baseline of NEPA encompasses impacts to additional aspects of the human environment—socioeconomic, environmental justice, recreation, cultural resources, wildlife and its habitat for non-sensitive species, air and water pollution—not included in the ESA environmental baseline of impacts to endangered species and critical habitat. The action to be analyzed in the scoping

notice, as well as the new actions mentioned above, would require changes in operations, which have never been analyzed in the first place.

In conclusion, we find the Bureau's initiative to address endangered fish below Aspinall Unit is an important exercise. However, we fear that unless the Bureau approaches this undertaking in the full spirit contained within the ESA and NEPA, that such an effort will be unable to guarantee species recovery. We have outlined assessment methodologies above that we believe will avoid such an eventuality, and look forward to working with the Bureau and other relevant agencies to ensure their appropriate incorporation into the current EIS process for Aspinall Unit.

Thank you for the opportunity to submit these comments and recommendations, and we look forward to your reply.

Sincerely,

John S. Weisheit
Living Rivers Conservation Director
The Colorado Riverkeeper

LR Press Release 03/03/04

Groups Demand Action to Halt the Extermination of Endangered Species in Grand Canyon

For immediate release

Contact: John Weisheit (435) 259-1063

Cell: (435) 260-2590

Environmentalists Demand Urgent Action to Halt the Extermination of Endangered Species in Grand Canyon National Park.

A coalition of national and international environmental groups blasted the Department of Interior today for ignoring mounting scientific and public policy evidence that a once highly touted federal river management program is failing to halt the continued loss of endangered species in Grand Canyon National Park.

In a [ten page letter](#) presented at the semi-annual meeting of the Glen Canyon Dam Adaptive Management Program (AMP) in Phoenix, Arizona, the groups charge that despite eight years and \$80 million dollars, one more of Grand Canyon's endangered fish species, the razorback sucker, has joined the growing list to become extinct in the Grand Canyon. Another endangered fish species, the humpback chub, has declined to only 1,100 fish from 8,000 in 1993.

"Their job is to comply with the law and to bring these fish back. Instead, they are merely engaged in pseudo-science in an effort to mask the gravity of the situation," says John Weisheit, director of Living Rivers' Colorado Riverkeeper program, which is

leading the coalition. "Touting new, unverified fish counts, while ignoring the evidence that regardless of the new numbers, the decline is headed toward zero. This is a huge injustice to our national park system, not to mention the endangered fish."

The Glen Canyon Dam Adaptive Management Program was established in 1995 following the completion of an Environmental Impact Statement which recommends strategies to mitigate the tremendous impacts of Glen Canyon Dam's operations on the river ecosystem in Grand Canyon National Park.

The letter reveals that these recommendations are often being ignored, and even when adhered to, they are not achieving the intended results.

In the event that endangered fish populations did not increase by 1998, water released from Glen Canyon Dam was supposed to shift toward a regime of at least partially mimicking the river's natural flow. This has not occurred.

- * A special set of flow recommendations for low water years was prescribed, but despite five years of drought, these recommendations have been ignored.

- * The program has spent much of its resources attempting to conserve Grand Canyon's remaining sediment, as 95 percent of the Canyon's sediment and nutrients have been trapped behind the dam. These efforts have all failed to bring any lasting benefit to fish habitat or stabilization of cultural sites as called for by the EIS.

- * Recent attempts to use dam operations to control alien fish predation on endangered native fish have been haphazard and have yet to demonstrate any meaningful results.

"As originally designed, the Adaptive Management Program was an excellent approach to addressing the serious impacts on Grand Canyon from this dam," adds David Haskell, retired Science Center Director for Grand Canyon National Park, who participated in the AMP program since its inception in 1995 and has monitored its progress since his retirement. "However, the 2002 AMP Report to Congress clearly indicated that six years of effort had not produced any beneficial results. Since then, the failure of the AMP to seek more effective methods to meet the goals of the Grand Canyon Protection Act has turned this once successful program into a dismal failure. The science done by this program in the past has been very good, but unless the decision makers involved in the AMP immediately seek to make the needed program adaptations, the serious decline of the river ecosystem in the Grand Canyon will continue."

The groups are calling for immediate changes to the program, beginning with and a new federal Environmental Impact Statement. The National Environmental Protection Act allows for such a study when new information and results reveal that the recommendations from a previous EIS to be inadequate.

"It's critical that a new EIS be completed before the AMP launches into its new scheme for installing a temperature control device on Glen Canyon Dam," says Michelle Harrington with the Center for Biological Diversity. "It was once thought that attempts to bring the Colorado River's water temperature to a level more consistent with native

conditions would be a simple proposition. The drought has taught us that disruptions to the food supply for the remaining endangered fish could be further disrupted, besides the fact that much of that food supply is being consumed by the growing number of alien fish. Temperature controls as well as the added impact of drought on management plans must be studied in a comprehensive manner before any such action is taken."

Previously, the AMP program has resisted efforts to undertake a new EIS, in part because Glen Canyon Dam proponents understand that such an EIS will have to explore the possibility of decommissioning Glen Canyon Dam as the best way to comply with the laws protecting the ecosystem in Grand Canyon's river corridor.

"Interior's actions paint a clear picture of disregard for the Grand Canyon Protection Act, Endangered Species Act, and National Park Service Organic Act," adds the Executive Director of the Waterkeeper Alliance, Steve Fleischli. "Why must the public always be forced into the courtroom in order to protect a piece of our famed natural heritage from government malfeasance? That needs to change."

LR Letter 03/03/04

Letter to AMP calling for SEIS on Glen Canyon Dam

March 3, 2004
Michael Gabaldon
Deputy Director of Operations
Bureau of Reclamation, Building 67
6th and Kipling
Denver, CO 80225-0007

RE: Supplemental Environmental Impact Statement for the Operations of Glen Canyon

Dear Mr. Gabaldon,

Living Rivers, Colorado Riverkeeper, American Whitewater, Arizona Wilderness Coalition, Bluewater Network, Californians for Western Wilderness, Center for Biological Diversity, Colorado Plateau River Guides, Escalante Wilderness Project, Friends of the Animas River, Friends of Arizona Rivers, Friends of the Earth, Friends of the River, International Rivers Network, Outdoor Adventure River Specialists, Inc., Tag-A-Long Expeditions, Inc., River Runners for Wilderness, Southern Utah Wilderness Alliance,

Waterkeeper Alliance and Wilderness Watch are extremely concerned about the failure of the Glen Canyon Dam Adaptive Management Program (AMP) to mitigate sufficiently the adverse impacts of the operations of Glen Canyon Dam on the Colorado River ecosystem in Grand Canyon National Park.

The most recent AMP report, submitted to Congress in 2002, and subsequent scientific conclusions clearly indicate that the AMP has made little progress in meeting the mandate of the Grand Canyon Protection Act (GCPA). Nor has the AMP met the goals established in the 1995 Environmental Impact Statement (EIS) for Glen Canyon Dam, the Record of Decision (ROD), the Biological Opinion that analyzed the environmental impacts of Glen Canyon Dam, nor subsequent objectives set by the AMP itself.

The AMP has failed because the original EIS has inappropriate limitations, the AMP administrative process is ineffective, and the AMP lacks responsible leadership from the agencies of the Department of Interior (DOI): Bureau of Reclamation (BOR), National Park Service (NPS), US Geological Survey (USGS) and US Fish and Wildlife Service (USFWS). Unless these fundamental deficiencies are corrected, the dedicated efforts of all involved will continue to fail to restore the ecosystem in Grand Canyon National Park.

At the same time, scientific evidence shows that the AMP can not succeed in meeting program goals while constrained by the limitations set by the current EIS. It is evident that unless additional, more effective management options are implemented, the AMP serves only the purpose of documenting the decline of the Grand Canyon river ecosystem. Thus, more than enough evidence exists to require the immediate preparation of a supplemental environmental impact statement (SEIS), to examine in detail and anew the impacts of Glen Canyon Dam based on the significant failures of the present efforts and the myriad of changed circumstances that affect the Colorado River system.

Since the release of the ROD in 1996, it is almost certain that the razorback sucker has joined the growing list of endangered species that have become extirpated in the Grand Canyon ecosystem. Grand Canyon National Park now faces the extirpation of yet another endangered species, the humpback chub. The ROD specifically foresaw the need for the recovery of this native fish, as well to establish a second population of humpback chub and to reestablish a population of the razorback sucker. Yet, scientific evidence indicates that neither objective will occur. The humpback chub's alarming decline and the failure to reinstate the razorback sucker tops a growing list of new scientific information that was not available or known when the 1995 EIS was completed.

Based on past failures, new information and new realities, which we detail below, the Bureau of Reclamation, together with her sister DOI agencies, is obligated to undertake the process dictated by the National Environmental Policy Act [NEPA] in relationship to the operation of the Glen Canyon Dam. According to the regulations implementing NEPA: "agencies **shall** prepare supplements to either draft or final environmental impact statements if: (i) the agency makes substantial changes in the proposed action that are relevant to environmental concerns; or (ii) there are significant new

circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts." 40 C.F.R § 1502.9(c) (emphasis added).

Here, the dramatic decline of the humpback chub, the extirpation of the razorback, the failure of the BOR and the AMP to abide by the terms of the Biological Opinion and to meet the goals of the Grand Canyon Protection Act, and the wealth of new information relevant to the recovery of these species and their habitat combine to require such a supplement.

Listed below are the primary areas of concern:

1. The AMP has failed to improve sediment balance that drives the physical ecological component of the ecosystem

New data collected since the EIS was completed confirms that the EIS needs to be modified to address sediment below Glen Canyon Dam. This is because the scientific community studying the native fish and involved in the recovery of these species, know far more about sediment dynamics than in 1992 when the EIS was developed. A core element of the ROD and the relevant Reasonable and Prudent Alternative (RPA) requires that BOR mitigate the impacts caused by the fact that sediment no longer enters Grand Canyon's river ecosystem. The plan required that experiments be conducted to conserve sediment in the ecosystem of the Colorado River. The first experiment took place in 1996 with subsequent attempts in the year 2000. In each case, efforts failed to produce permanent benefits of preserving beaches, stabilizing cultural sites, and enhance critical habitat conditions as intended. The report to Congress and all supporting sediment research since concludes that net sediment loss from the ecosystem will continue to occur. Natural sediment inputs, combined with organic nutrients, is a fundamental pre-dam ecosystem components necessary to sustain native fish species. Returning to peak-power flows, in a weak attempt to reduce rainbow trout spawning success, will likely accelerate further the rate of sediment loss.

There are other adverse environmental impacts of sediment loss below Glen Canyon Dam not previously anticipated. The continued loss of sediment and inability to regularly enhance beaches has brought about a change in NPS management strategies concerning cultural resource protection in the river corridor. While NPS policies favor the preservation of archeological sites *in situ*, the BOR now finds it necessary to consider immediate salvage operations to save what remains of sites threatened by further beach erosion. This will add federal costs to the program and increase tribal concern for these remnants of ancestral origin. These immediate and vital remedies were not considered in the original EIS.

The sobering conclusions regarding the inability to improve sediment resources have brought about discussions on how to augment sediment inputs in addition to reducing outputs. Any attempt to import sediment into the ecosystem below Glen Canyon Dam will be very costly and is not evaluated in the current EIS. In light of the inability to conserve sediment and meet Lower Basin water allotments as planned, options for improving the sediment and nutrient budget to benefit native fish and cultural sites must be explored in a SEIS.

2. The AMP is non-compliant with the Endangered Species Act and USFWS program recommendations

A. Razorback Sucker

The Biological Opinion uses urgent language to call for specific improvements of critical habitat for the humpback chub and the razorback sucker by 1998. The document states, "If the [Fish and Wildlife] Service determines a study design can not be developed that is expected to provide information to support removal of jeopardy to the razorback sucker and humpback chub populations in the Grand Canyon and associated tributaries, **such will be considered new information and may be grounds for reinitiating formal consultation.**" (p. 35) (emphasis added)

Considering that a live, adult razorback sucker has not been observed in Grand Canyon for the last few years, many senior scientists believe that the razorback sucker has been extirpated from the Colorado River in Grand Canyon National Park. The lack of response to respect performance criteria gives ample evidence that jeopardy has not been removed, and is sufficient ground for reinitiating formal consultation and the NEPA process immediately.

B. Humpback Chub

Monitoring by the USGS through the Glen Canyon Monitoring and Research Center (GCMRC), has documented a major and alarming decline in humpback chub population. Since 1995, when the EIS was completed, the adult humpback chub population in the Little Colorado River has declined by 50 percent. Two years ago the GCMRC scientists estimated that the population could be as low as 1,100 fish. In April of 2003, the USFWS reported, "Results of this ongoing study indicate that despite low catch rates of nonnative fishes in the Little Colorado River, humpback chub continue to decline and that aging adults are not being replaced in the spawning population." (Sponholtz, Pam and Randy Van Haverbeke)

It is undisputed that there has been a major decline in the population of adult humpback chub. Some federal scientists have recently argued that while humpback chub numbers have indeed declined, the present population is stabilizing. Yet, these scientists present no evidence to support this assertion. Privately, some of the same scientists are also saying that extirpation for humpback chub is quite likely. In any case, both this rate of decline and the low absolute number of fish, constitute a vastly different humpback chub assessment than was assumed in developing the original EIS, and the steps necessary for humpback chub recovery.

Furthermore, there has been no progress made in establishing a second viable population of humpback chub in Grand Canyon as mandated by the ROD. Nor has a Management Plan for the Little Colorado River been implemented to protect the critical habitat of the humpback chub from pollution, reduction of instream flows, or truncation of their habitat due to unforeseen geologic events such as debris flows or landslides.

The RPA states that if sufficient progress is not made to remove humpback chub and razorback sucker jeopardy by 1998, then Seasonally, Adjusted Steady Flows (SASF) must begin at Glen Canyon Dam. This has not occurred. Additionally, the RPA also stated that in low water (drought) years, dam releases should be regulated using the SASF alternative. This, too, is not occurring.

As razorback sucker and humpback chub recovery efforts represented one of the cornerstones of the original EIS process, this new information, combined with the information we are presenting, constitutes ground to start a SEIS process.

3. Persistent drought conditions are likely to further complicate achieving program goals and are not being adequately considered or addressed

The Colorado River watershed is experiencing a fifth year of significant drought. Many climatologists are forecasting multidecadal drought conditions for the basin due to the occurrence of oscillating sea surface temperatures. This has already dropped the water level in Lake Powell reservoir by 113 feet to 44 percent of storage capacity. While specific flow recommendations were prescribed in the RPA for low water years, no assessment of management options has been conducted to address the impacts of sustained drought on achieving GCPA goals.

The reduced elevation of Lake Powell reservoir has already stimulated changes in water quality and the aquatic environment below the dam. The river's temperature has increased about 2° C, which is changing the dynamics of the food web and increasing the rates of colonization by exotic species such as the New Zealand mud snail. This particular alien species was discovered in the ecosystem after the ROD was signed. As the surface of Lake Powell reservoir continues to drop nearer to the penstocks, new pathogens, parasites and other exotic species are likely to invade the ecosystem in Grand Canyon and complicate the conservation of endangered native fish. Elevated temperatures raise questions about how this may affect alien fish populations and this predation threat to endangered humpback chub.

Furthermore, more water development projects for the Upper Basin are now being considered to fully deplete the already over-allocated waters of the Colorado River. Drought, consumptive loss, and synergistic effects of these two elements were not considered in the EIS. Predictions confirm that due to factors such as drought and over-appropriation, low levels will become the norm, rather than the exception, for Lake Powell reservoir. As a result, the BOR and her sister agencies must revisit its review the environmental impacts of Glen Canyon Dam and update the analysis to account for this new development.

4. New information relating to implementation of a temperature control device has not been addressed

The drought situation has led to an increased concern over the unforeseen impacts associated with increased water temperature flowing into Grand Canyon from Glen Canyon Dam. While the original ROD encouraged managers to direct efforts to achieve warmer water temperatures to improve native fish recruitment, the EIS did not address

in any detail the full range of impacts associated with such experiments. In 1999 uncertainty surrounding these impacts caused the BOR to shelve its plans to install a temperature control device (TCD) for Glen Canyon Dam's penstocks. Only the threat of legal action associated with the declining humpback chub population has resurrected the proposal. Although in 2003 the AMP Science Advisory Panel recommended full TCD testing and possible construction, along with flow modification and extensive research/monitoring, DOI has taken no action until just recently and even then, the agency suggested a program that is much downscaled. The Environmental Assessment for the proposed TCD is not adequate because of incidental take and other critical habitat factors for humpback chub that has changed since the implementation of the ROD.

Another concern surrounding the TCD involves the impact of the parasitic Asian tapeworm, which could proliferate and heighten the potential of disease for the humpback chub. Since the Asian tapeworm was not discovered in the ecosystem until after the ROD, it too constitutes new information to be addressed in the SEIS.

Certainly, some of the risks associated with the TCD could be overcome by incorporating other operational strategies, such as importing sediment into the system to disadvantage hunt-by-sight predators, and by initiating a periodic spike flow. These were not addressed in the original EIS, and therefore will also need to be incorporated into the SEIS process.

5. Credibility of the AMP science program is in question

A central component of the original AMP design was the development and administration of an independent, peer-reviewed science program. This program would carry out unbiased scientifically credible studies to inform the AMP's decision-making process. A small science staff (less than 12) was to administer the program through the competitive bidding process and to award research contracts to the most competent bidder. Both the bidding process and final reports were to be peer-reviewed to assure quality and non-biased reporting. The GCMRC, the science management component of the AMP, is now operating much differently than established in the original guidelines set for this administrative component of the USGS. The science staff is very large and most programs are being done in-house with no independent peer-review.

Prior to the EIS the Glen Canyon Dam Environmental Studies program was seriously criticized by the National Research Council for this same failure to meet accepted methods to assure scientific credibility. An independent review of the current AMP science program would reveal a loss of integrity and standing when the GCMRC model was abandoned in favor of what currently exists today in the GCMRC.

At a time when the Grand Canyon is about to lose another native fish species, the AMP is cutting back on scientific work, seemingly at the request of the Western Area Power Administration, whose hydropower revenues are used to fund the science. The research for the 2000 Low, Summer Steady Flow (LSSF) represents one example of how the AMP science program has been affected. First, the experiment was fast tracked, with limited opportunity for outside input or competitive bidding for the monitoring. Pre-experiment flow data was not compiled and therefore the design of the experiment may

not have been properly formulated. Scientists did not start collecting data on the river until after the first spike flow occurred. Although the design of the experiment was released for the competition, the one proposed by the contractor was not accepted. Also, this experimental flow was originally proposed to benefit native fish with relatively low, steady flows in accordance with the Biological Opinion, but the final experiment allowed for less than the recommended time.

The original EIS assumed that experimentation and recovery efforts would be achieved with firm attention paid to proper scientific protocol and management of public funds toward endangered species recovery in Grand Canyon National Park. This is not occurring. In fact the opposite is occurring. The AMP has enacted budget reductions and caps without supplemental funds to adequately maintain and preferably improve monitoring and research in Grand Canyon National Park. Finally, AMP is not providing adequate management leadership while the USGS/GCMRC is not contributing credible independent data required by the mandates prescribed by the ROD, RPA and subsequent charters and guidelines. Together, these factors warrant immediate preparation of an SEIS.

6. Inability of the AMP decision-making process to address fundamental resource recovery requirements is limiting progress

The ROD called for the establishment of the AMP as a stakeholder group to advise the Secretary of the Interior on implementation of Grand Canyon programs. The application of the ROD is the sole responsibility of the AMP. The AMP has been, and continues to be, controlled by the water and energy groups, groups whose self-interest is to avoid long-term change from the status quo. These groups necessarily are not ultimately dedicated to the protection and recovery of the Colorado River and the native fish it should support.

While the make-up of the group has provided for a bias toward representing water and energy interests, it was anticipated that the program's mandate to mitigate downstream impacts of dam operations would ensure that sufficient attention would be given to the needs of the resource. This has not occurred, as exemplified by the failure to undertake RPA programs, the decline in humpback chub, the extirpation of the razorback sucker, continued loss of essential sediment, and accelerated degradation of archeological sites. A key reason for this continued program failure is that the AMP decision-making process continues to demonstrate a clear bias toward minimizing loss of hydropower. Also, the AMP evades recommendations that would create legal conflicts between the Organic Act, Endangered Species Act, NEPA and even GCPA. The workings, the make-up and the ineffectiveness of the AMP must be reevaluated in the SEIS.

Evidence to support prejudice for one resource over another recently occurred when the trout population suppression flows were modified in a fast-track manner without proper consultation or due process within the AMP. Moreover, the current Sunday flow regime has proved to be inadequate for true trout suppression and demonstrates the concerns over hydropower prejudice for efforts to conserve endangered species. There has also been a recent suggestion for a flow regime of 5,000 to 25,000 cfs for year 2005. These

proposed flows, the environmental impacts of which have never been addressed, are outside the range prescribed for the conservation of natural and cultural resources by the ROD and the Biological Opinion.

Flow experiments, especially those designed to benefit humpback chub recruitment have been of limited duration, and as such generated inconclusive results. Results of the LSSF were inconclusive because data was neither collected prior to initiating the flows nor afterwards. In this particular experiment the flow was not timely, or sufficient enough for the food web to adjust and respond. The RPA recommended, "experimental flows will be conducted for a sufficient period of time to allow for experimental design, biological processes to function, and for variability inherent in riverine ecosystems to be expressed" (p. 36).

Overall, the AMP is failing to achieve GCPA goals because the ROD and subsequent program design do not allow for meaningful adjustments in key, aquatic ecosystem elements. The program continues to focus on treating the symptoms of ecosystem decline rather than what is actually causing the decline. In other words, the habitat is in dramatic decline and the AMP is doing nothing meaningful—is failing to make any hard choices—to bring the habitat closer to pre-dam conditions. These critical ecosystem elements are well documented and include:

- A. Natural hydrograph that would redistribute sediment during the spring run-off and stimulate native fish spawning.
- B. Natural thermograph with warmer summer water temperatures and colder winter temperatures.
- C. Annual inputs of sediment, nutrients and woody debris to create generally turbid water conditions.

Again, these failures underscore the need to take a renewed look at a process that has not served the Colorado's native fish and has not followed the guidelines, recommendations and requirements set forth to achieve recovery of these species.

7. Our concerns for the First Nations

The AMP has not fully engaged the process that threatens their cultural and natural heritage in Grand Canyon. They have also been given a minimal amount of resources to monitor their cultural properties in Grand Canyon. This is a violation of the trust that was developed with the tribes during Glen Canyon Environmental Studies and is allowing the government to continue to minimize the value of these tribal resources.

8. Recommendations

Based on the above, the following steps are legally required as part of the effort to protect and restore native fish and their critical habitat to the Colorado River below Glen Canyon Dam.

A. The AMP must immediately recommend to the Secretary of Interior that preparation of a SEIS to assess the environmental impacts of the operation of Glen Canyon Dam begin within six months.

B. A SEIS could take several years and there are a number of interim actions the AMP must take, both in terms of science and in the operations, to help impede the further decline of natural and cultural resources in the Grand Canyon while we await a new ROD.

C. Because the SEIS could take several years the AMP must undertake interim actions within six months to help forestall the further decline of natural and cultural resources in the Grand Canyon until a new ROD is issued.

1. Reorganize the AMP to be proactive so that it is comprised of only the responsible agencies and sovereigns: BOR, NPS, USFWS, and the Tribes. (Participation by other stakeholders would be available through public process as explained below in #2.)

2. Require the AMP meet twice a year with a 30-day comment period prior to each meeting. This program would use interactive communication and video technology that was not available during the 1996 EIS process and would provide for more stakeholders to be heard.

3. Reorganize GCMRC to be an administrative organization outside of the DOI. This would remove or militate against agency bias and shortcomings, and be a positive step toward a truly independent science organization. Competition and protocol development should follow NPS guidelines for science activities within national parks.

D. Humpback Chub population and habitat monitoring

All reports and analyses by the AMP have focused on humpback chub numbers, and not the relative condition of the fish or health of the critical habitat. This must change. While some of this data has been collected, there has not yet been any ongoing analysis on the condition factors of the humpback as recommended by the USFWS. Additionally, factors relevant to habitat such as feeding habits, water quality, age class, genetics, and recruitment and migration patterns for all periods of the humpback chub's life span need to be documented. The new AMP must also determine the population level and changes in biological parameters that would trigger a cessation of handling humpback chub so as to avoid incidental take on the remaining population.

E. Follow the Biological Opinion for the Humpback Chub and the natural river hydrograph

As a baseline, all flow decisions should be evaluated by how well they mimic the natural hydrograph. So far, the AMP has ignored this fundamental principle of river ecology. Without it there will likely be no hope of establishing a second population for the humpback chub, or of restoring its critical habitat as called for in the RPA and required by law. AMP should continue intensive alien fish suppression at the Little Colorado River reach.

F. Expand the critical habitat throughout the Grand Canyon, including the tributary streams and the Glen Canyon reach.

G. Develop a scientifically sound monitoring program that extends current non-GCMRC programs through the SEIS process so continuity of ecosystem data sets is achieved. These data sets should be linked with water quality, lower and higher trophic levels, riparian vegetation and beach sand monitoring. GCMRC monitoring programs should be delegated to past or present contractors for one year and then all contracts should be opened for competitive bidding under the new AMP and the SEIS. If these contractors do not want the work then the Grand Canyon Science Center will conduct the monitoring as protocols dictate.

H. Initiate a comprehensive, cultural site degradation abatement program throughout the entire river corridor in accordance with NPS standards.

G. Initiate development of a River Management Plan for the Little Colorado River as called for in the RPA.

In conclusion, the Grand Canyon is treasured by the citizens of the world and the natural values that make up this spectacular place must not be compromised any further. We urgently request serious and immediate action to address these matters. We look forward to receiving a detailed response to this letter explaining the steps you will take to further the goals of the Grand Canyon Protection Act, the Biological Opinion and RPA, NEPA, and the protection and recovery of the Colorado's endangered native fish and their critical habitat, as is required by law. Thank you in advance for your efforts to meet your statutory obligations.

Take Action 03/07/04

Save Grand Canyon Native Fish: Demand EIS on the proposed temperature control device at Glen Canyon Dam

The last of Grand Canyon's native humpback chub are headed toward extinction, and the department of Interior is attempting to fast-track a controversial experiment that could kill what's left. Letters are urgently needed to ensure that a full environmental impact statement is prepared, and a sound recovery plan is developed for Grand Canyon's deteriorated river habitat.

On March 3 the Department of Interior began a 30-day scoping period for an Environmental Assessment (EA) to consider the feasibility of installing a temperature control device (TCD) at Glen Canyon Dam, Arizona to study the potential benefits of warming the temperature of water released from the dam to the downstream Colorado River through Glen and Grand Canyons.

First proposed in 1998 and scrapped in 1999, the temperature control device will take water from the warmer (upper) level of Lake Powell reservoir, as opposed to the reservoir's cooler (lower) elevations for turning the turbines that generate electricity.

Since completion in 1963, Glen Canyon Dam has been releasing water into Grand Canyon that is consistently about 47 degrees F, which are too low for native fish to spawn or mature. Before Glen Canyon Dam the river temperatures approached 80 degrees in the summer and near freezing in the winter.

While strategies to warm the water are critical to recovering Grand Canyon's native fish this device, especially on its own, may not be the best choice and its operation could actually bring the remaining native fish species closer to extinction by promoting the proliferation of alien fish that feed on the young native fish.

Living Rivers, Colorado Riverkeeper program and others are calling for:

- A full Environmental Impact Statement (EIS), as opposed to the much narrower and fast-tracked Environmental Assessment, as the magnitude of this federal action requires is too extensive for such limited environmental review.
- The potential for increases in the population of non-native fish species must be fully understood and addressed, including catfish, carp and Brown trout, which are known to prey on the young of endangered fish species.
- A full analysis of water quality concerns, including how they may contribute to new and increased levels of exotic animals and parasites, such as the New Zealand mud snail and the Asian tapeworm which are not native to Grand Canyon.
- The potential impacts on Grand Canyon's aquatic food web, and food security for Grand Canyon's native fish.
- The corresponding dam releases and flow regimes that must be undertaken in consort with temperature modification to mimic the historic flow pattern.
- The corresponding sediment augmentation that must also be undertaken in consort with temperature modifications to mitigate the loss of 95 percent of Grand Canyon's sediment and nutrients trapped behind the dam and to disadvantage hunt-by-sight alien fish predators.
- The impacts of sustained drought on the need for, and operations of, a temperature modification.
- The safety risks associated with operating temperature control device poses a risk to the safety of the dam.
- All potential alternatives to warming the water, including permanently lowering the reservoir levels, and decommissioning the dam.
- The range of new information not known when Glen Canyon Dam's first EIS was completed in 1996, including the continued decline of endangered native fish populations, the ineffectiveness of sediment conservation measures, the likelihood of long-term drought, and the deteriorating credibility of the science program advising dam managers.

Regional News 03/09/04

Many farms may not recover from this drought

By Gary Nabhan, director Center for Sustainable Environments Northern Arizona University

Whenever it has rained or snowed in the West this winter, ranchers and farmers have wondered whether the new moisture has been significant enough to break the drought and get their operations back to a normal business routine.

But the sad truth is that there is no "normal" condition in much of the arid West; we spend most of our time either in drought or recovering from it. And regardless of when the meteorological drought is finally broken, it will be many more years, if ever, that farms and ranches will be able to recover from what we might call hydrological and economic droughts. Reservoirs will take years to refill, and the food economy is fraught with instability.

Although this view may sound rather gloomy or cynical, a review of the consequences of the droughts in the 1930s and '50s bears me out. Range-fed sheep and cattle stocking rates never returned to what they were prior to those droughts. Because there were crop failures of dry-farmed grains and beans, many farms went belly-up in the Dust Bowl and never relied on rain alone again.

Still, two factors make this drought different than those in the '30s and '50s. First, today's farmers are not suffering crop failures as much as they are suffering from higher production costs that now keep them in debt. Rather than seeing their crops dry up because rains are sparse and reservoir levels are down, they are investing more in buying and transporting water, controlling pests and maintaining costly irrigation systems.

Since the drought began in 1997, Arizona farmers and ranchers have shouldered 22 percent more debt than they did before. Such debt has forced many out of business, so that we've been losing an average of 100 farms and ranches in Arizona since the drought began, opposed to the long-term average of 82 lost per year.

But the second, unparalleled factor at work today is much more insidious. Government policies on water allocation during drought have put farmers, ranchers and the food security they offer us at a selective disadvantage, whereas water-consumptive urban growth has continued unchecked.

During the past two years, when farmers in the Metro Phoenix area have been forced to cut back their irrigation by 30 percent, urban users have barely diminished their water use by 5 percent, and most of that savings has been due to the valiant efforts of city park managers to use less water.

Regardless of how much central Arizona farmers cut back on their irrigation needs, no more water is truly being conserved for wildlife habitats and future needs because 25,000 more users take up residence in Metro Phoenix every year. In general, residents of Southwestern cities have increased their per capita use by one-fourth over the past quarter century, while farmers have reduced per acre use by one-fifth. Is this fair?

The net effect is that during this drought, more food-producing land has been sold to shopping mall and subdivision developers than ever before. This is because there are few policies that assist farmers and ranchers in resisting urban sprawl. The long-term consequences of such gaps in land and water policy is that more and more of America's food is coming from off-shore sources. We have sacrificed some of the most fertile lands in the world to asphalt and concrete. In doing so, we have compromised our own food security and safety – few countries regulate pesticides and other contaminants to the extent that the U.S. does.

As an attempt to counter such devastating trends in the Southwestern states, the Center for Sustainable Environments is launching a branding campaign to help farmers and ranchers survive this drought. Their direct-marketed products can be labeled with tags and stickers urging consumers to "Get Yours Fresh from Canyon Country."

Nearly half of Arizona's consumers, when surveyed, say that they would be willing to pay more for such locally produced foods; they are particularly interested in fresh, good-quality produce and meats grown with water-conserving, environmentally friendly practices.

If households, restaurants and cafeterias choose to purchase more "Canyon Country Fresh" products, farmers and ranchers will gain more of each consumer food dollar, and will perhaps have the means to reduce their debts and recover from the economic drought.

It is time for Westerners to rally together to ensure that our region's farmers and ranchers are guaranteed enough water to provide our communities with secure food supplies. If we don't, we will be increasing our vulnerability to contaminated vegetables from Mexico and downer cattle from Canada.

###

Dr. Gary Nabhan, Director of NAU's Center for Sustainable Environments, is co-author of a new study on drought and food security, available online at www.environment.nau.edu. He will speak on this topic at the Southwest Direct Marketing Network Conference in Flagstaff, Monday, March 16 at 9 am at the Radisson Hotel

Take Action 03/12/04

SAMPLE LETTER: Temperature Control Device/Environmental Assessment

Ms. Nancy Coulam
Bureau of Reclamation
125 South State Street, Room 6103
Salt Lake City, UT 84138-1102
Phone: 801-524-3684
Fax: 801-524-5499
Email: ea_comments@uc.usbr.gov

Dear Ms. Coulam,

I submit the following scoping comments for the draft Environmental Assessment (EA) that the Bureau of Reclamation (BOR) is presently preparing for the proposed temperature control device (TCD) at Glen Canyon Dam, Arizona.

While it is critical that urgent action be taken to address the decline of endangered species in Grand Canyon National Park caused by Glen Canyon Dam's operations, the TCD initiative now underway may only further the native ecosystem's collapse. Its operation could actually bring the few remaining native fish closer to extinction, constituting an incidental take of endangered species.

The situation is particularly critical for the humpback chub, whose numbers have declined 85 percent since 1982. This decline, combined with abundant new information about the condition of the ecosystem in Grand Canyon since the TCD was recommended in 1995, compelled the BOR to halt the fast-tracking of the TCD proposal and undertake a more thorough review of the situation in Grand Canyon, including the

full range of alternatives available to address them. Specifically, I request the BOR address the following:

- 1) The present environmental review process be expanded to a full Environmental Impact Study to address the TCD and all new information that has come forward since the first Glen Canyon Dam EIS was completed in 1995.
- 2) Other alternatives to warming the water, including permanently lowering the reservoir and decommissioning the dam.
- 3) The potential for the TCD's operation to increase the population of non-native fish such as catfish, carp and brown trout, which are known to prey on the young of endangered fish species.
- 4) The effect the TCD will have on water quality, including new and increased levels of exotic animals and parasites. Specifically, it should address impacts to the New Zealand mud snail and the Asian tapeworm, which are not native to Grand Canyon ecosystem; and how will these impacts affect the recovery of the native fish, which were not addressed in the original EIS.
- 5) The TCD's potential impacts on the aquatic food web for Grand Canyon's native fish. This includes the impacts associated with the worsening drought situation and the quality and quantity of nutrients to provide carbon for the river's food chain.
- 6) The complimentary role other mitigation measures must play, especially sediment augmentation to replace the loss of 95 percent of Grand Canyon's sediment and nutrients trapped behind the dam, and the restoration of flow regimes that mimic the rivers annual, natural hydrograph.
- 7) The safety risks that these modifications to the penstocks may pose to Glen Canyon Dam, especially at low water levels.

Thank you for the opportunity to submit these comments.

Sincerely, Your name or organization

LR Letter 03/17/04

Letter of Extension for Scoping Period of TCD/EA

March 17, 2004
Ms. Nancy Coulam
Bureau of Reclamation

Salt Lake City, UT 84138-1102
Via Fax: 801-524-5499

RE: Request for 30-day Extension of scoping comment period for Glen Canyon Dam Temperature Control Device Environmental Assessment.

Dear Ms. Coulam,

Living Rivers requests that the Bureau of Reclamation extend by 30 days, to May 2, 2004, the deadline for receipt of scoping comments for the Glen Canyon Dam Temperature Control Device Environmental Assessment.

This proposal by the Bureau represents one of the most unique and significant interventions into the Grand Canyon ecosystem at a time when a federally listed endangered fish, the humpback chub, is declining toward extirpation in Grand Canyon National park. Never before have such modifications been proposed for Glen Canyon Dam, nor temperature control experiments been undertaken in Grand Canyon. The public should be given sufficient time to comment.

Despite this significance, the public has received very little notification on the matter, and as of today, there is still no information pertaining to this scoping period on the Adaptive Management website.

Also, because of the recent disconnect of the Internet from various agencies of the Department of Interior, as ordered by Judge Royce Lamberth of the United States District Court, information access is now more limited and will delay full participation of the public.

Thank you for your attention to this matter.

Sincerely,

John Weisheit
Conservation Director
Colorado Riverkeeper

Letter to LR 03/24/04

Letter Announcing Scoping For Temperature Control Device

United States Department of the Interior
BUREAU OF RECLAMATION
Upper Colorado Regional Office
125 South State Street, Room 6107
Salt Lake City, Utah 84138-1102
FEB 23 2004
IN REPLY REFER TO: UC-720 ENV-6.00

Subject: Glen Canyon Dam Temperature Control Device Environmental Assessment

Dear Interested Parties:

I am personally inviting you to assist the Bureau of Reclamation and its partners in scoping the issues to be considered in the development of an Environmental Assessment (EA) under terms of the National Environmental Policy Act. As you will see, we are again considering the feasibility of installing temperature control devices (TCD) on the penstocks at Glen Canyon Dam, Arizona to study the potential benefits of warming the temperature of water released from the dam to the downstream Colorado River through Glen and Grand Canyons.

Prior to construction of Glen Canyon Dam, Colorado River temperatures ranged from freezing to about 85 OF. Since construction of the dam, releases from the dam have been consistently cold (about 45-50 OF), adversely impacting native fish. Reviewing the condition of the native fish in 1994, the U.S. Fish and Wildlife Service's biological opinion on the operation of Glen Canyon Dam Environmental Impact Statement required Reclamation to evaluate the feasibility of using a TCD to warm the temperature of the Colorado River below Glen Canyon Dam.

In January 1999, Reclamation released a draft EA on an eight-unit TCD for Glen Canyon Dam. Reclamation did not finalize this assessment and National Environmental Policy Act process due to questions about potential adverse impacts of the eight-unit device on downstream aquatic resources, particularly endangered fish, the need for an accompanying science plan, and concerns about the frequency of use of the TCD. Reclamation has continued studying the potential for a TCD that could warm the Colorado River below the dam and assist in the removal of jeopardy from endangered fish. Based on these additional studies, Reclamation has decided to begin preparation of a new programmatic EA analyzing the environmental effects of construction and experimental operation of a two-unit pilot project TCD. A monitoring plan and experimental program for testing the TCD using adaptive management will be designed by the U.S. Geological Survey, Grand Canyon Monitoring and Research Center.

This notice announces the opening of a 30 day scoping period. During this time, Reclamation encourages you to raise issues and concerns that should be addressed in the EA. You should focus your comments on the potential environmental effects of construction and operation of a two-unit pilot project TCD, as well as reasonable alternatives to the proposal and measures to avoid or lessen environmental impact. Comments received before April 2, 2004, will be considered during the preparation of the EA. Reclamation will use the EA in its decision-making process to determine whether to construct and test a pilot two-unit TCD or if a more detailed environmental impact statement should be prepared.

Comments should be sent to the U.S. Bureau of Reclamation, attention Nancy Coulam, UC-720, 125 South State Street, Room 6103, Salt Lake City, UT 84138-1102 or by email to ea_comments@uc.usbr.gov. If you do not want to submit comments at this time, but would like to receive a copy of the draft EA and other mailings, please contact Reclamation at the same address or email. If you need further information, please contact Nancy Coulam at 801-524-3684.

Sincerely,

Rick L. Gold Regional Director

Letter to LR 03/24/04

Federal Register Notice for TCD

United States Department of the Interior
Bureau Of Reclamation
Glen Canyon Adaptive Management Working Group (AMWG)
Notice of Meeting
Agency: Bureau of Reclamation, Interior
Action: Notice of public meeting

Summary: The Adaptive Management Program (AMP) was implemented as a result of the Record of Decision on the Operations of Glen Canyon Dam Final Environmental Impact Statement to comply with the consultation requirements of the Grand Canyon Protection Act (Pub.1. 102-575) of 1992. The AMP provides an organization and process to ensure the use of scientific information in decision-making concerning Glen Canyon Dam operations and protection of the affected resources consistent with the Grand Canyon Protection Act. The AMP has been organized and includes a federal advisory committee (AMWG), a technical work group (TWG), a monitoring and research center, and independent review panels. The TWG is a subcommittee of the AWMG and provides technical advice and information for the AMWG to act upon.

Date and Location: The AMWG will conduct the following public meeting: Phoenix, Arizona—March 3-4, 2004. The meeting will begin at 9:30 a.m. and conclude at 5 p.m. on the first day and begin at 8 am and conclude at noon of the second day. The meeting will be held at the Arizona Department of Water Resources, 500 N. 3rd Street, 3rd Floor, Conference Rooms A and B, Phoenix, Arizona

Agenda: The purpose of the meeting will be to recommend to the Secretary of the Interior the FY 2005 budget and work plan. Other items for discussion include AMWG operating procedures, environmental compliance on proposed actions, basin hydrology, public outreach, as well as other administrative and resources issues pertaining to the AMP. To view a copy of the draft agenda, please visit the Reclamation web site at: http://www.usbr.gov/uc/envprog/amp/amwg/mtgs/01mar03/mtgs1_00.html.

To allow full consideration of information by the AMWG members, written notice must be provided to Dennis Kubly, Bureau of Reclamation, Upper Colorado Regional Office, 125 South State Street, Room 6107, Salt Lake City, Utah, 84138; telephone (801) 524-3715; faxogram (801) 524-3858; e-mail at dkubly@uc.usbr.gov (5) days prior to the meeting. Any written comments received will be provided to the AMWG and TWG members prior to the meeting.

For further information contact: Dennis Kubly; telephone (801) 524-3715; faxogram (801) 524-3858; e-mail at dkubly@uc.usbr.gov.

Dated: January 29, 2004 Dennis Kubly Chief, Adaptive Management Group, Environmental Resources Division, Upper Colorado Regional Office, Salt Lake City, Utah. FR Doc. 04-3347 Filed 2-13-04; 8:45 am Billing code 4310-MN-P

EIS/TCD Letter to Bureau of Reclamation

April 2, 2004
Ms. Nancy Coulam
Bureau of Reclamation
125 South State Street, Room 6103
Salt Lake City, UT 84138-11027

RE: Scoping Comments for proposed Temperature Control Device at Glen Canyon Dam

Dear Ms. Coulam,

Living Rivers, the Colorado Riverkeeper, and the undersigned organizations submit the following scoping comments pertaining to the Temperature Control Device (TCD) at Glen Canyon Dam as published in the Federal Register on February 17, 2004.

First, we find the notice in the Federal Register to be utterly vague, with no direct reference to the TCD environmental review process. Additionally, due to a Federal District Court order suspending public access to the Bureau of Reclamation via email and web pages, the public has been further inconvenienced in learning about this process. We therefore request that the scoping period be extended for at least another 30 days to adequately involve the public in this critical matter affecting the ecological integrity of Grand Canyon National Park. We also request that the Bureau of Reclamation seek consultation with the US Fish and Wildlife Service concerning the application of a TCD program for operations at Glen Canyon Dam.

While the 1996 Record of Decision (ROD) on the 1995 Glen Canyon Dam Environmental Impact Statement (EIS) addresses the need to pursue temperature control strategies at Glen Canyon Dam, it did so amidst a climate of much different information than presently exists. In fact, four years later the scientific controversy surrounding viability of such a proposal caused the Bureau of Reclamation to abandon its plans for this temperature control device (TCD). As noted below, even more information now exists to reinforce the concerns raised four years ago. This new information not only calls into question the merits of an independent TCD proposal, but the ROD's applicability to guiding Glen Canyon Dam operations as they pertain to endangered species recovery in Grand Canyon National Park. We therefore request that the proposed TCD be evaluated through an Environmental Impact Statement as opposed to the more cursory Environmental Assessment (EA) presently contemplated, and that this EIS, or a supplemental EIS, also address the areas of new information unknown or unforeseen when the 1995 EIS was prepared.

The initial EIS and ROD recommended pursuit of temperature modification strategies for Glen Canyon Dam releases amidst a range of other dam management proposals aimed at recovering endangered native fish at Grand Canyon. However, the Glen Canyon Dam Adaptive Management Program's most recent report to Congress, submitted in 2003, along with subsequent scientific conclusions clearly indicate that these programs have made little progress in meeting the mandate of the Grand Canyon Protection Act (GCPA). Nor have they met the goals established in the EIS, ROD, the Biological Opinion that analyzed the environmental impacts of Glen Canyon Dam, nor subsequent objectives set by the AMP itself.

The AMP has failed because the original EIS had inappropriate limitations, the AMP administrative process is ineffective, and the AMP lacks responsible leadership from the agencies of the Department of Interior (DOI): Bureau of Reclamation (BOR), National Park Service (NPS), US Geological Survey (USGS) and US Fish and Wildlife Service (USFWS). Unless these fundamental deficiencies are corrected, the dedicated efforts of all involved will continue to fail to restore the ecosystem in Grand Canyon National Park.

At the same time, scientific evidence shows that the AMP can not succeed in meeting program goals while constrained by the limitations set by the current EIS. It is evident that unless additional, more effective management options are implemented, the AMP serves only the purpose of documenting the decline of the Grand Canyon river ecosystem. Thus, more than enough evidence exists to require the immediate preparation of a supplemental environmental impact statement (SEIS), independent of the current TCD proposal, to examine in detail and anew the impacts of Glen Canyon Dam based on the significant failures of the present efforts and the myriad of changed circumstances that affect the Colorado River system. Since the release of the ROD in 1996, it is almost certain that the razorback sucker has joined the growing list of endangered species that have become extirpated in the Grand Canyon ecosystem. Grand Canyon National Park now faces the extirpation of yet another endangered species, the humpback chub. The ROD specifically foresaw the need for the recovery of this native fish, as well to establish a second population of humpback chub and to reestablish a population of the razorback sucker. Yet, scientific evidence indicates that neither objective will occur. The humpback chub's alarming decline and the failure to reinstate the razorback sucker tops a growing list of new scientific information that was not available or known when the 1995 EIS was completed.

As outlined below, the TCD must be evaluated through an EIS process, and this should be done in concert with a supplemental EIS process to address new information and new realities, which are also detailed below. The Bureau of Reclamation, together with her sister DOI agencies, are obligated to undertake such processes dictated by the National Environmental Policy Act (NEPA) in relationship to the operation of the Glen Canyon Dam. According to the regulations implementing NEPA: "agencies shall prepare supplements to either draft or final environmental impact statements if: (i) the agency makes substantial changes in the proposed action that are relevant to environmental concerns; or (ii) there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts." 40 C.F.R § 1502.9(c) (emphasis added).

Here, the dramatic decline of the humpback chub, the extirpation of the razorback, the failure of the BOR and the AMP to abide by the terms of the Biological Opinion and to meet the goals of the Grand Canyon Protection Act, and the wealth of new information relevant to the recovery of these species and their habitat combine to require such a supplement.

Listed below are the primary areas of concern:

1. New information relating to implementation of a temperature control device has not been addressed

The current drought situation has led to an increased concern over the unforeseen impacts associated with increased water temperature flowing into Grand Canyon from Glen Canyon Dam. While the original ROD encouraged managers to direct efforts to achieve warmer water temperatures to improve native fish recruitment, the EIS did not address in any detail the full range of impacts associated with such experiments. In

1999 uncertainty surrounding these impacts caused the BOR to shelve its plans to install a temperature control device (TCD) for Glen Canyon Dam's penstocks. Only the threat of legal action associated with the declining humpback chub population has resurrected the proposal. Although in 2003 the AMP Science Advisory Panel recommended full TCD testing and possible construction, along with flow modification and extensive research/monitoring, DOI has taken no action until just recently and even then, the agency suggested a program that is much downscaled. An Environmental Assessment for the proposed TCD is not adequate because of incidental take and other critical habitat factors for humpback chub that has changed since the implementation of the ROD.

Another concern surrounding the TCD involves the impact of the parasitic Asian tapeworm, which could proliferate and heighten the potential of disease for the humpback chub. Since the Asian tapeworm was not discovered in the ecosystem until after the ROD, it too constitutes new information to be addressed in a SEIS.

Certainly, some of the risks associated with the TCD could be overcome by incorporating other operational strategies, such as importing sediment into the system to disadvantage hunt-by-sight predators, and by initiating a periodic spike flow. These were not addressed in the original EIS, and therefore will also need to be incorporated into an EIS process for the TCD.

2. The AMP has failed to improve sediment balance that drives the physical ecological component of the ecosystem

New data collected since the EIS was completed confirms that the EIS needs to be modified to address sediment below Glen Canyon Dam. This is because the scientific community studying the native fish and involved in the recovery of these species, know far more about sediment dynamics than in 1992 when the EIS was developed. A core element of the ROD and the relevant Reasonable and Prudent Alternative (RPA) requires that BOR mitigate the impacts caused by the fact that sediment no longer enters Grand Canyon's river ecosystem. The plan required that experiments be conducted to conserve sediment in the ecosystem of the Colorado River. The first experiment took place in 1996 with subsequent attempts in the year 2000. In each case, efforts failed to produce permanent benefits of preserving beaches, stabilizing cultural sites, and enhancing critical habitat conditions as intended. The report to Congress and all supporting sediment research since concludes that net sediment loss from the ecosystem will continue to occur. Natural sediment inputs, combined with organic nutrients, are a fundamental pre-dam ecosystem components necessary to sustain native fish species. Returning to peak-power flows, in a weak attempt to reduce rainbow trout spawning success, will likely accelerate further the rate of sediment loss.

There are other adverse environmental impacts of sediment loss below Glen Canyon Dam not previously anticipated. The continued loss of sediment and inability to regularly enhance beaches have brought about a change in NPS management strategies concerning cultural resource protection in the river corridor. While NPS policies favor the preservation of archeological sites in situ, the BOR now finds it necessary to consider

immediate salvage operations to save what remains of sites threatened by further beach erosion. This will add federal costs to the program and increase tribal concern for these remnants of ancestral origin. These immediate and vital remedies were not considered in the original EIS.

The sobering conclusions regarding the inability to improve sediment resources have brought about discussions on how to augment sediment inputs in addition to reducing outputs. Any attempt to import sediment into the ecosystem below Glen Canyon Dam will be very costly and is not evaluated in the current EIS. In light of the inability to conserve sediment and meet Lower Basin water allotments as planned, options for improving the sediment and nutrient budget to benefit native fish and cultural sites must be explored in a SEIS.

3. The AMP is non-compliant with the Endangered Species Act and USFWS program recommendations

A. Razorback Sucker

The Biological Opinion uses urgent language to call for specific improvements of critical habitat for the humpback chub and the razorback sucker by 1998. The document states, "If the [Fish and Wildlife] Service determines a study design can not be developed that is expected to provide information to support removal of jeopardy to the razorback sucker and humpback chub populations in the Grand Canyon and associated tributaries, such will be considered new information and may be grounds for reinitiating formal consultation." (p. 35) (emphasis added)

Considering that a live, adult razorback sucker has not been observed in Grand Canyon for the last few years, many senior scientists believe that the razorback sucker has been extirpated from the Colorado River in Grand Canyon National Park. The lack of response in respect to performance criteria gives ample evidence that jeopardy has not been removed, and is sufficient ground for reinitiating formal consultation and the NEPA process immediately.

B. Humpback Chub

Monitoring by the USGS through the Glen Canyon Monitoring and Research Center (GCMRC), has documented a major and alarming decline in humpback chub population. Since 1995, when the EIS was completed, the adult humpback chub population in the Little Colorado River has declined by 50 percent. Two years ago the GCMRC scientists estimated that the population could be as low as 1,100 fish. In April of 2003, the USFWS reported, "Results of this ongoing study indicate that despite low catch rates of nonnative fishes in the Little Colorado River, humpback chub continue to decline and that aging adults are not being replaced in the spawning population." (Sponholtz, Pam and Randy Van Haverbeke)

It is undisputed that there has been a major decline in the population of adult humpback chub. Some federal scientists have recently argued that while humpback chub numbers have indeed declined, the present population is stabilizing. Yet, these scientists present no evidence to support this assertion. Privately, some of the same scientists are also saying that extirpation for humpback chub is quite likely. In any case, both this rate of

decline and the low absolute number of fish, constitute a vastly different humpback chub assessment than was assumed in developing the original EIS, and the steps necessary for humpback chub recovery.

Furthermore, there has been no progress made in establishing a second viable population of humpback chub in Grand Canyon as mandated by the ROD. Nor has a Management Plan for the Little Colorado River been implemented to protect the critical habitat of the humpback chub from pollution, reduction of instream flows, or truncation of their habitat due to unforeseen geologic events such as debris flows or landslides.

The RPA states that if sufficient progress is not made to remove humpback chub and razorback sucker jeopardy by 1998, then Seasonally, Adjusted Steady Flows (SASF) must begin at Glen Canyon Dam. This has not occurred. Additionally, the RPA also stated that in low water (drought) years, dam releases should be regulated using the SASF alternative. This, too, is not occurring.

As razorback sucker and humpback chub recovery efforts represented one of the cornerstones of the original EIS process, this new information, combined with the information we are presenting, constitutes ground to start a SEIS process.

4. Persistent drought conditions are likely to further complicate achieving program goals and are not being adequately considered or addressed

The Colorado River watershed is experiencing a fifth year of significant drought. Many climatologists are forecasting multidecadal drought conditions for the basin due to the occurrence of oscillating sea surface temperatures. This has already dropped the water level in Lake Powell reservoir by 113 feet to 44 percent of storage capacity. While specific flow recommendations were prescribed in the RPA for low water years, no assessment of management options has been conducted to address the impacts of sustained drought on achieving GCPA goals.

The reduced elevation of Lake Powell reservoir has already stimulated changes in water quality and the aquatic environment below the dam. The river's temperature has increased about 2° C, which is changing the dynamics of the food web and increasing the rates of colonization by exotic species such as the New Zealand mud snail. This particular alien species was discovered in the ecosystem after the ROD was signed. As the surface of Lake Powell reservoir continues to drop nearer to the penstocks, new pathogens, parasites and other exotic species are likely to invade the ecosystem in Grand Canyon and complicate the conservation of endangered native fish. Elevated temperatures raise questions about how this may affect alien fish populations and this predation threat to endangered humpback chub.

Furthermore, more water development projects for the Upper Basin are now being considered which would further deplete the already over-allocated waters of the Colorado River. The synergistic effects of drought and consumptive loss were not considered in the EIS. Predictions confirm that due to factors such as drought and over-appropriation, low levels will become the norm, rather than the exception, for Lake Powell reservoir. As a result, the BOR and her sister agencies must revisit its review the

environmental impacts of Glen Canyon Dam and update the analysis to account for this new development.

5. Credibility of the AMP science program is in question

A central component of the original AMP design was the development and administration of an independent, peer-reviewed science program. This program would carry out unbiased scientifically credible studies to inform the AMP's decision-making process. A small science staff (less than 12) was to administer the program through the competitive bidding process and to award research contracts to the most competent bidder. Both the bidding process and final reports were to be peer-reviewed to assure quality and non-biased reporting. The GCMRC, the science management component of the AMP, is now operating much differently than established in the original guidelines set for this administrative component of the USGS. The science staff is very large and most programs are being done in-house with no independent peer-review.

Prior to the EIS the Glen Canyon Dam Environmental Studies program was seriously criticized by the National Research Council for this same failure to meet accepted methods to assure scientific credibility. An independent review of the current AMP science program would reveal a loss of integrity and standing when the GCMRC model was abandoned in favor of what currently exists today in the GCMRC.

At a time when the Grand Canyon is about to lose another native fish species, the AMP is cutting back on scientific work, seemingly at the request of the Western Area Power Administration, whose hydropower revenues are used to fund the science. The research for the 2000 Low, Summer Steady Flow (LSSF) represents one example of how the AMP science program has been affected. First, the experiment was fast tracked, with limited opportunity for outside input or competitive bidding for the monitoring. Pre-experiment flow data was not compiled and therefore the design of the experiment may not have been properly formulated. Scientists did not start collecting data on the river until after the first spike flow occurred. Although the design of the experiment was released for the competition, the one proposed by the contractor was not accepted. Also, this experimental flow was originally proposed to benefit native fish with relatively low, steady flows in accordance with the Biological Opinion, but the final experiment allowed for less than the recommended time.

The original EIS assumed that experimentation and recovery efforts would be achieved with firm attention paid to proper scientific protocol and management of public funds toward endangered species recovery in Grand Canyon National Park. This is not occurring. In fact the opposite is occurring. The AMP has enacted budget reductions and caps without supplemental funds to adequately maintain and preferably improve monitoring and research in Grand Canyon National Park. Finally, AMP is not providing adequate management leadership while the USGS/GCMRC is not contributing credible independent data required by the mandates prescribed by the ROD, RPA and subsequent charters and guidelines. Together, these factors warrant immediate preparation of an SEIS.

6. Inability of the AMP decision-making process to address fundamental resource recovery requirements is limiting progress

The ROD called for the establishment of the AMP as a stakeholder group to advise the Secretary of the Interior on implementation of Grand Canyon programs. The application of the ROD is the sole responsibility of the AMP. The AMP has been, and continues to be, controlled by the water and energy groups, groups whose self-interest is to avoid long-term change from the status quo. These groups necessarily are not ultimately dedicated to the protection and recovery of the Colorado River and the native fish it should support.

While the make-up of the group has provided for a bias toward representing water and energy interests, it was anticipated that the program's mandate to mitigate downstream impacts of dam operations would ensure that sufficient attention would be given to the needs of the resource. This has not occurred, as exemplified by the failure to undertake RPA programs, the decline in humpback chub, the extirpation of the razorback sucker, continued loss of essential sediment, and accelerated degradation of archeological sites. A key reason for this continued program failure is that the AMP decision-making process continues to demonstrate a clear bias toward minimizing loss of hydropower. Also, the AMP evades recommendations that would create legal conflicts between the Organic Act, Endangered Species Act, NEPA and even GCPA. The workings, the make-up and the ineffectiveness of the AMP must be reevaluated in a SEIS process.

Evidence to support prejudice for one resource over another recently occurred when the trout population suppression flows were modified in a fast-track manner without proper consultation or due process within the AMP. Moreover, the current Sunday flow regime has proved to be inadequate for true trout suppression and demonstrates that concerns over hydropower prejudice for efforts to conserve endangered species. There has also been a recent suggestion for a flow regime of 5,000 to 25,000 cfs for year 2005. These proposed flows, the environmental impacts of which have never been addressed, are outside the range prescribed for the conservation of natural and cultural resources by the ROD and the Biological Opinion.

Flow experiments, especially those designed to benefit humpback chub recruitment have been of limited duration, and as such generated inconclusive results. Results of the LSSF were inconclusive because data was neither collected prior to initiating the flows nor afterwards. In this particular experiment the flow was neither timely, nor of sufficient duration for the food web to adjust and respond. The RPA recommended, "experimental flows will be conducted for a sufficient period of time to allow for experimental design, biological processes to function, and for variability inherent in riverine ecosystems to be expressed" (p. 36).

Overall, the AMP is failing to achieve GCPA goals because the ROD and subsequent program design do not allow for meaningful adjustments in key, aquatic ecosystem elements. The program continues to focus on treating the symptoms of ecosystem decline rather than what is actually causing the decline. In other words, the habitat is in dramatic decline and the AMP is doing nothing meaningful—is failing to make any hard

choices—to bring the habitat closer to pre-dam conditions. These critical ecosystem elements are well documented and include:

- A. Natural hydrograph that would redistribute sediment during the spring run-off and stimulate native fish spawning.
- B. Natural thermograph with warmer summer water temperatures and colder winter temperatures.
- C. Annual inputs of sediment, nutrients and woody debris to create generally turbid water conditions.

Again, these failures underscore the need to take a renewed look at the whole process, not just the TCD proposal, as this process has not served the Colorado's native fish and has not followed the guidelines, recommendations and requirements set forth to achieve recovery of these species.

7. Our concerns for the First Nations

The AMP has not fully engaged the process that threatens the cultural and natural heritage of the First Nations in Grand Canyon. They have also been given a minimal amount of resources to monitor their cultural properties in Grand Canyon. This is a violation of the trust that was developed with the tribes during Glen Canyon Environmental Studies and is allowing the government to continue to minimize the value of these tribal resources.

8. Recommendations

Based on the above, the following steps are legally required as part of the effort to protect and restore native fish and their critical habitat to the Colorado River below Glen Canyon Dam.

- A. The BOR must undertake an EIS for the proposed TCD. This EIS, or a supplemental EIS, must address all new information unknown or unforeseen when the original EIS was prepared.
 - B. As an EIS or SEIS could take several years and there are a number of interim actions the BOR and the AMP must take, both in terms of science and in the operations, to help impede the further decline of natural and cultural resources in the Grand Canyon while we await a new ROD.
 - C. Because an EIS or SEIS could take several years, the AMP must undertake interim actions within six months to help forestall the further decline of natural and cultural resources in the Grand Canyon until a new ROD is issued.
1. Reorganize the AMP to be proactive so that it is comprised of only the responsible agencies and sovereigns: BOR, NPS, USFWS, and the Tribes. (Participation by other stakeholders would be available through public process as explained below in #2.)

2. Require the AMP meet twice a year with a 30-day comment period prior to each meeting. This program would use interactive communication and video technology that was not available during the 1996 EIS process and would provide for more stakeholders to be heard.

3. Reorganize GCMRC to be an administrative organization outside of the DOI. This would remove or militate against agency bias and shortcomings, and be a positive step toward a truly independent science organization. Competition and protocol development should follow NPS guidelines for science activities within national parks.

D. Humpback Chub population and habitat monitoring

All reports and analyses by the AMP have focused on humpback chub numbers, and not the relative condition of the fish or health of the critical habitat. This must change. While some of this data has been collected, there has not yet been any ongoing analysis on the condition factors of the humpback as recommended by the USFWS. Additionally, factors relevant to habitat such as feeding habits, water quality, age class, genetics, and recruitment and migration patterns for all periods of the humpback chub's life span need to be documented. The new AMP must also determine the population level and changes in biological parameters that would trigger a cessation of handling humpback chub so as to avoid incidental take on the remaining population.

E. Follow the Biological Opinion for the Humpback Chub and the natural river hydrograph

As a baseline, all flow decisions should be evaluated by how well they mimic the natural hydrograph. So far, the AMP has ignored this fundamental principle of river ecology. Without it there will likely be no hope of establishing a second population for the humpback chub, or of restoring its critical habitat as called for in the RPA and required by law. AMP should continue intensive alien fish suppression at the Little Colorado River reach.

F. Expand the critical habitat throughout the Grand Canyon, including the tributary streams and the Glen Canyon reach.

G. Develop a scientifically sound monitoring program that extends current non-GCMRC programs through a SEIS process so continuity of ecosystem data sets is achieved. These data sets should be linked with water quality, lower and higher trophic levels, riparian vegetation and beach sand monitoring. GCMRC monitoring programs should be delegated to past or present contractors for one year and then all contracts should be opened for competitive bidding under the new AMP and a SEIS. If these contractors do not want the work then the Grand Canyon Science Center will conduct the monitoring as protocols dictate.

H. Initiate a comprehensive cultural site degradation abatement program throughout the entire river corridor in accordance with NPS standards.

I. Initiate development of a River Management Plan for the Little Colorado River as called for in the RPA.

In conclusion, the Grand Canyon is treasured by the citizens of the world and the natural values that make up this spectacular place must not be further compromised. We urgently request serious and immediate action to address these matters, beginning with a new EIS process.

Sincerely,

John Weisheit
Colorado Riverkeeper

LR Press Release 04/02/04

159 groups demand new EIS to save Grand Canyon from Glen Canyon Dam

Can Grand Canyon Survive Glen Canyon Dam? National Coalition Demands New Federal Study!

Contact:

John Weisheit
(435) 259-1063 (435) 260-2590

From Alaska to Florida, more than 150 environmental, social justice and recreation groups today are calling for a new federal study of if, and how, the nation's fourth tallest dam should continue to be operated. Charging that eight years of tinkering with flows from Glen Canyon Dam on the Colorado River have failed to reverse the dam's impacts on endangered fish in Grand Canyon National Park, as required by law, the groups insist that the government is legally compelled to prepare a new Environmental Impact Statement (EIS) on dam operations.

In an [eleven-page letter](#) being submitted today to the U.S. Bureau of Reclamation, which built and operates the dam, groups reveal how despite more than \$80 million dollars invested in fish recovery efforts, one more of Grand Canyon's endangered fish species, the razorback sucker, has joined the growing list to become extinct in the Grand Canyon. Another endangered fish species, the humpback chub, has declined to only 1,100 fish from 8,000 in 1993.

In response to the decline, the Bureau of Reclamation's Glen Canyon Dam Adaptive Management Program is accepting public comments on a fast-tracked proposal to install a temperature control device on the dam to warm the water flowing into Grand Canyon.

"This represents the continuation of the same flawed, piecemeal approach that has got us where we are," says John Weisheit, director of Living Rivers' Colorado Riverkeeper Program, which is leading the coalition calling for the new EIS. "Glen Canyon Dam has robbed Grand Canyon of the natural flows, sediment and nutrients, and warm water necessary to sustain the unique ecosystem of this World Heritage Site. The public has

had enough, and wants all of these issues addressed in comprehensive manner before we lose what little we have left."

Following completion of an EIS on Glen Canyon Dam in 1995, the Glen Canyon Dam Adaptive Management Program was established to mitigate the tremendous impacts of the dam's operations on the river ecosystem in Grand Canyon National Park. The coalition's letter demonstrates how these recommendations are being ignored, and even when adhered to, are not achieving the intended results, thus warrant a new EIS as prescribed for by the National Environmental Policy Act.

- * The program has spent much of its resources attempting to conserve Grand Canyon's remaining sediment, as 95 percent of the Canyon's sediment and nutrients have been trapped behind the dam. These efforts have all failed to bring any lasting benefit to fish habitat or stabilization of cultural sites as called for by the EIS.

- * Recent attempts to use dam operations to control alien fish predation on endangered native fish have been haphazard and have yet to demonstrate any meaningful results.

- * In the event that endangered fish populations did not increase by 1998, water released from Glen Canyon Dam was supposed to shift toward a regime of at least partially mimicking the river's natural flow. This has not occurred.

- * A special set of flow recommendations for low water years was prescribed, but despite five years of drought, these recommendations have been ignored.

"Bottom line, It's numbers, and we have far fewer fish now than when they started; that's way it's critical that a new EIS be completed before installing a temperature control device on Glen Canyon Dam," says Michelle Harrington with the Tucson-based Center for Biological Diversity. "It was once thought that attempts to bring the Colorado River's water temperature to a level more consistent with native conditions would be a simple proposition. The drought has taught us that absent natural flows and new sediment inputs, that disruptions in temperature changes could affect the food supply for the remaining endangered fish, and we could also see an increase in alien fish which prey on the natives."

"As originally designed, the Adaptive Management Program was an excellent approach to addressing the serious impacts on Grand Canyon from this dam," adds David Haskell, retired Science Center Director for Grand Canyon National Park, who participated in the AMP program since its inception in 1995 and has monitored its progress since his retirement. "However, the 2002 AMP Report to Congress clearly indicated that six years of effort had not produced any beneficial results. Since then, the failure of the AMP to seek more effective methods to meet the goals of the Grand Canyon Protection Act has turned this once successful program into a dismal failure."

To date, the Glen Canyon Dam Adaptive Management program has resisted efforts to undertake a new EIS, in part because Glen Canyon Dam proponents understand that such an EIS will have to explore the possibility of decommissioning Glen Canyon Dam

as the best way to comply with the laws protecting the ecosystem in Grand Canyon's river corridor.

"Interior's actions paint a clear picture of disregard for the Grand Canyon Protection Act, Endangered Species Act, and National Park Service Organic Act," adds Steve Fleischli, Executive Director of the New York-based Waterkeeper Alliance. "Why must the public always be forced into the courtroom in order to protect a piece of our famed natural heritage from government malfeasance? That needs to change."

Water ebbs, worry flows

Through several years of drought, Colorado and neighboring states have relied on Lake Powell to deliver water downstream. But as the reservoir's water levels drop, fears of a water war, or of severe shortages, rise.

By Theo Stein Denver Post Environment Writer Sunday, April 04, 2004 -

Lake Powell, the desert oasis that has served Colorado as a crucial fail-safe for water deliveries throughout the Southwest during five years of hard drought, is now more than half empty.

If the drought persists a year or two more, the 186-mile-long reservoir in Utah and Arizona could be drained dry as early as 2007, federal officials say.

That would propel Colorado - and 30 million other Westerners who depend on the Colorado River for their drinking water - into an uncertain future punctuated by recurring water shortages and decades of litigation, experts warn.

On Friday, the Bureau of Reclamation said it expects only 55 percent of the normal runoff to flow into Lake Powell between April and July. That guarantees the big reservoir, already down to 42 percent of capacity, will recede even further by 2005.

"Time is running out," said Pat Mulroy, director of the Southern Nevada Water Authority. "The drought no one thought would even happen is here."

Under the Colorado River Compact of 1922, the states of Colorado, Wyoming and Utah are required to allow an average of 7.5 million acre-feet per year to flow past a river gauge below Lake Powell for use by California, Arizona and Nevada.

The four upper-basin states have met their compact obligations during the five-year drought by releasing water from Lake Powell. But if Powell dries up - and hydrologists caution that is still a big if - the state could eventually be required to turn off the massive transmountain tunnels that have supplied Colorado River water to Front Range residents and Eastern Plains farmers for more than 50 years.

Federal and state officials have not thought through how they would react to the nightmare scenario of a severe extended drought. But Lake Powell's steadily declining levels have convinced many that the time to evaluate the vulnerability of the West is now.

"That's something we in Colorado need to address," said Scott Balcom, a Glenwood Springs water lawyer who represents the state on Colorado River issues. "These issues haven't been explored as deeply as we need to this year."

State Engineer Hal Simpson said that if the next year is dry, he will begin a formal process of developing a plan for shutting off state water users in the event that Powell drains.

Simpson, who spent most of the 1990s involved in fights with Kansas and Nebraska over Colorado's overuse of the Arkansas and Republican rivers, said developing a curtailment plan would be difficult.

"But if this year's predictions hold true and we drop Lake Powell an additional increment, we have to make sure we're in a position to administer the state's water," he said.

The forecast released Friday follows four years in which mountain runoff was 62, 59, 25 and 53 percent of average, and establishes the period as the driest five consecutive years in a century of record-keeping, Bureau of Reclamation hydrologist Tom Ryan said.

"We can handle another two or three more years like this," Ryan added. "Then it's too late to plan."

Lake Powell was created to be a 24.3 million-acre-foot water bank, storing snowmelt in wet years and releasing it in dry years. (An acre-foot is 325,851 gallons, or enough to supply two families for a year.)

As recently as 1999, the lake brimmed full, forcing engineers to spill excess water through the dam - water that was quickly slurped up by California.

But the lake's volume dipped to 10.2 million acre-feet this month, a level not seen since 1971 - when the impoundment was first filling.

Now the receding shoreline has stranded the once-bustling marina in Hite, Utah, and forced National Park Service officials to stop laying new concrete boat ramps to chase the falling waters for boaters at Wahweap, on the Utah-Arizona border.

Drought is also draining Lake Mead, Powell's slightly larger downstream sibling reservoir, which sits at 59 percent of capacity. During the past five years, the two vast impoundments have lost a volume equivalent to a full Lake Mead, officials say.

Several water experts point out that the lakes are functioning exactly as intended, and that the seven states that depend on the river still have time to prepare for a worst-case scenario - and settle contentious and unresolved issues outside of the courtroom.

"It makes you thankful for the people who had the wisdom to build Powell as big as it did," said Department of Natural Resources Director Russell George, Colorado's top water official.

Several former state and federal officials added that, at minimum, the threat of continued drought should force water managers to seriously consider questions that were once unthinkable.

For example, what would happen if Simpson had to start shutting down existing Western Slope water users to allow the legally required amount of water to flow to California, Arizona and Nevada?

Or should the administration of Colorado Gov. Bill Owens continue with plans to encourage diversions of more Western Slope water to the Front Range to provide for the estimated 2.8 million new residents the U.S. Census Bureau estimates will flood into Colorado by 2030?

"The moral is that if we think we have more Colorado River water that's developable, we'd better think again," said David Getches, dean of the University of Colorado Law School. "We may already be beyond the point of safe development of Colorado."

It's unclear whether, under a continuing severely dry scenario, there is additional water to be developed, agreed Denver Water Manager Chips Barry, whose agency is evaluating a project that will bring more water from the Western Slope.

Getches, the state's natural resources director under Gov. Dick Lamm, knows he is delivering an uncomfortable message.

"If there is a compact call, we hit the wall," he said. "We wouldn't be able to use water called by the lower basin. We have to think about that."

If Powell were to dry up, the upper basin might still have two or three years of grace before the Interior Department, which is the lower-basin river master, declares a "deficit" and orders Colorado, Wyoming and Utah to curtail their use.

The compact requires an average of 7.5 million acre-feet a year for 10 years, but the Bureau of Reclamation has been releasing 8.23 million acre-feet a year from Powell. State officials say Colorado would argue that it owed the lower basin no water until the 10-year average fell to the minimum of 7.5 million acre-feet a year.

In addition, Bureau of Reclamation officials would first drain Blue Mesa and other federally operated reservoirs in the upper basin before demanding more from the states. That might buy Colorado one more year of grace.

But after that, ranchers, ski resorts and cities whose water rights postdate 1922, the year of the compact, could be required to stop using the water they have come to depend on.

"One scenario is, we start with most junior rights and start regulating those until we get the desired amount of flow at the state line," Simpson said.

But very little of the state's western waters were developed prior to the compact, so experts warn that a call on the Colorado River has the potential to affect nearly everyone.

If the shutoffs proceeded in a strictly chronological order, the losers could potentially include:

The Colorado-Big Thompson project, which takes about 250,000 acre-feet of Colorado River water to Fort Collins, Loveland, Greeley and the farms of the Eastern Plains.

Denver Water's transmountain diversions, including water from Lake Dillon and the Fraser River Valley, which average 120,000 acre-feet a year.

Colorado Springs' supplies, including the Homestake Tunnel and the Frying Pan-Arkansas Project.

A large majority of the water users in the Gunnison Valley who draw water from Blue Mesa Reservoir - which would be one of the first to be drawn down by federal officials.

Summer mountain recreation, particularly golfing and rafting.

But Simpson said there might be an argument for spreading the shutoffs around the state's western basins based on criteria other than strict adherence to the prior appropriation doctrine.

"It gets quite complicated," he said. "And at the same time there would be some really big legal issues with other states that would have to be dealt with."

One of those issues involves whether the upper basin is required to contribute half of the 1.5 million acre-feet the United States owes Mexico every year. Colorado, Wyoming and Utah might demand credit for their contribution, several water lawyers said.

Other fights would likely erupt in the lower basin, where Arizona could get shut off completely.

"That would be the single most counterproductive thing they could do," argued Mulroy of the Southern Nevada Water Authority, whose agency is spending \$32 million this year alone to rip out turf across Las Vegas to free up more water.

Mulroy said a megadrought like those recorded in tree rings and other paleontologic records would require Westerners to suspend fiercely guarded traditions regarding water use. That could mean some residents of one state would temporarily give up the use of their water to prevent a crisis in another state, she said.

It could also mean suspending the "doctrine of prior appropriation," which has assumed an almost sacred position in Western water law, Mulroy said.

"We will have to shift from what's on paper to what's needed for homes and communities," she said. "It doesn't have to be perpetual, but in order to get through an emergency, it's going to have to happen."

Many water scholars point out that the laws governing the Colorado River, of which the 1922 compact is but one part, have never really been tested. Rather than a coherent whole, the "law of the river" - a mix of compacts, congressional acts and legal decisions - is "really a bunch of moving parts," said John Leshy, a Hastings College law professor who served as a lawyer with the Clinton administration.

"If there is a compact call, we really are in no man's land," he said. "If there can't be some sort of settlement patched together, we're looking at horrendous litigation."

Leshy said the legal fights could drag out for decades against a backdrop of severe water shortages.

"It would stack up as the biggest water war in the West."

Even if Powell doesn't bottom out, Bureau of Reclamation officials say it will take a minimum of 13 years to refill with average precipitation. With current demand in the upper and lower basins, an average inflow year will increase system storage only by about 3 percent, they said.

As long as Powell remains less than half full, Colorado could remain vulnerable to an extremely dry year.

"If Lake Powell is sitting there with 10 million acre-feet or less, we will always be at risk of the next 2002 or 2004," said Eric Kuhn, manager of the Colorado River Water Conservation District.

Others wonder whether the potential crisis may be a trial run for a rancorous new future that may be closer than anyone imagined.

"If this is the beginning of global warming," said Mulroy, "then we've got issues."

A top federal water official had a grimmer message: The massive plumbing network built to serve the exploding Western states has removed much of the cushion that was available in earlier decades.

"We're no longer fighting about the water we will need decades in the future," said Assistant Interior Secretary Bennett Raley, a former Colorado water lawyer.

"The crises we will face will be in normal years, and they'll be about meeting existing demands.

"There's just not enough water."

Letters to the editor

April 11, 2004

More serious problems

Your article on the natural draining of the Lake Powell reservoir served the public well in preparing those who rely on the Colorado River for sustenance. But the problem is actually more serious, considering other factors related to the lowering of reservoirs held back by high dams in desert regions such as the Colorado River basin.

For example, in the upper reaches of Lake Powell, the Colorado and San Juan rivers combined are currently flowing over 60 miles of exposed sediment fill. It is this sediment fill that closed the boat access at Hite Marina. Through natural erosion, these two rivers are re-mobilizing sediment and organic materials into Lake Powell. The re-mobilized sediment is advancing closer to Glen Canyon Dam and diminishing its lifespan, and the decomposition of the organic material is consuming the oxygen in the reservoir and lowering the water quality.

Another water-quality problem is that there is not enough input of fresh water, and the saline content of the reservoir is consequently much higher. Saline water is detrimental for agriculture and corrodes the plumbing systems in our homes and businesses.

Power production is also in jeopardy. When Lake Powell reaches a capacity of 6 million acre-feet, the turbines cannot be safely operated any longer. With only 10 million acre-feet in the reservoir at present, we are closer than we realize to occasional shutdowns of turbines at Glen Canyon Dam.

When a turbine shutdown occurs, the emergency river outlets must be opened to keep the river ecosystem in Grand Canyon National Park alive. This water comes from the very bottom of the dam where the water is not only very saline, but is also high in hydrogen sulfide, which is corrosive to the metal working parts of Glen Canyon Dam. It is obviously not ideal water for an ecosystem that has already lost four species of native fish.

More importantly, we are not fully aware of the amount of waste that occurs from evaporation and seepage from our reservoirs and canals. Basinwide, the total loss from such unconsumed water amounts to 3 million acre-feet per year.

Keeping Lake Powell drained and then decommissioning Glen Canyon Dam makes more and more sense. It is obvious that we have too much storage in the system and that we have planned our communities to be water-intensive, as opposed to water-conservative. If we want a healthy Colorado River ecosystem and healthy communities,

we must re-evaluate the way we manage the Colorado River system as soon as possible.

JOHN WEISHEIT

Regional News 04/08/04

Shorter winters, drier summers hint at climate change

By LORNA THACKERAY Of The Gazette Staff

Early snowmelt has become a hallmark of Montana's prolonged drought. Some scientists are beginning to think that it may be much more than that.

Full-fledged climate change, which could mean shorter winters and drier summers, is already under way across the Western United States, said Steve Running at the University of Montana.

"We have every reason to believe that it will continue or even accelerate," he said.

"Absolutely, we are in a multi-decadinal change in climate."

Running is director of UM's Numerical Terradynamic Simulation Group, which makes software for NASA's environmental satellites. The group operates the Montana Climate Center, which opened last fall in Missoula.

Evidence collected over the last 50 years suggests that rising temperatures have fostered a decline in springtime snowpack of 15 to 30 percent in Montana and that springtime peak river flows now come an average of two weeks earlier, he said.

The snowpack, which holds about 75 percent of the West's water supply, acts as a reservoir that keeps streams flowing in the summer months. If the melt continues to recede earlier into spring, resulting summer water shortages could affect everything from agriculture and hydropower to fish habitat, the professor said.

It's a fear that he shares with Belgrade native Kelly Redmond, Western regional climatologist for the National Oceanic and Atmospheric Administration Climate Center in Reno, Nev.

The degree of change in spring melt varies, Redmond said, but the trend toward earlier melt is widespread across the West. Yellowstone Basin snow begins to melt five to 15 days earlier than it did 56 years ago.

The trend becomes more pronounced as waters flow west. West of the Divide in Montana and into Idaho, Washington and Oregon, spring melt comes 15 to 25 days earlier, Redmond said.

"It's kind of taken us all aback," he said in a telephone interview. "It's kind of hard to see this happening right under our nose without us noticing."

Only in the last few years has early snowmelt drawn much interest, he said, but he expects to see research and public information on the trend accelerate.

Evidence for earlier melts is strong on a lot of fronts, Redmond said.

At the top of the list are temperature statistics. Records indicate that America is warming, especially in the West, and especially in February, March and April. For most of the West, Montana included, temperatures during that critical period have increased a half-degree to a full degree every decade for the last 30 to 40 years.

March 2004 stands out as a prime example, Redmond said. It was an "exceptional" month, the climatologist said.

All across the West, it was warm and dry. For south-central Montana, 2004 produced the fourth-warmest March since 1895. It was also among the driest.

"Normally, March is a snow production month," he said. "But this year it was a deficit month." Montana wasn't alone in its lack of snowpack. Utah started the month expecting near average spring runoff for a change, Redmond said. By the end of the month, the state was bracing for one of the lowest runoffs ever.

Statistics from Natural Resources and Conservation Service snow surveys show that snowpack declined 16 percent in Montana between March 1 and April 1. The losses were more severe elsewhere in the West, including Nevada, 54 percent; Arizona, 51 percent; New Mexico, 43 percent; Utah, 39 percent; and Wyoming, 19 percent.

A warm March and a warm winter worked together. In Montana, the average temperature from October through March was 3 degrees above normal - the 11th-warmest winter on record. Even winter-ravaged northeastern Montana surpassed its winter average by 1 degree.

Running said that studies of the Missoula area showed the number of frost-free days has increased 15 days there in the last 50 years and that annual snowfall has fallen from an average of 55 inches to 40 inches.

Related, but separate evidence of earlier snowmelt comes from studying peak spring flows for more than 1,000 streams in the Western states, Western Canada and Alaska over the last 50 years, Redmond said. Those studies show snowpack disappearing from one to three weeks earlier in the spring. What researchers measured was the "spring pulse" of all those streams.

Snowmelt begins after the pack has ripened, Redmond said. It accumulates enough heat that the entire pack reaches 32 degrees, before it starts to melt.

"When the snow begins to melt, it does it in a fairly abrupt fashion," Redmond said. Scientists can go back through streamflow records and mark the date when the water starts to come down - that's its spring pulse. Records show that the pulse happens almost simultaneously throughout the region. The pulses kick in usually within two or three days of each other, he said. Research shows that, from New Mexico to Alaska, the pulse is getting earlier, Redmond said. This spring a river gauge in California's Yosemite National Park recorded the spring pulse on March 6, the earliest ever in 87 years of monitoring.

A third body of evidence originated more than 40 years ago when then-Montana Climatologist Joe Caprio began collecting data on the life cycles of lilacs and honeysuckle, Redmond said. Caprio recruited 500 observers in 11 states to record when the plants first showed signs of life in the spring and when they blossomed.

Analysis of the information indicated that the plants are blooming seven to 10 days earlier now than they did 40 years ago, Redmond said. "They all kind of give a consistent pattern," he said of the temperatures, spring pulses and blooming dates.

Warmer springs and earlier melts mean a longer growing season and that plants will be using more water, Redmond said. It may also mean that more moisture will go directly into the atmosphere, he said.

"The major thing to sort out here has been whether this is a natural variation in climate or if it is something else," he said. "There is strong evidence that a good part of it is natural."

For Running, the debate has already been resolved. He said human activity is clearly playing a significant role in climate change.

"We'd better start getting serious about energy that's not based on petroleum," he said. If the world community doesn't find some solutions, consequences will be dire, Running said.

"People are going to have to face up to it head on or get used to less and less snowpack and more and more drought," he said.

Colorado tops list of rivers in danger

Radioactive tailings near Moab blamed
By Lee Davidson
Deseret Morning News

WASHINGTON — National environmental groups are declaring the Colorado "America's Most Endangered River," mostly because they say 110,000 gallons of

contaminated water seep into it daily through radioactive uranium tailings near Moab.

Photo caption: A pond is on top of uranium tailings at the old Atlas Minerals site near Moab in 1998. In the background is the Colorado. Environmentalists are worried that the tailings may be capped in place instead of being removed.

"The Colorado River is not yet the most polluted river in the country, but it could become so if the current problems are allowed to fester," said Rebecca R. Wodder, president of the environmental group American Rivers.

It and partner groups — ranging from the Sierra Club to the Grand Canyon Trust and Friends of the Earth — each year release a list of America's most endangered rivers. They plan to formally release it this morning at the National Press Club.

The groups explained in advance that they put the Colorado atop this year's list largely out of worry that the Energy Department may not remove tailings from the old Atlas uranium mill site adjacent to the river and instead cap them in place.

"Someday a big flood like those that raged through these canyons in the 19th century is going to lift that pile into the river and irradiate Canyonlands National Park. It is pure folly not to move this pile away from the flood plain of the Colorado River," said John Weisheit with the environmental group Colorado Riverkeeper.

Bill Hedden, with the Grand Canyon Trust, added, "As long as this material remains on the riverbank, it poisons the river every day and threatens water supplies with catastrophic failure."

The Energy Department is scheduled to release next month a draft environmental impact statement that will identify a preferred option for handling the tailings. Utah politicians have vociferously opposed capping it on site — the cheapest alternative — as have California politicians worried about radiation in their downstream drinking water.

About 13,000 tons of uranium tailings are on 130 acres at the Atlas site. Interim remediation by the Energy Department now includes dewatering the tailings and pumping contaminated groundwater to an evaporation pond on top of the pile.

However, environmental groups say an estimated 110,000 gallons of contaminated water still seep into the river from the unlined pond every day — with contaminants

including uranium, radium, ammonia, cadmium, arsenic, selenium and other heavy metals.

"Because this pile is so large and because we are so few in this remote region, they may be thinking they can save millions of dollars and justify their actions to stabilize this pile in place next to the river," Weisheit said. "Well, they would be wrong to think this way. Losing this pile to a big flood or the river's migration could affect Los Angeles as much as it would affect us here in rural Utah."

Sarah Fields, coordinator of the Nuclear Waste Committee of the Sierra Club Glen Canyon Group, said, "For thousands of years this tailings pile will remain toxic and radioactive to humans and animal life. In the scale of hundreds of years, it is inevitable that a catastrophic flood will consume this pile and devastate the down-river environment."

The environmental groups say the Colorado is also threatened — but not so dramatically — from human waste reaching it from boom towns in California and Arizona.

They say fast-growing areas there have the largest concentration of people in America that use septic tanks. They say overloaded systems are allowing high levels of nitrates to seep into the river and efforts to upgrade wastewater systems there are hampered by lack of federal support.

Also, the groups say that toxic ammonium perchlorate is trickling into the river from a former military facility near Henderson, Nev.

"Our tests last year found that perchlorate levels in winter lettuce irrigated by the Colorado were four times higher than the EPA's recommended safe dose for a glass of drinking water," said Bill Walker, vice president of the Environmental Working Group.

"The cropland irrigated by the river produces most of the lettuce and other produce sold nationwide during the winter months," he said, "which means that perchlorate is not just a local or regional problem but a concern for every American."

Wodder with American Rivers said, "The problems identified here all require immediate action, but those should be just the first steps towards a comprehensive restoration effort." She added, "We call on the nation's leaders to take the next step and develop a binding cleanup plan to ensure that the Colorado River can meet the many demands placed on it for generations to come."

LR Press Release 04/13/04

Colorado River: most endangered river for 2004

April 14, 2004

Cell - (435) 260-2590
Sarah Fields - (435) 259-4734

Uranium Waste Pile at Moab, Utah Threatens Public Health

(Moab, UT.) - American Rivers, a national river protection and advocacy organization, today announced it has designated the Colorado River as America's Most Endangered River for 2004. Their annual report's focus is on rivers facing the most uncertain futures, not on those with the worst chronic problems.

On the Colorado River the most dangerous and volatile situation is the Moab Uranium Mill site (former Atlas Mill) near Moab, Utah. There is an estimated 110,000 gallons of radioactive groundwater seeping into the River each day from a crude, unlined riverbank impoundment where almost 12 million tons of radioactive waste is stored. The National Academy of Sciences has warned that it is "nearly certain that the River's course will run across the Moab site sometime in the future." The Department of Energy (DOE) will soon release the Draft Environmental Impact Statement the site. The DEIS will not identify a preferred remediation alternative. Donald Metzler, DOE's Program Manager for the Moab Mill Project, has stated that the DOE has not yet made a decision regarding whether the impoundment will be capped in place or moved to an off-site location. The DEIS will announce the preferred alternative for groundwater remediation so that the U.S. Fish and Wildlife Service will be able to complete its Biological Opinion.

One of the partners for the Most Endangered River Initiative is the Colorado Riverkeeper, John Weisheit, who works daily from an office that is located within a mile of the Atlas Mill site, the second largest uranium waste pile in the United States. "Visitors come from all over the world to enjoy the Colorado River through Canyonlands National Park downstream. They enjoy the scenery, the rapids and all the good things one expects to find from such a treasured landscape. Someday a big flood like those that raged through these canyons in the 19th Century is going to lift that pile into the River and irradiate Canyonlands National Park. It is pure folly not to move this pile away from the floodplain of the Colorado River."

Many other grassroots activists from rural Utah are also working with the Colorado Riverkeeper, a project sponsored by Living Rivers, a river advocacy group from Moab that promotes large-scale restoration for the Colorado River. Among them is Sarah Fields, who too resides within a mile of the pile and has engaged herself in efforts to remove the pile for over ten years. Fields is also the coordinator of the Nuclear Waste Committee of the Sierra Club Glen Canyon Group. "It is a fact that for thousands of years this tailings pile will remain toxic and radioactive to humans and animal life. In the scale of hundreds of years, it is inevitable that a catastrophic flood will consume this pile and devastate the down river environment. As irresponsible as it was to put this pile by the River, it is equally as irresponsible to let it remain by the River."

As the Colorado Riverkeeper, Weisheit has an intimate background with the river as a professional river guide, who has led more than 250 expeditions through the famous rapids of Cataract Canyon in Canyonlands National Park. "Uranium waste piles have

been mitigated before through removal by the Department of Energy, including many others sites on the Colorado River and its tributaries upstream of Moab. But, because this pile is so large and because we are so few of us in this remote region, they may be thinking they can save millions of dollars and justify their actions to stabilize this pile in place next to the River. Well, they would be wrong to think this way. Losing this pile to a big flood or the River's migration could affect Los Angeles, as much as it would affect us here in rural Utah."

Through grassroots advocacy, Living Rivers and the Colorado Riverkeeper are currently building a national and international coalition for Colorado River protection and restoration and is now supported by over 170 groups.

Colorado River "Most Endangered" Colorado #1 on annual list released today -
www.americanrivers.org

(Washington, DC) American Rivers and its partners today designated the Colorado River the nation's Most Endangered River for 2004, citing mounting problems with radioactive, human, and toxic waste in the river that have been largely overlooked during interstate conflict over water allocations. The annual America's Most Endangered Rivers report highlights rivers facing the most uncertain futures rather than those with the worst chronic problems. American Rivers and its partners warned that without a coordinated national effort to clean up the sources of contamination, pollution levels in the river will take a sharp turn for the worse in coming years.

"The Colorado River is not yet the most polluted river in the country, but it could become so if the current problems are allowed to fester," said Rebecca R. Wodder, president of American Rivers. "A concerted national solution is necessary to problems that reach far beyond the banks of the river." The most dangerous and volatile situation is the Atlas Mill site near Moab, Utah. There, an estimated 110,000 gallons of radioactive groundwater seep into the river each day from a crude, unlined riverbank impoundment

where almost 12 million gallons of radioactive waste are stored. The National Academy of Sciences has warned that it is "nearly certain that the river's course will run across the Moab site sometime in the future." The Department of Energy will soon announce its plans for the site, but has signaled its intention not to relocate the material to a safer location.

"As long as this material remains on the riverbank, it poisons the river every day and threatens water supplies with a catastrophic failure. New evidence suggests that disposing of it in an underground salt formation might be an affordable alternative," said Bill Hedden with the Grand Canyon Trust. "The Energy Department must now expedite studies of this alternative to confirm if it is truly the ideal solution." --More-- Colorado River "Most Endangered"

Page 2 of 2

Of equal concern are the rising predictions for human waste reaching the river from riverfront boomtowns in California and Arizona. This area has the largest concentration of people in the United States using septic tanks. These overloaded systems allow increasing quantities of nitrates to seep into groundwater and the Colorado River. High nitrate levels in drinking water can deplete oxygen in infants' blood ("blue baby" syndrome) and are suspected to cause certain types of cancer. Local communities' efforts to upgrade their wastewater infrastructure have been hampered by lack of federal support.

"For too long we've ignored the connections between ground and surface water," stated Robert Glennon, professor of law at the University of Arizona and author of a recent book, *Water Follies: Groundwater Pumping and the Fate of America's Fresh Waters*. "Each of these pollution problems facing the Colorado River involves contaminants migrating through groundwater and eventually emerging into the surface waters of the Colorado."

Finally, in Henderson, Nevada, the toxic chemical ammonium perchlorate is trickling into the river from a former military facility. Perchlorate has been measured in Lake Mead at concentrations as high as 24 parts per billion, interferes with proper thyroid function and disrupts the body's normal hormonal balance. Produce grown with Colorado River water often contains trace amounts of the chemical and is sold at supermarkets nationwide. Even as scientists debate how much exposure to perchlorate is safe, Congress is considering relieving the Department of Defense of the responsibility to clean up after itself at Henderson and elsewhere.

"Our tests last year found that perchlorate levels in winter lettuce irrigated by the Colorado were four times higher the EPA's recommended safe dose for a glass of drinking water," said Bill Walker, Vice President/West Coast of the Environmental Working Group, which has studied perchlorate contamination since 1999. "The cropland irrigated by the river produces most of the lettuce and other produce sold nationwide during the winter months, which means that perchlorate is not just a local or regional problem, but a concern for every American."

"The ongoing drought situation for the Colorado River basin is exacerbating our water quality problems," says the Colorado Riverkeeper John Weisheit, who lives next to the river in Moab, Utah. "Lack of freshwater inputs and high evaporation from the reservoirs are increasing the rates of salt, phosphorous, nitrates, and heavy metals. Not only is this detrimental to our health and infrastructure, it is also detrimental to our national parks at Canyonlands and Grand Canyon. "

Groups call for action The groups called for action to ensure that the Colorado River can continue to be a liquid lifeline for the Southwestern United States. The groups called on the Department of Energy to commit to removing the uranium tailings to a more secure location out of the river floodplain. They called on Congress to reject proposed cuts in federal aid to communities seeking to construct or maintain wastewater treatment infrastructure. They called on Congress to deny requests from the Defense Department for relief from its obligation to clean up contamination at former military facilities. -- More-- Colorado River "Most Endangered"

Page 3 of 3

"The problems identified here all require immediate action, but those should be just the first steps towards a comprehensive restoration effort," said Rebecca R. Wodder, president of American Rivers. "We call on the nation's leaders to take the next step and develop a binding cleanup plan to ensure that the Colorado River can meet the many demands placed on it for generations to come."

Colorado River not unique While the situation along the Colorado River is particularly urgent, it is sadly far from unique. Scientific data reveals that America's rivers, streams, and lakes have become progressively more polluted since 1998. Conservationists warned that the White House and Congress have made little effort reverse this trend -- and have in fact cut law enforcement and spending on clean water over the past three years.

About America's Most Endangered Rivers Each year, American Rivers solicits nominations from thousands of river groups, environmental organizations, outdoor clubs, local governments, and taxpayer watchdogs for the America's Most Endangered Rivers report. The report highlights the rivers facing the most uncertain futures rather than those suffering from the worst chronic problems. The report presents alternatives to proposal that would damage rivers, identifies those who will make the crucial decisions, and points out opportunities for the public to take action on behalf of each listed river.

River News 04/13/04

Colorado River is ranked most endangered by group

By Judy Fahys The Salt Lake Tribune

The Colorado, polluted by uranium milling, toxic chemicals and human waste, is the nation's most endangered river, the environmental group American Rivers planned to announce today.

After being on the group's top-10 list four times previously, the Colorado River was singled out this year not because there might be water shortages but because there is too much contamination. The "most-endangered" designation will encourage government and citizens to act swiftly to address the growing pollution threat to a resource used by 25 million people, said Eric Eckl, a spokesman for the Washington D.C.-based environmental group.

"We believe the people who hold the fate of the Colorado River in their hands are more likely to make the right decisions if they know the American people are paying attention," he said.

American Rivers identified three major threats to the Colorado:

- * The 12-million-ton uranium waste pile from the river's banks outside of Moab. Because the tailings release uranium, ammonia and other pollutants into an area of the river prized for its endangered fish habitat and for recreation, many Utah leaders and environmentalists have pushed for the waste's removal, instead of the cheapest of the five solutions the Department of Energy is currently considering, capping the waste in place.
- * The area below Hoover Dam has the nation's highest concentration of people using septic tanks, which, as they become overloaded, leach nitrates into the river that are blamed for depleting the oxygen in infants' blood and for certain types of cancer. Charlie Cassens, a spokesman for Lake Havasu City, Ariz., said contamination prompted the city's 50,000 residents to endorse phasing out the septic systems in favor of a sewer system.
- * A Cold War missile-fuel plant site in Henderson, Nev., which releases 400 pounds of ammonia perchlorate daily. An ingredient of rocket fuel blamed for hormone disruption in humans, perchlorate has been found in high concentrations in Lake Mead and in trace amounts on leafy vegetables irrigated with Colorado River water. American Rivers said Congress should toughen clean water controls and clean up the site.

Dirty River

The environmental group American Rivers put the Colorado River at the top of its Most Endangered Rivers list this year because of three pressing threats.

This year the Snake was the only other Western river on the group's top-10 list, which was developed in collaboration with environmental groups. The Colorado River made the list previously because of the Glen Canyon Dam's impacts and the endless fight over rights to its water. Bill Hedden of the Grand Canyon Trust applauded the shift in focus this year.

"Every time we dump junk into it, someone else has to deal with it downstream," he said.

"We haven't thought much about the quality of the water so many people are drinking and putting on crops," he said.

Sarah Fields, a Moab environmental activist, noted that the Energy Department is set to announce its decision on the Atlas tailings next month. Like American Rivers, she opposes capping the tailings in place instead of moving them.

"It's obvious the river will impact the [current] tailings impoundment through flooding or if the riverbed meanders," she said.

Colo. River named most endangered

Shaun McKinnon The Arizona Republic Apr. 14, 2004 12:00 AM
Special report

Radioactive runoff, toxic rocket-fuel chemicals and human waste threaten the health of the Colorado River as much as the growing number of people who use it, according to a conservation group that today puts the Colorado at the top of a list of rivers at risk. The 1,400-mile Colorado is the nation's most endangered river for 2004, a title bestowed each year by American Rivers to focus attention on waterways facing uncertain futures.

Although the Colorado has been caught for years in squabbles over how much water-thirsty Western states can take from it, American Rivers cites water quality rather than quantity.

"The Colorado River is not yet the most polluted river in the country, but it could become so if the current problems are allowed to fester," said Rebecca Wodder, the group's president. Cited are three pollution sources that spew millions of gallons of contaminated water into the river each year:

- An abandoned Atlas Corp. uranium-tailings site on the river's bank just outside Moab, Utah. An estimated 110,000 gallons of radioactive groundwater seeps into the Colorado daily.
- A defunct war-munitions complex near Las Vegas. Ammonium perchlorate, a rocket-fuel additive, continues to contaminate Lake Mead.
- Septic-tank systems in river communities. Seepage from the systems has increased nitrate levels in the river just miles from where water is diverted into the Central Arizona Project Canal and a canal to Southern California.

The new report is not meant to cast doubt on Arizona's drinking water, American Rivers spokesman Eric Eckl said. The river itself and the reservoirs along its length help dilute the contaminants, and municipal treatment plants remove most of what remains.

At stake now, he said, is the river's long-term health.

"We're not trying to tell anybody they should be afraid of what's coming out of their taps, but we're asking people to not take that for granted," Eckl said. "People have been so focused on the conflict over who gets how many drops that the question of how clean this water is has gone largely unasked. Now that people are starting to ask that question, the answer is not very reassuring."

Other river advocates applaud the focus on the Colorado's water quality.

"We've spent per gallon more money putting the Colorado River to use for people than any other sizable river on Earth," said Bill Hedden, executive director of the Flagstaff-based Grand Canyon Trust. He said the report highlights "problems that people have created; there are decisions on the table that could provide answers to these things." Among pending decisions:

- The Department of Energy is about to release its statement on cleanup at the Moab site. Environmental groups want the tailings moved, but a plan to leave it in place would cost millions of dollars less.

"It's true the cost of capping it in place would be less," said Sarah Fields, who works for the group Living Rivers. "But over the long term, it would probably cost a great deal more."

- Congress is considering requests from the Defense Department to exclude some current and former military sites from certain environmental rules. That could affect efforts to fully remove perchlorate-tainted soil from the Nevada munitions complex.
- The Bush administration has proposed cuts in a federal loan program that helps communities upgrade water and wastewater systems. Lake Havasu City voters approved a \$500 million bond issue to help retire thousands of septic systems in that community, but the problem is larger.

"Our voters have stepped up to the plate to correct our local problem, but that doesn't have much of an impact on all the other areas that are developing up and down the river," said Charlie Cassens, a spokesman for Lake Havasu City. "We can't do it alone."

This isn't the first time American Rivers has focused on the Colorado. It put the river at the top of the endangered list in 1991, citing the environmental effect of Glen Canyon Dam and has included all or part of the river on the top 10 list three other times since then.

River News 04/27/04

U.S. may cut water to state / Southwest drought slashes Colorado River flows

By Stuart Leavenworth
Sacramento Bee Staff Writer
(Published April 27, 2004)

The Bush administration is threatening to impose unilateral water cutbacks on California, Arizona and Nevada if the three states can't come up with a plan to deal with a historic drought on the Colorado River.

Following five years of dry weather, the two largest reservoirs on the Colorado are roughly half-empty and dropping fast, and Interior Department officials are urging water agencies to work together on a contingency plan or have one imposed on them.

"We need the three basin states to get their act together and deal with shortages," said Assistant Interior Secretary Bennett Raley in a recent meeting with water officials from California, Arizona and Nevada. If the three states can't work out a plan, he said, the Interior secretary "will have to do it."

For years, Los Angeles, Las Vegas and other fast-growing cities in the region have depended on surplus water from the Colorado - supplies that exceed their entitlements. Now, the Southwest is shifting to a much drier period, and states are facing not only the loss of surplus but also cutbacks that could affect tens of millions of people.

In California, the water squeeze is already being felt statewide. With less water from the Colorado River, Southern California is pushing conservation, more use of groundwater banks and extra pumping from the Delta.

"We are entering some new territory," said Raley, who notes that the modern Southwest has never had to deal with an extended drought.

Since 1999, Lake Mead has dropped more than 80 feet and is at 58 percent of capacity. With less water pressure going through its turbines, Hoover Dam is losing some of its capacity to generate power, and Las Vegas is preparing to deepen its water intake in Lake Mead to keep up with a moving target.

Upstream, at Lake Powell, the water loss is even more dramatic. In four years, Powell has dropped nearly 120 feet, and now holds 42 percent of its maximum water capacity. Never before have both Lake Mead and Lake Powell been at such a low state at the same time, according to officials for the U.S. Bureau of Reclamation.

Water leaders in the Southwest are closely watching these lake levels, and so are those in other Western states. Under the 1922 Colorado River Compact, the upper-basin states of Colorado, New Mexico, Utah and Wyoming must deliver 7.5 million acre-feet of water to the three lower-basin states each year. Lake Powell was built so the upper basin could deliver on that promise, but now Powell's future is in doubt.

According to federal forecasts, drought and water deliveries could drain Powell in three years. In such a situation, the upper basin would be forced to forgo river withdrawals or risk a major court battle.

To head off that prospect, water officials from seven states have been meeting regularly in recent months, said Dennis Underwood, a former reclamation commissioner who now works for the Metropolitan Water District of Southern California. The most recent meeting was held Monday in Phoenix, where officials discussed options for keeping the taps flowing.

Some of those options, said Underwood, include storing lower-basin water in upper-basin reservoirs to reduce the huge evaporation that occurs in Lake Mead. Agencies are also discussing water trades and "forbearance agreements" - paying farmers not to irrigate - to help vulnerable areas through a drought.

One such spot is Las Vegas, the nation's fastest growing city and one that draws 98 percent of its water from the Colorado. Not wanting to gamble on their future, Nevada officials have been pressing for some type of interstate water-sharing arrangement.

Pat Mulroy, general manager of the Southern Nevada Water Authority, said the recent talks are a recognition that the regional water situation is serious. "People are finally realizing that the drought is real," said Mulroy, "and not something I thought up in a bar."

In a December speech in Las Vegas, Interior Secretary Gale Norton laid out some of the possible scenarios. Under the 2001 Interim Surplus Guidelines, Norton said she is

required to cut surplus supplies to California, Arizona and Nevada if the surface of Lake Mead drops to 1,125 feet in elevation - 10 feet below its current level.

Further down the road, Norton could use her court-appointed authority as Colorado "river master" to declare a shortage and impose cutbacks. Some water experts believe Norton could make such a declaration when Lake Mead's surface level hits 1,083 feet elevation - about 52 feet below its current elevation - but the law isn't specific.

To ratchet up the pressure, Interior officials invited Southwest water leaders and a group of journalists on a boat trip this month down the Grand Canyon, where Raley repeated his warning Norton was ready to take action. "Time lost now is time we may not be able to recover," said Raley, pacing across a sand bar like Gen. George Patton.

Some environmentalists say the Bush administration is delaying tough decisions by playing this kind of drawn-out pressure politics. This year, they note, the Bureau of Reclamation declared a partial surplus on the Colorado River, which further depleted Lake Mead. Now federal officials are preaching drought preparedness.

"The bureau is dragging its feet," said Jeff Van Ee, a water watchdog for the Sierra Club in Las Vegas. "They haven't taken this drought seriously."

Raley, who oversees the Bureau of Reclamation, said he started working closely on the drought problem in January. Before that, he helped seal a landmark settlement that quantified how much water California's cities and farms could draw from the Colorado River. By agreeing to limit its water withdrawals to 4.4 million acre-feet, California was given a 13-year grace period to continue receiving "surplus" water from the river.

Now, say water officials, that grace period appears to be moot.

River News 05/01/04

Looming Colorado River shortage forcing tough choices in the West

By Seth Hettena, Associated Press

GRAND CANYON NATIONAL PARK, Arizona — The Colorado River runs cold and fast through the Grand Canyon, a postcard picture of the water wealth that greens farms and slakes the thirst of booming cities.

But there's a lot less to the Colorado than meets the eye. Five years ago, the vast reservoirs at both ends of the Grand Canyon were essentially full, brimming with water for showers, kitchen sinks, irrigation, and ornamental fountains. Today, they are both half empty as drought in the region enters its fifth consecutive year, making this the driest five-year period on record.

The river supplies water to 25 million people in seven states and more in Mexico.

But with no end to the drought in sight, the Interior Department may be nearing the first declaration of a water shortage on the Colorado River, said Bennett Raley, the department's assistant secretary for water and science. Such a declaration would mean a cut in the amount of water that can be drawn from the river, Raley told reporters during a 224-mile rafting trip through the canyon in April.

"If current trends continue ... the secretary would be forced to take action certainly within three years and potentially within two," unless the states offer a solution, Raley said.

The severity of the cut would be up to the interior secretary, but even a small reduction would ripple across the West. The 1,400-mile-long river grows U.S. and Mexican crops, generates electricity, supports a huge recreation industry, and delivers water to some of the nation's driest and hottest cities, including Phoenix and Las Vegas.

Drought is already doing what environmentalists could only dream about: It's draining Lake Powell, the reservoir just upriver from the Grand Canyon that submerged hundreds of miles of scenic canyons and countless archaeological sites.

Powell is so low that hikers are beginning to explore glorious sandstone canyons once submerged under 100 feet of water. The lake has fallen to 42 percent of capacity, its lowest since it was filled in 1970. At the downstream end of the Grand Canyon is Lake Mead, the huge lake formed by Hoover Dam. It is at 59 percent of capacity and could reach the same state as Powell as early as 2008.

Las Vegas is almost entirely dependent on Lake Mead for water and is worried about the effect continued drought could have on its explosive growth. The city is stressing conservation to avoid a self-imposed drought emergency, and water managers are ripping out water-guzzling lawns.

In a shortage declaration, Arizona would be the first to suffer. Under a 36-year-old compromise the state now regrets, Arizona would lose all the Colorado River water that now goes to Phoenix, the nation's sixth-biggest city, before California would lose a single drop.

Colorado, Utah, New Mexico, and Wyoming are worried as well. Under a 1922 accord they would be required to cut their own water to guarantee a supply to California, Arizona, and Nevada.

While the states depend on a steady source of water, nature is anything but steady. A study of tree rings at the headwaters of the Colorado River found evidence of a drought as recently as the 16th century that lasted 20 years.

In fact, tree rings have led scientists to believe that much of the past century was unusually wet and that more dry years could lie ahead, said Robert H. Webb, a hydrologist who studies the Grand Canyon for the U.S. Geological Survey and is co-author of "Floods, Drought, and Climate Change."

"We have no idea how long this drought is going to last," Webb said. "Every indication says this one's gone beyond all our past experience."

Raley is pushing the states to do something unusual: share the water. The best chance of avoiding a shortage may lie in California, Nevada, and Arizona working together to help each other. One possibility is an interstate water bank in Lake Mead that the three states could share.

However, when it comes to water, the states are more used to bickering than cooperating. Arizona and California waged legendary battles over the Colorado, including Arizona's comical effort to stop construction of a dam intended to divert water to Los Angeles by sending five soldiers to the river in 1934.

During the rafting trip, Raley asked three water managers from Arizona, California, and Nevada what they would do, hypothetically, to prevent the interior secretary from declaring a shortage next year. As they discussed the problem, the age-old feud between California and Arizona flared again.

"I'm not going to be looking to California to help me out. I'm not figuring Arizona's going to do much to help California until the reservoirs turn around," said Sid Wilson, general manager of the Central Arizona Project, the 336-mile concrete channel that carries Colorado River water to Phoenix and Tucson.

However, Wilson did say that Arizona is trying to help Nevada.

Pat Mulroy, general manager of the Southern Nevada Water Authority, says she will have to turn to Arizona or California for help if the river continues to shrink. But Mulroy isn't optimistic.

"All the legal mechanisms are set up for disaster," she said. "We can't seem to get the idea that if we share we get so much further."

Drought Settles In, Lake Shrinks and West's Worries Grow

By KIRK JOHNSON
and DEAN E. MURPHY

POUCE, here — in the quiet and menacing, the drought that has parched much of the West is growing much harder to shrug off as a blip.

Those who worry most about the future of the West — politicians, scientists, business leaders, city planners and environmentalists — are increasingly predicting that a world of scarcity that they and younger generations anticipate may not be a passing phenomenon but rather the result of a harsh climate shift.

Contrasting this with the drought cycles even the last 600 years bears witness, strongly suggesting that the relatively wet weather across much of the West during the 20th century was a fluke.

DRY SPELL
For those and growing

across much of the West during the 20th century was a fluke. In other words, scientists who study these things and make long-range predictions are predicting that the drought of the 21st century may be one of the biggest growth spurts in the nation's history — not least because of a natural increase.

That shift is shaking many assumptions about how the West is run. Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming, the states that depend on the Colorado River, are preparing for the possibility of a new shortage for the first time since the Hoover Dam was built in the 1930s to control the river's flow. The top water official of the Bush administration, Bruce W. Bledsoe, said recently that the federal government might step in if the water crisis for the state among farmers and cities is not solved with existing supplies, a move that a lot of people here has criticized as the growing urgency.

"Before the drought, we had 30 years of a wet cycle and 30 years of the most growth ever," said John R. S. Smith, the New Mexico Basin engineer, who is responsible to find new water supplies for the suburbs of Albuquerque that still see rain a generation ago.

DRY SPELL Articles in this series will examine the effects of prolonged drought on states in the Colorado River basin.

PAGE, Ariz. — At five years and counting, the drought that has parched much of the West is getting much harder to shrug off as a blip.

Those who worry most about the future of the West — politicians, scientists, business leaders, city planners and environmentalists — are increasingly realizing that a world of eternally blue skies and meager mountain snowpacks may not be a passing phenomenon but rather the return of a harsh climatic norm.

Continuing research into drought cycles over the last 800 years bears this out, strongly suggesting that the relatively wet weather across much of the West during the 20th century was a fluke. In other words, scientists who study tree rings and ocean temperatures say, the development of the modern urbanized West — one of the biggest growth spurts in the nation's history — may have been based on a colossal miscalculation.

That shift is shaking many assumptions about how the West is run. Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming, the states that depend on the Colorado River, are preparing for the possibility of water shortages for the first time since the Hoover Dam was built in the 1930's to control the river's flow. The top water official of the Bush administration, Bennett W. Raley, said recently that the federal government might step in if the states could not decide among themselves how to cope with dwindling supplies, a threat that riled local officials but underscored the growing urgency.

"Before this drought, we had 20 years of a wet cycle and 20 years of the most growth ever," said John R. D'Antonio, the New Mexico State engineer, who is scrambling to find new water supplies for the suburbs of Albuquerque that did not exist a generation ago.

The latest blow was paltry snowfall during March in the Rocky Mountains, pushing down runoff projections for the Colorado River this year to 55 percent of average. Snowmelt is the lifeblood of the river, which provides municipal water from Denver to Los Angeles and irrigates millions of acres of farmland. The period since 1999 is now officially the driest in the 98 years of recorded history of the Colorado River, according to the United States Geological Survey.

"March was a huge wake-up call as to the need to move at an accelerated pace," said Mr. Raley, assistant secretary of the interior for water and science.

Losing Water at Lake Powell

Photo caption: The loss of nearly 60 percent of Lake Powell's water led to cracks five feet deep in the dried lake bed near Hite, Utah, as the Colorado River cut a new channel in the sediment.

Some of the biggest water worries are focused here on Lake Powell, the vast blue diamond of deep water that government engineers created in one of the driest and most remote areas of the country beginning in the 1950's. From its inception, Lake Powell, the nation's second-largest artificial lake, after Lake Mead in Nevada, was a powerful

symbol across the West. Some saw it as a statement of human will and know-how, others of arrogance.

Powell, part of the Glen Canyon National Recreation Area, has lost nearly 60 percent of its water and is now about the size it was during the Watergate hearings in 1973, when it was still filling up. White cliffs 10 stories high, bleached by salts from the lake and stranded above the water, line its side canyons. Elsewhere, retreating waters have exposed mountains of sediment.

The tourist economy here in Page has been battered. The National Park Service, which operates the recreation area, has spent millions of dollars in recent years just to lay concrete for boat-launch ramps that must be extended every year, a process that one marina operator here called "chasing water."

Daniel C. McCool, a professor of political science at the University of Utah and director of the American West Center, says Powell is the barometer of the drought because what has happened here is as much about politics, economics and the interlocking system of rules and rights called the law of the river as it is about meteorology.

Part of the lake's problem, for example, dates to a miscalculation in 1922, when hydrologists overestimated the average flow of the Colorado River and locked the number into a multistate agreement called the Colorado River Compact. The compact, along with a subsequent treaty with Mexico, requires Lake Powell to release 8.23 million acre-feet of water each year below the river's dam, Glen Canyon, no matter how much comes in.

Because the river's real average flow was less than the 1922 compact envisioned, Powell very often released more than half of the water the Colorado River delivered. But it did not really matter because the upper basin states were not using their share. Now, communities from Denver to Salt Lake City and Indian tribes with old water rights in their portfolios are stepping forward to stake their claims. Lake Powell, which has been called the aquatic piggy bank of the upper West, is overdrawn.

If water levels continue to fall, Powell will be unable to generate electricity as early as 2007 or sooner, some hydrologists say. And it would be reduced more or less to the old riverbed channel of the Colorado River not long after that. Even now, the lake's managers say, it would take a decade of historically normal rainfall to refill it.

"If we're only in the middle of this drought, then Lake Powell might be very close to some very dramatic problems," said Dr. John C. Dohrenwend, a retired geologist for the Geological Survey who lives near the lake.

Insufficient water for the Glen Canyon Dam turbines would be only the beginning. At that point, much of the lake bottom would be exposed, creating a vast environment for noxious weeds like tamarisk and thistle. The next step in the spiral would come at what is called "dead pool," where decades' worth of agricultural chemicals at the lake bottom would begin mixing more actively with the reactivated river. The question then,

environmentalists say, is what would happen to the Grand Canyon, just south of the dam.

An Issue That May Go to Congress

"Americans won't stand for the Grand Canyon being endangered," said John Weisheit, the conservation director for Living Rivers, an environmental group in Moab, Utah, that advocates removing the dam at Glen Canyon and allowing the river to return to its natural course. "In another year, they're going to be talking more seriously about Powell in Congress."

But the fact is, no one knows: the weather could change tomorrow. Many past Western droughts have ended suddenly, with a bang of precipitation. But some dry spells persisted for generations. From about 900 to 1300, scientists say, periodic drought in the West was the norm. Only a few times during that period, according to tree-growth measurements, was precipitation anywhere near the relatively high levels of the 20th century.

"What is unusual is not the drought periods, but the above-average wet periods," said Dr. Robert Webb, a hydrologist with the Geological Survey who specializes in the Colorado River.

The uncertainty has local, state and federal officials along the 1,450-mile river scurrying to secure water allotments while also preparing for the worst.

Already in Las Vegas, the regional water agency is removing the equivalent of a football field of grass every day from front lawns, playgrounds and golf courses to save on outdoor watering. Farther downriver, Arizona officials are pumping billions of gallons of water into aquifers to save for an even less rainy day.

Electricity has become a concern. The Western Area Power Administration, the federal agency that distributes power from hydroelectric projects in the Rocky Mountain West, plans to reduce by about 25 percent the amount of electricity it can promise in future years.

Conserving on a Large Scale

In Los Angeles, a representative from the West's largest urban water agency, the Metropolitan Water District of Southern California, is among a group of Western water officials dusting off plans to help limit evaporation from reservoirs, which could save billions of gallons. One idea is to pour a nontoxic substance over the reservoirs to form a water-trapping barrier.

The group, which has been holding meetings, is even looking at far-off solutions like raising the height of Hoover Dam so that more water could be collected and saved during wet times.

"We understand we have a problem and we are working on it," said the Los Angeles representative, Dennis Underwood, a former head of the federal Bureau of Reclamation, which oversees dams and reservoirs in the West.

There are also worries downstream from Powell at Lake Mead, which serves Nevada, Arizona and California. It could drop low enough as early as next year to force officials to declare a drought emergency. That would hurt the booming southern Nevada economy through significantly higher water rates and outright bans on things like new swimming pools, said Patricia Mulroy, general manager of the Southern Nevada Water Authority.

Mr. Raley of the Interior Department said he wanted the states to consider a water bank, in which unused water could be leased or sold across state lines. Some previous efforts to create banks, with federal oversight, have been contentious because they were seen by smaller states as a means to funnel more of the river to water-guzzling California.

But the notion of cutting private water deals on the Colorado is gaining broader acceptance, in large part because of the drought. The most celebrated example was a deal last year to sell irrigation water in the Imperial Valley of Southern California to the urban water district in San Diego.

Some advocates for agriculture fear that water-to-the-highest-bidder could ravage ranches and farms if owners were induced to sell their irrigation rights. But private-market supporters say the truth, like it or not, is that farmers own most of the West's water, and ultimately there will be fewer of them.

There is some concern that if the Colorado River goes into crisis, the ensuing tangle of litigation over water rights, endangered species and border disputes could undo the system of Western water law that has evolved over the last 100 years.

Some say that would be a good thing.

"The law of the river is hopelessly, irretrievably obsolete, designed on a hydrological fallacy, around an agrarian West that no longer exists," Professor McCool at the University of Utah said. "After six years of drought, somebody will have to say the emperor has no clothes."

Water officials in Arizona and Nevada say they would also like to rethink the law of the river to put their states on a more equal footing in sharing the Colorado River. But Mr. Raley said such talk invites disaster and chaos, especially during a drought.

"This isn't the time to plunge into chaos," he said.

Other people who live here on the fringe of Lake Powell say that the West's great reservoirs have, in their very decline, proved their value in stretching out limited water resources and underlined the difference between past civilizations here that anthropologists say were wiped out or displaced by drought.

"Those people back then had nothing to catch and save their water — now we do," said Ronald W. Thompson, district manager of the Washington County Water Conservancy District in southwestern Utah.

"I'm a believer that history repeats itself — long-term drought could return," Mr. Thompson said. "But I suspect our civilization can weather this."

Kirk Johnson reported from Page, Ariz., for this article and Dean E. Murphy from Grand Canyon National Park.

LR in the News 06/01/04

Waterkeeper Alliance inaugural magazine issue

Forty years ago, an enormous public outcry stopped the construction of two major dams that would have inundated Grand Canyon National Park. The famed Colorado River and its unique desert ecosystem would be preserved-or so it was thought.

However, a less noticeable, but lethal blow had already been delivered. On Jan. 23, 1963, the United States Bureau of Reclamation began filling a reservoir behind the 700 foot-high, Glen Canyon Dam upstream from Grand Canyon National Park. Immediately Glen Canyon Dam unleashed a current of devastation on the park. Four decades and numerous violations of federal laws later, the dam has nearly destroyed all the native habitat of Grand Canyon's famed river corridor.

Ninety-five percent of the sediment and nutrients that should flow into Grand Canyon's riverine ecosystem are trapped behind Glen Canyon Dam. The loss of sediment is eroding recreational beaches, reducing sandbar habitat for native fish, disturbing prehistoric cultural sites and gives an advantage to predators, like exotic trout species, that hunt-by-sight. It's also reduced the input of woody debris that should be providing carbon for a healthy food web. In contrast, the sediment behind the dam is filling Lake Powell and has already plugged 100 miles of canyons with thick, weed infested mud flats.

Seasonal water temperatures that previously fluctuated from freezing to 80 degrees now range from 47 to 50 degrees. The lack of warm water prevents the trigger necessary for native fish reproduction, but gives a reproductive advantage to non-native fish species. These non-native fish not only compete for available food, but also feed on the few young native fish that manage to hatch.

Natural flows, which fluctuated seasonally from 3,000 to 90,000 cubic feet per second (cfs), can now fluctuate daily and are restricted to only 8,000 to 20,000 cfs. This has

been devastating to the Grand Canyon's unique desert ecosystem. Native fish, like the razorback sucker, depended on high, natural flows to spawn. Without these flows, the species has become extirpated in the Grand Canyon. In fact, of the eight native Colorado River fish, four have died out and two are struggling for survival. At least twenty-four alien fish species now thrive in the artificial environment.

Fish haven't been the only animals to suffer though. Of the 50 to 100 native insect species (nobody counted before the dam) that once formed the food base of the Grand Canyon, none remain in the Colorado River today. They have been replaced by twenty-five families of alien invertebrate species, including the New Zealand mudsnail and the Asian tapeworm.

In 2001, Living Rivers' Colorado Riverkeeper began to draw public attention to the failure of federal efforts to reverse the impact Glen Canyon Dam has had on the Grand Canyon's river ecosystem. The group has built a nationwide coalition to demand major changes in the operation of this program. It has assembled a network of scientists to aid in formulating these strategies, as well as legal experts to prepare for litigation should these strategies not be acted upon.

LR Press Release 06/16/04
New USGS report on drought

For immediate release

Contact: Owen Lammers - (435) 259-1063/(435) 260-2590

USGS says no clear evidence that "Early 21st Century Drought" is waning.

In a paper released today by the United States Geological Survey on what is now being called the "early 21st Century drought," there is no clear evidence that wetter periods lie ahead for the Colorado River basin.

Titled, "Climatic Fluctuations, Drought, and Flow in the Colorado River", the paper discusses several mechanisms for predicting future Colorado River flows. Two forecast indices reveal dry times for the next five to thirty years, and one indicates that we should be experiencing higher flows now, but they have yet to materialize.

What is undisputed, the paper notes, is that this is the driest period in 500 years for the Colorado River basin. Flows into Lake Powell reservoir are averaging just 5.4 million acre feet per year--50 percent of normal. Even the dry Dust Bowl years between 1930 and 1937 had flows that averaged 10.2 million acre feet, the paper says. (To reflect today's current rate of consumption above Lake Powell, the amount would be adjusted to 7.5 million acre feet.)

Conversely, the paper points out how data from the past 450 years show that the years actually sampled to determine the legal allocation of Colorado River water amongst the seven Colorado River states, were part of the highest ever for the historic record

(1906-1930). The paper also states that the most unusual aspects of Colorado River flows are the periods of high flow and not the periods of drought.

"Its time that we recognize the dry periods are the norm for the Colorado River basin, and that we are using far more water than the river can provide," says Owen Lammers, Living Rivers executive director. "Regardless of whether we're at the beginning of significant climate change, or just moving through a sustained drought period, the bottom line is that our use of Colorado River water is based on mistaken mathematics which must be corrected before all excess storage runs dry."

Western drought worse than Dust Bowl

By ANGIE WAGNER
Associated Press Writer

LAS VEGAS -- The drought gripping the West could be the worst in 500 years, with effects in the Colorado River basin even worse than during the Dust Bowl years, scientists at the U.S. Geological Survey say.

"That we can now say with confidence," said Robert Webb, lead author of the new fact sheet released Thursday. "Now I'm completely convinced."

The drought has produced the lowest flow in the Colorado River on record, with an annual average flow of only 5.4 million acre-feet at Lees Ferry during the period 2001-2003, adjusted for the effect of Glen Canyon Dam. By comparison, during the Dust Bowl years, between 1930 and 1937, the annual flow averaged about 10.2 million acre-feet, the report said.

Scientists use tree-ring reconstructions of Colorado River flows to estimate what conditions were like before record-keeping began in 1895. Using that method, the lowest five-year average of water flow was 8.84 million acre-feet in the years 1590-1594. From 1999 through last year, water flow has been 7.11 million acre-feet.

"These comparisons suggest that the current drought may be comparable to or more severe than the largest-known drought in 500 years," the report said.

Environmental groups say water managers should take heed.

"The water managers, they just continue to pray for rain," said Owen Lammers, director of Living Rivers and Colorado Riverkeeper. "They just say, well, we hope that things change and we see rain."

Lammers said the report reinforces the need to figure out a better way to manage the Colorado River before reservoirs run dry.

"Once our reserve supply is gone, we have no plan of action for what to do," he said.

The report said the river had its highest flow of the 20th century during 1905 to 1922, the years used to estimate how much water Western states would receive under the 1922 Colorado River Compact.

The compact should now be reconsidered because of the uncertain water flow, said Steve Smith, a regional director for the Wilderness Society.

"We've got to figure out a new way of distributing the water that exists in the Western United States and be a lot more deliberate about our cautious and efficient use of the water," he said.

The report didn't surprise water managers.

"The big lesson is communities cannot afford to put all their eggs in the proverbial basket. You need .. a diverse portfolio of resources," said Adan Ortega, spokesman for the Metropolitan Water District of Southern California, the largest wholesale water supplier in the country.

Ortega said the water district is increasing water storage, buying water from farmers and investing in alternatives to the Colorado River.

Vince Alberta, spokesman for the Southern Nevada Water Authority, said water use in southern Nevada this year is actually down and the authority continues to enforce watering restrictions, impose fines for water waste and promote conservation.

"I think we can be successful managing this drought, but it's going to take a unified effort with everybody making sacrifices," Alberta said.

Herb Guenther, director of the Arizona Department of Water Resources, said the agency continues to plan for a continuing drought.

"It's serious, but the sky is not falling. Of course, we wish it would in the form of rain," he said.

Webb said predicting when the drought will end isn't easy because the Colorado River is difficult to forecast.

"It's sort of a split-personality river. It has headwaters up in Wyoming as well as headwaters in Colorado," Webb said. "Those two regions tend to respond to different things. ... We can't explain it very well."

Droughts seldom persist for longer than a decade, the report noted. But that could mean the current drought is only half over.

"If you're a betting person, you will bet that we will come out of this drought next year," Webb said. "It's a very severe event and these things tend to end fast. There are other indications, though, that suggest that this drought could persist for as long as 30 years.

"We don't really know."

EDITOR'S NOTE -- Angie Wagner is the AP's Western regional writer, based in Las Vegas.

Current Colo. River Basin dry spell could be worst in 500 years

April Reese, Land Letter Southwest correspondent

A new report by the U.S. Geological Survey suggests the drought parching the Colorado River Basin could be the worst in 500 years, prompting water watchdogs to warn of an impending water crisis in the region. But federal water managers say there is still plenty of the West's most precious natural resource to go around.

The USGS report -- "Climatic Fluctuations, Drought, and Flow in the Colorado River" -- summarizes the most recent data on drought and water supplies in the basin. It says the current dry spell reduced flows in the Colorado River to the lowest levels on record -- about 5.4 million acre-feet (maf) during 2001-2003.

Looking at five-year averages, 7.11 maf flowed down the Colorado between 1999 and 2003. The next-lowest five-year period occurred more than 400 years ago, from 1590-1594, according to tree ring data.

"These comparisons suggest that the current drought may be comparable to or more severe than the largest-known drought in 500 years," the report states.

USGS researchers also noted that the period used by federal water managers to divvy up the river's water under the Colorado River Compact -- 1905-1922 -- had some of the

highest flows of the 20th century. The average flow for that period was 16.1 maf, more than the twice the level of recent flows.

Gregory McCabe, a Denver-based USGS scientist who co-authored the report, said a confluence of climatic forces from both coasts is responsible for the current drought.

While alternately cool and warm currents in the Pacific Ocean have long been known to influence conditions in the Interior West, researchers have found that East Coast weather dynamics also play a role. "When you have a warm North Atlantic, you have a good chance of drought," McCabe said.

Does the current system work?

If drought is the normal condition in the Colorado River Basin, water managers need to change their way of thinking, said Owen Lammers, executive director of Living Rivers, an advocacy group based in Moab, Utah.

"Whether it's five, 10 or 15 years [long], we're going to face this at some point, so we might as well put in place a system to deal with it," he said. "In order to do that, we have to address the demand question. So let's start doing it, instead of waiting until we're in a crisis."

Storing water underground, where less is lost to evaporation and sediment build-up, could be part of the solution, Lammers suggested. But since nature is cutting the supply, water managers and consumers have to cut demand, he added. Switching from water-intensive crops such as alfalfa, which is grown to feed cattle, to less thirsty food crops and adopting municipal conservation and efficiency measures could cut the region's consumption of Colorado River water in half -- enough to bring demand in balance with supply, Lammers said.

Under the Colorado River Compact, signed in Santa Fe, N.M., in November 1922, the river's water was divided equally between upper and lower basin states, with the line drawn at Lee's Ferry, located above the Grand Canyon in northern Arizona. Colorado, New Mexico, Utah and Wyoming fell above the line, while Arizona, California and Nevada fell below.

Each basin was to receive 7.5 maf per year. Allocations for individual states vary widely, from California's 4.4 maf to Nevada's 300,000 acre-feet (Land Letter, Feb. 5).

If the drought continues, which many scientists say is likely, Lake Powell and Lake Mead could run dry, Lammers warned.

"Right now we're seeing twice as much water being used in Lake Mead than is coming [into the reservoir] from Lake Powell," he said. "At that rate, we're going to see Lake Powell empty in two to three years, then Lake Mead not long after that. In 2006, there's going to be real, real problems. That's when we may not have enough water to meet all the allocations downstream."

But Bureau of Reclamation spokesman Barry Wirth pointed out that Lake Powell and other reservoirs in the Colorado River Basin are fulfilling their purpose as a water insurance policy and so far have passed the most severe drought test since the system was built.

Bennett Raley, assistant Interior secretary for water, said that even if the drought worsens, there will be enough water.

"We think the drought is serious but not a crisis, because under any foreseeable scenario, there's going to be water for the economic engines of the West to continue to grow and prosper," he said in a phone interview from Denver, where BuRec was meeting with USGS researchers to discuss the drought. "Even under severe drought, the West doesn't dry up and blow away."

Raley noted that about 5 maf of the 7.5 maf allocated to the lower basin states is used for agriculture. If the drought worsens, some of the water consumed by farms could be transferred to cities, he said. Some urban areas have already cut deals with farmers to secure more water (Land Letter, March 18).

The federal government has a limited role to play in preparing the region for an extended drought, he added. "I just am at a loss where in the Colorado River Compact it requires Soviet-style planning," Raley said.

The federal government will step in to help resolve disputes between states, as it did when tensions over water use flared between Arizona and California, Raley said. "The federal government has said pretty strongly that if the states don't come up with a solution, it will fill the vacuum."

But so far, the states have been proactive in working together to find solutions to water challenges, he added. The upper basin states met in Salt Lake City recently, and drought was a priority topic of discussion at a meeting of the Western Governors' Association in Santa Fe this week.

Electricity output slashed as Powell water level shrinks

Article Published: Monday, July 05, 2004

By Theo Stein Denver Post Staff Writer

Plummeting water levels in Lake Powell have drastically slashed electricity generation at the reservoir's Glen Canyon Dam, forcing power authorities to cut deliveries to utilities from the Front Range to Provo, Utah.

Federal officials fear that \$100 million worth of hydropower generated annually by Lake Powell could dry up completely by 2009 - if dam managers continue releasing water at pre-drought rates.

That would deal a crushing economic blow not only to utilities that depend on cheap hydropower from Lake Powell, but also to a host of federal and state programs, including Colorado's endangered-fish recovery efforts.

Meanwhile, water levels in Lake Powell have fallen so low that Colorado and neighboring states are considering asking the federal government to preserve the lake's water for drinking supplies, which would cut hydropower production even further.

"We are looking to see if there are ways to slow down the decline of Lake Powell and Lake Mead," said Russ George, Colorado's natural resources director. "We can't make more water. We're asking ourselves: 'Are there things we can be doing to avoid taking water out?'"

Federal officials say they welcome state input on how best to manage the water supply in Lake Powell and its sister reservoir in Arizona, Lake Mead, during the drought.

On June 17, the seven Colorado River basin states - California, Arizona, Nevada, Utah, Wyoming, New Mexico and Colorado - asked the U.S. Bureau of Reclamation for a series of computer models simulating the impact of various drought and water-delivery scenarios. The results will form the basis of a report to the Interior Department offering recommendations for water management during the drought and after.

Interior Secretary Gale Norton "is very serious about the states being in the lead as long as possible," Bennett Raley, the assistant Interior secretary who oversees the Bureau of Reclamation, said last week.

Only if the states can't develop a conservation plan will the federal government step in, Raley said.

Lake Powell and Lake Mead were designed decades ago to provide drought-proof supplies of drinking water for the arid Southwestern states along the Colorado River. Cheap hydropower from Mead's Hoover Dam and Powell's Glen Canyon Dam was a side benefit that became a critical foundation for the region's 20th century urban and industrial growth.

The five-year drought has already drained Lake Powell to 43 percent of capacity, reducing the pressure of water entering Glen Canyon's turbines. That lost pressure, or "hydraulic head," has slashed the dam's generating capacity by some 30 percent, leading to higher costs for Colorado's electric utilities served by the Western Area Power Administration.

In 2002, WAPA, which sells power from dams in the Colorado River Storage Project, raised rates 18 percent. During the past two years, WAPA was forced to buy \$135 million worth of power to honor existing contracts with Colorado and Utah utilities. The power administration also had to slash deliveries by a quarter this year.

If Glen Canyon Dam's output is cut completely, "(our) power could be priced out of the market," warned WAPA's Brad Warren.

And still Lake Powell continues to fall.

Last winter's meager snows were expected to yield only half the average runoff to the Colorado River, continuing a trend that started with the onset of drought in 2000.

Powell is so low that federal hydrologists estimate there is a 20 percent chance that drought could eliminate hydropower within five years. A repeat of the disastrous 2002 drought year - or even two more marginally better years like 2004 - could interrupt electric generation even sooner.

"If hydro is curtailed, they'll be forced to go from low-cost electricity that's locked in to higher-priced power and the vagaries of the market," said Jim Owens, a spokesman for the Edison Electric Institute, a Washington, D.C.-based industry group.

Those costs are already being passed on to customers.

"We had a 10 percent rate increase in 2002 and another small increase last year," said Jim Van Someren, a spokesman for Westminster-based Tri- State Generating and Transmission, the Colorado River Storage Project's biggest customer.

This summer, the Tri-State board will probably have to consider another rate hike for 2005, he said.

If the drought worsens, falling hydropower revenues also will shrink the revolving fund that contributes \$50 million each year to environmental programs, including the state's endangered-fish recovery efforts.

Since 1988, \$138.7 million has been raised by federal and state agencies for the recovery program, which seeks to restore healthy populations of the Colorado pikeminnow, the razorback sucker, humpback chub and bonytail in the upper Colorado and San Juan river systems.

Glen Canyon has contributed about \$51 million. By contrast, Colorado, Wyoming and Utah only gave \$14.6 million during the same time period.

Protecting that federal contribution "is at the top of our agenda," George said.

Some environmental groups, such as Living Rivers of Salt Lake City, believe a more cost-effective way to recover the four endangered fish is to decommission the Glen Canyon Dam once drought drains the lake behind it.

They believe the region has entered a drier climate regime that was much more common in the past.

Owen Lammers, the group's executive director, chafes at the description of dam's hydropower as clean, cheap energy.

"That ignores the tremendous impact the dam has had on Grand Canyon and Glen Canyon," Lammers said.

Lammers said it is likely that Lake Powell will take many years to refill - if it refills at all. That will reduce electric revenues in perpetuity and put pressure on federal officials to divert money from projects meant to repair the damage caused by plugging up the river.

"If we can encourage 10 million households in the basin to put in a couple of compact fluorescent lights," Lammers said, "we can eliminate the power needed from Glen Canyon Dam - at a cost that's one-seventh of the power the dam produces."

**Federal scientists admit failure of Grand Canyon endangered fish recovery effort
Environmentalist amplify call for new approach**

Contact: Owen Lammers 435-259-1063

In a draft paper circulated last week, lead scientists for the federal program overseeing endangered fish recovery in Grand Canyon National Park noted that their principal approach has been a "failure".

For more than ten years dam managers have been emphasizing a specific flow regime from Glen Canyon Dam asserting that it would reverse the decline of the endangered humpback chub. Instead, the declines have averaged about 14 percent annually since the early 1990s the draft paper says.

"While they may still tinker with the details of their paper, the word failure will continue to ring loud and clear," says Owen Lammers, Living Rivers/Colorado Riverkeeper executive director. "We've been arguing for years that the Bureau of Reclamation heed the advice of the Fish and Wildlife Service and implement flows more consistent with the river's natural hydrograph if they want to stop the decline of native fish populations, but instead, even after admitting failure, they want to head further in the wrong direction."

The paper advocates moving away from what has been called Modified Low Fluctuating Flows, which restrict dam operators to water releases between 5,000 and 25,000 cubic feet per second. Restrictions were also place on the hourly rate for increasing and decreasing flows from the dam, not to exceed 4,000 and 1,500 cubic feet per-second per-hour respectively.

Previously, dam operators were free to increase or decrease flows based on electricity demand. The paper argues that upwards of \$50 million annually have been lost in hydropower revenues since these flows have been implemented.

"The Bureau of Reclamation wants to say they tried it and it didn't work, but they never actually implemented what was asked of them by the Fish and Wildlife Service to recover the fish," says Lammers. "They now want more variable flows which may restore revenues, but it may be game over for the last remaining humpback chub."

The authors also state their flow regimes have "failed to produce their intended benefits for sediment resources in Grand Canyon." With 95 percent of Grand Canyon's sediment and nutrients trapped behind Glen Canyon Dam, it was hoped that tinkering with flows may help to redistribute sediment to aid in fish recovery.

It was also hoped that efforts to reposition sediment would help to stabilize archeological sites disturbed by dam operations. The paper states that their experience now is that there would be exposure of some cultural sites no matter how the water is managed.

In 1994 the Fish and Wildlife Service recommended that the Bureau of Reclamation not peruse the Modified Low Fluctuating Flows, but what were called Seasonally Adjusted Steady flows. These flows would have caused releases from Glen Canyon Dam to more mimic the Colorado River's flow, which historically has ranged from 500 to more than 100,000 cubic feet per second. But since such flows would have further compromised

hydropower revenue, they were opposed by the Bureau of Reclamation ten years ago, and are absent from the discussion in this new draft paper.

"Nothing that the Bureau of Reclamation had expected to achieve when it began its recovery program a decade ago has worked," adds Lammers. "This latest information adds to the mounting evidence mandating the Bureau of Reclamation to undertake a new Environmental Impact Statement on how and if Glen Canyon Dam should continue to be operated so as to comply with federal environmental laws."

Living Rivers/Colorado Riverkeeper and more than 200 groups from across the country are calling for a new Environmental Impact Statement that evaluates the decommissioning of Glen Canyon Dam as the most effective means to restore the natural process necessary to reverse the decline of endangered species in Grand Canyon.

[EVIDENCE FOR THE FAILURE OF THE MODIFIED LOW FLUCTUATING FLOW ALTERNATIVE \(MLFFA\) TO BENEFIT MOST ECOLOGICAL RESOURCES IN GRAND CANYON](#) [96k PDF File]

LR in the News 07/15/04

Grand Canyon Endangered Fish Fail to Recover

[Environmental Network News](#)

FLAGSTAFF, Arizona, July 15, 2004 (ENS) - Scientists for the federal program overseeing endangered fish recovery and sediment restoration in Grand Canyon National Park have come to the tentative conclusion that their main approach has been a "failure."

In a draft paper dated June 22 and circulated last week, eight scientists analyzed the results of water flow variation policies and control of fish in the Colorado River below Glen Canyon Dam.

Members of the Grand Canyon Technical Working Group concerned about ecology and those concerned about power production both show the "surprising" preference for more variable daily flows, the scientists found.

The Colorado River has cut a cleft across Arizona known as the Grand Canyon (Photos courtesy USGS Grand Canyon Monitoring and Research Center) Authors of the draft paper include four U.S. Geological Survey scientists with the Grand Canyon Monitoring and Research Center in Flagstaff, two members of the Western Area Power Administration, one scientist from the University of British Columbia, and one from Ecometric Research Inc.

Since the early 1990s, dam managers have used a specific flow regime from Glen Canyon Dam known as Modified Low Fluctuating Flows, asserting that it would reverse the decline of an endangered fish known as the humpback chub. Instead, chub declines have averaged about 14 percent annually since the early 1990s, the draft paper says.

Emphasizing that the analysis is "a work in progress," the authors suggest moving away from the regime, which restricts dam operators to water releases between 5,000 and 25,000 cubic feet per second.

Restrictions are also placed on the hourly rate for increasing and decreasing flows from the dam, not to exceed 4,000 cubic feet per-second and 1,500 per-hour.

The paper is entitled, "Evidence for the Failure of the Modified Low Fluctuating Flow Alternative (MLFFA) to Benefit Most Ecological Resources in Grand Canyon."

"While they may still tinker with the details of their paper, the word failure will continue to ring loud and clear," says Owen Lammers, Living Rivers/Colorado Riverkeeper executive director.

Lammers sees the points made in the paper as evidence for the correctness of the Living Rivers/Colorado Riverkeeper position.

"We've been arguing for years that the Bureau of Reclamation heed the advice of the Fish and Wildlife Service and implement flows more consistent with the river's natural hydrograph if they want to stop the decline of native fish populations," said Lammers.

Previously, dam operators were free to increase or decrease flows based on electricity demand. The paper states that upwards of \$50 million annually in hydropower revenues has been lost since the Modified Low Fluctuating Flow Alternative has been implemented.

The endangered humpback chub found in the Grand Canyon's Colorado River "The Bureau of Reclamation wants to say they tried it and it didn't work, but they never actually implemented what was asked of them by the Fish and Wildlife Service to recover the fish," says Lammers. "They've been promoting more variable flows which may restore revenues, but may be game over for the last remaining humpback chub."

The modified low flow alternative has not succeeded in restoring natural sediments in the canyon, while 95 percent of sediment and nutrients remain trapped behind Glen Canyon Dam. The paper states, "There is currently little debate that ROD flows have failed to produce their intended benefits for sediment resources in Grand Canyon."

In 1994 the Fish and Wildlife Service recommended that the Bureau of Reclamation not pursue the modified low flow alternative, but instead adopt Seasonally Adjusted Steady flows that would have caused releases from Glen Canyon Dam to parallel the Colorado River's natural flow, around 500 to 100,000 cubic feet per second.

But, says Lammers, since such flows would have further compromised hydropower revenue, they were opposed by the Bureau of Reclamation 10 years ago, and are absent from the discussion in the new draft paper.

The Glen Canyon dam on the Colorado above Grand Canyon. (Photo courtesy USGS)
The authors say the modified fluctuating low flow approach "provides an excellent example and warning to practitioners of adaptive management about the difficulties that scientists encounter in trying to determine the ecological impact of a policy change."
The authors suggest treating this approach as one of a range of options.

The modified low flow has benefited "the recreational rafting community and trout fishers who care more about catching lots of fish than catching big fish," the paper states, and these stakeholders will want the policy included among future experimental treatments."

But because the strategy is not a "win-win option for all stakeholders," the paper points to the ethical question of who should pay for it.

Currently, power utilities and their ratepayers are subsidizing the modified low fluctuating flows at the cost of some \$50 million annually, improving the quality of Grand Canyon for some recreational uses.

"It is one thing to impose such cost to deal with some broad public interest such as protecting an endangered species, but quite another one to impose it for the benefit of particular stakeholders," the authors say.

They urge that the cost issue be addressed "openly and quickly as part of the overall adaptive management planning process, before it leads to a breakdown in the collaboration among stakeholders that has made adaptive management possible in Grand Canyon in the first place."

Living Rivers/Colorado Riverkeeper and more than 200 groups across the country are calling for a new Environmental Impact Statement that evaluates the decommissioning of Glen Canyon Dam to restore the natural process that would reverse the decline of endangered species in Grand Canyon.

LR Press Release 07/16/04

Chasing Water: Lake Powell Launch Ramps Can't Stay Open

For immediate release

Contact: Owen Lammers - (435) 259-1063

Despite a reported \$2 million investment in 2003 and a projected \$2.8 million this year, Glen Canyon National Recreation Area has had to officially close four of its six boat launching facilities due to declining water levels at Lake Powell reservoir.

Meanwhile, signs at the recreation area's most popular launch ramp, Wahweap Marina, reads "launch at your own risk" as the reservoir has now dropped below the level of the concrete ramp extension completed earlier this year.

"It's going to be an ongoing problem as the reservoir continues to drain due to climate change," says John Weisheit Living Rivers/Colorado Riverkeeper conservation director. "In two years we may be at the end, with the reservoir surface area reduced by 77% and even the two remaining ramps left high and dry."

Publicized as "America's Houseboat Destination", Lake Powell plays host to some of the largest, most luxurious houseboats in the world. But concerns are arising that it may become impossible to launch and retrieve houseboats should levels continue to drop. "It's going to be difficult. Hopefully the park service will work with us to maintain a portion of the (Wahweap) ramp for houseboats," Len Cook, who offers houseboat management services, told the Lake Powell Chronicle this week.

During the past month the Park Service has been looking at old maps and successfully discovered the location of Wahweap's original asphalt launch ramp, which has been submerged for the past three decades. It's hoped that this historic access will be able to serve visitors in the coming months.

Declining reservoir levels and boat ramp closures have hurt Lake Powell marketing efforts. Aramark, the principal concessioner on Lake Powell, is offering to the public special savings up to \$1400 that includes \$700 in free gasoline for a houseboat rental. Aramark has also offered, to Utah residents, an additional \$200 in gasoline to drive to Lake Powell.

"It's amazing the money being invested to keep Lake Powell's houseboat industry alive," adds Weisheit. "But nature may eventually bring it all to a close. We'll know soon enough."

How Drought Just Might Bring Water to the Navajo

New York Times by Kirk Johnson

Published: July 23, 2004

WHITE ROCK, N.M. - Once a week, Bennie Yazzie drives half an hour over the bone-rattling dirt roads of the Navajo Nation to get drinking water. It sloshes out a long blue hose at a cost of 3 cents a gallon - except when it doesn't. A few weeks back, the coin-fed meter was broken and no one at the little oasis of White Rock knew how to fix it.

"Another 35 miles on bad road," Mr. Yazzie said of his journey to the next-nearest pump.

The Navajo struggle for water on these unforgiving lands long predates the drought that has settled over the West in the last five years. On a reservation nearly five times the size of Connecticut, more than a third of the residents have no running water for themselves, their gardens or their livestock. So they go to water stations like White Rock, 50 miles from the nearest real town, to shower, wash clothes or socialize, making the best of a situation that would make most Americans shudder with its matter-of-fact adversities.

But in an odd and deeply paradoxical way, the drought itself - and the fundamental ways it is making many Westerners rethink the future - may finally bring running water to the Navajo. The tribal council could vote at any time on a settlement to end a 30-year legal standoff with New Mexico over how to divide the waters of the San Juan River, a major tributary of the Colorado River. Tribal leaders had contended that history and treaty entitled them to the entire flow of the river; the state said the tribe was overreaching.

A preliminary agreement reached late last year - one of the largest Native American water deals in history, gallon for gallon - reduces the tribe's claims and in return provides for a \$600 million federal pipeline that would snake south through the reservation, with feeder systems reaching into the communities, called chapters here. The pipe would also take water to the equally thirsty city of Gallup, N.M., just outside the reservation's southeast border.

It all sounds quite neat - a perfect package of interlocked, coinciding interests, which is how supporters of the plan have sold it on the reservation and off. But the vote is expected to be close. Some hard-liners on the council say that the compromise is a surrender and that the Navajo should continue to push for the whole river. Promoting the proposal has also aggravated some very old, unhealed scars and brought voice to anguished questions of Navajo destiny.

Some in the tribe say a deal that benefits Gallup is just too bitter a pill to swallow, given the long history of hostile racial relations there. Old-timers still remember the storefront signs that said "No dogs or Indians."

What brought people together, and subsequently exposed their differences, was the dawning awareness of scarcity. When water in the San Juan was abundant, people involved in the settlement say, the murky question of who had first dibs on the river's flow was not so important. But when the river nearly dried up in 2002 - the drought's worst year here so far - that mind-set abruptly changed. Tribal farmers saw the intake system for their irrigation canals come perilously close to being unusable. Non-Indian farmers feared a "call" of water rights - an emergency legal sorting out, in which the oldest claims gets priority. The Navajo claims, by far the oldest, might win, giving the

tribe the whole river. Knowing precisely who was entitled to what suddenly looked a lot better.

"The settlement is essential for certainty, and the drought has created awareness of the need for certainty," said John R. D'Antonio, New Mexico's state engineer, who is in charge of administering water rules. "It's forced us to go out and be more deliberate; the drought may be a blessing in disguise in that regard."

At the heart of the resolution, negotiators say, are interlocking trade-offs, developed so that - at least in theory - each private interest must support someone else's goals to have its own needs satisfied.

For the Navajo, that means being asked to embrace the idea that the pipeline taking water to people like Mr. Yazzie would also benefit Gallup. Non-Indian farmers, who stand to have their water rights bolstered, and made far more valuable, by having the legal issues finally settled, were asked to become boosters for the Navajo cause. Gallup officials have become enthusiastic backers of Navajo water sovereignty.

"It's a vast sea change in thinking on both sides of the cultural divide between Indian and non-Indian," said Mark Edwards, a consultant to Gallup on the water settlement. "It says that we have a common future, that we have a common direction to go in, that your doing well is important for me to do well."

But that has not made it easy.

Jason John, a hydrologist in the tribe's water management branch, visited dozens of chapters to sell the plan, and he said that in general the closer a community was to Gallup, the more opposition he faced. Gallup, which has about 20,000 residents, and about equal numbers of whites and Indians, is the closest thing to a downtown across much of Navajo country, but many people Mr. John visited said they still feel stigmatized by white-owned businesses, through higher prices or poor service.

"Even though it would mainly benefit the Navajo tribe, there were just some people there who have had a long history with Gallup, and it's understandable," he said. "All they know is what they've lived through, so it's hard for them to go and understand something I'm telling them."

Desperate for water, officials in Gallup have tried hard to smooth out their rough edges. Business groups have been armed with talking points to support the settlement. Other people are closely monitoring negotiations to watch for any hint of language that might offend.

At a recent public meeting in Farmington an engineer from the Gallup water department was describing a water treatment facility proposed for the city. It would skim the water's surface for impurities, and it was called a scalping plant. Mr. Edwards, the city consultant, all but jumped from his seat.

"Please, please," he begged the engineer. "Isn't there anything else you can call it?"

Indian and non-Indian politicians say they also struggle with widespread disbelief that anything will really happen. Congress, in addition to the Navajo Council, must approve the plan, and even under the most optimistic timetable, the pipeline would not be completed until 2016.

The Navajo settlement also has consequences downstream on the Colorado River at Lake Powell, the huge reservoir in Utah that has lost more than half its water since 1999. Under the water-law agreements called the Colorado Compact, all states that share water from the Colorado River and its tributaries get a precise annual allotment. The upper basin states of New Mexico, Utah, Colorado and Wyoming have never used their full shares, and that surplus - along with two decades of wetter than normal precipitation before the drought - is essentially what allowed Powell to be filled. The Navajo settlement, one of many pipeline projects planned around the West to tap the Colorado's flow, would gradually use up New Mexico's allotment on the San Juan, leaving only the minimum legally required amount sent downstream for use by Mexico and the lower basin states of California, Arizona and Nevada - and none left over for Powell to store except in the wettest years.

But the real heart of the deal is not hydrology but human nature.

To get backing for the pipeline plan, for example, the Navajo negotiators compromised many of the tribe's old claims, which date back to 1849 and earlier. Under the agreement, the tribe would get only 55 percent of the water available for use in the San Juan - though even that amount is immense, more water than is allotted to the entire state of Nevada from the Colorado River. In return, the tribe would get the pipeline and other benefits, including a timetable for completion of a big federal irrigation project that was authorized by Congress in 1962.

Some holdouts on the Navajo Council say they are not sure the tribe's long-term interests are being served.

"There's nothing wrong with asking for the entire river," said Irvin M. Keeswood, who represents the Hogback chapter near Farmington. Most Hogback households already have running water. Mr. Keeswood said he was undecided about his vote. "This is a one-time shot for us, so it has to be the best we can get," he said.

Other council delegates argue that the spirit of compromise must be seized, or might be lost forever.

"Like any settlement, you go in with expectations and walk out with something less," said LoRenzo C. Bates, a delegate from Upper Fruitland who supports the plan. "For the Navajo to give up its claim on more than 40 percent of the river, that's a considerable compromise. But the certainty is the thing; we'll have something now that we can say is ours."

For many non-Indians, the give-and-take has been just as difficult. One lawyer who pushed his non-Indian clients to back the settlement said that refusing to negotiate, if it led to a court-ordered settlement, could be disastrous for everyone.

"It was like playing Russian roulette - the stakes were so huge," said Gary Risley, who practices law in Farmington. "The Navajos might win and suck the whole thing up, or we might win and they'd have no water for anything."

Underpinning much of the story of the settlement is the question of the future.

The growth arc of northern New Mexico and the West as a whole, demographers say, is toward an urban future, not the agriculture-based economy on which the Colorado River basin agreements were premised. That growing consensus, and its implication that cities will probably be required to buy out farmers' water rights over time, became a dynamic in the negotiations, water experts like Mr. Risley say, as non-Indian farmers sought certainty that the water they owned could eventually be sold with no legal entanglement or uncertainty about how much water belonged to the Navajo.

Here on the reservation, by contrast, many people say that keeping young people from fleeing to the cities means doing everything possible to make life less of a hardship. Lack of water is only one of many holes in the fabric, residents say. In White Rock, telephone service, mail delivery and reliable electricity are also widely unavailable.

"The older generation was stronger - technology has made us lazy," said Jennifer Juan, an artist who lives four miles from the White Rock water station. Ms. Juan stopped by for a shower on a recent morning with her 8-year-old son, Teton. Showers cost \$1.01 each.

Ms. Juan said she once lived in Santa Fe, so she knows how strong the lure of town life can be and how much people take its luxuries for granted.

"It's amazing to think that they can just walk around the corner and take a shower," she said. "How blessed they are that they can do that."

LR in the News 07/25/04

Time to take another look at Glen Canyon Dam

Commentary
Salt Lake Tribune
Sunday, 07/25/2004

by Eleanor Inskip

This drought may be the blessing we need to take a fresh, honest look at the alternatives and the consequences of trying to continue with dams - especially Glen Canyon. And as a result, a fresh, honest look at former Congressman Jim Hansen's outdated ban on studying Glen Canyon Dam's decommissioning, now up for annual reconsideration by Congress.

This winter Lake Powell's principal purpose, water supply, is likely to be tapped for the first time in history. Never before has the reservoir's water storage been a benefit to downstream water users. During its 40-plus years, Lake Powell has lost from 30 to 40 million acre feet of water from evaporation and seepage. This water loss represents a four- to five-year supply for water users below Lake Powell, or more than 20 years of Utah's Colorado River water allocation. As the drought began we had stored only 23 million acre feet and the water supply continues to drop.

Lake Powell exists to satisfy a water accounting formula - a commitment by the states of Utah, Wyoming, Colorado and New Mexico to deliver on average 8.25 million acre feet of water per year to Arizona, Nevada, California and Mexico. Since 1922 this promise, part of the Colorado River Compact, has been met without using the stored water behind Glen Canyon Dam. But now nature is testing this antiquated compact for the first time. And dam or no dam, if nature does not provide the water, we are stuck. The federal government, as the ultimate water master, will likely pro-rate every state's allocations based on what the river is actually delivering, and the 8.25 million acre feet rule that led to Glen Canyon Dam will go the way of Prohibition.

We need to be looking at ways of saving this water. California, Nevada and Arizona are already doing so by instituting water-saving methods and storing Colorado River water in underground aquifers. Ground water storage loses as little as 1 percent without evaporation, as compared to more than 50 percent loss associated with what Lake Powell is finally providing.

And we need to be looking at ways of saving the river itself. We used to think that hydropower and dams were wholly beneficial, causing little damage to the environment. We now know differently. As the World Wildlife Fund reported in its recent study, *Rivers at Risk*, many of the benefits conferred by dams like hydropower are canceled out by wasteful water use and environmental damage. Dams disrupt the ecological balance of rivers by depleting them of oxygen and nutrients and affecting the migration and reproduction of fish and other freshwater species, the report states.

It's ironic that in addition to prolonging the ban on studying the decommissioning of Glen Canyon Dam, this year's Interior appropriations bill also includes \$64 million for the continued removal of dams and the restoration of rivers in Florida. Since 1993 taxpayers have spent \$1 billion for Everglades restoration.

We need to ask our legislators, Reps. Matheson, Cannon and Bishop, as well as Sens. Hatch and Bennett to do some house cleaning. Ask them to remove this ban and allow monies to be spent on the study of alternatives, solutions and restoration of the Colorado River.

The Colorado River is all we've got, and it's not much. Even in a good year, the Colorado River provides just 3 percent of the amount of water that annually flows down the Mississippi River. This water is precious - it is life itself for humans and all the other living creatures in the West. And while damming it up may have been the way of the past, it's not the way of the future.

Eleanor Inskip, author of *Glen Canyon Before Lake Powell*, is a Colorado River historian and program director at Living Rivers in Moab.

The Colorado's troubled waters

River Basin hasn't been this dry since the late 16th century

By BRENT ISRAELSEN for The Salt Lake Tribune

The Colorado River and its tributaries begin without drama, dripping from snowfields 14,000 feet above sea level. By the time they reach places like the Gates of Lodore in northwestern Colorado and Cataract Canyon in southern Utah, they are raging torrents, scouring the landscape with earsplitting fury before running into giant manmade dams that put an end to the river's fury!

During the past five years, the river has met an even more formidable foe: a prolonged drought.

This "early 21st century drought," as scientists now call it, is believed to be the most severe in more than a century.

Since 1999, annual water inflows to Lake Powell have averaged 7.1 million acre-feet (MAF) well below the 12.4 million acre-feet average during the previous 100 years and less than half the 15.1 MAF volume that was the basis for dividing the river among seven states in 1922. (One MAF equals about 326 billion gallons.)

This year's inflow is forecast at a dismal 5.6 MAF, according to a new report from the U.S. Geological Survey (USGS).

During the past five years, the river's average annual flow into Lake Powell is smaller than it was during the dustbowl years of the Depression, when the flow averaged about 10.2 MAF.

"We're in a nasty midterm drought," says Tom Ryan, hydrologist for the U.S. Bureau of Reclamation, which manages the dams on the Colorado River, the biggest single source of water in the Southwest.

According to tree-ring data, it hasn't been this dry in the Colorado River Basin since the late 16th century--about the time Shakespeare began writing his plays. At that time, the river was running at an annual average of about 8.8 MAF.

"The current drought may be comparable to or more severe than the largest-known drought in 500 years," states a new USGS report.

What the tree-ring and other historical evidence cannot predict, however, is what will happen in the coming years.

"The question is, where are we moving?" says David Meko, associate research professor at the Laboratory of Tree Ring Research at the University of Arizona.

Meko noted that the last prolonged drought in the river basin, in the late 1970s, was followed by an extremely wet period in the early 1980s that forced flood-control releases from Glen Canyon Dam on Lake Powell, which used to fill nearly every year in the 1980s and '90s. The current drought has pulled Lake Powell down to about 42 percent of capacity. Ryan predicts it will take 15 years of normal precipitation to fill the reservoir again, although a wet cycle like that of the early 1980s could fill it in four years.

Farther downstream, Lake Mead behind Hoover Dam in Nevada is down to 51 percent of capacity.

The surface of the lake, which supplies 85 percent of Las Vegas' water, has dropped to about 1,125 feet, becoming uncomfortably close to the 12-foot-diameter intake for one of the pipelines that sends water to Sin City.

The upper layer of the lake contains lower-quality water that can overtax water-treatment plants.

To reach deeper and cleaner water, the Southern Nevada Water Authority is spending an unanticipated \$6.4 million this summer to install a "sleeve" that would extend the intake downward another 70 feet.

"If the lake were higher, we would not have to pursue this project," said Marc Jensen, the Las Vegas water agency's director of engineering.

Despite the less-than-cheery news about low lake levels and river flows, federal officials say they are far from panic mode.

The reservoirs on the Colorado River are doing what they are designed to do, says Ryan. "People became accustomed to seeing Lake Powell full or near full. I don't think people know that Lake Powell was meant to go down."

Bennett Raley, U.S. Interior Secretary Gale Norton's point man on Western water issues, says the drought is a "serious matter" and a "wake-up call" but not a "crisis."

A few more years of this dryness, however, could test like never before the laws and officials that manage the Colorado River, arguably the most over-allocated in the nation.

"You have to be concerned because you don't know whether you're in the sixth year of a six-year drought or the sixth year of a 15-year drought," says Don Ostler, director of the Upper Colorado River Basin Commission.

Seven states, including Utah, divide the Colorado River, which is governed by interstate compacts, international treaties, several court decrees and federal statutes known collectively as the "Law of the River."

The law has worked reasonably well in recent decades, mainly because there was plenty of water to go around. The upper Colorado River Basin states of Utah, Wyoming, Colorado and New Mexico were using much less than their full share of the river. And abundant precipitation was keeping the river and its reservoirs full of water, providing a "surplus" that allowed the lower basin states of Nevada, Arizona and California to use more than their legal share.

The time of plenty on the river appears to be over.

The upper basin states along with American Indian tribes are planning to increase their take of the river at the same time Lake Powell – the "bank account" that helps the upper basin meet its obligations to the lower basin--is shrinking.

If the drought continues, Powell could reach its lowest outlet, located at 3,370 feet above sea level, in three years. At that point, only water that flows into the reservoir will be allowed to flow out of it, making contractual water deliveries to the lower basin more difficult. Power generation from Glen Canyon's hydroelectric turbines would come to a virtual standstill, as would motorized boat recreation.

"There is the potential for significant problems, particularly for the lower Colorado River Basin," says Ostler. "That basin has become accustomed to using surplus water. In a drought, you don't have surplus water. That can put them in a bind."

Arizona, which holds the most junior rights on the river, would be hit first, followed by Mexico and Nevada. California, with its senior rights, would be the last to be affected by shortages, although the state only recently has been living within its 4.4 MAF share of the river.

Las Vegas would suffer the most from shortages, because, unlike the other river users, it has no agricultural "buffer" in its 300,000 acre-foot share. Cutbacks would be passed on directly to homeowners and businesses, including the giant casinos and resorts upon which the city has built its economy.

Declaring shortages on the river will not be an easy task for the Interior Department, which would find itself caught in a heated feud between jealous states.

"There are some absolutely intriguing questions about the relationship between the upper basin and the lower basin that we'll answer as time goes on," says Raley. "But unlike prior times, when all the fights were almost always about the future, the drought will be about now."

"We only have so much water and no [interior] secretary can increase that."

But Interior, Congress and the Colorado River states should re-examine the river's limits and adjust the Law of the River accordingly, says Owen Lammers, director of Living Rivers, a Moab-based environmental group.

"We should be preparing for significantly lower flows than were planned for 80 years ago."

Lake Powell is at the heart of the battle over restoring natural flow

Shaun McKinnon The Arizona Republic Jul. 25, 2004 12:00 AM

PAGE - Stranded on a reddish rock shelf 60 feet above the surface of Lake Powell is a string of blue and white plastic floats, the kind that mark water boundaries. No one threw them up there or dropped them from the canyon rim 50 feet above. They just ended up there as the reservoir shrank.

The boats across the bay at Wahweap Marina are docked at water's edge, but the trucks, SUVs and trailers are crammed into an awkward, makeshift parking area, a rocky patch that two years ago was underwater.

Above the marina, the white "bathtub rings" etched into the canyon walls by years of subtle seasonal shifts in lake level look more like ghostly afterimages from a picture long gone, a reminder of how much of itself the reservoir has lost.

The scars chiseled by five years of drought on the Colorado River are impossible to ignore here in the shadow of Glen Canyon Dam, no matter how many boaters or fishermen continue to use the reservoir. To the West's water managers, they are battle scars, proof that the system works. Store water in amounts this vast and the 30 million people tethered to the river can survive the worst of dry spells.

But to others, the reservoir and the dam are ugly symbols of a good idea taken too far. The lake's declining volume - it is at its lowest level since it was first filled in the early 1970s - has revived talk of draining it and decommissioning the dam. At the very least, some conservationists say the conditions here, nearly 700 miles from the river's pristine headwaters, are evidence that the West's growth has come at a destructive cost to its rivers and the environment.

From a windy ridge overlooking Wahweap, John Weisheit sees the ugly symbol. A veteran river guide, Weisheit is the conservation director for Living Rivers, one of the groups arguing that unless Lake Powell is drained and the Glen Canyon Dam taken down, the river and the singular ecosystem it supports through the Grand Canyon will die.

"I've been coming here for 32 years, and it looks like it did when I first started coming," said Weisheit, dressed in faded jeans, a T-shirt and a "Colorado Riverkeeper" cap. His car is littered with books and colorful folders of literature about the Grand Canyon and how it has suffered because of the dam. "Lake Powell is draining, and we might as well get used to it," he said. "This is the way it's going to be. We need to find ways to live without the lake, because our bad water management practices are killing the Grand Canyon. We don't need Glen Canyon Dam. We never did."

Just about every Western water agency and even other environmental groups dispute Weisheit's claim. They insist that there are plans to help restore the Grand Canyon and that without Powell, this drought would have plunged the West into chaos.

What is undeniable is that the Glen Canyon Dam changed the Colorado River and the Grand Canyon in a way that has made them less hospitable for native species.

The debate over those changes has helped frame the broader discussion of how to develop the West's water resources without destroying natural habitat. Urged on by conservation groups, an increasing number of government agencies and courts say the environment should be considered a water user, like a city or a state, and among their solutions is reducing the number of dams.

Lake Powell's role

From his office at the Carl Hayden Visitors Center, Ken Rice commands one of the best views anywhere of the Glen Canyon Dam. A wide window takes in both the downriver side of the dam and a slice of Lake Powell. Rice, who manages operations at the dam for the U.S. Bureau of Reclamation, admits the sight can be distracting.

The lake's low level is obvious from up here. But Rice said he doesn't see failure, even though the bureau's own hydrologists suggest Powell could become so low in as soon as four years that the dam may not be able to release any water downstream.

"It's doing exactly what it was designed to do," he said. "You take us out of the equation and (Lake) Mead would be way down, maybe even too far down to generate power."

Lake Powell was built primarily to store water on behalf of the upper-basin river states, which are required to deliver a minimum amount of water each year to the lower-basin states. In a typical year, the Colorado River would replace the water released to the downriver states from Powell. In a drought year, the lake level falls. Five consecutive dry years have lowered Powell by more than 100 feet.

At least two sets of scientists have run models of the drought-impaired river without Powell in the system. Both concluded the lake is critical to the West's survival. One study said Lake Mead would have fallen to about 9 percent of its capacity by now, which would cut off Las Vegas from 90 percent of its water.

Hydrologists for the Central Arizona Project, which delivers Colorado River water from Phoenix to Tucson, also ran models on a Powell-less West. To start, there would have been no CAP, which was approved in part because Powell was adding new storage.

Over 40 years, the time span since the dam was completed, at least 45 million acre-feet of water, a 100-year supply for nearly 2 million people, would have flowed unused into the Gulf of California. And without Powell, Lake Mead would have fallen low enough to produce West-wide shortages in 2002, according to the model.

That's not reason enough for Weisheit and groups like his and the Glen Canyon Institute. They cite figures about how much water from Powell is lost each year to

evaporation and show evidence that government efforts to restore the downstream ecosystem have failed.

"There are so many holes in the system right now," he said. "Instead of slapping on a Band-Aid, let's start fresh. If this drought, this climate change, gets worse, it doesn't matter how many reservoirs you have, there's not going to be enough water. And even if the lake recovers, the problems will remain."

Page needs Powell

In Page, there is no debate over the value of Lake Powell. Without the lake, there is no Page, which otherwise would sit on a plateau high above the Colorado River. News reports about the lake's low level upset business owners, who say the media have painted an unfairly bleak picture of Powell.

"People who have not come here before or who come once a year are very happy with what they find," said Joan Nevills-Staveley, executive director of the Page-Lake Powell Chamber of Commerce and Visitors Bureau. "This probably is the optimum lake level for camping. We don't want it to stay there," she quickly added, "but a lot of the canyons are now accessible that weren't before."

It's not surprising to get the chamber outlook from the chamber boss, but Nevills-Staveley knows a bit about Lake Powell and the Colorado River. Her father was the first commercial river runner, taking tourists down the San Juan River and the Colorado from Mexican Hat, Utah, to Lees Ferry, beginning in 1938. Nevills-Staveley herself helped start the first concession operations on the lake's upper arm, at Hite Marina, which has closed because of the drought.

From her cramped corner of a narrow storefront office on Page's main drag, Nevills-Staveley tries to reassure people when they call that there's still ample water to boat and fish and that camping and hiking opportunities abound.

She is Page's own encyclopedia at times: "How many motel rooms do we have?" an office worker yells after picking up an incoming call. "Fifteen-hundred-and-one," Nevills-Staveley replies. She scoffs at the drain-the-lake crowd: "It's not a well-thought-out plan," she said. "Most of us thought it was funny, because it is. It's ludicrous.

Then we saw they were serious, and there's been a lot of misinformation since then." When the idea was first floated, "people called and canceled houseboat rentals and river trips through the Grand Canyon," she said. "It was scary. The standard answer here is 'Yes, there is less water, but there is still over 400 feet at the dam.' "

In 1997, a group of Page residents formed Friends of Lake Powell to help counter the anti-dam movement. Paul Ostapuk, an environmental scientist for Salt River Project in Page, said the groups behind the proposal don't have nearly the support they claim.

He also suggests their focus on restoring Glen Canyon ignores the reality of the region. "The lake when it was full only covered 13 percent of Glen Canyon," Ostapuk said. He pulls up a picture on his laptop computer, which he set up in the lobby of a hotel up the

hill from the dam. "It isn't like there was nothing to see. But that's the picture that gets painted. The lake at half-full years ago was a spectacular place to come. The lake now is still a spectacular place."

Managing nature

Above Lake Powell, the Colorado River runs wild and muddy, just as it did when Maj. John Wesley Powell first explored it in 1869. Then, the river was unpredictable, its flow fluctuating wildly with the seasons. It stirred sediment, earning its name - Colorado, or red-colored - from the rusty tinge it took on after carving its way through Utah's canyon lands.

Glen Canyon Dam changed that. Once the water is impounded behind the giant concrete structure, the silt and sediments settle. The water temperature drops as the lake deepens. By the time it passes through the power turbines at the dam, it is cool and clear.

That's not good for the native fish species, which like warm, muddy water, but it's ideal for non-native trout, which like to eat native fish. The population of the endangered humpback chub, a fish that evolved over millennia and lives only in the lower Colorado River, has fallen by nearly 70 percent since 1989, and scientists blame the dam.

Federal officials launched an adaptive management program nearly a decade ago to try to help the fish and other species. A key was to mimic the river's old flow patterns and move sediment. In 1996, then-Interior Secretary and former Arizona Gov. Bruce Babbitt oversaw an engineered flood, which was meant to move sediment and help rebuild beaches and restore fish habitat.

That experiment is now considered largely unsuccessful, but others have followed, including the removal of trout from areas where chub live.

Nikolai Ramsey works for the Grand Canyon Trust, a conservation group working to protect the Colorado River's geologic masterpiece. He is the group's representative on a regional committee that evaluates the adaptive management program.

Ramsey works in Flagstaff, a steep 130-mile drive from the dam, but he shuttles among Flagstaff, Page, Phoenix, Salt Lake City and the Grand Canyon often and has watched the work up close in the Canyon. He still believes it's possible to manage the river for human use and still find ways to protect endangered species and habitat.

"There is some human arrogance on our part in thinking we can manage the river by mimicking natural conditions," he said. "But we can take a shot. Let's push the science as far as we can and have the science drive the management actions. Let's see if we can't have both the conserving of the human values that derive from the dam being there and also the environmental values. We still think that's possible."

He said the idea of removing the dam is not without logic, but the political and practical realities are that it's there "and it does achieve its purposes."

Environmental shifts

Along the receding shorelines of Lake Powell and Lake Mead, biologists are watching the effects of the drought as it reveals long-buried box canyons and takes water back from marshes and inlets. Already, thickets of tamarisk, a fast-spreading invasive tree, have appeared on the upper end of Lake Mead, where water levels have dropped dramatically.

Tamarisk, also known as salt cedar, can kill out native plant species, but it also provides an attractive nesting spot for birds, including the endangered Southwestern willow flycatcher. That happened at Roosevelt Lake northeast of Phoenix, and the lake's operator, Salt River Project, was forced to spend millions of dollars to create a new nesting area for the bird. Without that habitat plan, SRP could not allow those areas of the lake to be inundated with water once lake levels began to rise again, eliminating critical water storage.

"That could happen up there, but we can't really predict it," said Lesley Fitzpatrick, a wildlife biologist for the U.S. Fish and Wildlife Service. "It would depend on how fast the trees grew and how long the water stays low. It happened over a long time at Roosevelt."

Early surveys haven't turned up any flycatchers in either reservoir, but Fitzpatrick said she has seen other changes. Habitat has dried up in some places, forcing birds and other wildlife to move on. In some ways, she said, the ebbing and flowing of the lakes mimic the old river, exposing habitat and then drowning it again later, but "the scale is different and the timing is different."

And that's the point, said Weisheit, the river guide and environmentalist. No amount of tinkering with the dams and the lakes will ever restore the Colorado River to the way it was. The river needs to run freer, even if that means the West has to make do with less water.

"We need to face reality," he said, packing up his car for the return trip to his home in Moab, Utah. "We live in a desert. We need to reduce our water use. As long as Glen Canyon Dam is here, the Grand Canyon is at risk." He watches another carload of tourists pull up and snap pictures.

"People will still come here," he said. "Moab makes as much money as Page, and it's not dependent on a reservoir that is consumptive, expensive and polluting. When the Grand Canyon is dead, do you think people are going to come out here? And who are they going to blame? The whole world is watching." If the drought persists and Lake Powell falls so low that it can't generate power, a level the lake could reach by 2007, then its economic value will be reduced to local recreation, especially if the bureau begins to manipulate water releases to restart the turbines.

The worst-case scenario up and down the river is dead pool, when the lake drops too low to let water out at all. The downriver states could survive on Lake Mead storage, but the river's economy would crash. A dry river would be an environmental catastrophe,

Nikolai Ramsey said, and if the lake didn't recover quickly, natural habitat could be lost for years.

But Ramsey isn't ready to buy the all-or-nothing equation yet. "We're still in a good place where there is human and environmental synergy possible," he said. "When power is lost and flows become less flexible for resource management actions, then we're in trouble. "Then it becomes more dam vs. Grand Canyon."

What keeps him and other river watchers optimistic is that even in a long drought, there's usually a year with normal rain and snow, and normal at this point would buy the Colorado time, maybe enough to keep itself alive

The next big drought may be more painful

By Brent Israelsen for the Salt Lake Tribune

If history is a guide, this six-year drought should have ended already. Chances are good it will end this year. Or next. But what if it doesn't? How many more years of below-normal precipitation can Utah withstand before the state's economy and way of life begin to suffer? What if this drought is the beginning of an epic change in climate? What happens during the next prolonged drought, 50 years from now, when Utah's population is more than twice its current size? Will there be anything left for fish and wildlife that depend on streams?

These are questions that should keep state water planners and environmentalists restless through these balmy summer nights. For now, though, Utah's chief water czar, D. Larry Anderson, appears to be sleeping just fine -- mainly because he has, as he puts it, a good "cushion." That cushion is the huge volume of water used by Utah's farms and ranches, which accounts for about 80 percent of the state's total developed water supply.

During droughts, agriculture -- which draws water directly from streams and small reservoirs -- takes the hit. Municipal supplies, which are built around large reservoirs with several years of built-in storage, are less susceptible to prolonged dry spells. "There will be some cushion," Anderson says, sporting a "Slow the Flow" T-shirt. "We have plenty of water for the foreseeable future."

The problem is, not all of it is available for drinking. Of the approximately 7.3 million acre-feet of water that flows through the state each year, only about 1.2 million acre-feet can be delivered today for culinary use. Residents consume nearly 1 million acre-feet per year. The rest of the state's water supply goes to agriculture, the Great Salt Lake, evaporation and to states downstream on the Colorado River.

Assuming current population trends and per-capita rates of consumption, culinary water demand is expected to rise to 2 million acre-feet by 2050, leaving a deficit of about 800,000 acre-feet above the deliverable supply of 1.2 million acre-feet. State water officials hope to squeeze about half of that water from people, through conservation. After all, about two-thirds of Utahns' water use is for landscaping, and experts estimate about half of that is wasted. The state hopes to cut Utahns' per-capita water consumption by 25 percent by 2050.

As subdivisions sprout up in once-irrigated fields, another 264,000 acre-feet are expected to become available, as agricultural water rights convert to municipal and industrial rights. After conservation and agricultural conversion make their contributions, Utahns in 2050 still would be short about 136,000 acre-feet.

That deficit, Anderson says, would be made up from any combination of three major new water projects now on the drawing board. Each of them would require enormous public investment at a time when existing water infrastructure, such as delivery systems and treatment plants, need to be expanded or replaced.

The Bear River is considered the next most likely source of water for the Wasatch Front, which hopes to siphon about 150,000 acre-feet a year. The total project would cost about \$600 million.

In southwestern Utah, water managers from Washington and Iron counties are eyeing a \$400 million pipeline project that would deliver water from Lake Powell, more than 120 miles away. A third, though less likely, project contemplates a 115-mile pipeline that would run from northern Flaming Gorge in Wyoming to the Weber River Basin drainages near Coalville. Estimated to cost about \$300 million, the pipeline could deliver about 60,000 acre-feet of water a year to the Wasatch Front.

Environmentalists say the new water-development projects would unnecessarily disrupt ecosystems and landscapes. They argue for more emphasis on conservation, better planning, curbs on growth and a shift in planning.

"During this drought, there's been no discussion about the environment," laments Owen Lammers, director of the Moab-based Living Rivers. "It's been people, people, people. We want to make sure the environment has a seat at the table in managing human demands."

Erica Thoen, of the Salt Lake City-based Utah Rivers Council, criticizes the state's water goal of reducing per-capita daily consumption by 25 percent by 2050 -- as too weak. Utahns, she notes, already have reached much of that goal during this current drought. In Salt Lake City, for example, residents have cut their water use by 18 percent. Today, a Salt Laker consumes about 214 gallons per day -- 10 percent less than the statewide target of 240 gallons four decades from now.

And the city's conservation director, Stephanie Duer, says she believes the city can do even better. A larger sampling of 16 major water agencies around the state suggests that, despite a growing population, total water use in Utah has declined 19 percent

since 2000. So is the state goal too wimpy? State officials defend their conservation goal, which was established well before this six-year drought began, as being achievable and sustainable without being draconian.

"Beyond [25 percent], things get tougher," says Anderson. "The environmental community wants us to do it tomorrow. We can't force it down [residents'] throats." To get more than 25 percent, water agencies would have to increase water rates and cities would have to enact restrictions on landscaping and limit the size of residential building lots, which Anderson says are too large.

He does not believe, however, in the need for government curbs on growth, noting the potential for obtaining more water through conservation and converting more agricultural shares. "We don't think water is a limiting factor," Anderson says.

However, to date the state's plans for providing water to ever-increasing populations have not factored in the possibility of climate change caused by global warming, which many leading scientists say could significantly alter how and when Utah gets its precipitation.

"We've got to get away from historic planning and look at new hydrologic realities of a shrinking snowpack and changing seasonality of runoff," says Fred Wagner, a Utah State University professor emeritus and expert on global warming. "It is potentially a serious problem that needs serious analysis."

Global warming notwithstanding, the current drought has given water officials plenty of pause. "Long-term drought cycles of many years should be expected," says Richard Bay, chief engineer of the Jordan Valley Water Conservancy District. "We'll make it through this [drought] quite nicely. The next time this occurs, with an increased population, that will be the true test."

Water consumption in Utah is down, but is it enough?

LR in the News 07/26/04

Glen Canyon Dam flow regime a 'failure,' report says

April Reese, Greenwire Southwest correspondent

A 13-year-old experiment aimed at improving ecological conditions in the Colorado River watershed below Glen Canyon Dam is failing and needs a management overhaul, according to a draft report by a group of scientists that monitors the dam's environmental effects.

Since 1991, Glen Canyon Dam has operated under "modified low fluctuating flows" (MLFF), intended to help recover the endangered humpback chub and other species

downstream in Grand Canyon National Park without scaling back power production or recreational activities such as rafting.

MLFF involves daily variations in flow. For example, on weekdays in July, daily fluctuations vary from 10,500 cubic feet per second (cfs) during the late evening and early morning off-peak hours to 18,500 cfs during peak times in the late afternoon and early evening. Still, the MLFF is a highly regulated version of the river's historic flows, which seasonally ranged from as little as 500 cfs to as much as 100,000 cfs.

Under the current flow regime, the endangered humpback chub, which once thrived throughout the Colorado River Basin but now occupies only the lower basin in the Little Colorado River, continues to spiral toward extinction, declining by an average of 14 percent each year, according to the draft report.

"One of the justifications for the MLFF policy was apparently an assumption or prediction that MLFF would have beneficial ecological effects relative to the more violent diurnal flow variations that preceded it," the report says. "We show that no such beneficial effects are evident in the ecological system (except to abundance of exotic trout), and in fact the move to MLFF is correlated with a relatively sharp decline in humpback chub recruitment."

Hydropower production has also declined under the low fluctuating flows, the report notes. The Western Area Power Administration, which sells power from Glen Canyon Dam, has had to cut its electricity generation by roughly 25 to 30 percent, or 400 to 440 megawatts, in recent years. To make up the difference and meet power contract commitments, WAPA purchases power from other producers -- an expensive stopgap measure.

In fact, the only beneficiaries of the modified low fluctuating flow regime have been exotic trout that eat endangered chub and the rafting industry, the report concludes.

"At present, power utilities and their ratepayers are essentially subsidizing, at considerable cost, improvement in the quality of Grand Canyon for some recreational uses," the report reads. "It is one thing to impose such costs to deal with some broad public interest such as protecting an endangered species, but quite another one to impose it for the benefit of particular stakeholders."

The issue of flows from the dam needs to be addressed "openly and quickly" before it "leads to a breakdown in the collaboration among stakeholders that has made adaptive management possible in Grand Canyon in the first place," the authors warn.

Management of Glen Canyon Dam and the Colorado River's resources in the park is overseen by a diverse group of stakeholders called the Adaptive Management Work Group, which monitors how well policies are working and suggests changes in course when necessary. Participants range from Bureau of Reclamation officials to fisheries biologists, environmentalists, hydropower interests and American Indian tribal representatives. The stakeholders periodically examine the latest scientific information

on the river and make management recommendations to the Interior secretary, who decides whether to implement them.

The draft report, written by the technical arm of the group that advises the stakeholders on scientific matters, suggests that a switch to a more variable flow pattern may benefit both ecological resources and power production in the Grand Canyon.

Carolyn Hinkley, a spokeswoman for the Western Area Power Administration, agrees. "It has cost us \$50 million a year more with the modified low flows," Hinkley said. "When we have fluctuating flows, it does allow us to meet demand more easily."

Experimental flows over the past two winters that have increased daily fluctuations in an attempt to reduce the exotic trout have enhanced power production, Hinkley said.

But others contend dam managers should embrace more variable flows that mirror natural, seasonal fluctuations. These "seasonally adjusted steady flows," which were recommended by the Fish and Wildlife Service a decade ago, would attempt to mimic the Colorado River's highly dynamic natural flow, advocates of such measures say.

But mimicking the river's historic low-flows would result in drastically reduced power production and revenues for WAPA, said Owen Lammers, executive director of Living Rivers, an advocacy group based in Moab, Utah. Lammers and other critics of current management practices charge that WAPA has too much influence over management decisions, a charge the agency dismisses.

"We have one vote just like any of the other representatives on that group," said Hinkley, the WAPA spokeswoman. "It takes two-thirds of the group to decide on what direction to take."

The ecosystem's needs are not the only factors to be considered, stakeholders point out. Through the adaptive management work group, they must also weigh the needs of boaters and other recreationists, American Indian tribes, irrigators and cities that depend on the dam for hydroelectric power and its reservoir, Lake Powell, for water supplies.

Lammers said the draft report provides further evidence that BuRec, which operates the dam, needs to consider a new approach for dam operations. "There's been an abundance of new information that reinforces that we need to take a much different look at what's needed to recover the resources in Grand Canyon," he said. "Right now, they're operating without a net."

Living Rivers and about 200 other environmental groups have asked BuRec to draft a new environmental impact statement that would examine both seasonally adjusted steady flows and the decommissioning of Glen Canyon Dam, either of which they say could reverse the decline of the humpback chub.

Hinkley said WAPA and other stakeholders are meeting to sort out an experimental flow regime to address the concerns laid out in the draft report.

[EVIDENCE FOR THE FAILURE OF THE MODIFIED LOW FLUCTUATING FLOW ALTERNATIVE \(MLFFA\) TO BENEFIT MOST ECOLOGICAL RESOURCES IN GRAND CANYON](#) [96k PDF File]

Odds seem long, time short for Canyon chub

By Mitch Tobin
ARIZONA DAILY STAR

LITTLE COLORADO RIVER - Pitted against a 710-foot dam, blue-ribbon trout fishery and the water demands of 25 million people, humpback chub are swimming upstream to survive.

The prehistoric-looking minnows once numbered around 100,000 in the Grand Canyon. But today - four decades after Glen Canyon Dam transformed the Colorado River from warm, muddy and variable to cold, clear and calculated - the population is down to about 3,000.

"It's as if you took a rhino or an elephant out of the African heat and tried to raise them in Alaska," said David Haskell, who ended his 33 years with the federal government as science director of Grand Canyon National Park from 1994 to 1999.

Tens of millions of dollars already have been spent to help the chub. An even bigger bill may be coming as officials consider retrofitting the dam or altering its releases, now regulated more by the Sun Belt's demand for air conditioning than nature's ebb and flow. Even if society doesn't fully accept the ethical, aesthetic, ecological and educational rationales for saving rare creatures like the chub, the strict Endangered Species Act could make the spending mandatory.

The radical change to the Colorado let rainbow trout thrive below the dam and helped many of the river's other introduced fish species, some of which feast on the natives. But the frigid water has made it virtually impossible for chub to spawn in the Colorado, forcing them to swim up the last 10 miles of a tributary, the Little Colorado, to reproduce.

Just since 1989, the estimated number of chub in the Grand Canyon has fallen by two-thirds, drawing the fish further down a path to oblivion already blazed by the bonytail chub, roundtail chub, razorback suckers and Colorado squawfish.

"The population may be so small now that it's ecologically extinct and can't come back," said Chuck Minckley, a U.S. Fish and Wildlife Service biologist whose doctorate examined the chub's history since 1908.

Environmentalists have long dreamed of decommissioning the dam that created Lake Powell, with radical factions fantasizing about blowing it up and the mainstream arguing it will back up with sediment anyhow and be vulnerable to collapse.

Activists vow they'll sue by year's end to force a new study of how and whether to operate the dam - a linchpin of the plumbing system that feeds Tucson and Phoenix via the 336-mile Central Arizona Project canal, plus Las Vegas and Southern California.

The first environmental impact statement, finished in 1995 after 50,000 public comments, was funded by \$104 million in hydropower revenues.

With record drought gripping the Colorado's basin - Lake Powell hasn't been this low since it was filling in the 1970s - federal officials say the reservoir is more valuable than ever.

"If we did not have the Glen Canyon Dam, Arizona would be in a serious crisis today," Interior Secretary Gale Norton said in Phoenix last week. "You don't survive a long-term drought unless you have storage."

The Bureau of Reclamation, overseen by Norton, won't even consider damming the dam, but is again contemplating a major modification to the upstream face that would let warmer water pass through its turbines - and cost up to \$160 million.

It wouldn't be the first time the chub altered how the dam is run. In 1996, former Arizona Gov. and then-Interior Secretary Bruce Babbitt opened its 8-foot- wide floodgates with much fanfare to re-create spring floods. Weeks later, the experiment was hailed as a success in creating beaches for boaters and backwaters for chub. But researchers now say whatever gains were made were fleeting. Sand bars washed away within a year.

More experimental floods in the spring of 2000, followed by low flows all summer, forced the dam to cut power generation when it's most lucrative, hitting energy buyers with \$21 million in extra costs, according to the Colorado River Energy Distributors Association.

Falling water spinning blades of turbines lets Glen Canyon Dam produce 1,300 megawatts at full capacity and power 3 million homes. Cutting that supply means utilities must find more costly substitutes, said LaVerne Kyriss of the Western Area Power Administration, which markets the dam's energy.

Environmentalists counter that the dam's power supply could be offset if 10 million homes replaced two standard light bulbs with energy-saving compact fluorescents.

A river transformed

Before the government's 20th-century dam-building campaign, the Colorado's flow was as uneven and mercurial as the topography and climate of its 244,000-square-mile basin, which extends from sand dunes in Mexico to the glaciers of Wyoming's Wind River Range.

In spring, the river could roar with turbid snowmelt at 100,000 cubic feet per second, only to shrink to a trickle of 3,000 cfs in summer. Water temperatures ranged from near freezing to more than 80 degrees.

Today, just below the dam, the Colorado is a nearly constant 46 degrees because water is drawn through turbines from hundreds of feet below the surface, where sunlight can't penetrate. Rafters who fall overboard may flirt with hypothermia in July. Young chub that survive the thermal shock are often paralyzed and vulnerable.

Though fickle in its flow, the Colorado has become the lifeline of the Southwest. Starting with Hoover Dam in the Great Depression, colossal dams and aqueducts were built to capture floods and survive the droughts. The Sierra Club and its leader, David Brower, blocked plans in the 1960s to plug the river in the Grand Canyon, but only after they had accepted Glen Canyon in exchange for the government's scrapping a dam that would have submerged part of Dinosaur National Monument in Colorado.

Brower carried regrets to his grave. And for people like former Tucsonan Dave Foreman, a disenchanted D.C. lobbyist for the Wilderness Society, the 5.4 million cubic yards of concrete epitomized the perils of political compromise. On the 1981 spring equinox, Foreman and other founders of Earth First staged their first protest.

Egged on by Tucsonan Edward Abbey, whose novel "The Monkey Wrench Gang" depicts a band of saboteurs plotting to blow up the dam, they unfurled a 300-foot, black-plastic banner down the dam's ivory face, making it look as if they'd cracked their concrete demon.

Even before the dam, chub had to compete with non-native fish introduced as early as the late 1800s, sometimes by the agencies now struggling to recover the endangered fish.

The rainbow trout fishery at Lees Ferry, which would disappear if the dam did, now attracts anglers from around the globe, provides hundreds of jobs and brings in \$20 million per year, said Terry Gunn, co-owner of Lees Ferry Anglers and the adjoining Cliff Dwellers Lodge.

"Every dollar is important to this (economically depressed) area," he said.

Brown trout prey on chub, he said, but the impact of rainbow trout is overblown since they're insect-eaters and studies have found other fish in the stomachs of fewer than 1 in 100 rainbows.

Recent experimental flows and limited removal of non-native fish have been both costly and ineffective, he said. "We're all in favor of the recovery of the humpback chub. But, so far, they haven't done anything to really help the chub."

Little Colorado sole nursery

Because the Colorado's main stem is so cold and clear - giving sight-based predators a leg up on their prey - the Little Colorado has become the sole maternity ward for the

Grand Canyon's chub. The LCR, as it's known, starts on 11,403-foot Mount Baldy in the White Mountains, then snakes to the northwest, often as a trickle, before reaching the Painted Desert and Navajo Reservation.

Near the confluence with the Colorado, the river glistens like one of the turquoise necklaces fashioned thousands of feet above on windswept plateaus dotted with hogans and sagebrush. Up close, the river looks more like skim milk and the shores are encrusted with a white ring. The dissolved minerals also emerge from solution to form small dams and falls in a process similar to the creation of stalactites and stalagmites.

You could drink the water in an emergency, river rats say, but soon you'd be losing as much fluid in diarrhea. So the researchers who arrive here by helicopter bring their own water, along with a half-ton of other supplies, to support their 12-day surveys.

Biologists set about 20 hoop nets a day. They return the following morning to measure the fish, record their reproductive status and use syringes to inject half-inch, \$4 transmitters similar to the microchips used to reunite pets with their owners. Scientists can infer population trends and growth rates by continually recapturing the fish because each tag, when passed through a special wand, emits a unique 12-character code.

"That's his social security number," said Dennis Stone, a Fish and Wildlife biologist who has spent up to 120 days a year in the Canyon.

In 1993, Stone saw the LCR at 20,000 cubic feet per second. Three months ago, the 70 degree river was at its base flow of 240 cfs, fed entirely by Blue Springs.

"If Blue Springs ever dries up, these fish are toast," he said.

Below Lower Atomizer Falls, Stone swims across the river to check nets, a wad of tobacco between cheek and gum, only his bespectacled head visible. The call of canyon wrens cascades from red spires along with the slanted sunlight, creating a setting so sublime as to appear unreal, like a 19th-century, Romantic-era landscape painting.

On the shore, the smell is almost marine, the mud sometimes becomes quicksand and the thick ribbon of riparian vegetation - mesquite, acacia, cattails and salt cedar - lashes the researchers' shins. Atop a sand terrace, volunteer Bill Pine and biologist Josh David pluck captured fish from a plastic bucket, struggling to hold the muscle-bound creatures in their hands.

"This is a fish made to run the rapids," said Pine, a scientist at the Mote Center for Fisheries Enhancement in Sarasota, Fla. "It's a body shape built for speed, and it's highly evolved for this river."

Embedded scales make the chub feel leathery, and its nostrils have flaps to keep out sediment. Its big, sickle-shaped tail, like a tuna's, propels it through swift water. The namesake hump is thought to act like a rudder and help keep it near the bottom of the river.

"They're about as charismatic as a fish gets," David said.

The LCR's chub have become one of the nation's most intensively studied fish populations, but much of their biology remains shrouded in mystery. Some scientists, however, fear repeated handling of the chub could be hurting them.

David suspects young chub may be eaten while in the nets. He'd like to use underwater cameras to examine that, plus the escape rate from nets and spawning behavior, which has never been observed directly.

"Know anyone with \$15,000 for a chub study?" he asked.

Search for warmer water

Federal officials will need a lot more than that to make Glen Canyon Dam chub-friendly.

The proposed temperature-control devices - derided by critics as band-aids - would draw water from closer to Lake Powell's sunny surface, instead of the reservoir's chilly depths.

Getting Congress to fund the project will be a challenge, but it could be operational as soon as 2007, said Dennis Kubly of the Bureau of Reclamation.

Fitting just two of the dam's eight penstocks, at a cost of \$20 million each, would probably gain the most bang for the buck, Kubly said. The trick, scientists and federal officials agree, is to warm the releases enough to help the chub, but not so much that its non-native predators benefit even more.

Similar technology is already used at Flaming Gorge Dam in Wyoming, Shasta Dam in California and some five dozen other sites Reclamation studied.

"In almost every example, the outcome has been positive," Kubly said.

The devices won't, however, do anything to stop the dam from trapping 95 percent of the Colorado's sediment.

Replicating the natural system would require adding up to 10 million tons of silt per year, the 1995 environmental study said. Proposals have been floated to use trucks, barges or a slurry pipeline that would have cost \$50 million to build in 1995 and \$10 million per year to run.

Environmentalists say the sediment is crucial not only for chub, but the rest of the Grand Canyon ecosystem. But the cost would be astronomical, requiring four tandem-trucks to dump silt every minute, in perpetuity, said Owen Lammers, executive director of the Moab, Utah-based Living Rivers.

"When you look at trying to restore the natural process in the Grand Canyon, the cheapest way to do it is decommissioning the dam," he said.

Lammers and other dam foes say Lake Powell's storage could be handled upstream in existing reservoirs, thus saving billions of gallons lost to evaporation behind Glen Canyon Dam.

"We only need it because we're incredibly an overconsumptive basin in terms of water use," he said. "We've been used to living high on the hog, and what it's gotten us is a destroyed Grand Canyon."

Let the Colorado run again

The Denver Post, Sunday, August 1

Writers on the Range by John Weisheit

As our rafts bounced through what was supposed to be the last rapid on the Colorado River before its transition to the slack water of Lake Powell, we were surprised to hear the rumble of whitewater downstream.

The half-mile-long Imperial Rapid, submerged for three decades, had re-surfaced. The natural draining of the nation's second-largest reservoir was underway, but how far would it go?

Climate change in the region has lowered the reservoir 120 feet over the past five years. This drop should have been sufficient to expose half the remaining 21 rapids that were also submerged by the reservoir, yet only Imperial has come out so far. A look around from the raft revealed the problem: We were floating over a massive slab of sediment that had built up in the decades since Glen Canyon Dam was finished.

The remainder of our descent was through a ditch framed by gray cliffs of sand rising 25 feet on either side, with dump-truck-sized chunks calving off like icebergs.

The ditch widened as we caught up with the slack water of the reservoir, now 30 miles below Imperial Rapid but still 140 miles from Glen Canyon Dam.

Although Lake Powell reservoir is just 40 percent full and has lost 50 percent of its surface area, it has dropped only 20 percent in elevation. The reservoir is still 445 feet deep near the dam. It's like a wide funnel: There's more water stored at the top. But scientists predict it will fall more rapidly if present climatic conditions persist.

The reservoir's elevation could also drop three times faster over the next three years than it has over the past five. If that happens, it would cause hydroelectric power production at the dam to cease in 2006. By 2007, a condition known as "dead pool"

would be created, which means the dam would basically become useless as a power generator. The reservoir, however, would still stretch 104 miles upstream, contain approximately 2 million acre-feet of water and sediment, and rest 234 feet above the original river bed at Glen Canyon Dam.

Still submerged would be most of Glen Canyon's 125 signature side canyons, which inspired the canyon's pre-dam river runners along with the mounting numbers of present-day advocates for Glen Canyon's restoration. Nature's crash course in water scarcity is helping to amplify the mounting economic and environmental liabilities associated with Glen Canyon Dam and Lake Powell, raising the prospect of decommissioning the dam and uncovering the remainder of the canyon.

Glen Canyon Dam was completed in 1963, as a water-storage facility for downstream users. Because of other storage facilities built in the basin, principally Lake Mead behind Hoover Dam, it will be this winter before Lake Powell's storage will, for the first time, actually contribute to downstream water use.

Over the years, Lake Powell will have lost 40 million acre-feet of water from evaporation and seepage, while providing only 23 million acre-feet in storage. This lost water represents nearly three years of the entire annual flow of the Colorado River. It's not surprising that people are looking for more efficient ways to save this valuable water. California, Nevada and Arizona are already doing so by storing Colorado River water in underground aquifers. They lose as little as 1 percent of the water to the environment, compared to the more than 60 percent of water that is lost at Lake Powell.

Concern is also mounting over the damage Glen Canyon Dam is causing to the downstream ecosystem in Grand Canyon National Park. Four of the Canyon's eight native fish are already gone, as are otters, muskrats and a host of birds, insects and reptiles. Despite more than \$200 million invested in efforts to mitigate the dam's impacts, biologists say these declines will continue.

As the drought continues, a growing number of scientists are questioning whether there will ever be enough water to fill Lake Powell. But I have a different question: Once the reservoir dies a natural death, shouldn't we finish the job and let the river run again?

LR Press Release 08/09/04

Solution Proposed for Failing Federal Program to Save Grand Canyon.

Contact: Owen Lammers - (435) 259-1063

(Phoenix) Living Rivers/Colorado Riverkeeper, the lead advocate for protection of the Colorado River, called for immediate action to address the main impediments to failing federal efforts to recover endangered native fish in Grand Canyon National Park.

At the semi-annual meeting beginning today of the Glen Canyon Dam Adaptive Management Working Group (AMWG), Living Rivers/Colorado Riverkeeper presented a [letter](#) emphasizing that the continued decline of critical resources including endangered species in Grand Canyon's Colorado River is a result of the program's lack of effective management strategies needed to comply with the Grand Canyon Protection Act.

"It's so simple. All they have to do is follow their own charter," says Dave Haskell, former science director for Grand Canyon National Park and now policy director for Living Rivers/Colorado Riverkeeper. "But they merely focus on implementing increasingly complex research projects that continue to fail to achieve the stated program goals."

Since established in 1996, the AMWG has spent more than \$100 million on efforts to change the operations of Glen Canyon Dam, but has failed in its principle objective, recovery of endangered, native fish. Since the program began, the razorback sucker has disappeared from Grand Canyon, while the humpback chub has declined 14 percent per year to as few as 1,000 adult fish.

This week's meeting has been extended an extra day to discuss future strategy, and follows an unprecedented three-day retreat held last month in an attempt to fix the ailing program.

"Any strategy must define what constitutes program success, and there in lies the problem," adds Haskell who is attending the meetings. "The stated goals are lofty but there is no clearly defined strategy to attain them. They state that it may not be possible to mitigate some of the impacts caused by the dam, but they do not indicate which ones. It will be impossible to determine when the program has actually met the goals."

Living Rivers/Colorado Riverkeeper is requesting that not only does AMWG make its goals clear to the public, but that it execute its authority to implement a range of activities which its science has determined are needed to recover Grand Canyon's deteriorating river ecosystem: Annual inputs of large amounts of nutrient laden sediment, seasonal variability of water flows that creates the dynamic physical environment, and seasonal variability of water temperature. "The very foundation of National Park System natural resource stewardship is the protection of ecosystem processes, for it is these processes that sustain the diversity, abundance and distribution of native species.... The success of this AMP [Adaptive Management Program] must be measured by how well it protects and enhances these critical ecosystem processes." the letter states.

The letter further points out that the AMWG charter allows it far reaching authority "...if needed, [AMWG can] develop recommendations for modifying the Glen Canyon Dam Environmental Impact Assessment Record of Decision, associated [dam] operating criteria, and other resource management actions pursuant to the Grand Canyon Protection Act."

"There's no question that the AMWG has greater authority to restore the natural integrity of Grand Canyon's famed river ecosystem, the question is, will they use it," says Haskell.

More than 200 organizations have joined Living Rivers/Colorado Riverkeeper in demanding that AMWG exercise its mandate and undertake a new environmental impact statement on the operations of Glen Canyon Dam, including evaluating the dam's decommissioning as one alternative for meeting Grand Canyon Protection Act goals.

Department of the Interior
1849 C Street, NW
Washington D.C. 20240

RE: Comments Relative to the Reporting Requirements and Congressionally Mandated Goals of the Glen Canyon Dam Adaptive Management Program.

The Glen Canyon Dam Adaptive Management Program (AMP) has been in operation for nearly eight years, and a comprehensive research and monitoring program has been functioning for over 15 years. Progress in understanding the ecological processes that drive the aquatic ecosystem of the Colorado River in the Grand Canyon has been reported and is generally considered to be meeting the science program goals as stated in the EIS ROD and AMP Charter. In contrast, the relative success of the AMP in using this information to achieve the goals of the Grand Canyon Protection Act (GCPA) has been poorly and inconsistently reported. The GCPA requires the AMP to submit an annual report to Congress and the Governors of the basin states. As defined by item E of the AMP Charter, the AMWG is to "review and provide input on the report required in Section 1804 (2) of the Act The report will include discussion of dam operations, the operation of the AMP, status of resources, and measures taken to protect, mitigate, and improve the resources defined in the Act." To date, only a single report combining the

information for water years 1999-2001 has been submitted. Progress in mitigating the adverse impacts to Grand Canyon resources during 2002 and 2003 has yet to be reported. The AMP is obligated to ensure that Congress and the public are kept up to date as to whether this program is succeeding. Duties, Section F of the AMP Charter charges the AMWG to "Annually review long-term monitoring data to determine the status of resources and whether the AMP Strategic Plan goals and objectives are being met. More importantly, the AMWG is directed to "if needed, develop recommendations for modifying the GCDEIS ROD, associated operating criteria, and other resource management actions pursuant to the Grand Canyon Protection Act.

The science program has identified the key ecosystem processes that create and maintain the ecological integrity of the Colorado River in the Grand Canyon. There are: Annual inputs of large amounts of nutrient laden sediment, seasonal variability of water flows that creates the dynamic physical environment, and seasonal variability of water temperature. The very foundation of National Park System natural resource stewardship is the protection of ecosystem processes, for it is these processes that sustain the diversity, abundance and distribution of native species. The National Park System was created by Congress to protect the health and diversity of our nation's unique natural and cultural heritage. The success of this AMP must be measured by how well it protects and enhances these critical ecosystem processes.

The single report submitted to date clearly indicated that none of the dam related impacts to key ecological processes or other affected resources such as the Humpback Chub had been successfully mitigated. In fact, many of these components and critical resources were in a state of decline. It is unclear how the AMWG defines success. The minutes of your recent retreat indicate this unfortunate ambiguity, as one participant asked, "How do we get to the end" Although the ROD provides for the AMP to operate "indefinitely". Fiscal responsibility alone requires that at some point either the goals are achieved, or its admitted that they can't be achieved. It's critical that the AMWG review how it defines program success, and does so in terms of the conditions of Grand Canyon resources.

In summary, considering the continued decline of the ecosystem taking place in Grand Canyon National Park, it is imperative that the AMWG rededicate itself to achieving the goals of the GCPA, or recommend a new program that can. The AMWG must clearly define success in terms of the condition of Grand Canyon resources, meet the reporting requirements of the GCPA, clearly articulate the success or failure of adaptive management actions in these reports, and immediately request a Supplemental EIS and a new ROD that will enhance the AMWG's ability to achieve the success contemplated by the GCPA.

Living Rivers/Colorado Riverkeeper and our supporting groups from across the country look forward to hearing from you as to how and when the AMWG will address these matters.

Sincerely,

David Haskell
Policy Director, Living Rivers

Lake Powell a liability to water management

Arizona Republic OpEd

Rather than grouching about a name change for Lake Powell proposed by a handful of Colorado residents, I suggest that The Republic move on from opining on this trivia to discussing the hard facts regarding the detrimental effects Lake Powell will have on the availability of water in the future ("It's a lake, dammit," Editorial, Aug. 1).

Undisputable scientific data now point strongly to the fact that Lake Powell has become a water-management liability, and the situation is only going to get worse. The average annual flow of the Colorado River up until 1990 was 12 million acre-feet. During the past decade the flow has dropped to 10 million acre-feet. The Department of Energy estimates that the long-term climate change will reduce the flow to less than 7 million acre-feet by 2050.

The upper basin states are now using 5 million acre-feet of this water and the lower basin states and Mexico are using 8.25 million. There is now an annual deficit of 3.25 million acre-feet. To make matters worse, Powell loses a half-million acre-feet each year to evaporation, increasing the deficit to 3.75 million acre-feet a year. There are only 9.5 million acre-feet of water left in Powell.

In the very short term, use of this water will delay the crises, but there will not be enough water to fill the reservoir again. In order to maximize the availability of any future excess water, it should be stored in underground aquifers that eliminate evaporation. The governor should be praised for supporting this innovative concept.

David Haskell, Camp Verde

Pressure to restore river corridor intensifies

April Reese, Greenwire Southwest correspondent

Environmentalists monitoring an 8-year-old federal program to restore the Grand Canyon below Glen Canyon Dam this week called on the government to better define

its strategies, conduct more on-the-ground restoration and revise the environmental impact statement (EIS) governing the effort.

In a letter to the Glen Canyon Dam Adaptive Management Work Group, the nonprofit group Living Rivers ticked off a litany of complaints about the restoration program and urged its managers to rethink its strategy for the lower canyon. The work group is comprised of 26 stakeholders with some management responsibility for Grand Canyon National Park's river corridor.

The restoration program was enacted by the Clinton administration to meet provisions of the Grand Canyon Protection Act, which directed the Interior Department to "protect, mitigate adverse impacts to, and improve the values for which Grand Canyon National Park and Glen Canyon National Recreation Area were established."

Participants in the work group range from Bureau of Reclamation officials to independent fisheries biologists, environmentalists, hydropower interests and tribal representatives. The stakeholders periodically examine the latest scientific information on the river and make management recommendations to the Interior secretary, who decides whether to implement them.

The letter, written by Living Rivers policy director Dave Haskell, a former director of Grand Canyon National Park's Science Center, charges the work group with failing to review the latest scientific data on the canyon's resources. The program's charter instructs the work group to annually evaluate monitoring data to assess conditions in the canyon and to determine if the program's objectives are being met, Haskell noted.

The letter states that scientists have identified three critical actions that are necessary to restore pristine conditions in the Grand Canyon: annual inputs of large amounts of sediment, seasonal variability of water flows and seasonal variability of water temperature.

Living Rivers and about 200 other environmental groups have asked BuRec to examine a range of alternatives to meet those goals, including the decommissioning of Glen Canyon Dam. But so far no serious consideration has been given to that proposal, critics say.

Living Rivers maintains that other attempts to improve conditions in the canyon have largely failed and that a new EIS should be drafted to address new and emerging concerns, including the dam itself. Haskell urged the group to exercise its authority to recommend undertaking a new review.

"Considering the continued decline of the ecosystem taking place in Grand Canyon National Park, it is imperative that the AMWG rededicate itself to achieving the goals of the Grand Canyon Protection Act, or recommend a new program that can," Haskell wrote.

"Any strategy must define what constitutes program success, and therein lies the problem," added Haskell, who delivered the letter to the work group at its meeting in

Phoenix this week. "The stated goals are lofty, but there is no clearly defined strategy to attain them."

The letter is the latest in a series of critical missives from groups unhappy with the program's progress. But environmentalists are not alone in their complaints.

Last month, the working group's own scientists raised questions in a report about the effectiveness of the Colorado River flow regime adopted by the group (Greenwire, July 26). According to the report, the endangered humpback chub, which inhabits a small area of the canyon near the confluence of the Colorado and Little Colorado rivers, is declining at an average rate of 14 percent despite efforts to help the fish. The science advisers recommended a 24-month review of the program, beginning in October.

BuRec spokesman Barry Wirth, who attended the meeting of the adaptive management work group this week, urged patience. Recovery of the Grand Canyon ecosystem will be a long process involving plenty of trial and error, he said.

"We've committed substantial resources in working on these issues," including recovery of the humpback chub and sediment replenishment, he said, citing as examples several projects to control trout, which compete with the chub.

BuRec contends that the experimental nature of the program has allowed managers to better understand the ecological dynamics of the Grand Canyon -- an essential step in improving conditions there.

Experimental flows, while unsuccessful in replenishing beaches over the long-term, nevertheless produced valuable data that can be used to improve the next round of experimental flows. And the new effort to remove non-native fish from the river may be helping the chub, although the results of that experiment will not be known for another year or two (Greenwire, March 8).

Wirth also emphasized that the work group includes 26 representatives from a range of interests, all of whom have a say in management of the canyon. "It's a diverse effort, and I think the reality is a substantial amount of effort has gone into addressing these issues," he said.

As the work group continues to wrangle with its mission, environmentalists are also urging Congress to kill a long-standing rider to BuRec's appropriations bill that prohibits expenditures on studies for decommissioning Glen Canyon Dam. The provision was first added to the agency's spending bill in 1996, and it remains in this year's House-approved bill for fiscal year 2005.

"What's wrong with allowing science to look at this?" asked Owen Lammers, executive director of Living Rivers. "Isn't that what the adaptive management program is all about?"

LR in the News 08/16/04

Colorado River 'at critical juncture'

By Michael Gardner San Diego Union Tribune

August 16, 2004

SACRAMENTO - Struggling Utah farmers sacrificed water to save a school on the verge of shutting down because its well ran dry. Montana ranchers are selling off their herds. In Arizona, the Marines pitched in to help build watering holes to keep rare sheep from dying of thirst.

A persistent drought has upset lives and livelihoods from Montana to New Mexico, drawing comparisons to the Dust Bowl days. Fields have been left unplanted. Homeowners are being paid to tear out lawns. Hydropower generation is threatened. Ducks are disappearing and forests are becoming kindling.

"The drought threatens to change the very fabric of Montana's rural communities and landscape, placing the birthright of descendants of pioneer families on the auction block," Gov. Judy Martz said in a recent speech.

Although Mother Nature has punished the West for several years in a row, the developing crisis also can be traced to other factors: growth, resistance to tough conservation, global warming and an overly optimistic estimate of the Colorado River's ability to deliver water.

The spine of the West - fused by the Colorado River and the Rockies - has been hit the hardest. Although supplies of water have been squeezed along the coast, from Seattle to San Diego, the pain there is not as widespread or as deep.

Urban water purveyors across California, while nervous, say there is no need for rationing this year because of average-sized snowpacks in the north and adequate storage.

For now, climate experts can offer only hope that relief will arrive.

"I don't think we can discount the possibility of a recovery, but the likelihood is one out of four, maybe one out of five, for a really wet year," said Dan Cayan, a climatologist at Scripps Institution of Oceanography in La Jolla.

Scarier still is this emerging question: What if stubborn dry spells are the norm and the traditional cycle of normal-to-wet bounty is the exception? Tree ring records and other data suggest the West may be in for longer, drier periods in the coming decades, some experts say.

Scramble for water

This latest string of dry years has hit states dependent on the Colorado River basin, at one time a seemingly eternal well for 25 million people, millions of acres of farmland and an assortment of endangered and other animals.

Lakes Powell and Mead, the two massive reservoirs that catch the Colorado, are less than half full, exposing long-submerged landscapes to direct sunlight for the first time in decades. It could take a 10-year run of average rain and snow to refill the reservoirs.

Lake Powell, which straddles the Utah-Arizona border, is at a historic low level. Nevada's Lake Mead has been lower only twice before, counting the period when Lake Powell was filled for the first time.

"We are at a critical juncture in the history of the Colorado River, a river we all depend on for our lives," said Jack August, an Arizona historian who studies water trends.

California draws enough water out of the Colorado for more than 1 million households a year. Seventy percent of San Diego County's drinking water comes from the river.

The frantic hunt for more supplies has states pondering expensive options. Colorado and Nevada are scouting pipeline routes to ship water to parched regions. Some farmers may be paid far more than their crops are worth to leave fields unplanted. Las Vegas home builders have been banned from planting grass in front yards.

California plans to increase the size of a handful of reservoirs, but squabbles over who should pay for the work have slowed progress.

Shrinking Colorado River flows sent Metropolitan Water District, the Los Angeles-based wholesaler for most of Southern California, scurrying to secure more water from Lake Oroville, north of Sacramento.

In Colorado, reservoirs remain about half full. New Mexico's largest lake, Elephant Butte, is critically low. In Oregon, southeastern farmlands are in dire straits. Wyoming's thirst is the worst it's been in 110 years.

"My cattle are gone," lamented Montana rancher Bob Redfield, forced to sell 100 head because there was no water for hay.

Said Utah farmer Charlie Holmgren: "We always thought we were invincible." That mood has darkened with each day of blue skies. His water source, Bear Lake, "is pretty well gone."

"It will force some people out of agriculture in this valley," Holmgren said. "We're hanging on - this year."

Farther south, farmers in Blanding, Utah, decided to put classrooms before crops. When the school's well ran dry, they gave up water to keep kids from being bused out of town, Mayor Toni Turk said. Power generators and water purveyors grow more nervous as Lake Powell evaporates.

The coal-fired Navajo Generating Station in northern Arizona may be forced to spend millions to extend a water line that draws cooling water from Lake Powell.

"Without that water, a major coal-fired plant goes down," warned Sid Wilson, general manager of the Central Arizona Project, the state's major water supplier.

The facility generates the power to pump water throughout Arizona and helps keep the lights on in Los Angeles, Las Vegas and Tucson.

The Western Area Power Administration, which delivers energy to 15 states, has for the first time formed a drought emergency planning team. It has spent \$500 million over the past few years on outside power, much of it in response to drought-imposed limits on hydropower generation.

Outside Las Vegas, Lake Mead, which stores water for Southern California households and Imperial Valley farms, is circled by bathtub rings. If the lake's level continues to drop, even power out of mighty Hoover Dam could be at risk.

Recreation tourism, a large part of the West's economy, may suffer if the drought persists. Rivers without rapids are no fun to run and shriveled streams are no lure to fish.

"If you own a vacation cabin in Bear Lake you used to have waterfront property. Now you have beachfront property," said Larry Anderson, Utah's director of water resources.

In California, docked boats already have been ordered out of Folsom Lake. In Page, Ariz., the National Park Service has spent \$5 million to extend boat ramps to Lake Powell and its 145 miles of shore. Ramps are open, but "launch at own risk" signs are posted in some spots.

Looking on the sunny side, National Parks Service official Char Obergh said, "I don't say it's bad. The lake looks different. People who have never been here don't realize it's low."

Wildlife concerns

Wildlife is suffering, too. Resource managers are working to save bighorn sheep in the Cabeza Prieta refuge in Arizona, prairie chicken along the eastern plains of New Mexico and silvery minnow in the Middle Rio Grande.

"The effects are going to be tougher on wildlife than I've ever seen," said Dale Hall, southwest regional director for the U.S. Fish and Wildlife Service. Conservation groups report dramatic reductions in the number of fish and ducks in some areas. The Dolores River, which runs 250 miles through Colorado and Utah, has lost 75 percent of its trout.

Anxious federal fish and wildlife officials are mapping plans to net rare fish and hold them in captivity, a distasteful but perhaps necessary step to preserve some species.

Duck numbers are down 11 percent nationally, pressuring officials to scale back season and bag limits.

Water development has almost always clashed with the environment. If the drought deepens, so, too, will that rift.

In Las Vegas, for example, plans to drill wells could deplete groundwater needed for a nature refuge. Environmentalists worry about Metropolitan Water District's bid to acquire more water from Northern California.

"The big question is how much water can you divert without the environment going to hell," said Tom Graff, an attorney with Environmental Defense, a nonprofit organization.

MWD officials insist there are adequate safeguards for fish and wildlife.

Elsewhere, bark beetles have overrun trees weakened by drought. Subsequent infernos devour forests and the firefight consumes billions of gallons of water.

"The precious water we did have was being used to put out fires" during a miserable 2002, said Dawn Taylor Owens of the Colorado Department of Water Resources.

Pressured by shortages and the U.S. Interior Department, water managers along the Colorado River basin for the first time are scrambling to map emergency responses. They are negotiating deals to clear historic legal and political barriers to water sharing and storage. Farmers across the West will likely be pressured to sell more of their water.

Closed-door talks have been "animated" and "at times, intense," said Bennett Raley, the Bush administration's lead negotiator on water issues. "The history of the Colorado River is, if the states fail to solve issues, the federal government steps in."

Environmentalists and water managers say the drought is more than just a lack of rain and snow over the past five years. Some cities were slow to impose restrictions. Financial woes and environmental foes have stalled storage projects. And experts say pollution may be accelerating a warming trend, reducing the number and intensity of storms.

Yet lingering dry spells are nothing new. Some believe the West has been blind to the Colorado's limits, relying on overly optimistic projections for more than 80 years. Original calculations done in 1922 to divide the river were based on a wet year.

"Demand is far more than the river can deliver," said Owen Lammers, executive director of Living Rivers, a Utah environmental group.

Population pressures

Growth is exploding in areas more suited for saguaros than subdivisions.

Nevada's population increased from 500,000 in 1970 to nearly 2 million in 2000. During that same period, Arizona grew from 1.8 million to 5.1 million people, Utah increased from 1 million to 2.2 million residents and Colorado's population nearly doubled, topping 4.3 million.

Sprawl also has exacerbated problems in California. As more families migrated to inland from the coast or to the Central Valley from San Jose, outdoor water use has skyrocketed to keep lawns lush and pools filled.

There are nearly 36 million Californians, compared with 20 million three decades ago. Riverside County's population more than tripled to 1.5 million during that period. San Bernardino County had 700,000 residents in 1970. Now it has 1.7 million.

Previous droughts have inflicted harsh lessons on the Southern California, forcing strict conservation. Residents use less water today than they did in 1990, according to the Metropolitan Water District. The MWD also spent \$2 billion to build an 800,000 acre-foot reservoir near Hemet in Riverside County that could supply more than 1 million households if needed.

"Conservation has become a way of life," said Dennis Underwood, an MWD vice president.

The past winter and spring delivered some relief in a few states, but not enough snow fell to refill depleted lakes and groundwater basins. A warm spring accelerated the melting of snow, making it difficult in some areas to capture flows.

California's outlook remains tenuous after a hot, dry spring. The state's fortunes seemed to be looking up in February, said Maurice Roos, California's chief hydrologist.

"Things looked pretty bright," he said. "Then the bottom fell out."

GLEN CANYON - NEWS RELEASE
For Immediate Release
Char Obergh
September 1, 2004

GLEN CANYON NATIONAL RECREATION AREA (GLCA) ANNOUNCES
OPPORTUNITY FOR PUBLIC INPUT FOR NAVAJO GENERATING STATION (NGS)
WATER INTAKE MAINTENANCE PROJECT

PAGE, AZ The National park Service has initiated work on an environmental assessment for the installation of new water intake facilities for NGS on the grounds of the existing pump house facility. The current facility is located adjacent to Lake Powell at an elevation of 3,734 above sea level on land leased to Salt River Project (SRP) by the Navajo Nation.

The purpose of the project is to ensure the future availability of cooling water for NGS operations due to the continuing decrease of water surface elevation of Lake Powell associated with the ongoing drought. The full pool elevation of Lake Powell is 3,700 feet above sea level. Current projections indicate that lake surface elevation could fall below the existing NGS water intake elevation of 3,470 feet above sea level by 2009. If severe drought conditions persist, these reduced lake levels could be reached as early as 2006

The work will include slant drilling through sandstone bedrock of five new 54-inch diameter holes in which new water intake pipes and submersible pumps will be installed to withdraw lake water at an approximate elevation of 3,350 feet above sea level. The new intake structures will require Salt River Project to obtain a new easement within the boundary of the GLCA prior to construction.

Borings from the drilling will be transported by truck to land applied at a large ash disposal site on NGS grounds. The proposed modified water intake structure will not change the annual volume or the seasonal pattern of water withdrawals from those already being made by NGS.

This notice is an opportunity for the public to identify any issues or concerns they may have regarding this project. All comments are due by September 24, 2004, and should be mailed to :

EcoPlan Associates, Inc., 701 W. Southern Avenue, Suite 203, Mesa, Arizona 85210 or email dsmith@ecoplanaz.com or 480.733.6666; fax 480.733.6661

Lake Powell Draining: Water Intake Tubes for Coal Plant to be extended

Contact: John Weisheit - (435) 259-1063

Today it was announced a major coal-fired power plant adjacent to Lake Powell reservoir may be left high and dry by rapidly falling reservoir levels, unless it receives approval from the National Park Service to begin a major extension of its water intake infrastructure.

Environmental clearance is being sought to extend the water intake tubes for the Navajo Generating Station 120 feet to the near-natural elevation of the Colorado River. What the National Park services is calling a "maintenance project." involves five 54-inch-diameter holes being bored 150 feet through Navajo sandstone for the installation of pipes and submersible pumps to move 17 million gallons of cooling water per day from Lake Powell to the power plant.

"This is not maintenance, but a multi-million dollar undertaking in an effort to preserve outdated and terribly polluting technologies," says John Weisheit, conservation director for Living Rivers/Colorado Riverkeeper. "We must prepare for the end of Lake Powell by investing resources into more appropriate energy paths such as conservation or solar and wind, not trying to prolong dirty coal and dams."

Due to climatic changes over the past five years, Lake Powell's water level has fallen 127 feet to 3573 feet above sea level, and is now declining at a rate of 21 inches per week. It is projected that absent a major change in rainfall patterns, that Navajo Generating Station's power plant intakes will be exposed as early as 2006. The hydroelectric power plant at Glen Canyon Dam will suffer a similar fate, but will have to be shut down as lowering its intakes is not technically feasible.

The Navajo Nation has benefited little from power from either Navajo Generating Station or Glen Canyon Dam over the past four decades, as many homes still do not have electricity. Small photo-voltaic power stations and wind turbines are now being used to provide energy to individual homes on the reservation.

"Our prayers continue to be answered," says Thomas Morris Jr. a Navajo medicineman working for decommissioning Glen Canyon Dam. "Let the power plant fall idle, as it has brought nothing but asthma and other illnesses to our people in exchange for a few jobs. We must follow nature's lead, and the revival of the Colorado through our land, not the past mistakes."

Navajo Generating Station was completed in 1974 to provide the electricity necessary to pump Colorado River water from Lake Havasu reservoir to Phoenix and Tucson through the Central Arizona Project. It was built as a substitute for dams proposed in Grand Canyon National Park that were defeated by public opposition in the 1960s. The Bureau of Reclamation is the largest shareholder in the Navajo Generation Station at 24.3%. Other partners include Salt River Project, Los Angeles Dept. of Water & Power, Arizona Public Service Company, Nevada Power, Tucson Electric Power.

Conservationists protest Utah lease offers

By Dan Nailen for The Salt Lake Tribune

The federal government set a record with its June oil and gas lease auction in Utah, offering 281,000 acres of Utah lands for development as part of the Bush administration's push toward more domestic energy production.

Records are made to be broken, though.

The next quarterly lease auction slated for Sept. 8 easily outpaces the June sale, with 362,665 acres spread across 223 parcels. Among the leases up for purchase, all or portions of 21 of the parcels - 19,338 acres in all - contain wilderness characteristics, according to the Bureau of Land Management, inspiring howls from conservationists both inside and outside of Utah.

"The Bush administration is once again exploiting wilderness-quality public lands for private gain," said Rep. Maurice Hinchey, D-NY., lead sponsor of America's Redrock Wilderness Act, a bill aimed at designating 9.1 million acres of Utah BLM land as wilderness. "The BLM should not be sacrificing the nation's natural heritage for short-term profit when it has acknowledged that some of these lands have wilderness characteristics."

The Outdoor Industry Association, National Outdoor Leadership School and Trout Unlimited all filed protests of different aspects of the upcoming lease sale.

The BLM did defer sales on 30 parcels of wilderness-quality land, including areas near Fisher Towers, Desolation Canyon, Jack Canyon, Labyrinth Canyon and White River. At the same time, many of the leases being offered in Utah are in areas seldom explored in the past, including parts of Juab, Millard, Sanpete and Sevier counties.

"The underlying, driving force is clearly the economics of oil and gas, with oil [prices] hitting record highs and the gas demand outstripping our ability to produce," said Kent Hoffman, who directs the BLM's mineral programs in Utah.

Hoffman noted that the record amount of acreage involved in the auction is due in large part to the Forest Service playing catch-up with a backlog of Forest Service land nominated by oil and gas industry entities for exploration.

"On this particular sale, the Forest Service gave us over 100,000 acres," Hoffman said. "On prior sales, they've been probably 25 percent of that or less. Even less than that. Sometimes nothing."

Plans for auctioning leases on Forest Service land near Strawberry Reservoir raised a red flag for members of Trout Unlimited, a group dedicated to preserving and restoring fish habitat. In a protest letter to the BLM, Paul Dremann, the vice president for conservation of Utah's Trout Unlimited chapter, outlined the millions of dollars spent through the years in restoring the Strawberry Reservoir fishery and expressed concern that oil and gas exploration nearby "has a high potential of severely impacting" the fishery.

"We've been working for so darn many years on fishery restoration there that we kind of feel like we kind of have ownership in helping that restoration," Dremann said Monday. "So this has been kind of discouraging."

Also of particular concern to conservationists are available leases along the Green River and along the southern parts of eastern Utah's Book Cliffs. While BLM officials note that available tracts along the Green River have "no surface occupancy"

stipulations - meaning there could be no roads or drill pads within a half-mile of the river - people like John Weisheit, co-founder of the Colorado River Plateau River Guides organization for outfitter employees, say that's not good enough.

"You can still hear it," Weisheit said, describing similar "no surface occupancy" projects, noting that on trips down Montezuma Creek, the sound of nearby drilling projects is easily heard in the middle of the night. "And if there's any lights at all, you can still see them."

Weisheit is worried that opening up areas along Utah's most scenic rivers to drilling will only provide minimal oil or gas, while adversely affecting the livelihoods of guides and outfitters forever.

"What's the point of doing a river trip if you have to hear and smell and see all this oil development?" Weisheit said. "Our point is, is nothing sacred? Do we have to drill every inch?"

The BLM's Hoffman notes that of the 18 million acres of Utah land available for oil and gas exploration, only four million are currently spoken for - a far cry from a one-time high of 16 million acres under lease. With the current drive for domestic energy production, he said, the industry will no doubt keep driving the acreage under consideration for drilling higher and higher.

"The industry is clearly in the mode of trying to increase their lease space so that they have opportunities to explore," Hoffman said. "That is the underlying, driving force for all of this stuff."

On the range, gas trumps wildlife

<http://www.csmonitor.com/2004/0909/p13s02-sten.html>

Mark Clayton Staff writer of The Christian Science Monitor

09/09/2004

At Sand Wash, Utah, a dusty slice of back country 45 miles from the nearest paved road, river-raft guide John Weisheit lectures tourists about the history of the Green River and the wilderness experience that will soon unfold for them.

Climbing into rafts, they float on chocolate waters, following the path of 19th century explorer John Wesley Powell, beneath the cliffs of Desolation Canyon. No car engines or cellphones mar this trip far away from it all.

But soon, Mr. Weisheit says he may chop all wilderness references from his little lecture. They'll ring hollow, he says, if Sand Wash, a onetime crossing for pioneers and cattle, echoes instead with the sounds of diesel engines and drilling rigs exploring for oil and gas.

Wednesday, in the biggest sale of its kind in Utah history, the federal Bureau of Land Management (BLM) offered at auction oil- and gas-exploration leases on more than 360,000 acres of rugged back country - including UT-201, a 120-acre chunk of Green River flood plain that abuts Sand Wash, and another 16,000 acres a few miles away.

Not long ago such remote regions seemed on track to one day become officially protected wilderness areas. Now they're part of a huge debate over the proper use of public lands in the United States. At issue: When does energy security trump wilderness protection?

No one claims the oil and gas from public lands will free the nation from dependence on foreign oil. The amount of oil in the Rocky Mountain West is negligible - less than a year's supply for the nation. But the region's gas could supply the nation for a few years and, by lowering prices, save consumers billions of dollars. So should the US encourage such energy development wherever it's economically viable? Or, in the case of wilderness, does some higher standard apply?

To hear the White House and the oil and gas industry tell it, gaining access to public lands is a key to greater energy self-sufficiency.

"Basically, we've taken large chunks of the country and put it off-limits to any kind of exploration or development," said Vice President Dick Cheney at a town hall meeting in Hot Springs, Ark. "We don't drill off the East Coast, we don't drill off the West Coast.... Large parts of the Rocky Mountain West are off-limits."

Some 29 percent of the Rocky Mountain area's gas reserves are "effectively off limits" because of conditions that limit drilling, estimates a 2003 report done for the US Department of Energy by the National Petroleum Council, an industry lobby group. If such restrictions were removed nationwide, that easier access to public lands could save consumers \$300 billion over 20 years, the report says, thanks to lower natural gas prices.

But such figures almost certainly overstate the case, energy analysts and environmentalists counter.

For example, domestic energy production is apparently not being held up by a lack of oil and gas leases. Since 1982, the US has leased or offered for lease 229 million acres of public land for oil and gas development across 12 Western states, according to a new report by the Environmental Working Group (EWG), a Washington-based environmental organization. That represents nearly 9 of every 10 BLM acres and covers an area bigger than Colorado, New Mexico, and Arizona combined.

That doesn't leave much to exploit. In the five richest geological basins in Montana, Wyoming, Colorado, Utah, and New Mexico, only 15 percent of the oil and 12 percent of the gas reserves on federal lands are off-limits, according to a 2003 joint study by the US departments of Energy, Interior, and Agriculture.

Drilling for gas is already on the upswing in the region. Five Rocky Mountain states saw drilling activity in August rise to their highest levels in a decade. Wyoming had 84 rigs

operating versus an annual average of 38 over the past decade - 121 percent higher. For Utah, the 22 rigs operating are 76 percent higher than the average over a decade. For New Mexico, it's 30 percent; Montana, 166 percent; and Colorado, 171 percent.

Yet the energy produced from public lands is minuscule. Interior Department records show that only enough oil was produced between 1989 and 2003 to supply the nation for 53 days and enough natural gas for 221 days at current rates of consumption, the EWG report adds.

"These numbers put a hole in the argument you hear all the time from the oil industry and their allies that, 'If we could only get access, we could reduce our dependency on foreign oil,' " says Dusty Horwitt, coauthor of the EWG report. "In fact, they've had almost unfettered access, but dependence on foreign oil has increased significantly."

Nor are energy companies knocking each other down to drill more. EWG analysts say BLM's data show about 13 percent of public land is leased and 4 percent currently producing oil or gas. The US Department of the Interior, which oversees the BLM, reports smaller totals: 8 percent and 1 percent, respectively.

"You need to remember we are not talking about significant quantities of oil - or natural gas, for that matter," says Gal Luft, executive director of the Institute for the Analysis of Global Security in Washington, which focuses on energy security. "Tactically it may sound like a lot, but strategically it is not a lot of oil or gas."

But the federal study, which estimated there were 123 trillion cubic feet of "technically recoverable" natural gas in areas already open to leasing - enough to fuel the nation's needs for about six years at current consumption rates - may be too rosy.

Such numbers overstate the case because only about half of technically recoverable gas is likely to be found, says Michael Lynch, president of Strategic Energy & Economic Research in Winchester, Mass. "It will help on the margins - and of course the industry would rather have it than not," Mr. Lynch says. "But any notion that you're going to change the US energy balance significantly is an exaggeration."

Despite this, the federal government is pushing to open more public land anyway. A series of land-use decisions and proposals over the past four years shows the US is gearing up to make an average of 12.7 million acres a year available to oil and gas drilling, says the EWG report.

"We're not challenging the vast majority of these proposed leases," says Liz Thomas of the Southern Utah Wilderness Alliance, an environmental organization, in Moab, Utah. "What we oppose is leasing these very remote places." Her group has been trying to block energy exploration on what she calls "wilderness quality" lands.

No land is being stripped of protections, says Rebecca Watson, assistant secretary for Land and Minerals Management at the Department of the Interior. She concedes, however, that in some areas where seasonal drilling prohibitions intended to protect wildlife overlap, these will be adjusted to give companies time to get in to drill for oil and gas.

"Nobody's advocating going into wilderness areas or parks," Ms. Watson says. "We're simply asking: 'Are all those constraints necessary, or are there other ways to protect these lands?' "

In fact, the BLM in Utah set aside from Wednesday's auction tens of thousands of acres of land that might otherwise have been leased - much of it for further environmental review, officials say.

Rather than a lack of land to lease, the real obstacle may be the leasing stipulations and conditions placed on exploration and development - conditions environmentalists say are vital, but oil men decry.

"The problem for us wasn't getting leases; the problem was being able to drill and develop those leases," says Geoff Ice, exploration manager at Rosewood Resources Inc. His Dallas oil and gas company has been working with three other companies for several years to get the necessary environmental approvals to drill on an 80,000-acre parcel near the Book Cliffs region of Utah. "It's just been ridiculous things holding us up. We got to the point where we're not as active in Utah anymore. We just got tired of fighting it."

Even so, environmentalists aren't optimistic such lands will be protected. The Book Cliffs region of Utah - a 250-mile-long escarpment with cliffs 2,000 feet high - is the longest such continuous formation in the world and serves as home to mountain lions, bald eagles, and peregrine falcons. But it sits on the edge of a zone of major oil and gas production. Back at the Green River, environmentalists worry scores of wells could be operating within a few miles of historic Sand Wash within a few years.

"Despite talking about protecting these lands, all the BLM has done is open them to oil and gas," says Nada Culver, a Wilderness Society attorney based in Denver. "They went through the full analysis for thousands of acres that met all the legal requirements for wilderness - but now they're not going to designate them wilderness, they're going to drill on them."

Who owns the land?

* The United States government owns nearly a third of US land, but the share varies widely by state - from a high of 88 percent in Nevada to a low of 0.4 percent in New York.

* Throw in the amount owned by states and government holdings account for 40 percent of US land.

* In China, the state owns all the land. Reformers leased it to farmers in the '80s. But as the economy boomed, local officials began taking it back for roads, dams, and other projects. More than 30 million have lost their farms.

LR Press Release 09/14/04

Release of Flaming Gorge Dam Draft EIS

September 14, 2004

For immediate release

Contact: John Weisheit - (435) 259-1063

Comprehensive basin-wide plan needed to avoid extinction

The Bureau of Reclamation (BuRec) announced the completion of a draft plan to halt the path toward extinction of four native caused by the operation of Flaming Gorge Dam on the Green River in Utah. After more than three years of delay, the draft environmental impact statement calls for modifying dam operations to mimic the conditions of a natural river, as BuRec has implemented elsewhere on the Colorado watershed.

"This is the same failed strategy that BuRec applied to Glen Canyon Dam to help restore native fish in Grand Canyon, yet the agency provides no rationale as to why it will work any better at Flaming Gorge Dam," says John Weisheit, conservation director of Living Rivers and Colorado Riverkeeper from Moab, Utah.

Flaming Gorge Dam, located near the Utah and Wyoming border on the Green River, is a water storage and hydroelectric facility that can store 3.8 million acre-feet of water for downstream consumption. The facility became fully operational in 1964. The Green

River is the major tributary of the Colorado River. The native fish became endangered because high dams, such as Flaming Gorge and Glen Canyon, have altered the natural river conditions that native fish require to reproduce and reach adulthood, namely water temperature, seasonal flow, the suspension of sediment and nutrients, and the ability to migrate freely through the tributary streams.

Before the dams and diversions of the Colorado River system, the native fish thrived in vast numbers for millions of years throughout the Colorado and its tributaries. "There is no way we are going to protect these endangered species through a piecemeal approach to dam operations," adds John Weisheit. "We must work toward the restoration of habitat throughout their entire historical range, which necessitates a comprehensive EIS to address the operations of all dams throughout the basin."

The draft EIS for Flaming Gorge Dam fails to analyze the significant problems associated with the vast plumbing system of dams and diversions on the rivers of the Colorado basin. These issues include the inefficiency of having too much storage in the system and the consequent water losses due to evaporation. Today the Colorado River system has the ability to store over 60 million acre-feet of water. On average the Colorado River produces 14 million acre-feet of water and the total annual loss due to reservoir evaporation alone amounts to 2 million acre-feet per year.

In the last decade, state water management agencies have initiated programs to store Colorado River water in depleted underground aquifers near cities and farms. Such programs offer a reasonable and prudent alternative to reservoir storage, which would in turn provide more water for humans and help to restore river habitat for the endangered fish.

The Colorado, Green and San Juan rivers carry incredible amounts of sediment into the reservoirs of the basin. Sediment loads during the 20th century were estimated to vary from 45 to 180 million tons annually. The problems associated with sediment accumulation in reservoirs was acknowledged by the Bureau 100 years ago, but the agency has never provided a systematic program to solve the impending problem. Sediment impairs the ability of a reservoir to store water as space is displaced by sediment fill. Impaired reservoir storage also impacts the ability to safely bypass waters around dams during big floods.

These will be key topics that Living Rives and other groups will reiterate at public meetings planned for October 12 - 21 in Utah cities that include, Moab, Salt Lake City, Dutch John and Vernal; a meeting in Wyoming at Rock Springs is also scheduled. Written comments from the public on the draft EIS are due November 15, 2004.

Flaming Gorge may alter flows, temperatures for native species Endangered: Dam seeks to revive fish

By Joe Baird for The Salt Lake Tribune

Native fish have been missing their spawning cues and pools for so many years along the Green River that four species are now endangered.

Last week, the Bureau of Reclamation released a proposal to address the problem, essentially by modifying the water flows and temperatures at Flaming Gorge Dam to more closely mimic seasonal water conditions that existed downstream before the dam was built in the 1960s.

By doing so, bureau environmental specialist Beverly Heffernan says the razorback sucker, humpback chub, Colorado pikeminnow and bonytail can be revived - both through higher spring flows that will signal the spawning season and the creation of sand bars and side channels where eggs will be better protected from predators.

"What we're trying to do is provide a more natural flow to the river while continuing to meet our obligations to provide a storage reservoir and hydroelectric power under the Colorado River Storage Act," said Heffernan, who is based in the bureau's Provo office.

But the draft environmental impact statement - now in the public comment period - has been panned by environmentalists. Fishing guides who operate in the trout-rich waters below the dam also have expressed concerns.

For John Weisheit, conservation director of Moab-based Living Rivers, the issue is one of shortsightedness. Contending that this same proposal has failed elsewhere, he calls for a whole new assessment of the Colorado River system - of which the Green is a main tributary.

"The needs of the fish, the environment, the national parks were never addressed when decisions were made about how to allocate water from the Colorado River and its main tributaries, so we have these big problems now," said Weisheit. "The problem with this is, it doesn't work. They tried experimental flows in the Grand Canyon and at Glen Canyon Dam, and there is no record of success."

Weisheit says what's needed is "a big picture" review of the Colorado system, which he predicts will eventually result in the dismantling of dams such as Flaming Gorge and Glen Canyon because of decades-long sediment buildup in the reservoirs.

Heffernan says that issue is beyond the scope of her agency's charge.

"Decommissioning is not an option," she said. "The question isn't a matter of doing everything you can to save all of the fish; it's helping the fish survive under the mission we are given. What this [environmental statement] tells us is that we can achieve the flows and temperatures recommended without harming any of the other resources or purposes of the dam."

Among the resources below the dam is one of the nation's most acclaimed trout fishing areas. And at least one outfitter has conflicting emotions about the bureau's proposal.

"It all depends on how radically they alter the stream flows," said Dennis Breer, who owns a fly fishing guide service in Dutch John. "I've been involved with this process since 1990, when they began experimenting with the flows, and we saw some strange things happen. We've also seen in some cases that what's good for the native species is also good for the trout. But every time they move [the water flow] up and down it impacts the trout. So what we're concerned about is the extremes."

Heffernan says those concerns will be addressed.

"Under some circumstances the water could be too warm for the trout," she said. "We're working with [the Utah Division of Wildlife Resources] to further analyze these areas."

BuRec proposes boosting Flaming Gorge Dam flows to aid fish

Sept. 17 - April Reese, Greenwire reporter

The Bureau of Reclamation has proposed releasing more water from Utah's Flaming Gorge Dam to reverse the decline of four species of endangered fish on the Green River. But the proposal, included in a draft environmental impact statement last week, will not be enough to recover the fish, environmentalists contend.

The 40-year-old dam, authorized by Congress as part of the Colorado River Storage project in 1956, was built to create a 91-mile-long reservoir for water users in the upper Colorado River Basin. As the largest dam on the Green River, Flaming Gorge also provides vast quantities of hydropower, roughly 217 million kilowatt hours (kWh) in 2002.

Federal wildlife biologists began to suspect the dam was harming native downstream fish as far back as the 1980s, and in 1992 the Fish and Wildlife Service issued a biological opinion stating that the dam was aiding the decline of four endangered fish: the razorback sucker, Colorado pikeminnow, humpback chub and bonytail.

That prompted BuRec, which operates the dam, to study how changing the dam's operation might reduce harm to fish (Land Letter, June 12, 2003). FWS followed with an updated biological opinion in 2000, including flow recommendations for Flaming Gorge. That biological opinion provided the basis for the draft EIS.

The new proposal calls for releasing as much as 8,600 cubic feet of water per second (cfs) from the dam during years with abundant water supply and 4,600 cfs during dry years. Under current operations, reservoir releases range from 800 to 4,600 cfs.

BuRec and FWS are hoping that an increase in flows will help create sandbars and side channels, which serve as nurseries for the fish, and otherwise improve habitat. The plan also calls for the warming of water released from the deepest parts of the reservoir to more closely mimic ambient river temperatures. Dam operators will tweak an existing "temperature control device" to warm the flows, officials said.

"Our proposal is to re-operate the dam to help the fish but maintain the other authorized purposes," such as water storage, power generation and recreation, said Beverly Heffernan, an environmental specialist at BuRec's Provo, Utah, office. Operating the dam to simulate natural flows should not have a significant effect on power generation, Heffernan said.

Larry Crist, a fisheries biologist with FWS's Utah office who helped write the 2000 biological opinion, said the draft EIS does a good job of incorporating FWS's recommendations. "It will provide a way of operating that allows for the recommendations to be met," Crist said.

Unlike some dams, Flaming Gorge does not cut off endangered fish from historical spawning grounds, he said. Most of the habitat for the endangered fish is downstream of the dam.

But John Weisheit, conservation director for Living Rivers, a Moab, Utah-based environmental group, questioned whether increasing releases from the dam will help the fish. Similar efforts at Glen Canyon Dam to aid endangered humpback chub in the Grand Canyon have not been successful, he said (Land Letter, Nov. 20, 2003).

"They're just slapping a bunch of Band-Aids on a bunch of gaping wounds," Weisheit said. "From the top of the [Colorado River] drainage to the bottom, it's the same thing: The temperatures are wrong and the flows are wrong. We're not working with the river; we're forcing the river to work for us."

Living Rivers is pushing for a more comprehensive EIS to evaluate what can be done to recover endangered fish throughout the Colorado River Basin while addressing human water needs.

"There is no way we are going to protect these endangered species through a piecemeal approach to dam operations," Weisheit said. "We should be looking at this more holistically. Which dams should we get rid of to help endangered fish and minimize evaporation loss? Why aren't we storing this water in places like aquifers where it won't be evaporated?"

But in the case of Flaming Gorge Dam, higher flows already have a proven track record of making a positive difference for fish, Heffernan said. Working under an earlier 1992 biological opinion that called for experimental increases in flows, BuRec saw improvements in fish habitat, she said. That experiment is what led FWS and BuRec to try releasing more water from the dam, she added.

Environmentalists had asked the bureau to include decommissioning the dam in its list of alternatives in the EIS, but the agency decided not to consider that option, citing its mandates under the Colorado River Storage Project and the Flaming Gorge National Recreation Area acts.

"Congress, in its wisdom, directed us to build the dam, and we did," Heffernan said. "We were authorized to build the dam, and to operate it. We don't have the authority to decommission the dam. That would take an act of Congress."

Furthermore, public comments on the draft EIS "overwhelmingly" opposed decommissioning, she said. "There are a lot of people who use the reservoir and the river for recreation, and they would like to see that maintained."

Crist said removing or breaching the dam is not necessary to improve conditions for endangered fish. "I think it's still possible to have the dam and recover the fish," he said. "The other way [decommissioning the dam] would work too. But I think it's possible to have the benefits of the dam and help the fish."

The higher flows are part of a larger recovery effort that includes controlling non-native fish that compete with endangered species and restoring habitat, Crist said.

If the new proposal is approved, BuRec and FWS will monitor the effects of the increased flows and temperatures and revise dam operations if necessary, Heffernan added.

"We acknowledge we don't have all the answers yet, but this is based on the best available science," she said. "This is really just part of an ongoing effort. It will take a number of years to get some good data to determine whether it's working or not."

The bureau will hold a series of public hearings on the draft EIS in Utah and Wyoming in October, Heffernan said.

RE: Environmental Assessment (EA) for proposed water intake structures at Navajo Generation Station near Page, Arizona.

Dear Mr. Smith:

Thank you for allowing Living Rivers and Colorado Riverkeeper this opportunity to provide public comments for the proposed construction of water intake structures at Navajo Generation Station (NGS). This facility is administratively managed by Salt River Project (SRP). The facility adjoins lands administered by the National Park Service and the tribal government of the Navajo Nation.

Concerns for better due process

We are very dissatisfied in the minimalist approach concerning due process for this environmental assessment. We feel that the general public was not adequately informed about this EA and hope that public notification from the National Park Service and the Salt River Project will improve in the future, and will also include more

accessibility to information. For example, this would include more contact information with the administrative agencies, and include resource information for public dissemination through the Worldwide Web and local public libraries.

We therefore ask formally that the process for gathering public comments be extended for 30 days and that measures are taken to better engage the public within this 30-day extension.

Concerns about SRP energy policy

The need and purpose for this proposed construction project is the result of climate change. Climate change has produced an unprecedented, but not unexpected, drought in the Colorado River basin. The average Colorado River flow has been reduced by 50 percent in the last six years. Climate change occurs naturally, but it is now accepted that humans do impact climate through the consumption of fossil fuels, which increases the temperature of the atmosphere and the surface of the oceans. NGS burns fossil fuel and thus contributes to the degradation of the world's climate. The management of NGS must be aggressive and accountable in their policies concerning a positive transition from burning fossil fuels to providing alternative energy programs that will eliminate toxic pollution and greenhouse gases from the atmosphere.

This would also include eliminating impacts from fossil fuel consumption and how it affects local and regional residents as it relates to known health problems such as asthma and exposure to toxic heavy metals such as mercury.

We ask that SRP conduct public meetings and to specifically consult with all regional stakeholders with the purpose of developing a progressive policy for providing an alternative to fossil fuel consumption that will protect the atmosphere from further degradation and to improve human health.

Concerns about water rights

The contract for the water rights at NGS is to be renewed in 2009. It would be reasonable and prudent that SRP first secure their water rights before investing a significant amount of money to finance this proposed construction project.

Concerns about bore drilling

The diameter and quantity of the drilling bores appears excessive. Please explain why five bores must be drilled and why at 54 inches in diameter?

Impacts to Traditional Cultural Properties and critical wildlife habitat

It is not clear that new lands are to be developed for the pumping station, service roads or waste facilities for this proposed construction project. We ask that the specialists at the National Park Service and Navajo Nation be consulted and provide clearance for this project's proposal as it relates to the cultural resources of the First Nations in the region of the Colorado Plateau.

We also ask that the US Fish and Wildlife Service be consulted concerning impacts to threatened and endangered species. This would include the potential mortality the intake structures would pose to endangered fish species.

Concerns for the geologic integrity of the host rock

There is considerable spalling of rock that is naturally occurring along the margins of the reservoir due to drought-diminished reservoir levels. We are assuming that the strength of the host rock of Lake Powell reservoir has weakened due to decades of water saturation from the reservoir. We would ask that if construction does proceed at NGS that the core samples from the drilling operations be analyzed by a professional consultant to determine how much structural integrity in the host rock has been lost. We believe this knowledge can be extrapolated for the structural integrity of man-made structures such as Glen Canyon Dam, and natural features that are federally protected, such as Rainbow Bridge.

Impacts from sediment storage in Lake Powell reservoir

The NGS facility is located downstream of Navajo Canyon, which is a large tributary drainage that erodes considerable amounts of soft Mesozoic shale and sandstone into Lake Powell reservoir. A sediment study should be conducted to determine when sediment from Navajo Canyon would impact the water intake structures at NGS.

This would also include the sediment accumulation due to natural turbidity flows along the inundated river channel of the Colorado River. This information on sediment fill should be shared with the National Park Service and with Bureau of Reclamation to provide to them better information in the management of their facilities. Especially as it relates to safety at Glen Canyon Dam.

Impacts to visitors at Glen Canyon National Recreation Area

The impacts to noise levels, the view shed and light pollution should also be addressed at the pumping station. Visitors and campers to Glen Canyon National Recreation Area would appreciate that such impacts be eliminated.

Thank you for this opportunity to provide comments and questions. Please do not hesitate to contact us should you require further assistance.

Sincerely yours,

John Weisheit Conservation Director

Norton Excels as Water Spin Doctor

September 28, 2004

By David Haskell for My Turn/Arizona Republic OpEd

The recent editorial by Secretary of Interior Gail Norton followed the format frequently used by administration "spin doctors". It starts with a positive title, "Water Use Takes Wisdom". If the title rings true there is an implication that the messages to follow are also true. Unfortunately this is rarely the case. This ploy was also used by Norton to tout the Administrations Clear Sky Act, legislation that substantially damaged decades of past Congressional progress in cleaning up sources of air pollution. Examination of the points made by Norton in this article reveals the lack of timely leadership and wisdom associated with her Colorado River management policies.

Her first message was that Arizona is not in a water crisis. The entire Southwest is in a water crisis and the quicker we realize this fact the better chance we have in avoiding the most serious consequences. Most long-range weather pattern experts predict that we are in the 6th year of a multi-decade severe draught. Substantial water conservation measures and actual reductions in use throughout the basin are needed to reduce future impacts on the economy and natural resources. This is particularly true for cities that depend on Colorado River water.

The presence of Lake Powell will certainly not prevent a crisis. Reservoirs do not create water they only store it during years when flows exceed the total annual use. The 1922 Colorado River Compact allocated 15 million acre feet of water to be used by the seven basin states. Even though Colorado River flows were at historically high levels during recent decades, the average annual flow has only been 13 MAF. If the draught experts are correct this flow will be reduced to about 9.5 MAF by 2050. It is clearly evident that from now on there will be little excess water to be stored by these reservoirs, and the 500,000 acre feet of water lost by Lake Powell each year from evaporation will make the situation even worse. In future years Lake Mead will provide all of the storage needed in the lower basin.

Perhaps Norton's least wise policy has been to declare that there is "surplus water" in the Colorado River system. Declaring a surplus each year allows the states to continue to use their inflated Compact allocation even though the river has not delivered that amount of water for nearly a decade. The severity of the current situation could have been reduced if Norton had declared a shortage three years ago, requiring a reduction in water use before a crisis occurred. Actually achieving significant reductions in water use in the seven basin states will take several years. Waiting until we run out of water before starting to initiate cutbacks can only result in the chaos of hastily implemented mandated emergency measures.

Norton implies that the Gila River water adjudication process will somehow result in helping the draught situation. Regardless of which entity ends up with legal rights to the CAP allocation, this process will not increase Arizona's Colorado River allocation or conserve water. The Salt River Project managers have been reducing CAP water deliveries for agricultural purposes for the past three years. This is a very prudent action. Further reductions in use should be implemented and water saved stored in underground aquifers.

Secretary Norton did make one important point, "water is the Southwest's most precious resource, and we must work together.... to wisely use and manage the Colorado River". Unfortunately, we have seen little evidence of "wise" leadership from this Secretary of the Interior.

Artificial recharge of aquifer at Las Vegas

Sunday, October 10, 2004 Copyright © Las Vegas Review-Journal

Valley has two water savings accounts

Local providers have been socking away water since 1987
By HENRY BREAN

J.C. Davis, spokesman for the Southern Nevada Water Authority, stands next to a well at the water authority's North Well Field on Valley View Drive. The pumps draw groundwater to supplement what the valley gets from the Colorado River.

It's a warm fall day, neck deep in the worst drought on record, and the pumps are churning at the Southern Nevada Water Authority's North Well Field on Valley View Drive.

At the moment, and throughout the hottest part of the year when water use is at its peak, the pumps are being used to draw groundwater to supplement what the valley gets from the Colorado River.

Soon, however, that flow will be reversed, and over the next six months or so several billion gallons of treated drinking water from Lake Mead will be pumped directly into the ground.

That may sound like a reckless waste, but it's really the opposite.

Since 1987, local water providers have socked away 275,000 acre-feet of water using a process called artificial recharge. About 13,000 acre-feet was injected into the ground during the first three months of this year. Another 17,000 acre-feet is due to be pumped down by year's end.

An acre-foot is 325,851 gallons, roughly the amount of water consumed by the average Las Vegas Valley household every 17 months.

"A lot of the public is not even aware that we've been squirreling away water for years," said J.C. Davis, spokesman for the water authority. "It's important they understand that we aren't operating without a net."

It is called the Southern Nevada Groundwater Bank, but local water officials didn't invent it. They only gave it a name.

The storage area itself has been here far longer than people have, trapping melted snow from the past 10,000 winters in a 1,000-square-mile matrix of dirt and rock generally found 500 to 1,200 feet below the surface.

Now the valley's principal aquifer is being used much like a common savings account.

Each year, Nevada is allowed to consume 300,000 acre-feet of water from the Colorado, minus any surplus water that might be available during wet years. Any portion of the 300,000 acre-feet that isn't used goes into the bank, so the less water the valley consumes, the more it can save.

"It's a two-for," said Pat Mulroy, water authority general manager. "The community creates a drought cushion for itself by conserving."

"There in that bank is the water we might need in a protracted drought."

And in the use-it-or-lose-it world of water law, artificial recharge allows Nevada to get the full benefit from its comparatively meager share of the river, even when the water is not immediately needed to meet demand.

The practice is nothing new. Artificial recharge has been around for thousands of years, helping humans grow crops and survive in arid climates from ancient Persia to 1930s California.

Arizona, a state almost entirely dependent on its groundwater supplies, began large-scale banking 10 years ago and has put away more than 1.8 million acre-feet so far.

Artificial recharge also is used to stabilize and replenish areas where groundwater has been overpumped, causing the earth to subside and wells to fail. Over the past three

years, the Las Vegas Valley Groundwater Management Program has injected more than 7,000 acre-feet of water into selected parts of the valley for just that purpose.

"Most people forget that aquifers are finite, and it takes a long time to replenish them. Nature does that very, very slowly," said Tom Harbour, water planning supervisor for the Central Arizona Project. "With artificial recharge, we're kind of helping nature along."

The water authority and its member agencies operate the largest injection-based artificial recharge system in the world.

The system employs 77 wells, most of them in the northwest part of the valley. Some of the wells are used both to put water into the ground in the fall, winter and spring and take water out in the summer.

On paper, the water authority has yet to make a withdrawal from its bank, though technically at least some of the water put in has been pumped out again by the roughly 9,000 residential and commercial groundwater wells throughout the valley.

"I don't think we'll need to tap the bank for some time. I hope that's the case," said Kay Brothers, the water authority's deputy general manager for engineering and operations.

When the valley is forced to use its bank -- if, for example, the drought reduces the state's Colorado River allocation or local water use surpasses supply before new resources can be tapped elsewhere in the state -- there should be enough water put away to supplement what we get from Lake Mead for at least a decade, Brothers said.

Then there is Nevada's other water savings account, one forged not by pumps but by policy.

Through a cooperative agreement struck in 2001, the water authority has secured 110,000 acre-feet of credits in Arizona's groundwater bank.

Nevada hasn't had to tap that bank either, but when it does, the only thing flowing from Nevada to Arizona will be money.

Cashing in the credits works like this: Arizona surrenders some of its 2.8 million acre-foot Colorado River allocation to Nevada, which pulls the water from Lake Mead. If necessary, Arizona replaces that water by tapping its groundwater reserves or paying farmers not to irrigate some of their crops. Nevada pays Arizona for any costs associated with pumping and delivering the groundwater Arizona needs to replace the Colorado River water it has given up.

Unlike Nevada's injection-based system of artificial recharge, Arizona benefits from permeable soils that allow the use of spreading basins, which Harbour described as "very, very leaky ponds" that can let up to 7 feet of water seep into the ground each day.

The state also channels water into normally dry streambeds with similar results.

The Central Arizona Project, which channels water 350 miles from the Colorado River to Phoenix, Tucson and farms in between, has five spreading basins in operation, one

under construction and another in the design and permitting phase. Water also is banked by the Salt River Project and the Arizona Water Banking Authority.

The agreement between Nevada and Arizona allows the Silver State to bank a total of 1.25 million acre-feet in Arizona through 2050. So far, though, little progress has been made toward that goal because Arizona must first satisfy its own water needs before it can start setting aside water for another state.

Larry Dozier, deputy general manager of the Central Arizona Project, said that by 2016 officials in Arizona hope to have met most of that state's water storage targets and have close to 1 million acre-feet set aside for Nevada.

"The darned river hasn't cooperated," Dozier said. "It got dry, and there hasn't been a lot of surplus water."

The two states are now discussing a way around that. "What we're talking to Arizona about is firming up the 1.2 million acre-feet," Mulroy said.

In effect, the plan being discussed involves Arizona extending Nevada a line of credit.

"We would let them take their water out before they put it in," said Dozier, who sees the idea as a way of building the kind of cooperative spirit long absent from Western water politics. "Our answer is, we think we have the capability to do it, and it's good to have friends when there is a drought on the river."

Dozier added that a number of "policy and political implications" will have to be addressed, but he thinks some kind of agreement could be reached by the end of the year.

Lake Powell services closing for the winter

Lack of visitors, chance to renovate led to the decision

By Ray Grass Deseret Morning News

For the first time since Lake Powell was a mere puddle, the lodges and restaurants, lakewide, will close for the winter season.

Even though Lake Powell is 130 feet below "full-pool," it's the lack of visitors that's forcing the closure.

It was announced late Tuesday that Lake Powell marinas will shift into a seasonal winter schedule.

"We will close down all lodging and restaurants on Nov. 15 and they will remain closed until March 14," said Steve Ward, director of public relations for ARAMARK. "There will be limited service with respect to boat rentals, tours and fuel."

ARAMARK, which owns concessionaire rights to five marinas on the shores of the lake, has been in negotiations for three months with the National Park Service to initiate the closure.

The park service gave its approval last week and since then ARAMARK management has been working through details involved in the closing.

Those individuals with room reservations at the lakeside properties, mainly Wahweap and Bullfrog, will be relocated to Page, Ariz., the city a few miles south of Wahweap.

Those calling the marinas for reservations will be offered room options in Page.

"This is not something that has resulted from the low lake level," Ward said. "We've been experiencing a drop in visitation since 1999. And it didn't happen just at Lake Powell. Other parks, such as the Grand Canyon, have experienced the same slowdown. With lower visitation we've had to reduce staff."

"Last year we did not have the staff to take care of all the tourists and do the season maintenance that was required. This winter we want to renovate three buildings, more than 100 rooms and 60 houseboats. This winter the staff will concentrate on those projects."

When the lake first started to fill, Wahweap would close when temperatures began to cool. At the time it was the only marina on the lake offering restaurant and lodging facilities.

A few years later, however, marinas went to year-round operation and have remained open since.

Uplake, at Bullfrog, the Defiance House Lodge and gift shop, the Bullfrog marina store and the fuel dock at Halls Crossing will close Nov. 1.

Wahweap lodging, the Rainbow Room restaurant and gift shop, and the store at Dangling Roper will close Nov. 15. All will reopen on March 14.

The onshore facilities at Hite will not reopen until May 1.

What will remain open are:

- * At Bullfrog, the on-water convenience store, service station, fuel dock and trailer units.

- * At Hite, the campground, trailers and an on-call status for essential groceries and supplies.

* At Hite, the pay-at-the-pump fuel station.

* At Dangling Rope, the fuel dock.

* And at Wahweap, the boat tours, campgrounds, limited boat rentals, the marina store and fuel.

"Like most national parks, Lake Powell is considered a seasonal destination by most visitors," according to Dale McFarland, district manager, Lake Powell Resorts & Marinas. "Our guests will be best served if we use the winter months to prepare for the peak season. "

Currently, the lake level is down about 130 feet from "full-pool."

Boat owners are being told they can launch at Wahweap and Bullfrog ramps at their own risk, and that the best ramp is at Halls Crossing. The public ramps at Antelope Point and the Stateline are closed.

For more information about the winter 2004-05 seasonal schedule, you may log on to www.lakepowell.com or call 1-800-945-LAKE.

Coachella Valley aquifer recharge program

Balancing growth and water supply Summit called to vet ideas to avoid possible shortage of high-quality water

By Benjamin Spillman The Desert Sun October 20th, 2004

Every year, the aquifer under the Coachella Valley is "overdrafted" by enough water to serve 300,000 households.

That means that though the underground water supply is vast, users are taking out much more water than goes back in.

"We are living on borrowed time," said Mark Beuhler, assistant general manager of Coachella Valley Water District.

That, one estimate says, could mean an end to the "high-quality" water supply in less than 80 years. Or, it could mean ground collapsing into an emptier aquifer.

To combat these possibilities, more restrictive water rules, pipelines that would tap Colorado River and Northern California water supplies and increased scrutiny of homeowners' landscaping could all be in the Coachella Valley's future.

Water stewards and community leaders in the desert region known for cheap water, abundant golf and lush lawns will meet today in Indian Wells for a discussion of what steps to take to maintain the water supply that built a multi-billion tourism and agriculture industry in the area.

The water symposium, sponsored by the water district, will include leaders of area water districts and communities, farmers, golf course operators and environmentalists.

That this diverse collection of groups, often at odds over water management, is coming together at the symposium shows there is increasing focus on ensuring the valley's long-term water future.

A 35-year water plan

The water district has already embarked on a 35-year, \$250 million to \$300 million water management plan it says will reverse the ongoing overdraft, now estimated to be about 150,000 acre-feet annually. An acre-foot is enough water to supply up to two households for a year.

The water plan aims to reduce overall water consumption in the Coachella Valley by about 7 percent. It also calls on increasing the annual imported water supply from about the current 400,000 to about 560,000 acre-feet.

It suggests dividing water conservation among domestic users and typical businesses, farms and golf courses. Under the plan, domestic users will use 10 percent less water by 2010, golf courses will use 5 percent less by 2010 and farmers will use 7 percent less by 2015.

The imported water, which will come from Northern California via the State Water Project and the Colorado River via the Coachella Canal and the Colorado River aqueduct, will be used to recharge the underground water supply.

Collapsing ground?

The aquifer has shrunk an estimated 5 million acre-feet since 1936 and is estimated to have a 30 million-acre-foot capacity, Beuhler said.

But despite the massive size of the aquifer, he said implementing the water management plan is important to avoid future problems like ground subsidence.

Beuhler said there have already been isolated instances of subsidence, a phenomena that occurs when the ground collapses into an emptied aquifer, around the valley.

He said by the time the problem is widespread it could be too late to solve it.

"Everything sinks, the buildings, their foundations can crack," Beuhler said. "It is not a significant problem yet but it is coming."

Not just quantity, quality

Although CVWD aims to avert problems associated with the aquifer overdraft, the water management plan has been criticized, in part, for not taking water quality into account.

For example, the Agua Caliente Band of Cahuilla Indians are wary of the plan to recharge the high-quality ground water, the result of thousands of years of snowmelt from the mountains and rainfall, with lower quality water from the Colorado River.

River water has more salt and other contaminants. The tribe, which has its own water rights, estimated in 2002 that under CVWD's plan the "high-quality" groundwater supply would be gone in 80 years.

Beuhler said that estimate though, was a "gross oversimplification," though he conceded that Colorado River water has more salinity than local groundwater. All over Southern California, water users, including those in Los Angeles, use water from the Colorado River.

Nonetheless, in a letter to CVWD, the tribe recommended using Northern California water from the State Water Project to recharge the aquifer.

But that could require building a costly pipeline toward Beaumont or Yucca Valley, the closest physical connections to the Northern California water.

Golf course questions

Others suggested further strengthening conservation measures and increasing the cost of water for golf courses and other large users.

"There is no respect for water," said Joan Taylor, president of the Palm Springs branch of the Sierra Club. "It shouldn't be so cheap that they can squander it on golf courses."

Taylor said golf courses should rely more on recycled and imported water, not ground water. Currently, about 72 of the valley's approximately 115 golf courses rely on groundwater.

Robert White, vice president of the Hi-Lo Desert Golf Superintendents Association said the golf community has already reduced water consumption on courses by 11 percent in the last three years.

Many local golf courses are converting to irrigation systems that read the weather and there is research into hybrid grasses that use up to 21 percent less water, White said.

"We are just very, very careful with the amount of water," said White.

He said much of the wasted water in streets comes from homeowners who over-water lawns.

Bermuda or creosote?

Steve Robbins, general manager of CVWD said convincing homeowners to convert from lawns to desert landscaping is another important water management goal.

The district may consider offering incentives to remove grass, Robbins said. Las Vegas, for example, has paid homeowners as much as \$1 for every square foot of turf they remove.

"That becomes very, very expensive water," Robbins said.

So far CVWD has focused on educational campaigns to alert homeowners to "lush and efficient" desert foliage. It is also promoting a landscaping ordinance that would reduce the amount of water available to new developments by 25 percent.

But many homeowners in the desert are accustomed to keeping lush, green lawns.

"I believe (lawns) should have grass," said Rick Sullivan, of Palm Desert.

Sullivan recently watered a patch of grass at his Palm Desert Country Club home.

He said without grass, the area would resemble more isolated desert communities like Lake Havasu City, Ariz., where he also has a home.

"It's green, it gives off oxygen, it's pretty," he said of the benefits of maintaining a grassy lawn.

Landscaper Karen Lien, also of Palm Desert, said desert homeowners with roots in wetter climates seem to prefer grass to desert landscaping.

"They want a tropical looking courtyard," Lien said. "They don't care about water, at all."

Benjamin Spillman can be reached at 760-778-4643 or by e-mail .

Aquifer facts

*Since 1936, the 30 million-acre-foot aquifer has diminished by 5 million acre feet. Every year, the aquifer is overdrafted by 150,000 acre-feet. That's enough to supply service to 300,000 households.

*Water plans calls for households to reduce use by 10 percent and for golf courses to reduce use by 5 percent.

*Another way to re-charge the aquifer is to pipe in water from rivers or water sources elsewhere.

WATER-SAVING TIPS

*When planning a garden, plant items with similar watering needs together and chose water-efficient plants, including local, native vegetation.

*Integrate rocks, bricks and gravel into landscaping.

*Lawns with grass should be watered before sunrise or after sunset to maximize water absorption into the soil and minimize loss due to evaporation.

###

Coachella Begins Groundwater Recharge New facility can recharge Valley's aquifer with up to 40,000 acre-feet annually. By: Compiled by staff Published: Jun 18, 2009 The same amount of water used by approximately 40,000 desert households each year will be pumped back into the ground over the next 12 months thanks to a new project by the Coachella Valley Water District. CVWD recently began replenishing groundwater in the east valley at its newest recharge facility in south La Quinta. The new facility can recharge the Coachella Valley's aquifer with up to 40,000 acre-feet of water annually. One acre-foot is 325,851 gallons.

"With this latest project, CVWD responds to the statewide water crisis and takes another step towards protecting our local water resources," says General Manager-Chief Engineer Steve Robbins.

Every year, the Coachella Valley uses almost 400,000 acre-feet of groundwater, but on average only 63,000 acre-feet is replenished naturally through rain or snow melt. Over time excess pumping depletes the aquifer, threatens water supplies to the local population and compromises future growth in the valley.

To replenish groundwater, the new facility uses Colorado River water delivered to the valley via the Coachella Canal, across 120 miles to Lake Cahuilla in La Quinta. The water then travels along existing irrigation pipes, is pumped into 39 recharge basins and left to percolate into the ground.

Extensive scientific modeling and a pilot program were conducted by CVWD over the past decade to locate sites in the east valley that would most impact the aquifer level. In 30 years, the groundwater level in the eastern Coachella Valley will be an estimated 25-105 feet higher than it would have been had CVWD not built the new recharge facility.

"Recharge at this new facility will help reverse two decades of groundwater depletion in the La Quinta-Indio area," says Robbins.

As a responsible steward of the Coachella Valley's groundwater resources, CVWD now operates four groundwater recharge facilities that replenish water back into the ground. Combined, these sites have recharged over 2.2 million acre-feet of water since 1973. Two facilities at Windy Point and Mission Creek are jointly operated with Desert Water Agency in Palm Springs using water from the agencies' entitlements to the State Water Project.

Because the aquifer lies below the entire valley, recharge benefits all local residents and businesses. By replenishing the aquifer, CVWD ensures that a reliable supply of groundwater will continue to be available, across the entire valley, now and for future generations.

CVWD recharge programs are partially funded by fees charged to large water users that pump more than 25 acre-feet of groundwater per year, such as farms, golf courses and Home Owners Associations.

The Coachella Valley Water District serves over 106,000 residential and business customers across 1,000 square miles, primarily in Riverside County, but also in portions of Imperial and San Diego counties.

LR Letter 11/15/04

Comments: DEIS Flaming Gorge Dam

Mr. Peter Crookston
Bureau of Reclamation
Provo Area Office
302 East 1860 South
Provo, Utah 84606

RE: Comments on Draft Environmental Impact Statement on operations at Flaming Gorge Dam

Dear Mr. Crookston,

Living Rivers and Colorado Riverkeeper submit the following comments on the Draft Environmental Impact Statement (DEIS) for the re-operation of Flaming Gorge Dam to benefit endangered fish, as released on September 7, 2004.

While the four-year effort to produce this document has proved useful in generating a better understanding of the challenges facing the recovery of endangered fish below Flaming Gorge Dam, the analysis is not yet sufficient to support the proposed action. The water supply and hydrograph assumptions do not correlate with present trends. The role of endangered fish recovery relative to other operational objectives has yet to be properly clarified. The proposed action fails to address the pitfalls in the structure and mandate associated with the proposed Adaptive Management Program as experienced with Reclamation's recovery efforts for endangered fish at Grand Canyon. The DEIS did not properly review the merits of recovery efforts through a dam decommissioning alternative. Lastly, as noted in our scoping comments of July, 2000, Colorado River endangered fish recovery should be tiered to a programmatic EIS that evaluates recovery needs and barriers throughout the historic range of these endangered fish species. We hope these matters will be properly addressed prior to completion of the Final EIS (FEIS).

1. Water availability

The DEIS failed to sufficiently address how long-term water availability will impact fish recovery in the lower Green River, and as a result did not sufficiently demonstrate whether the proposed recovery efforts can be successful in this limited stretch of river.

Flow scenarios did not take into consideration the prospect of how climate change will affect river flows. The present drought has demonstrated that flows may be significantly

lower than forecasted as precipitation patterns for the Green River watershed may be changing. The Department of Energy has forecasted how western rivers as a whole may experience a 30 percent reduction in flows over the next 50 years due to climate change.

2. Action Alternative is not consistent with the natural hydrograph

The DEIS acknowledges the recommendation to manage the recovery of endangered fish species on a dam-controlled river by mimicking the historic natural hydrograph and thermograph, as much as possible. We believe that the flow recommendations of the DEIS departs from this prescribed treatment. We believe the spring peak flow of the Action Alternative is much reduced and therefore diminishes the success in achieving the goal to recover endangered fish. We also believe that the Action Alternative's base flow, from the summer to winter season, is higher than the historic hydrograph and too does not reflect compliance with the biological data.

Furthermore, instead of timing releases from Flaming Gorge Dam with the natural flow of the Green River, the flow recommendation of the Action Alternative is timed to meet the natural hydrograph of the Yampa River, a tributary of the Green River downstream of the dam. We believe this too diminishes the recovery of endangered fish in the Green River, especially in Reach One (Flaming Gorge Dam to the confluence with the Yampa River).

We believe the DEIS overlooked the benefits associated with the Run of the River Alternative, as suggested by the National Park Service. We encourage Reclamation to scrutinize further the possibilities of implementing such an action plan. We believe strongly that matching the historic attributes of the river is what will eventually provide a greater measure of success in the recovery of endangered fish species, until which time the dam can and will be successfully decommissioned, as is inevitable.

3. Clarify the priority of satisfying the Endangered Species Act

The DEIS sometimes refers to the recovery of endangered fish as distinct from the authorized purposes of Flaming Gorge Dam (Sec.1.1). At other times the DEIS implies that the authorized purpose of Flaming Gorge Dam does include the improvement of critical habitat for fish and wildlife. The FEIS must make clear that fish recovery is paramount as the Bureau of Reclamation must comply with the Endangered Species Act first and foremost, then allow for other dam operational benefits to be pursued accordingly.

4. Adaptive Management Program protocols

The DEIS indicates that the Action Alternative includes the implementation of an Adaptive Management Program concerning the future operations at Flaming Gorge Dam. This program will consist of the Flaming Gorge Working Group and a Technical Working Group. The purpose of the Flaming Gorge Working Group is to provide a check and balance system for the purposes that authorized Flaming Gorge Dam, including the

recovery of endangered fish. The purpose of the Technical Working Group is to provide scientific expertise for the program.

Such a program has been underway for nearly ten years at Glen Canyon Dam, but the results have been disastrous. One more species has gone extinct, the Razorback Sucker, and the Humpback Chub has declined to nearly irreversible numbers. This has occurred for the lack of: a) a clear mandate for independent, peer-reviewed science that is removed from politics, b) to guide the decision making process by placing fish recovery at a priority below power generation, c) not ensuring there are sufficient funds to operate the program.

Reclamation must identify how the Flaming Gorge Dam Adaptive Management Program will avoid the pitfalls that have plagued the program at Grand Canyon.

Reclamation must also outline how this program will address uncertainties associated with the operations at Flaming Gorge Dam, and how future supplemental National Environmental Policy Act compliance will be required.

We believe that such uncertainties could include, but not limited to: progressive global warming, extended and prolonged drought, extreme flood events, higher sediment transport, increased human consumption, modifying selective withdrawal (temperature control), and the control and removal of exotic fish.

This should also include a call by the Lower Basin to deliver the minimal annual requirement of 8.23 million acre-feet at the Compact Point (Lee's Ferry, Arizona). As well as dam operations that further compromise the ecosystem values that authorized the creation of Dinosaur National Monument, Ouray National Wildlife Refuge, and Canyonlands National Park.

We also believe that another management decision of the immediate future should include a fish passage at the Tusher Wash Diversion Dam near Green River, Utah. This would include a device that prevents mortality of endangered fish from entrapment in the irrigation and hydropower projects associated with this diversion dam.

Therefore, we do expect that the working groups and the general public will have comprehensive access to all information that pertains to the operations of the Green River and Flaming Gorge Dam. This should be accomplished through the web pages of the Bureau of Reclamation and through a regular newsletter that is mailed to all interested parties.

For the agencies, scientists and the general public to be well informed, it is imperative that all program information is made available promptly and that this information is disseminated liberally and is not discretionary. It is also imperative that adequate time be allowed for the public to process this information in a timely manner so as to maximize public outreach opportunities in the NEPA decision making process.

5. The Decommissioning Alternative

The DEIS dismissed the decommissioning alternative without sufficient justification or analysis, other than to say, "[decommissioning] does not meet the purpose and need for the proposed action." The principle objective in fish recovery programs is to restore natural processes, which include seasonal flows, temperature, sediment, nutrients and migration.

Decommissioning Flaming Gorge Dam can best meet these objectives and thus should be thoroughly evaluated. While the dam makes some contributions to water storage, power generation and recreation, these contributions are not significant regionally, and are replaceable, whereas the endangered fish are not.

The DEIS also did not fully evaluate the potential for dam failure, and the impacts this may have on endangered fish recovery, as well as other downstream impacts to Dinosaur National Monument and Canyonlands National Park.

6. Basin-wide concerns

Reclamation continues to address fish recovery in the Colorado River watershed in a piecemeal fashion without consideration of the natural species' range, or macro-social and environmental changes that may be affecting the watershed. It's critical for Reclamation to develop a programmatic EIS involving all the recovery needs of endangered fish species in the watershed and the best approaches to resolve them.

We believe the overarching problems that must be thoroughly studied in such a system wide, programmatic approach would include, but not limited to:

- Diminished water supply and water quality • Increased water demand • Over allocation of water rights • Quantifying the water rights of the First Nations • Impacts to national wildlife refuges, parks and monuments (including the international biosphere at the Colorado River delta) • Removal of exotic species • Sedimentation in the reservoirs • Dam safety • Modernizing the Law of the River • Alternative energy production and conservation • Water storage and conservation alternatives

We believe such a study would show conclusively that the Colorado River system would benefit by having some of its infrastructure removed and that alternative storage strategies, such as the artificial recharge in depleted aquifers, can provide:

- Increased habitat for endangered species • Restore the natural attributes of the river and its tributaries • Reduce water loss from evaporation • Reduce salinity • Provide protection from extended drought • Eliminate the consequences of high dam failure • Prompt a sediment management plan

7. Closing statement

Thank you for this opportunity to comment on the DEIS for Flaming Gorge Dam. We encourage the Bureau of Reclamation to proceed in producing a Final Environmental Impact Statement and we look forward to the subsequent Record of Decision. Please feel free to contact us at any time should you require any additional information or assistance from us.

Sincerely yours,

John Weisheit

LR Letter 11/16/04

Comments: Supplemental EA for experimental flows in Grand Canyon

November 16, 2004
Mr. Dennis Kubly
Bureau of Reclamation, Upper Colorado Region
125 South State Street, Room 6107
Salt Lake City, Utah 84138-1102

Re: Draft Supplemental Environmental Assessment. Proposed Experimental Actions For Water Years 2005–2006, Colorado River, Arizona, in Glen Canyon National Recreation Area and Grand Canyon National Park.

Dear Mr. Kubly,

Living Rivers and Colorado Riverkeeper submit the following comments on the Supplemental Environmental Assessment (EA) concerning proposed experimental releases from Glen Canyon Dam to conserve sediment and to disadvantage non-native fish at Grand Canyon National Park, as released on November 5, 2004.

1. Introduction

Living Rivers is keenly aware of the rapidly declining Humpback Chub population, as well as other Grand Canyon native fish species, caused by the operations of Glen Canyon Dam. This also includes the acute reduction in stored fine sediments, which are needed to provide rearing habitat for endangered fish, to preserve the cultural heritage of the First Nations and to provide camping beaches for visitors in Grand Canyon National Park.

While the purpose of this EA is in response to modify the operations of Glen Canyon Dam to conserve both sediment and endangered fish and to test methods to mitigate such impacts, the proposed actions, especially as they pertain to sediment retention and habitat-building, are fundamentally flawed. Of critical concern to us is how the EA does not evaluate any alternatives for increasing the sediment load below Glen Canyon Dam, as the dam is entirely responsible for blocking 95 percent of historic sediment load from ever entering the river ecosystem in Grand Canyon.

To adequately address the problems associated with sediment retention and augmentation, as well as the problems associated with non-native trout species,

necessitates a Supplemental Environmental Impact Statement (EIS) and not the cursory analysis undertaken in this EA. Such an EIS must fully evaluate the decommissioning of Glen Canyon Dam in addition to other appropriate alternatives to meet sediment needs and to disadvantage non-native trout populations in Grand Canyon.

We believe the need for a Supplemental EIS stems far beyond the above and includes a host of other issues affecting the dramatic decline in Grand Canyon Humpback Chub populations. This would include water temperature, water quality, historic seasonal flows, nutrients for the food web and the ability to migrate in response to the environmental needs of endangered fish. The reduction in adult Humpback Chub population constitutes significant and new information to that which was evaluated in the 1994 Fish and Wildlife Service Biological Opinion and the 1996 Final EIS on Glen Canyon Dam operations.

Lastly, the public process for this proposed action has been wholly unsatisfactory once again, as when the initial EA was first presented in October of 2002. The Bureau of Reclamation (Reclamation) and its Adaptive Management Program (AMP) for Glen Canyon Dam must overhaul its procedures for public participation.

2. Insufficient sediment to justify further experimentation outside of augmentation

The EA focuses on utilizing experimental flows from Glen Canyon Dam to manage sediment for the benefit of Humpback Chub populations. However, the abundance of study and experimentation done previously has already demonstrated conclusively that in the long-term, little to nothing will be gained from the proposed action. The sediment conserved during this experiment will return to the river and flow downstream to Lake Mead. The resources of Reclamation and the AMP would be better invested in aggressively pursuing alternatives that stand a greater likelihood of achieving this goal.

Ninety five percent of the historic sediment load for Grand Canyon native fish remains trapped in Lake Powell. In theoretical optimum conditions, such experiments, as proposed in the EA, could manage only five percent of the sediment that would exist in natural conditions. This five percent has already proven insufficient to meet the sediment and nutrient requirements to recover native fish. Sediment is a key missing component for advancing the recovery of native fish in Grand Canyon (Rubin, et. al., EOS v83, n25, 2002). The proposed action focuses solely on flood releases to store this minimal amount of sediment on the margins of the river, while at the same time failing to demonstrate any long-term availability of sufficient sediment to aid recovery in the future. Reclamation must therefore address through an EIS process methods to augment sediment into the system.

3. Climate change and the associated effects on long-term habitat improvement

The EA ignores climatic factors that will affect the proposed experimental releases. The Colorado River watershed is experiencing much lower flows than were anticipated when such spike flows for sediment conservation were first conceived in the original EIS. The US Geological Survey (USGS) has reconstructed the historic climate conditions for the Colorado River basin. Their findings indicate that a sustained and severe drought could

lie before us and that such a climate regime would affect resource management challenges (Webb et. al. 2004) (Meko et. al. 2004). Furthermore, the Department of Energy projects that the Colorado and other Western rivers will see a 30 percent decline in flows over the next fifty years due to climate change (Accelerated Climate Prediction Initiative 2002).

This is already proving to be a problem for the proposed action. Sediment conservation strategies require a sufficient amount of water in Lake Powell to generate optimum flood flows. USGS scientists have stated that the ideal flood magnitude for sediment conservation in Grand Canyon should be 60,000 cfs (Weile 2003). At present the spillway portals, which must be utilized to achieve this target, are perched above the current reservoir level. The EA ignores this and now suggests that the maximum flow for this experimental release need only be 41,000 cfs. It is quite possible that this flood magnitude will not prove sufficient in 2004, much less in subsequent years should river flows remain below that necessary to refill the reservoir.

4. Timing of spike flows and sediment deposition will provide no benefits to native fish rearing

Under ideal circumstances sediment inflows from the Paria River would be better conserved through dam releases at low flow, with the spike flow commencing in conjunction with the natural rearing of Humpback Chub in the spring and summer. Past experiments have already demonstrated that much of the habitat building from spike flows disappears within six months after the spike. Since the proposed action would occur six to seven months in advance of the Humpback Chub's ability to benefit from it, there is no justification to time such flows so far in advance. To be of any benefit such spike flows should be timed to coincide with the natural high flows entering Lake Powell.

5. Proposed flows ignore Fish and Wildlife Service opinion for the recovery of Humpback Chub

The EA of 2002 stated that the present flow regime from Glen Canyon Dam (Modified Low Fluctuating Flow or MLFF) has failed to benefit the habitat of the Humpback Chub. This conclusion resulted from data provided by the Grand Canyon Monitoring and Research Center (Coggins and Walters 2001), which found that a dramatic reduction in the Humpback Chub population has occurred since this flow regime was implemented.

This flow regime was selected as the preferred alternative by the Secretary of Interior despite objections by the Fish and Wildlife Service (FWS) in its 1994 Biological Opinion. That opinion specifically stated that the MLFF alternative would "likely destroy or adversely modify designated critical habitat." FWS recommended the alternative known as the Seasonally Adjusted Steady Flow (SASF). FWS, in conjunction with the Department of Biological Sciences at Northern Arizona University, reiterated these recommendations in their September, 2002 report, Monitoring and Research: The Aquatic Food Base in the Colorado River, Arizona during 1991-2001 (Benenati, et. al., 2002). This report states, "We recommend a decade of Seasonally Steady Flow alternative, with spring beach building flows as the climate permits and unlimited hydropower ramping within 10% of the predicted seasonal mean. We feel these flows in

combination with alien fish suppression and thermal modification of GCD could make Grand Canyon a sanctuary for native fishes of the Colorado River basin."

The proposed experimental releases outlined in the EA will continue to conflict with these recommendations in two ways. First, as noted above, the habitat-building releases do not occur at the preferred time-period of the annual, historic snowmelt, to which these native fish are naturally attuned. Second, the prescribed fluctuating flows for non-native fish suppression would disrupt the food supply for the native fish species and transport sediment out of the Grand Canyon river system.

Additionally, the EA does not sufficiently analyze the impacts to other habitats with their associated species caused by experimental releases inconsistent with the river's natural hydrograph.

6. Water quality

As the reservoir is now only 38 percent full, the potential exists for water quality problems to materialize during the experimental release, which were not addressed in the EA and must be prior to any experimentation. The reservoir water extracted at the depth near the river outlet works may be high in sodium, phosphorus, nitrogen, hydrogen sulfide, dissolved oxygen and heavy metals. We are curious how Reclamation and US Geological Survey will monitor the water quality should this experiment proceed, and will these chemicals impair the food web and habitat of the endangered fish of Grand Canyon?

7. Public review process

Reclamation did not fully comply with the spirit of the public review process as outlined by NEPA and the AMP Charter. Two weeks notice was given to submit comments for this Supplemental EA and to our knowledge no public meetings were scheduled or noticed.

The AMP is charged to fully involve the public in all its activities. Similar insufficient outreach occurred during the EA in 2002 and we voiced our dissatisfaction then, asking Reclamation to assert greater diligence in the future. Once again we are compelled to remind Reclamation that public participation must include ample time for citizens to learn about, and to become engaged in, all activities pertaining to the operations of Glen Canyon Dam and its associated impacts to Grand Canyon National Park.

8. Supplemental EIS needed

The proposed actions in this EA, either separately or in combination with other actions contemplated by Reclamation and the AMP, are not seriously addressing the precipitous decline of endangered Humpback Chub in Grand Canyon National Park. This decline, described by key investigators including Lew Coggins, Carl Walters and others, while not surprising considering the lack of management activities given on behalf of the Chub, was not anticipated when the Record of Decision was signed. Therefore, under National Environmental Policy Act (NEPA) regulations found at 40 CFR 1502.9(c)(1)(ii), these new data represent "significant new circumstances or information relevant to

environmental concerns," triggering a requirement to prepare a Supplemental EIS (SEIS) to the 1996 Glen Canyon Dam EIS.

The Bureau of Reclamation, the National Park Service and other agencies are likely in violation of the Endangered Species Act and the Grand Canyon Protection Act for failing to ensure protection and recovery of the Humpback Chub population in Grand Canyon National Park. Reclamation, in conjunction with National Park Service and other relevant agencies, should immediately begin work on such an EIS for the full recovery of the Humpback Chub populations in Grand Canyon National Park. Such an EIS must address all issues affecting the Humpback Chub. This would include water temperature, water quality, seasonal flow, a healthy food web, sediment and nutrient loads and impacts from non-native fish. Most importantly the EIS must evaluate the decommissioning of Glen Canyon Dam as one of the alternatives to meet Humpback Chub recovery objectives.

9. Conclusion

Living Rivers and Colorado Riverkeeper finds this EA and the experiment proposed to be a waste of public resources. The crisis facing the Humpback Chub in Grand Canyon is quite serious, but it has yet to be taken seriously by Reclamation and the AMP. We believe the AMP process favors power and water resources, which are replaceable, over endangered species, which are not replaceable. The proposed habitat-building experiment is unlikely to materialize any benefits due to general lack of sediment in the system. Even if such sediment were available, it would not be distributed in a timeframe to benefit the Humpback Chub. Regardless, such sediment would be insufficient to mitigate the loss of 95 percent of sediment and nutrients now trapped behind Glen Canyon Dam.

This EA further demonstrates Reclamation's and the AMP's unwillingness to follow the recommendations of FWS, and as a result, will lead to the further declines in the Humpback Chub populations in Grand Canyon National Park. Reclamation must abandon this EA and proposed experimentation and conduct a full EIS on new operating regimes for Glen Canyon Dam, including decommissioning, to fully recover endangered fish habitat in Grand Canyon National Park.

Thank you for the opportunity to submit these comments and recommendations.

Sincerely,

John Weisheit

Glen Canyon Dam test flow raises questions about future management

LAND LETTER Thursday, December 2, 2004
COLORADO RIVER

April Reese, Land Letter Southwest reporter

GLEN CANYON DAM, ARIZ. -- Eight years after an experimental flood aimed at boosting the faltering ecosystem in Grand Canyon National Park, dam operators have opened the bypass tubes once again. But whether or not the experiment fares better than its failed predecessor, Grand Canyon stewards say it will undoubtedly raise difficult questions about how the dam should be managed in the future.

Beginning Nov. 21, the Bureau of Reclamation, which operates Glen Canyon Dam, unleashed 224,000 acre-feet of water through four giant bypass tubes over 90 hours. Scientists and dam managers hope the high flows, rushing down the canyon at 41,000 cubic feet per second (cfs), will stir up sediment flowing in from tributaries downstream from the dam and deposit sand in the Grand Canyon's river channel, building beaches and sandbars to help endangered fish and provide camping areas for rafting expeditions.

"This is amazing," said Sam Spiller, lower Colorado River coordinator with the Fish and Wildlife Service, watching cylindrical torrents of water blast through four bypass tubes at the base of the dam. "Even during a drought season, we're going to go ahead and take advantage of the sediment."

The experiment was initially scheduled for January, but dam managers decided to release the high flows in November to capitalize on recent storms that have swelled the Colorado River's tributaries with sediment in recent weeks.

"The sediments have come down from these storm events," Spiller said. "The question is, can we put these sediments up [on the banks] and restore some of our beach habitat?"

The deposition of sediment creates pools and ripples that provide important habitat for the humpback chub, one of four endangered fish that persist in the Colorado River, and encourage willow growth, which supports southwestern willow flycatchers, an endangered bird.

"The sediment, sand, mud and silt play an important role in the ecosystem," said Chip Groat, director of the U.S. Geological Survey.

An earlier 45,000 cfs test flow in 1996 failed to keep deposited sediment in the system long enough to benefit the ecosystem, largely because the release was too long, eventually scouring the beaches and sandbars it had built, scientists said.

"If there's too much [water], the sediment just erodes -- it goes down to Lake Mead," said Denny Fenn, director of the Geological Survey's Southwest Biological Science Center.

The test flow was the result of a proposal from the Glen Canyon Dam Adaptive Management Work Group, which makes recommendations on dam management and protection of downstream resources, as required under the Grand Canyon Protection Act. The group is comprised of hydropower interests, environmentalists, Park Service officials and other stakeholders.

The release dropped the level of Lake Powell, now down to about 375 feet, by 2-and-a-half feet. But the water sent downstream will go to meet delivery obligations under the Colorado River Compact, which divvies up the river's water among seven western states. Releases from the dam will be lowered in the coming months to offset the high flows sent downstream during the experiment, Bureau of Reclamation officials said.

The Western Area Power Administration, which generates power from the dam, estimates that it lost almost \$2 million during the test flow, which bypassed water around the power plant. But the loss of power generation will be made up for during fluctuating flows over the next few months, said Clayton Palmer, who represents WAPA in the working group.

While the long-term effect of the experiment will not be known for at least a year, preliminary measurements suggest the flows have deposited sediment onto beaches and sandbars. But it remains to be seen whether enough sediment has been loaded into the river to offset the constant erosion that occurs during normal releases from the dam, said Scott Wright, a hydrologist with the Grand Canyon Monitoring and Research Center.

"What we've seen in the past is there's consistent erosion of sand in the canyon under normal power plant operations," he said. "The question is whether ... we can overcome the erosion that happens during regular plant operations."

Scientists are taking a trip down the river this week to examine the new sandbars, he said. "I think they will be there, but there's also a question of how long the sandbars will last." Monitoring will continue over the next year and a half.

A changed ecosystem

Even if the test flow proves to be a long-term success, the Grand Canyon ecosystem faces a myriad of other problems, scientists note. The water in the river is cooler than it was historically, because most of the water that flows downstream has languished in the deep, cool reservoir behind the dam before being released. And while dam managers have altered flows to help the ecosystem, the river no longer rages and whimpers the way it did historically (Land Letter, Dec. 11, 2003).

Those changes, along with the invasion of exotic fish, are largely responsible for the extinction of four species of native fish and for the endangered status of the four

remaining native fish species in the Grand Canyon, including the humpback chub (Land Letter, Oct. 30, 2003).

Today, the Colorado River, named for its historic reddish hue, is a very different river. "It's clear, it's cold, it's got a lot of trout, which compete with the native fish, and the flow regime is drastically different from what it used to be," Wright said.

And while the test flow may have helped carry sediment loaded into the river by its major tributaries, most of the sand that would flow downstream is trapped by the dam. Managers estimate that 92 percent of the sediment that would be carried downstream by an undammed river is settling behind Glen Canyon Dam -- a growing underwater sandbox that also limits water storage capacity.

Some environmental groups question whether such experiments will be enough to recover the ecosystem in the Grand Canyon.

"The proposed habitat-building experiment is unlikely to materialize any benefits due to general lack of sediment in the system," wrote John Weisheit of Living Rivers in a letter to dam managers. "Even if such sediment were available, it would not be distributed in a timeframe to benefit the humpback chub."

But Nikolai Ramsey, who represents Grand Canyon Trust in the working group, said he hopes the test flow will have a positive ecological effect. "This experiment is a watershed event," Ramsey said. "It's possible that many resources will benefit -- so much is tied to sediment."

What next?

If the test flow is effective, such flows would need to be replicated on a regular basis to help the ecosystem recover over the long-term, scientists say. But working group members disagree on whether the law allows for regular bypasses of the power plant. WAPA believes it does not; environmental groups insist that it does.

"The issue is, can you conduct those kind of flows on a regular basis and conform to the law?" Palmer asked. "The 1968 Colorado River Basin Act doesn't allow bypasses of the power plant, unless it's hydrologically necessary. ... That is going to be a problem. So we're not advocating at this point that [high flows] be conducted on a regular basis."

But if the test flow demonstrates that regular high flows are what the ecosystem needs, managers should adjust dam management accordingly, Ramsey argued. "If this experiment works, why shouldn't we do this every year?" he asked.

On the other hand, if the experiment fails, managers are left with another difficult dilemma.

"During the eight years of adaptive management, we tried various things, and the resources continued to decline," Ramsey said. "If this doesn't work, it's going to be highly suggestive that the Grand Canyon resources will not be able to be restored to

any kind of health with the dam still there. So if this experiment doesn't work, what do we have left?"

There is at least one option that has not yet been tried. Dam managers have suggested building a sediment slurry pipeline that would deliver sediment from behind the dam into the river on the other side. But some working group members contend that would be expensive and may not work. Scientists are currently doing a feasibility study on the pipeline proposal.

Another option might be to try the high test flow again when more sediment is coming into the Colorado River from its tributaries, Wright said.

"What's left are very difficult and expensive alternatives," Palmer said.

One solution the working group will not discuss, Ramsey said, is decommissioning the dam, an option that Living Rivers and a handful of other groups have been pushing for several years. The working group's approach has been to restore the Grand Canyon's resources to the greatest extent possible while maintaining the human benefits from the dam. But with little left to try, that unacknowledged "gorilla in the room" may become increasingly difficult to ignore, Ramsey said.

"The dam has generated significant benefits, but if its existence is tied to the Grand Canyon's demise, well it's just not worth it," he said. "If we learn that there's nothing we can do, I think we'll inevitably be on the side that we'll have to look at removing the dam. Those are strong words, but I think this experiment will have those kinds of implications for a lot of us."

Colorado Compact: Ageless or dried up?

12/19/2004 12:57:57 AM

Water storage revisited: As Western officials tout the system for weathering the drought, critics say increasing demand makes it untenable

By Joe Baird
The Salt Lake Tribune

LAS VEGAS - The refrains were uttered again and again during a yearly gathering of Western water officials here last week: The Colorado River Compact is working. The historical seven-state agreement, signed in 1922, will survive the current drought. The half-full reservoirs are a sign of success, not failure.

Whether their tone was defensive or simply reassuring, Colorado Compact supporters felt compelled to speak up for a system that is being tested as never before. The worst

drought in 100 years has placed unprecedented strains on water users in both the upper and lower parts of the Colorado River Basin. Planners are now on a crisis footing, and reduced allocations are in the offing. The real hunkering down may be yet to come.

Critics call the compact, and particularly a reservoir system anchored by Lake Powell and Lake Mead, an anachronism, a relic of wetter, headier times that has been overtaken by the West's rapid urban growth.

But without the compact, which allocates 15 million acre-feet of water annually among Utah, Wyoming, Colorado, New Mexico, Nevada, Arizona and Colorado - plus 1.5 million acre-feet for Mexico - advocates argue that the current situation could be a lot more dire than it is. "During this early 21st century drought, this system has continued to provide resources," Colorado Supreme Court Justice Gregory Hobbs told members of the Colorado River Water Users Association. "Even with severely ranging characteristics, in high-flow years and low-flow years, it has worked. And it has proven vital."

The current drought, now in its sixth year, "is our wake-up call in the Colorado River Basin," acknowledged Steven Griles, deputy secretary of the Interior. "But there are lots of signs that the [compact] states will meet the challenge."

Colorado River Compact detractors call such talk wishful thinking. The template has changed, they say. And water officials have been slow to adjust to what they call a new reality for the Colorado and its water storage assets.

David Haskell, policy director for the environmental group Living Rivers, believes the original compact was signed and allocations made under incorrect assumptions. Tree-ring science, he says, now shows that the 1900s was one of the wettest centuries on record, and that the 1980s - when Lake Powell was filled - was the wettest decade in that wet century. As a result, the compact states have been living large, artificially.

"Saying the compact is working is like sitting in a room full of food and never being hungry," Haskell said. "But now they're down to their last few hamburgers and everything is changing."

"What we've got now is a whole lot of demand and less supply," he added. "It worked up until now because it was an extremely wet century and the '80s was an extremely wet decade. Were it not for that decade, Lake Powell would never have been more than half-full. It would be empty now. What you've seen is a system that has been working under very beneficial circumstances."

Water officials beg to differ. The compact states have weathered the drought very well, they say. And regardless of history, a Lake Powell now 130 feet below capacity is still providing users with both power and water. The compact system predicted periods of drought and shortage. The system is working exactly as it was intended to.

If anything, compact state participants say they are getting better at their jobs, and they cite a number of recent developments as evidence:

* A landmark deal struck last week in which Arizona agreed to sell Nevada 1.25 million acre-feet of its share of Colorado River water for \$330 million over the next 15 years.

* California's commitment two years ago to live within its annual 4.4 million acre-feet allotment of Colorado water.

* An adaptive management plan for Glen Canyon that calls for the removal of non-native fish species, such as trout, while at the same time rehabilitating native species, such as the Humpback Chub.

* Last month's experimental test flow at Glen Canyon, designed to return sediment to the Grand Canyon, restoring beaches and creating backwater habitat for native fish species.

"In the last four years we've seen some remarkable practices," said undersecretary Griles.

But again, compact critics, such as Haskell, wonder which century Western water officials are living in.

"The question now is, how do we plan for the future now that we know what kind of water deliveries are likely?" he said, citing projections that show a future average annual allotment of 13.5 million acre-feet - or 3 million less than is allocated now, when one includes Mexico's annual share of Colorado water.

Living Rivers, like the Glen Canyon Institute and other environmental groups, is calling for the decommissioning of Glen Canyon, moving a portion of that water into the more efficient Lake Mead and using underground aquifers - as Arizona does now - to bank the rest. "We've got far more underground storage capacity than storage capacity in the Colorado River system," said Haskell. "Powell has outlived its utility and become a liability. You can't deny that Lake Powell hasn't delivered during the drought, but that's really the wrong question. It's not a sustainable system."

But that has been, and continues to be a catastrophic alternative to Western water officials, who consider Powell and Mead the linchpins of the entire Colorado River Basin. Pulling the plug on Powell would invite economic disaster, they say. "These dams were built to fluctuate," said Colorado justice Hobbs. "The reality is, without the Colorado River Compact, our water storage problems would be much worse than they are right now."

St. George Pipeline

Dixie likely to need a pipeline
Arid county could grow to 648,000 people by 2035

By Joe Bauman

Deseret Morning News
Washington County's population is skyrocketing, leading to projections that by 2050 — and perhaps as soon as 2035 — as many as 648,000 people will live in Utah's arid southwest.

When that happens, said Ron Thompson, director of the Washington County Water Conservation District, the county will have to supply about 210,000 acre-feet of water to serve those residents. At present, developed water supply is only 72,000 acre-feet, he said Monday during a meeting of the governor's Water Delivery Financing Task Force.

Gov. Olene Walker organized the group to devise recommendations about two big water projects, the Bear River Project and a pipeline from Lake Powell to supply Washington County, mostly St. George. (A spur pipeline to Cedar City is possible, too.)

Projections about the number of people who would be served by the Bear River Project are still being formulated and should be released soon. But amazing predictions already are on the record for booming Washington County.

"Our county has gone from just under 90,000 in 1990 to today, just under 116,000 people," Thompson said.

One steadily rising curve, the one that Thompson believes is more realistic, shows the 648,000 level by 2035; another, based on state projections, shows that many people by 2050.

Complicating the picture is that the 210,000 acre-feet projection is based on Washington County's managing to conserve an enormous amount of water. Without that conservation, according to Thompson, the need would be another 80,000 acre-feet.

Either way, the huge water demand can't be met without the pipeline, according to a chart Thompson released. It shows the lion's share of new potential water, 70,000 acre-feet, will come from a Lake Powell pipeline.

The 120-mile pipeline and its Fort Pearce Reservoir would cost \$370 million in today's dollars. Assuming they would be built in 2018, and adjusting for expected inflation, Thompson said the cost at that time would be \$593 million.

"The route for the pipeline essentially follows the state highway system," he said.

The problem with that is the highway not only goes through two counties, it also dips into Arizona and back to Utah.

Along the way, U.S. 89 climbs through rugged terrain called the Cock's Comb, south of Paria, Kane County. The site is 3,000 feet higher than St. George, necessitating a pumping station for the pipeline. From the Cock's Comb, the water flows downhill. Thompson expects the revenue from hydroelectric power would pay for the pipeline's operations and maintenance.

However, that doesn't cover the construction costs. Even if water users repaid most or all of the construction cost, state funding may be needed if the project is to be built.

With two states, a pair of counties and a huge initial expense, a regional project involving the state of Utah may be the way to build the project, according to Thompson.

"This cannot be accomplished without a strong state-local partnership," he added.

Larry Anderson, director of the Utah Division of Water Resources, said 1,370,000 acre-feet of Upper Colorado River Basin water belongs to Utah. About 1 million acre-feet is used today. Some of the remaining amount — perhaps as much as 200,000 acre-feet — is water Indian tribes are entitled to.

That leaves 74,000 acre-feet in the Colorado River system. In order to take water out of Lake Powell for a St. George pipeline, the state may have to pay the federal government for storing the water in that reservoir.

State treasurer Ed Alter wondered if an incremental approach, such as acquiring rights of way and reservoir sites, might be the best approach for large water projects.

"The way to make these feasible is not to put them off for 15 years but to start eating the elephant in small bites," he said. "I'd like to see the state plan to get involved and accumulate resources."

Otherwise, he warned, prices could "escalate on us" until the cost becomes almost insurmountable.

"Environmental work needs to get started now," said Thompson.

Rep. Ron Bigelow, R-West Valley, noted the Legislature faces many other funding demands.

"Every time we do the budget, the question is where do we spend the funds," he said in an interview after the meeting. "There are always many needs."

Transportation needs are high on the state's considerations and there are the normal funding requirements. "And now you throw in water" projects, he said. "The task of the Legislature is to identify priorities and determine which of the priorities gets funding."

Bigelow said he has questions about whether big water projects can be funded within the next couple of years.

Merritt Frey, executive director of the Utah Rivers Council, who attended the meeting as an observer, said conservation should be stressed in Washington County.

"St. George has an incredibly high per-capita water use, compared with the rest of the state, which is already pretty high," she said. "So we would say conserving should be the first order of business down in St. George."

Frey said southwestern Utah could do much more to save water.

Canyon river runner numbers may increase

Ananda Shorey
Associated Press
Dec. 24, 2004 12:00 AM

More river runners may soon be challenging the rapids of the Colorado River through the depths of the Grand Canyon, under a proposal by the National Park Service.

The agency wants to increase the total yearly passengers by 3,856 - from 22,461 to 26,317 - as part of a revised Colorado River management plan.

A panel of scientists, geologists, professors and consultants is considering increasing the passenger totals, while reducing the number and length of trips, as well as group sizes for some areas.

Some launches also may be shifted into non-peak seasons. The number of months that non-motor boats use the river could increase from three to six months.

"People will still have plenty of opportunities to go down the river, but there will be some changes in the way the system operates," said Rick Ernenwein, who is heading up the plan.

The public has until Jan. 7 to comment on 13 alternative plans for the 277 miles of Colorado River from Lees Ferry, south of Lake Powell, through the Grand Canyon to the edge of Lake Mead. A group of experts will then analyze the comments before submitting a final environmental impact statement.

A final environmental statement could be completed by spring, Ernenwein said.

Once the regional director of the Park Service approves a plan, some parts could be implemented immediately, Ernenwein said. Others could take a year or longer.

Eight alternatives are being considered for the river from Lees Ferry to Diamond Creek, through the heart of Grand Canyon National Park. This is the section where the majority of river trips are conducted.

On another section of the river stretching from Diamond Creek to Lake Mead, the Park Service wants to lower pontoon boat use and cap the number of passengers at 150 daily.

The park wants to increase the overall operations in this area while reducing the group sizes. It would also like to eliminate peak use by spreading trips out. Five alternatives are being studied.

Experts began discussing in January 2003 on whether to alter the number of recreational and commercial river runners allowed to use the Grand Canyon.

A panel of experts then came up with suggestions about how to better manage the corridor.

The main purpose of the 10-year plan is to protect the natural and cultural resources while allowing as many people as possible to enjoy the area, Ernenwein said.

"If we don't protect the resources in the river corridor, it will change the type of experience people have," Ernenwein said.

Some environmentalists are critical of the Park Service's plan. David Haskell, policy director for Living Rivers, a group that promotes river restoration, said it doesn't go far enough.

"We feel like the Park Service has fallen short, in particular in not addressing the group size of commercial groups," Haskell said.

Besides further decreasing the commercial group sizes, Haskell said the Park Service needs to phase out or stop allowing motorized boats on the river.

"It's a money issue rather than a resource-protection issue," Haskell said.

LR Letter 02/01/05

Grand Canyon CRMP DEIS comments

February 1, 2005
Mr. Joseph Alston, Superintendent
Grand Canyon National Park
P.O. Box 129
Grand Canyon, AZ 86023

Re: Draft Environmental Impact Statement for the Colorado River Management Plan at Grand Canyon National Park

Dear Mr. Alston,

Living Rivers and Colorado Riverkeeper submit the following as comments on Grand Canyon National Park's Draft Environmental Impact Statement (DEIS) for the Colorado River Management Plan.

On August 1, 2002, Living Rivers provided scoping comments for the DEIS process (see attached), which specified that it was paramount that the National Park Service (Park Service) not limit the DEIS scope to merely addressing human activity in the river corridor of Grand Canyon National Park (Grand Canyon). The ecological and cultural integrity of the river corridor is in serious decline, and its must not be ignored by any management plan pertaining to the river. Such an omission violates the spirit of, if not the letter of, the Organic Act, Endangered Species Act, National Historic Preservation Act and Grand Canyon Protection Act.

These earlier comments also stressed that the stewardship goals of the Park Service for this EIS include necessary criteria to restore critical river corridor habitat of the threatened and endangered species within the Park's jurisdiction, and that this responsibility be tiered with the stakeholders of the Adaptive Management Program, especially the Fish and Wildlife Service, the Bureau of Reclamation, and First Nations.

The DEIS, however, has ignored this responsibility. It considers the fate of the Grand Canyon's broad ecosystem problems to be subservient to the Park Service's views on the needs and expectations of human visitation within the river corridor. This approach wholly ignores resource protection, the Park Service's prime directive.

As a result, the deteriorating river ecology in Grand Canyon will be exacerbated should Preferred Alternative H (Alternative H), as presented in the DEIS, be implemented. This alternative should be abandoned, and the Park Service should refocus the plan on developing a management plan that will first satisfy the urgent needs of the ecosystem, then address how visitors should interact with it.

To achieve this, the Park Service should implement the following:

1. Properly Define the Problem

This public process has been a valuable opportunity for the Park Service to build support for the prudent management of the resource. Indeed, most participants have indicated a strong preference for a healthy Grand Canyon ecosystem. What is controversial is the role humans will play in the management of Grand Canyon, and this must not be limited to visitation but other impacts as well, especially Glen Canyon Dam. Alternative H is a marginal job addressing the former, and pays little attention to other impacts.

Alternative H attempts merely to placate the wishes of non-commercial and commercial boaters, while doing nothing to benefit the resource. Indeed, Alternative H is little more than a political compromise arising from the historical controversy regarding human access to the river, with no regard for the health of the river itself.

Alternative H will not unite human interests behind the critical management goal of placing the resource first. What is good for the river is good for its visitors, but not vice-versa. The Grand Canyon cannot adjust to the demands of people, but people can and must adjust to the demands of the Grand Canyon. This is especially true now as the Grand Canyon's native river ecosystem is nearing a state of total collapse, and it's the job of the Park Service to reverse this. It is the resource that the public comes to visit. It should not be devoid of the ecology, which belongs there, because the Park Service is too focused on whom, how and for how long humans can play on the river. The Park Service has the legal, scientific, and public responsibility to redirect its approach to correct this.

2. Wilderness Management as a Preferred Alternative

Considering that the Wilderness Act contains provisions to improve the ecological integrity of wilderness areas such as Grand Canyon, Alternative B provides a more logical choice from which to develop the management plan. But this too, will require some enhancement.

For example, beaches and sandbars have diminished significantly because of Glen Canyon Dam operations. These sand deposits are essential for the recovery of endangered native fish, for preserving Traditional Cultural Properties (in-situ), and for human recreation. Guidelines must be established regarding the level of impact these critical habitat components can sustain. Alternative H wholly ignores this and advocates increasing use contrary to published reports from the Grand Canyon Monitoring and Research Center (GCMRC), and others, that conclude the habitat is degraded. If the resource cannot be sustained under the present use, how can this use be increased?

When looking at the sandbar situation alone, visitor numbers must be reduced. Moreover, as the beach habitat continues to decline, so should the number of visitors present in the river corridor. Visitor numbers must be determined by the amount of available sand in the system as determined by GCMRC monitoring information.

Conversely, the Grand Canyon beaches can only sustain more use if more sediment is supplied. The experimental flows of 1996 failed to provide any lasting sediment augmentation, and there is yet no evidence to suggest that further experimental flows will improve the situation. The Park Service has done little to assert its role as guardian of this critical habitat component. At minimum, the management plan should be arguing ways to improve the sediment/beach situation. The management plan should argue for seasonally adjusted steady flows while opposing load following generator operations, which have proven to be more detrimental to maintaining a minimal sand balance.

Given the extensive new information since new Glen Canyon Dam operational guidelines were first established, mainly the continued decline of endangered fish populations and the conservation of sediment, this management plan should establish as a priority an aggressive advocacy position for the river corridor within its capacity as a member of the Glen Canyon Dam Adaptive Management Program. The CRMP should demand that the river corridor receive the necessary sediment, and other habitat modifications, to allow for the recovery of endangered fish as directed by science.

Recognizing the inherent constraints built into the Glen Canyon Dam Adaptive Management Program, the CRMP should also require the Park Service to engage the Secretary directly if recovery efforts continue to fail. Specifically, the Park Service should advocate for a supplemental EIS on the operations of Glen Canyon Dam, to explore the full range of alternatives available to achieve endangered fish recovery in the Grand Canyon, including decommissioning the dam.

Another means of increasing camping sites within the river corridor is to more aggressively pursue the eradication of exotic vegetation, which has encroached on camping areas. The management plan should explore programs to engage river runners in such activities. Special permits should be available for river runners who want to participate in such restoration efforts. With proper training, supervision and tools, the exotic plant problems could be managed in a matter of years, at a limited cost. When completed, the camping carrying capacity could be adjusted upward accordingly.

3. Concerns for Threatened and Endangered Native Fish

a. The Refuge at the Little Colorado River

Since Glen Canyon Dam became operational the sole remaining rearing habitat for endangered Humpback Chub has been the Little Colorado River (LCR). In addition to the Park Service's recommendation to change human use regulations as described in the DEIS, swimming in the LCR should be eliminated until which time the recovery goals for the endangered fish of the Colorado River has been achieved. The only exceptions to this rule should be provided to the reasonable needs of the First Nations and the fishery biologists.

Living Rivers does not concur with the Park Service view that motorized trips have less impact on Humpback Chub than oar trips. A motorized boat should never approach the Little Colorado River for any purpose, including scientific research. Moving parts and

accidents from petroleum products must be avoided at all costs, especially until such time as it is demonstrated that the Humpback Chub is in full recovery.

Additionally, a component of this management plan should include an action item to mitigate toxic spills that might occur in the drainage of the Little Colorado River in and above the Grand Canyon.

b. Consultation by US Fish and Wildlife Service

The consideration of endangered and threatened native fish in the Colorado River at Grand Canyon within the DEIS is not adequate and requires consultation with the US Fish and Wildlife Service.

4. Climate Change and Global Warming

The Park Service must evaluate the impacts, and the Colorado River corridor management actions to be taken, should reduced water releases from Glen Canyon Dam occur as a result of drought and climate change.

The Department of Energy and others have advised water managers to expect the volume of water produced by the Colorado's watershed to be reduced significantly and progressively due to climate change. Their reports state that the Colorado River reservoir levels will be reduced by more than one-third and water releases by as much as 17 percent, which will result in reductions in hydropower generation by as much as 40 percent. Scientists have also warned that the Upper Basin may not meet its obligation to deliver its full requirement of water to the Lower Basin before 2010. Such changes in Grand Canyon will reduce fine sediment storage, concentrate rocks and boulders at rapids, degrade water quality and compromise fish recovery plans. They may also impact the types and number of boats that run the river, and the number of days it may take them to complete the trip.

5. Recreational Access to the River Corridor

The DEIS fails to solve the disparity of the access issue between commercial and non-commercial river runners. The DEIS largely favors access for concession contractors in the summer and non-commercial river runners in the winter. This suggests segregation and discrimination. Access should be equitable for all users and at all times. A common pool system, such as has been implemented at the Boundary Waters and the Deschutes River, is the access model that should be pursued by the Park Service in Grand Canyon.

Conclusion

Living Rivers recognizes the effort the Park Service has made in developing this DEIS. But it's clear that despite all the hard work, the Park Service has ignored its stewardship mandate as prescribed in the 1916 Organic Act. Without the natural ecological integrity of the river, which carved it, Grand Canyon itself loses its integrity, as does the Park Service and the stakeholders in this process. The principle objective of the Final EIS must be the restoration and recovery of the natural processes and native species to

Grand Canyon's river corridor that are impacted by the activities of humans, and with a management plan that articulates how this can best be achieved.

Thank you again for the opportunity to submit these comments on the DEIS.

Sincerely yours,

John Weisheit

Parched Colorado River Basin struggles to write drought plans

GREENWIRE Friday, February 11, 2005

WATER RESOURCES

April Reese,
Greenwire Southwest reporter

SANTA FE, N.M. -- For the first time since the Bureau of Reclamation began building the elaborate plumbing system to deliver water to Colorado River Basin states in the 1930s, the West is bracing for severe and potentially long-lasting water shortages.

Five years of drought and explosive growth in the basin's booming cities have drawn down reservoirs to half capacity or less as the seven states scramble for strategies to cope with what some meteorologists predict could be a 20-year dry spell.

The states are facing a federal ultimatum: Write a drought plan by April 1 or have one imposed by Interior Department bureaucrats.

"Although we do not know how long or severe the drought will be, we must face our collective responsibility to plan for the likelihood that water supplies may be limited in the lower basin over an extended period of time," Interior Deputy Secretary Steven Griles warned the Colorado River Water Users Association in December.

Droughts are notoriously hard to predict. So while some basin states -- Arizona, New Mexico and Utah -- have been periodically soaked since last fall, it's too early to say if the increased precipitation is an anomaly or the end of a dry spell that's now in its sixth year. Scientists say the conditions now are similar to those that plagued the West in the 1950s, the region's last major drought.

"One good year doesn't solve the drought," said Dennis Underwood, vice president of the Metropolitan Water District of Southern California. "It would take a number of years of good years like this to recover."

Even if the heavens open and the basin recovers quickly, the experience of the past few years underscores the need for a drought strategy, water managers say.

Booming population stresses Colorado River

Called the "River of the West," the Colorado supplies water to 25 million people and 3.5 million acres of farmland. Under the Colorado River Compact, the landmark agreement for managing the river signed by the states' delegates in 1922, water is divided between the upper basin states -- Colorado, New Mexico, Utah and Wyoming -- and the lower basin's Arizona, California, and Nevada.

Each basin receives 7.5 million acre-feet a year under the compact, and Mexico receives 1.5 million acre-feet under a separate agreement. An acre-foot is the volume of water covering an acre to a depth of a foot, translating into 325,851 gallons -- a year's worth of water for two households of four.

Until now, the river and region's two biggest reservoirs, Lake Powell and Lake Mead, have yielded enough water to ensure that all the states received their allotted shares.

But population growth in the basin has worn thin the safety net provided by the water management system. The river's water is already over-allocated, and the Bureau of Reclamation reports that Lake Powell was just 35 percent full and Lake Mead 58 percent at the start of February.

As water supplies have declined, population has grown. Between 1980 and 2000, the West's population increased 47 percent. There were 1 million people living in Arizona in the 1950s, for example; today, the state is home to almost 5 million.

So rain or shine, the states must keep working hard on their water-shortage plans. During a speech in Denver last week, Interior Secretary Gale Norton tried to keep the pressure on the states. "I trust that the basin states will continue to work with us on drought mitigation strategies," she said. "Time is of the essence."

The basin's water managers say the basin will eventually draft a water shortage plan that everyone can agree on, but probably not in time to meet Interior's deadline. "There's not going to be shortage criteria in April," said Larry Dozier, deputy general manager of the Central Arizona Project, which delivers water to the Phoenix and Tucson and regional farmers. "That's a given."

The states have agreed to come up with recommendations for a shortage strategy by mid-April, to be followed by a plan in the ensuing months, according to Dozier and other state officials who participated in a conference call with Interior last Friday. The plan will be folded into an environmental impact statement and vetted through a public process dictated by the National Environmental Policy Act. The EIS would probably take about two years, they said.

Strategies start taking shape

Two strategies being mulled by the states appear particularly promising, Anderson and other water officials say. One calls for building a small reservoir in the lower basin to capture "over-delivered" water that would otherwise run downstream after storms, and starting the Yuma desalting plant in southwestern Arizona. Building the new reservoir and cranking up the desalting plant would save about 200,000 acre-feet of water a year.

Getting the Yuma plant running would, in effect, provide a new water source for Mexico, freeing more water from the Colorado River that could be diverted upstream for the states (Land Letter, Aug. 21, 2003).

Even though it would be expensive to bring the Yuma plant on line -- the bureau has put the price tag at \$25 million -- avoiding economic damage from water shortages could make the project worth it, said Dennis Underwood, vice president of the Metropolitan Water District of Southern California.

"It's like your car or your house," said Underwood, who was a former BuRec commissioner when the agency discovered the plant's design flaws. "If you keep deferring the maintenance, eventually you pay the price."

The basin states are also considering changing the operations of the river's two biggest reservoirs to balance declining water levels. When Lake Powell's levels rise, for example, it could release water so Lake Mead recovers more quickly, water managers say.

Several states have taken their own steps to deal with the drought as well, including paying farmers to temporarily fallow their lands and "banking" water in underground storage or in neighboring states for future use.

If Norton were to order water cutbacks in the basin -- something no Interior secretary has ever done -- the Central Arizona Project would be the first area hit because it is considered a junior partner under terms of the river compact.

Central Arizona officials say the hierarchy is unfair. They urge that all the states share the pain of a shortage equally, but they recognize their chances are slim. "We'd love to get that changed, but the political stars have to be aligned just right," Dozier said.

So far, the drought's pain has been greatest in the upper basin. Under the compact, the upper basin states must deliver 8.23 million acre-feet to the lower basin states and Mexico. The upper basin has met that obligation, but at a price. Farm production is down 40 percent in many areas, the Upper Colorado River Commission says. Meanwhile, the lower basin continues to receive its full share of Colorado River water, lessening the impact of the drought there (Land Letter, Oct. 7, 2004).

Just as drought and population growth test the limits of the Colorado River delivery system, the rules of the compact appear to be at odds with the basin's hydrology, providing a perverse incentive for the states to use as much of their legal share of water as they can. By storing water for Nevada, Arizona will take more of its Colorado River apportionment -- a strategy it hopes will buffer it against any future claims on unused water, most likely by California (Land Letter, Dec. 9, 2004).

And Colorado, concerned that the drought could force cutbacks in the upper basin, is exploring ways to tap its unused Colorado River water. It has said it will take the necessary steps to defend its water rights in case an interstate shortage strategy fails.

Despite their different agendas, the basin states share a common desire to come up with a fair solution to deal with potential shortages and stay out of court, water officials said.

"People are always predicting these big fights in the basin. ... But we've mostly been able to stay away from that, and I think that is the goal of every state -- not to go to court," said Larry Anderson, director of the Utah Division of Water Resources. "We certainly want to determine what our own destiny is, and not leave it up to the hands of judges."

LR Letter 02/18/05

Moab Mill tailings pile: Comments DOE's DEIS

February 18, 2005
Mr. Don Metzler
Moab Federal Project Director
U.S. Department of Energy
2597 B 3/4 Road
Grand Junction, CO 81503

Re: Remediation of the Moab Uranium Mill Tailings, Grand and San Juan Counties, Utah, Draft Environmental Impact Statement (DOE/EIS-0355D).

Dear Mr. Metzler,

Living Rivers, Colorado Riverkeeper, Colorado Plateau River Guides, River Runners for Wilderness and Colorado Outward Bound West submit the following comments concerned with the Draft Environmental Impact Statement (DEIS) for the Moab Uranium Mill Tailings. Collectively our mission statements promote protection of the natural and cultural heritage of rivers. We would like to thank the Department of Energy (DOE) for their efforts to prepare this DEIS for public review and appreciate this opportunity to participate.

1. Summary

It is our position that the Moab Mill's tailings pile be moved by the existing railroad to an off-site disposal area in the Mancos shale deposits north of Moab. We agree with the Environmental Protection Agency that the Off-Site Disposal Alternative at Crescent Junction is superior to the disposal alternative at Klondike Flats. The site at Crescent Junction is more isolated from human activity, has a thicker deposit of shale and is more protected from the agents of erosion.

It is also our position that the ground water pollution from the Moab Mill site should be remediated to successfully remove all jeopardy to the threatened and endangered species of the Colorado River downstream, including the wetlands of the Moab Sloughs. We are convinced that this can not be accomplished by leaving the pile capped on-site and adjacent to the Colorado River.

Our position also includes moving the pile off-site to eliminate future risks to human health for residents of developed areas along the Colorado River downstream, and to the visitors of federally protected public lands downstream. These public lands include the national parks at Canyonlands and Grand Canyon, the national recreation areas at Glen Canyon and Lake Mead, and the wildlife refuges of the Lower Colorado River Complex. This also includes the water users identified by the Colorado River Compact, specifically Arizona, Nevada, California and the Republic of Mexico.

It is also our position that the White Mesa Mill Alternative in San Juan County should be abandoned for the reasons stated by the Ute Nation from the White Mesa Reservation, as presented to the DOE at the public meeting held there on January 27, 2005. This alternative will affect the Ute Nation's quality of life and their values concerning the protection of their cultural heritage and their sacred sites.

The DOE must also acknowledge the official position of the City Council of Moab and Grand County Council, which have identified the Off-Site Disposal Alternatives at either Klondike or Crescent Junction as superior. This alternative will meet the objectives and goals of the local citizens in order to remove them from environmental and social harm.

The members of our organizations that live in Grand County strongly object to moving the toxic contents of the Moab Mill site to any other county in Utah. This is a Grand County problem and the impacts from these toxic materials should not be passed on to our neighbors in San Juan County.

2. The DOE is unsuccessful in removing doubt concerning the compromise of the On-Site Disposal Alternative during a probable maximum flood

We are convinced that the tailings pile at the Moab Mill must be moved away from the Colorado River because the suggested reasons identified with the On-Site Disposal Alternative in the DEIS are, at best, speculative.

a. The Moab Mill site was originally chosen for reasons of convenience and not for reasons of providing long-term environmental protection from the consequences of historic flooding along the Colorado River.

b. The federal government has already moved uranium waste piles away from the floodplains of the Colorado River and its tributaries and it is reasonable to expect the federal government to remain consistent with this precedent.

c. Independent scientists have demonstrated that it is reasonable to suggest that Colorado River flooding may compromise the Moab Mill's tailings pile during a probable maximum flood in the next 200 to 1000 years. That ground water remediation may not be geologically feasible with the pile capped in place. These scientists are associated

with the National Academy of Sciences, U.S. Geological Survey and academics from the state universities at Salt Lake City and Tucson.

d. The Bureau of Reclamation manages high dams, both concrete and earthen, on the Gunnison and Dolores rivers. These dams will likely be decommissioned in the next 200 to 1000 years. At some point in this time-period these dams will no longer provide flood control for the downstream environment. It is also possible that, as these dams age and fill with sediment, the spillway mechanisms will experience flood flows greater than the original design specifications, which could result in a possible catastrophic breach that could subsequently compromise a tailings pile capped in place at Moab Valley.

e. The threat of flooding that could compromise the On-Site Disposal Alternative is significant when considering the intent behind the legislation for protection of downstream resources. This legislation includes the National Park Service Organic Act, the National Historic Preservation Act, the Clean Water Act, the Rivers and Harbors Act and the Endangered Species Act. This would also include Executive Orders such as #11990 (wetlands protection) and #13007 (sacred sites).

3. The DOE must ensure consultation with the work performed by the University of Utah at Salt Lake City and the University of Arizona at Tucson

We request that all findings from Mr. Phil Gardner and Mr. Kip Solomon, at the University of Utah at Salt Lake City, be included as a part of the public record for the Final Environmental Impact Statement (FEIS). These studies indicate that ground water remediation at the Moab Mill site would best be served by moving the pile from the river.

We also request that all findings, pending the completion of work now being performed by Mr. John Dohrenwend and Mr. Victor Baker from the University of Arizona at Tucson, be considered as part of the public record for consideration by the FEIS. These studies will concern the effects of a probable maximum flood at the Moab Mill site and would serve as a valuable exercise in the peer-review process of DOE's contractor-based science and engineering reports that are deemed speculative.

We would also request that the work already completed by Mr. Dohrenwend be submitted as part of the public record for the FEIS. Mr. Dohrenwend's reports were recently published in the Times-Independent, the weekly paper of Grand County. By using existing photographic evidence from over-flight and satellite imagery, Mr. Dohrenwend has demonstrated that the findings of the DOE contractors concerning river migration are speculative and that a reasonable doubt does exist to conclude that the Moab Mill site could be compromised by a probable maximum flood.

4. The DOE must ensure consultation with applicable federal agencies

The DEIS is not thorough because consultation with the Bureau of Reclamation (Bureau) was not sought in an official capacity. This is an oversight on the part of the DOE that must be corrected. The Bureau is the federal regulatory agency that has jurisdiction over water quality for the Colorado River. The Bureau is also a partner in the Upper Colorado River Endangered Fish Recovery Program and the Lower Colorado

River Multi-Species Conservation Program. The Bureau has already produced publications analyzing and modeling a probable maximum flood in the Colorado River drainage and their expertise in this regard should be fully considered.

Some of the dams that the Bureau has designed have had engineering components that have become problematic. Some Bureau dams have failed entirely, such as Teton Dam. The Colorado River basin dams that have had design problems include Fontenelle, Flaming Gorge, Navajo, Glen Canyon and Hoover. The problems include seepage erosion at the earthen dams and river outlet and spillway failures at the concrete dams.

Living Rivers brought this oversight to the attention of the Bureau of Reclamation at Salt Lake City on January 27, 2005. We formally ask DOE that consultation with the Bureau is initiated and that their comments be included in the FEIS.

We also remind DOE that a full consultation with the U.S. Fish and Wildlife Service (USFWS) concerning the Endangered Species Act is required for the FEIS. This would include the reasonable and prudent alternatives of USFWS's Biological Opinion.

We also request consultation with the U.S. Geological Survey in the FEIS concerning this agency's recent analysis and modeling of a probable maximum flood in the Moab Valley; Report 2005-5022 became publicly available on February 11, 2005.

We also request that the State Department should be allowed to weigh in on FEIS concerning U.S. treaty obligations with the Republic of Mexico, and because the Colorado River delta has been designated as an International Biosphere Reserve.

IV. Global warming and climate change

The DOE sponsored the Accelerated Climate Prediction Initiative (Initiative), which was administered by the Pacific Northwest National Laboratory. Much of the consequent analysis and modeling from this Initiative has been recently published and would be useful in the consideration of alternatives for the Moab Mill's tailings pile. We request the DOE consult with the principle scientists of the Initiative for the FEIS concerning the effects of climate change on the Colorado River. The report of the Initiative acknowledges that extreme variables of climate are likely to occur and due to the impacts of increasing greenhouse gases in the atmosphere. Examples of impacts from climate change would include reduced water quality as a result of diminished flows, increased sediment loads, channel narrowing of the river, and catastrophic flooding in local and regional watersheds.

V. Cost analysis

Human health, national parks, endangered species and cultural heritage are priceless things. We will support the DOE to save taxpayer money so that the savings could be applied to other worthwhile service projects to protect the general health and welfare of the American people. However, because it is reasonable to assume that the On-Site Disposal Alternative may fail and that subsequent clean-up costs would be astronomical, the On-Site Alternative should be abandoned for reasons that it would

potentially save taxpayer's money in the long-term. The Off-Site Disposal Alternative, though more expensive, provides greater economic and environmental security. The additional cost is therefore justified and potentially serves to be the most affordable alternative in the DEIS.

VI. The river community

People depend on the Colorado River for economic security and for the enrichment of their lives through visitation at Canyonlands National Park and Glen Canyon National Recreation Area. Living Rivers, Colorado Riverkeeper, Colorado Plateau River Guides, River Runners for Wilderness and Colorado Outward Bound West represent various parts of a constituency we call the river community. The intent of this community is to partake in the organizing and participation of river trips through Canyonlands National Park and Glen Canyon NRA. The reasons include recreation, employment, education in the sciences and arts, and the monitoring of the Colorado River's environmental quality and cultural heritage.

The professional river guides represent the day-to-day users of the Colorado River. Over 300 active professional river guides have hundreds of multiple-day river trips and thousands of one-day trips that have spanned a career, for some, as long as 40 years. Their clients (numbering in the thousands annually) include the general public, special populations, and educational and cultural institutions. Another large constituency of the Colorado River users that are represented by the thousands are the non-commercial river runners who come to enjoy the benefits of Canyonlands National Park for the same reasons as stated above, which includes employment through incidental support services.

The On-Site Disposal Alternative must be abandoned for the reasons that this river community would suffer economic and social hardships should the Moab Mill's tailings pile fail in a probable maximum flood with the eventual outcome of irradiating the river corridor of Canyonlands National Park and Glen Canyon NRA. This could also affect the river community of Grand Canyon National Park and Lake Mead NRA.

In conclusion the risk to the downstream ecosystems and the health of millions of people is much too high to justify keeping the Moab Mill site along the shores of the Colorado River. The principle objective of the Final EIS must be the safe removal of the pile from the Colorado River, to stop the groundwater contamination of the Colorado River and the Moab Sloughs, and to contain these toxic materials at an off-site location in a responsible and efficient manner.

Thank you again for this opportunity to provide comments. Please do not hesitate to contact us should you require assistance in regard to this letter.

Sincerely yours,

John Weisheit, Conservation Director
Living Rivers and Colorado Riverkeeper

Communities still face drought, tree-ring researchers say

Tree rings in West indicate drought may not be abating
Scientists say wet periods are not historically uncommon in the midst of long dry spells

By Arthur H. Rotstein
The Associated Press

TUCSON, Ariz. - A vigorously wet winter has buoyed spirits in Arizona and other Southwest states parched by drought. But history recorded in tree rings suggests it's far too soon to even think the region is near an end to its long dry spell.

Researchers say tree rings have shown that wet periods aren't uncommon during droughts. So the wet weather that has greened up Arizona, made dry rivers run and even caused flooding isn't necessarily a sign of things to come.

Wet breaks in past big droughts usually have lasted only a year or two before a return to dry conditions, said David Meko, a principal researcher at the University of Arizona's Laboratory of Tree-Ring Research.

Scientists can see a historical record of past droughts by looking at the thickness of a tree's rings. Since trees grow more during wet periods, the rings will grow thicker at those times. Trees grow less in dry times so those rings will be thinner.

According to tree ring analysis, there have been numerous extended droughts throughout the West over the last 500 years. The current drought has been partly blamed for the proliferation of tree-killing insects and has contributed to enormous wildfires of recent years.

How long it takes to overcome a drought varies.

Building up depleted reservoirs, restoring soil moisture and allowing vegetation to recover, particularly trees whose crowns and roots have been damaged by prolonged lack of water, could take years, said Thomas Swetnam, director of the tree ring laboratory.

"This is a deep deficit, many years in the making," said Kelly Redmond, Nevada state climatologist with the Western Regional Climate Center in Reno. "You wouldn't want to see the kind of thing that would get you out of it in one year," because it would mean inundation and massive flooding, with its own consequences, he said.

Besides, Redmond said, only part of the West has really seen strong rain or snowfall: California, most of Utah and Nevada, Arizona, New Mexico and southern Colorado. Elsewhere, it's been lackluster at best, he said. Still, some people are just happy to see the wet weather that has been moving regularly through the area in recent months.

"The lakes are filling and it looks pretty promising," said Bob Prosser, who runs the Bar-T-Bar Ranch in northern Arizona. "I think it's late enough and wet enough that it'll certainly do some good." At a minimum, he said, he'll have a good forage crop for his cattle this spring.

Bob Ginn, a retired Air Force colonel and flight instructor in Tucson, said he sees the rainfall "as a definite plus."

"I like the rain as a change from normal Tucson, dry and windy, and I like what it does because we garden, and I'm somewhat of a nature photographer so I expect a lot of wildflowers," Ginn said.

Moab tailings could wash into Colorado River

Moab tailings could wash into Colorado River
A matter of when, not if, U. professor says of uranium-mining waste

By Joe Bauman Deseret Morning News

If the Moab uranium tailings pile stays where it is, eventually a big flood will wash it into the Colorado River.

"Not could. It will happen. It's just a matter of when," says one of the authors of a report on the subject, D. Kip Solomon, a University of Utah professor of geology and geophysics.

Even if no giant flood hits in the near future, radioactive and chemical contamination apparently has leached from it and migrated under the river. On the other side of the Colorado are a nature preserve and the city of Moab.

About 11.9 million tons of uranium tailings and contaminated soil were left near the Colorado River, three miles northwest of Moab, when Atlas Minerals Corp. stopped production in 1984. According to the U.S. Department of Energy, the wastes cover 130 acres and were placed in an unlined impoundment.

Atlas "placed an interim cover over the tailings pile in 1995," the DOE adds. The department has been preparing an environmental impact statement about what to do with the tailings, which at the closest point reach to within about 1,000 feet of the river.

Gov. Jon Huntsman Jr. recently wrote to the DOE expressing his determination that the pile should be hauled away from the river as soon as possible.

"Recent flooding in the St. George and Santa Clara regions of Utah also demonstrated the swift and immense force of moving water in the desert," he wrote.

Huntsman's concerns are backed by studies, including one published in December 2003 by Solomon and Philip Gardner, a graduate student at the U.

DOE studies found ammonia and uranium in gravel below the Matheson Wetlands Preserve across the river, the researchers wrote.

"The magnitude of these concentrations and the location of the highest values suggest that groundwater from the mill tailings is flowing under the Colorado River and impacting groundwater" beneath the preserve, they added.

"We believe that there are fluids that have migrated underneath the river," Solomon said in a telephone interview.

Contrary to earlier expectations of the DOE, the river was not a barrier to the flow. A lot of contaminated fluids are discharging into the Colorado, he added. But some of it goes under the river to the Moab side.

Whether this occurs depends on the amount of water in the river and how much groundwater pumping is going on.

When the uranium mill was working, operators leached out material they needed by pouring fluids on the tailings. This caused material to leak out of the pile.

"They were pushing fluids beneath the river toward Moab," he said. Now that operations have ceased, whether the flow is still occurring "is a little uncertain."

The study uncovered "very, very permeable gravel deposits beneath the mill tailings, beneath the river and beneath the entire Matheson Wetlands Preserve," Solomon added.

Permeable gravel is important for two reasons, he said:

- The layer amounts to a hydrological "superhighway." It's a pathway along which groundwater can migrate under the river. If enough pumping takes place on the tailings side, water might flow toward it. If the reverse is true, water could flow from the tailings toward Moab.

In that case, some controls may be possible through pumping.

- The "very coarse gravels" show that the Colorado River has flooded in the past, bringing in gravel and boulders. "The river has migrated laterally over very large distances through geologic time," he said.

Above the gravel is about 15 feet of fine, silty material. The tailings are on top of the silt, approaching within 1,000 feet of the river in one place.

The tailings amount to "a house that's literally built on sands and silts," Solomon said. "They're not founded on any really competent material," meaning they could easily wash away.

At 24 and 30 feet below the surface, geologists uncovered organic material. A lab in Florida checked the age of the wood and peat through carbon dating.

Radiocarbon dates for samples from the two floods ranged between 1860 and 1980 for the most recent, and between 990 and 1090 AD for the earlier material. That is about when flood waters carried them in.

The samples were taken from a bore hole on the Moab side of the river. But the debris indicate the river's violence throughout the zone.

The report by Gardner and Solomon explains, "The radiocarbon ages of these two samples indicate that there have been two flood events in the last 1,000 years that have scoured down to 24 and 30 feet below present land surface, respectively, at a distance of more than 260 feet from the present river channel."

During January's flooding, the Santa Clara River in southwestern Utah rapidly ate away at its banks.

"The biggest meander was 700 feet," said Jan Sandberg, engineer for the city of St. George. "There was a lot of meandering in lots of areas." "In the city of Santa Clara, it took a huge bite, took out a bunch of prime real estate," said Dean Cox, emergency services director for Washington County.

An erosion of 700 feet would not quite bring the Colorado River onto the Moab tailings. But the Santa Clara destruction happened with just one flood, and that river is far smaller than the Colorado.

If a big enough flood were to race through the Colorado, said Dianne Nielson, executive director of the Utah Department of Environmental Quality, "We're going to have uranium mill tailings strewn along the banks and sandbars along that river for distances downstream."

That, Nielson added, is unacceptable.

Another Step towards Extinction for Grand Canyon Native Fish

March 3, 2005

For immediate release

Contact:

John Weisheit - (435) 259-1063/(435) 260-2590

Another Step towards Extinction for Grand Canyon Native Fish

Recovery Experiments Fail Again

Phoenix, AZ. Leaders of the ten-year old federal program responsible for guiding recovery of endangered native fish in Grand Canyon National Park are undertaking their annual meeting today amidst a climate of mounting bad news.

A major experiment they undertook last November has likely contributed to further declines in fish counts, pushing the dwindling Humpback Chub population much closer to extinction.

Known as the Glen Canyon Dam Adaptive Management Working Group (AMWG), the team is charged by the Secretary of Interior to reverse the environmental decline of Grand Canyon's river ecosystem resulting from the operation of the 710-foot Glen Canyon Dam upstream.

New data being discussed at today's meeting reveal that a key recovery indicator, the number of juvenile fish, declined 63 percent following an experimental release from Glen Canyon Dam that began on November 21.

"It is very unfortunate for Grand Canyon's resources that the Adaptive Management Working Group is faced with an impossible task, as these declining ecosystem conditions simply can't be mitigated with the dam in place. Rather than report this fact to the Secretary of the Interior, they continue to tinker with expensive minor adjustments in dam operations that always have failed to achieve any meaningful long-term success," says David Haskell, policy director for Living Rivers. "They've spent nearly a decade tinkering with Glen Canyon Dam's operations while the ecology of Grand Canyon continues to collapse."

Adult fish populations have been estimated to be as low as 1,000 as compared to 8,517 in 1993, the year following passage of the Grand Canyon Protection Act. The 90-hour, 41,000 cubic-feet-second release was supposed to help restore beach and sandbar

habitat for the native fish. Ninety-five percent of the sediment and nutrients Grand Canyon would normally receive are now trapped behind the dam. The experiment was designed to work with inputs of sediment from the tributaries below Glen Canyon Dam in an effort to preserve and redistribute the five percent that is still available.

Analysis following the flows revealed that indeed improvements in sandbar habitat had occurred, but the high dam release, a winter storm, or both, caused the young Humpback Chubs to be flushed downstream into Lake Mead.

Additionally, as was documented following a similar experiment in 1996, these habitat improvements are only temporary as the sandbars are again deteriorating due to a lack of continued inputs from upstream.

"At best this can be described as a more successful failure," adds Haskell. "These experiments, will never succeed because they ignore fully restoring the natural processes the native fish require, which includes the pre-dam flow of sediment and nutrients."

Because of the ongoing decline of endangered native fish, Living Rivers and coalition of 200 groups across the country are calling for a new Environmental Impact Statement of Glen Canyon Dam that evaluates the merits of decommissioning the dam to achieve habitat recovery and restoration in Grand Canyon. ###

Data shows dam had negative effect on fish

By SALLY SPAULDING The Daily Sentinel

An experiment at Glen Canyon Dam designed to build beaches below the dam may have damaged endangered fish, according to preliminary data.

Initial results from the November experiment show evidence that young fish in the river system declined during the experimental high flows released from the dam for 60 hours in late November. That may mean a decline in young endangered fish such as the dwindling Humpback Chub.

"We caught two-thirds fewer fish when we sampled after the experiment," said Lew Coggins, a fish biologist with the Grand Canyon Monitoring and Research Center, the science division of the Glen Canyon Dam Adaptive Management Program that is charged with maintaining the Grand Canyon's river ecosystem.

"We anticipated, at least in the short term that (the experiment) would have somewhat of a negative effect on young fish in the system, and we saw some evidence of that," Coggins said.

Coggins said it was speculation, however, to say the number of juvenile fish in the system truly dropped by two-thirds, saying testing conditions changed because of flooding during sampling times.

The turbid water during sampling after the experiment made it difficult to say the data was conclusive.

Coggins said the experiment was not designed to benefit endangered fish but was focused on building new beaches.

That's what bothers environmental groups such as Living Rivers, a Moab-based group that advocates the decommissioning of Glen Canyon Dam.

"Beaches are short-term successes because it will continue to wash down to Lake Mead without more sand being allowed into the system," said David Haskell, policy advisor for Living Rivers. "Beaches only last a few months, and the fish are suffering."

Sally Spaulding can be reached via e-mail at sspaulding@gjds.com.

Efforts to Hide Sensitive Data Pit 9/11 Concerns Against Safety

New York Times

By CHRISTOPHER DREW

They are just pieces of cardboard, and they cover less than a square foot on the side of railroad tank car. But behind them lies a post-9/11 competition between public safety and national security.

For decades, emergency-response teams approaching train wrecks have peered at the signs through binoculars to see what dangerous chemicals might be leaking. But federal officials will soon decide on a proposal to remove the placards from all tank cars. Their fear is that terrorists could use them to lock in on targets for highly toxic attacks.

The idea has sparked an outcry from firefighters and rail workers, who say removing the signs could endanger their lives. They say federal officials seem more focused on guarding against a terrorist attack than on the daily threat of accidents.

"There's this feeling that you have to secure everything possible in every way possible for every possible kind of terrorist attack," Garry L. Briece, executive director of the International Association of Fire Chiefs, said.

The dispute illustrates a growing push to mask sensitive data about the nation's industrial base from the prying eyes of potential terrorists. In the tug of war over tank cars and other industrial information, critics question whether the move toward secrecy is overwhelming safety concerns and even chilling debates over how to eliminate the vulnerabilities.

People who live near chemical and nuclear plants, dams and oil and gas pipelines complain that it has become harder to find out about disaster plans and environmental hazards, and some have sued for more information. Engineering reports have been stripped from government Web sites, and several agencies are creating new controls on sensitive information that go far beyond the wide-ranging classification system built in the cold war.

Federal officials say although they are trying to strike a reasonable balance, some clashes are inevitable, and more are likely to occur. If delicate information leaks out, "it gives our adversaries too much of a picture of what our vulnerabilities are," Jack L. Johnson Jr., chief security officer at the Department of Homeland Security, said.

Internal government e-mail messages show that months before the train bombings last March in Madrid, transportation officials stopped the Defense Intelligence Agency from releasing a report on rail vulnerabilities in the United States.

The messages, which were obtained by The New York Times from a former federal official, show that the report was intended to spark debate among officials on improving rail security. But after complaints from the industry, one senior transportation official helped block the report by arguing that if it became public "I could foresee this paper being a handout in the next session of Al Qaeda's rail-attack course."

A similar secrecy question is unfolding in Washington. On Tuesday, the District of Columbia Council extended a ban on shipping hazardous cargo through Washington.

Even as it opposed the ban, the CSX railroad company quietly re-routed some cargo away from Capitol Hill last spring. But citing security, railroad and security officials refused for months to tell the Council about the rerouting. It turns out that the railroad simply shifted the cargoes to tracks in other neighborhoods. Federal and railroad officials said the other tracks seemed less likely to be targets.

A Council member, Kathy Patterson, said, "There was just a total alliance between the homeland security and railroad officials that was very disheartening."

Another hot area of debate over secrecy is the atomic energy industry. The Nuclear Regulatory Commission has stashed away an enormous trove of documents about nuclear power plants, suspending access to much of its Web site while weeding out reports that might aid terrorists.

A spokeswoman for the commission, Sue F. Gagner, said that access to 380,000 documents was suspended last October and that 120,000 had been made available again.

"We think it's very important to be diligent about having information that could potentially be helpful to a terrorist," Ms. Gagner said.

The commission has also issued classified orders on how the plants guard against terror attacks, and citizens' groups have been fighting in court to demand public input.

"You can hide the information, but if the vulnerability still exists, the bad guys will find it," said Gary D. Bass, executive director of OMB Watch, a group in Washington that supports more openness. "So let's reduce the vulnerability instead."

Mr. Bass said similar debates had prompted some complexes like a sprawling sewage plant in Washington to switch to less-toxic chemicals.

In some instances, new dictates have eclipsed broader health and safety concerns.

Living Rivers, an environmental group in Utah, sued a federal agency after it had refused to release flood maps showing what areas would be inundated if major dams failed. A federal judge ruled for the agency, saying he agreed that releasing the maps "could increase the risk of an attack on the dams."

The shift to greater secrecy began after the Sept. 11, 2001, attacks. Mr. Johnson, of the Homeland Security Department, said a captured training manual showed that Al Qaeda

expected to glean 80 percent of what it needed to plan attacks in the United States from open sources.

The government has turned to a smorgasbord of new controls for withholding sensitive - but unclassified - information.

The Homeland Security Department has designations like "Sensitive Homeland Security Information" and "Protected Critical Infrastructure Information." Airport workers use "Sensitive Security Information" to hold back the details of pat-downs. The Federal Energy Regulatory Commission stamps "Critical Energy Infrastructure Information" on pipeline maps.

Officials said many companies had long resisted disclosing security flaws to the government out of fear of leaks. Mr. Johnson said that the department was blending what it obtained from the companies with intelligence about terrorist intentions and that it intended to share much of that analysis with local officials who agree to keep it confidential.

Sometimes the battles are more visible. Since chlorine leaking from a derailed tank car killed nine people and injured hundreds last month in South Carolina, the fight over the railroad placards has emerged as the most potent symbol of the debate.

The Homeland Security and Transportation Departments have been considering whether to remove the placards since August.

Firefighters, railroad workers and large chemical companies are adamant about keeping the placards. Statistics show that chemicals leak from dozens of rail cars a year and that deaths occur periodically.

The chlorine placard is black and white. It has a skull and crossbones and the number 1017, the chlorine code. Without placards, "we'd be completely in the dark" at many crashes, said Joe Ashbaker, a supervisor in the San Bernardino County Fire Department in California.

The railroads have their doubts. "We were for the placards, until 9/11, when it became clear they presented a security risk," the industry's lobbying group, the Association of American Railroads, said in a statement.

The railroads also say they are working to create a system that meets security and safety needs.

But two studies by the Transportation Department have shown that the alternatives, electronic systems that could transmit lists of chemicals on a train by radio or satellite, would be more expensive, cumbersome and less effective on safety. Texas A&M University is finishing another study.

Jamie Conrad, a lawyer for the American Chemistry Council, which lobbies for large chemical makers, said he could see how a placard might "advertise a little bit" the best cars to attack.

"But where we come down is that if you take it off, you know that people will be killed in accidents," Mr. Conrad said. "And you're basically balancing that against the theoretical prospect that terrorists might be lurking on that corner."

Walt Bogdanich and Jenny Nordberg contributed reporting for this article.

Fish numbers drop after Grand Canyon flood

ARTHUR H. ROTSTEIN

Associated Press

TUCSON, Ariz. - The number of juvenile endangered fish recovered in the Colorado River declined dramatically after officials flooded the Grand Canyon in an effort to aid them and their fragile ecosystem. But scientists aren't sure what the fish decline means or why it happened.

"We're trying to get the same answer," said Jeff Lovich, chief of the Grand Canyon Monitoring and Research Center in Flagstaff. "We don't know what their fate is."

Following a 90-hour experimental water release from Glen Canyon Dam into the canyon in November, 63 percent fewer endangered humpback chub juveniles were trapped than before flooding.

Lovich said there are three possible explanations: The fish were washed downstream, they died, or they're still in the river and scientists couldn't accurately sample them after the simulated flood.

During the flooding, the Bureau of Reclamation released as much as 41,000 cubic feet of water a second from four of the dam's giant steel tubes. Scientists hoped to redistribute 800,000 metric tons of sediment to create beaches, substrate used by plants and backwaters and pools to help the fish breed.

The dam, built 40 years ago to assure the West's water supply, has altered the landscape dramatically. The chub is the last of four endangered fish species surviving in the canyon and one of only four native species of fish left among eight that once swam through it.

Scientists set out hoopnets centered around the mouth of the Little Colorado River - a spring-fed tributary into the Colorado - and at two other locations downstream to catch the juvenile humpback chubs to count, tag and release before the flooding.

The fish, which belong to the minnow family and spawn primarily in the warmer-water Little Colorado, were counted again after flooding.

The fish caught after the flooding tended to be somewhat larger, up to a bit over 7 inches in length. That suggested that the smallest fish declined most significantly, said Lew Coggins, a fisheries biologist.

Water releases from the Glen Canyon Dam are much colder, generally between 46 and 54 degrees Fahrenheit. The humpback chub's eggs have a much higher survival rate in the Little Colorado's temperatures of about 61 degrees.

Scientists are looking at installing temperature control devices in the future to release warmer water closer to the surface of the reservoir.

They also note that sampling conditions were different during the flood because of an unexpected natural flood in the Little Colorado.

"We have to admit that all of our results have to be interpreted with that caveat - that we had different conditions," Coggins said.

The change in conditions could have affected fish behavior.

"People want to know right now what did the fish do, and sampling showed this reduction of about 63 percent," Lovich said. "But we don't have the answer right now."

Officials estimate there may be about 3,000 fish in the Grand Canyon today, down from about 10,000 in the last decade.

Environmental critics such as Living Rivers, based in Moab, Utah, said the flooding likely pushed the dwindling chub population closer to extirpation. It contends that the dam, which creates Lake Powell along the Arizona-Utah line, is exacerbating the collapse of the Grand Canyon's ecosystem and should be decommissioned.

"It makes sense to get rid of Glen Canyon Dam, because it's the one changing the ecosystem of the Grand Canyon," said spokesman John Weisheit. "It's dying."

Glen Canyon Dam experiment brings mixed results

April Reese
Land Letter Southwest reporter

SANTA FE, N.M. -- Three months after an experiment aimed at improving habitat for the endangered humpback chub in the Grand Canyon, the preliminary results are in, and it appears the fish did not fare well.

Following a 90-hour experimental release of 224,000 acre-feet of water from the Glen Canyon Dam into the canyon in November, the number of juvenile humpback chub dropped 63 percent, according to Barbara Ralston, a biologist with the Grand Canyon Monitoring and Research Center.

Ralston said that other factors aside from the test flow may have contributed to the decreased numbers. Natural flooding in the Little Colorado River may be partly to blame for the flushing of the fish downstream or scientists may have undercounted the fish in muddy, post-flood conditions, she said.

During the flooding, the Bureau of Reclamation released water into the canyon at a rate of 41,000 cubic feet per second (cfs) from four giant bypass tubes. Scientists and dam managers hoped the high flows would stir up sediment flowing in from tributaries downstream from the dam and deposit sand in the Grand Canyon's river channel, building beaches and sandbars to help the humpback chub (Land Letter, Dec. 2, 2004).

The hope was that the deposited sediment would create pools and ripples, which provide important habitat for the chub, one of four endangered fish that persist in the Colorado River.

John Weisheit, conservation director for Living Rivers, said that even without the unexpected variable of high flows from the Little Colorado River, the chub would probably not have benefited much from the experiment.

"Whether they got flushed out of the Little Colorado doesn't really matter, because once they get in to the main stem, it's too cold for them, it stuns them, and they become prey to non-native fish," said Weisheit, who advocates breaching or removing Glen Canyon Dam to restore the Grand Canyon ecosystem. "As long as Glen Canyon Dam is still there, they're going to continue to have losses like this."

However, scientists note that the latest experiment has been more successful than previous test flows. A 1996 experiment, which sent 45,000 cfs down the river, failed to keep deposited sediment in the system long enough to benefit the ecosystem, largely because the release was too long, eventually scouring the beaches and sandbars it had built.

Three months after the shorter test flow in November, a considerable amount of sand has remained in the upper area of the canyon, although below that 40-mile stretch, deposition was "a bit of a wash," Ralston said -- sand was deposited in some areas, but eroded from others. Scientists will travel the river again in a few months to see how much of the newly deposited sand is still there, she said.

Ralston said the preliminary results of the November experiment are encouraging enough to merit further test flows, and the Grand Canyon Monitoring and Research Center is discussing a long-term plan for conducting periodic artificial floods.

But David Haskell, a former Grand Canyon National Park employee who currently works as the policy director for Living Rivers, which is calling for a new environmental impact statement of Glen Canyon Dam that evaluates the merits of decommissioning it, says the latest experiment is not much of an improvement.

"At best this can be described as a more successful failure," he said. "These experiments will never succeed because they ignore fully restoring the natural processes the native fish require, which includes the pre-dam flow of sediment and nutrients."

Nikolai Ramsey of the Grand Canyon Trust was more equivocal. Grand Canyon scientists are only three months into a year-and-a-half-long monitoring effort, and it's too early to make sweeping conclusions about the experiment's effectiveness, he said.

Ramsey, who represents the Trust on the Glen Canyon Dam Adaptive Management Work Group, which makes recommendations on dam management and protection of downstream resources, said experimental high flows may work -- with better timing.

"The sediment improved in some cases, and didn't improve in others," he said. "We need to know how often and when to do this kind of thing, and we need to know how to protect the chub from unintended impacts," he said.

One option may be to unleash experimental flows when juvenile fish are not at the confluence of the Little Colorado and Colorado rivers, he said.

Dam safety: High hazard dams

Terrorism poses new threat to dam safety

121 are perched above populated areas across Utah

Copyright 2005 Deseret Morning News By Lee Davidson Deseret Morning News

State records show that eight unsafe dams loom upstream from Salt Lake City. Three others sit above Provo. Four are above the Ogden area. Eleven sit above the wall-to-wall cities of Davis County.

A crew from the U.S. Bureau of Reclamation — Scott Jensen, left, Brad Winters, Lenny Washburn and Chip Todhunter — drill holes below Echo Reservoir dam in as part of efforts to examine stability of the earth levee. Jason Olson, Deseret Morning News

In fact, state officials say 121 unsafe dams are perched above populated areas in 26 of Utah's 29 counties and would likely kill people if they fail.

"It's not that they are crumbling and are ready to fall down immediately — they're not. But they don't meet minimum standards of safety. And in some sort of extreme event, like major flooding or an earthquake, they are not considered safe," said David Marble, assistant state engineer for dam safety.

That may be disconcerting as this year's mountain snowpack is far heavier than during the recent extended drought, posing a tougher-than-in-years test for dams during upcoming spring runoff. One dam in Utah has already partially failed this year (the first in four years), with tense moments occurring elsewhere amid early flooding.

But the good news is that big strides have been made to improve Utah dam safety over the past 15 years. The most dangerous dams have been repaired or replaced (and repair work disclosed they often were in worse shape than feared). Governments also vastly improved monitoring of major dams.

"But we still have a long way to go," Marble said. At recent spending levels, decades could be needed to fund all the upgrades needed at those 121 unsafe dams. Meanwhile, officials hope for no more repeats of the 89 full or partial dam failures that have occurred in Utah historically.

Making progress

A computer-assisted analysis of state records shows Utah has made much progress since the last time the Deseret Morning News looked in-depth at the condition of state dams — 17 years ago in 1988.

At that time, officials rated as safe a mere 7 percent of those dams classified as "high hazard," defined as those where failure would likely kill people and cause extensive damage. (Also, that 1988 story reported that several Utah dams had broken in the '80s after not acting on earlier federal studies that warned they were unsafe).

Photo: The Lower Enterprise Dam, in Washington County, had water flowing over its top for a time this year. Matt Lindon, State Of Utah

In comparison, now 44 percent of such Utah "high hazard" dams meet all minimum safety standards — more than a sixfold improvement. But that still means 56 percent of such dams are considered unsafe during extreme events.

A few months after the old 1988 Deseret News story, one of the few dams that was then considered to be safe — the then relatively new, 4-year-old Quail Creek Dike on the Virgin River — broke early on New Year's Day 1989.

It sent a 40-foot-high wall of water toward St. George, making 1,500 New Year's revelers scramble for high ground early in the morning. No one died, but 50 to 60 homes were destroyed or damaged, and hundreds of livestock animals were killed.

Marble said all that created political pressure to improve Utah's dam safety program. The Legislature passed a law in 1990 aimed at improving safety. Among other things, it led to studies that raised minimum standards for dam safety. It also required dam owners to perform studies of what steps are needed to bring their dams up to those higher standards.

With concern that resulting repair costs could bankrupt some dam owners, the Legislature passed a law saying the state could not order upgrades to dams until the state offered a grant covering at least 80 percent of the cost.

Since then, the state has awarded more than \$40 million in grants to help upgrade or replace dangerous local dams. Such construction has been completed at 21 "unsafe" locally owned dams and is ongoing at three others. Meanwhile, work at 118 other "unsafe," state-inspected dams is awaiting funding.

Additionally, the federal government owns or inspects 25 high hazard dams in Utah — and says they meet safety standards or are undergoing construction to meet them. Many of those federal dams also have been repaired or upgraded in recent years.

Are cities safe?

The state developed a risk rating system to identify and prioritize for repair those dams that it considers to be unsafe. Results show that the most heavily populated areas in Utah also have the most "unsafe" dams.

Salt Lake County has 18. Utah County is close behind with 16, and Davis County is third with 11. All counties except Daggett, Kane and Grand have at least one unsafe dam.

Photo: A crew from the U.S Bureau of Reclamation get ready to drill holes below Echo Reservoir dam. Jason Olson, Deseret Morning News

The city with the most "unsafe" dams immediately above it — eight — also happens to be the state's largest: Salt Lake City.

Unsafe dams in or immediately upstream from Salt Lake City include: Rotary Glen Park Dam; Red Pine Dam; Red Butte Dam; Chandler Drive Dam; School Pond Dam; Sugarhouse Dam; Federal Heights Dam; and Shriners Dam.

Sandy in Salt Lake County has the second-most "unsafe" dams above it, seven.

Heber, Payson and Whiterocks (Duchesne County) each have four unsafe dams immediately above them.

Six cities have three "unsafe" dams immediately above them: Bountiful, Center Creek (Wasatch County), Centerville, Huntington, Kaysville and Provo.

Eleven cities have two "unsafe" dams immediately above them. And 50 sit beneath at least one unsafe dam. (See accompanying charts for a list, location and rating of all unsafe dams.)

Dangerous data hole

Photo: Scott Jensen, left, and Brad Winters of the U.S. Bureau of Reclamation examine a core sample they retrieved while drilling holes below Echo Reservoir dam. Big strides have been made to improve Utah dam safety over the past 15 years. And governments

also have vastly improved monitoring of major dams to prevent problems. Jason Olson, Deseret Morning News.

The state's risk rating system has a problem. It relies on engineering studies that dam owners were ordered to complete about work needed to bring dams up to current standards. But such studies have never been completed on 35 "high hazard" dams.

So, they have been left off priority lists, and their true risk is unknown.

"We don't really know whether they are safe, or exactly where they would fit on priority lists," said Marble, who became head of the state's dam safety program last year. "At this point, we can't document that they are safe, so we're going to assume they are unsafe."

He said the state has begun a push again for completion of those studies by owners. With that, he said, 20 of those dams are at the point that they have started exploratory drilling or are well under way with preparations for studies. Most of the other 14 have started some preliminary work or expressed willingness to do so, he said.

He said the state has the power to restrict operations at a dam if an owner will not do the work in a reasonable period, "but we try to work with them in a positive proactive way." That includes reminding them of the "carrot" of state funding for upgrades.

Repair priority

For the 143 state-inspected, high-hazard dams where detailed engineering studies have been completed, the state created a risk score to prioritize them for repairs.

Risk scores could range from zero to a possible 775, based on numerous factors about dam conditions and how many people they could endanger. A score of zero meant the dam met all current minimum safety standards — and 45 dams initially received that score (or were constructed after standards were raised).

All others had problems and had an average score of 111.

Among the worst initial scores were: 635 by the Piute Dam on the Sevier River near Marysville; 588 by the Holmes Dam on Holmes Creek above Layton; 480 by the Porcupine Dam above Avon, Cache County; 380 by Logan First Dam above Logan; and 363 by Rocky Ford Dam above Minersville.

All of them have since been repaired or replaced, although a second phase of construction at Piute is still under way. After construction, the dams' scores essentially become zero as they then meet all minimum safety standards.

"Holmes Creek Dam was a big concern," Marble said, talking about the highest risk dams. It is just two miles above Layton and the rest of the heavily populated Davis County.

"It was built in the early 1900s by a method we call hydraulic fill, or sluicing. Essentially, they took a sand pile on top of a hill, and ran water over it and collected it between

some dikes. They would wash the sand in and let it settle out, " he said, adding many early dams in Utah were built that way and are essentially sand piles.

"They have been shown to be problematic, especially in an earthquake. They have a very high potential for liquefaction," he said. Holmes also had extra seepage, which could lead to internal erosion of a dam that could cause it to break apart. In fact, Holmes had partially failed in 1924 and 1983, with some repairs made thereafter.

"What we did is went in and completely removed the dam and completely rebuilt it. Interestingly enough, the bulk of the construction was out of the same material," but modern construction techniques provide better compacting and density of material, plus drains to control interior seepage, Marble said.

Other repairs Deseret Morning News graphic

Another dam of highest concern was Logan First Dam. Its old spillway could pass only 1 percent of the potential maximum flood expected there. The U.S. Army Corps of Engineers say dams should pass 100 percent of such flooding and consider it an emergency situation when a dam can pass only 50 percent. (If flood waters go over the top of a dam, they often cause quick, extreme erosion and failure.)

While state inspections had for years urged upgrades, the dam's owner, Utah State University, repeatedly said it could not afford them unless the Legislature came up with money. It finally did through the upgrade program it passed for all dams in 1990. Logan First Dam now meets all minimum standards, Marble said.

Also, Mountain Dell Dam in Parley's Canyon was long one of the biggest concerns in the state and had an initial risk rating score of 250. Salt Lake City Public Utilities Director LeRoy W. Hooton Jr. remembers how that dam scared officials during heavy snowmelt runoff flooding in 1983.

Officials figured they came within an hour of having water go over the top of the dam that year (which could easily lead to quick erosion and failure). It was saved only as they released as much water as they could through outlets and spillways, even though that flooded downstream areas and turned 1300 South Street into a long "sandbagged river."

"We couldn't take a chance of overtopping the dam, but we still got awfully close," he said about that year when the mountains went from "freezer to furnace" almost overnight to produce record snowmelt runoff flooding. He said vibration at the concrete dam was so intense when all outlets were open that officials feared it would cause cracking.

After the 1983 floods, officials took several steps to prevent further problems at Mountain Dell. The biggest was building the modern Little Dell Dam just upstream in 1993. After it was completed, Mountain Dell was never allowed to fill to more than two-thirds its capacity.

Also, Hooton said numerous improvements were completed at Mountain Dell, including raising its height and performing studies to ensure it should be safe during an earthquake. "The improvements have really taken the worry out of running that dam," Hooton said.

Surprise inside

Marble said repair work has often brought unhappy surprises once crews dug into dams for repairs.

For example, at Rocky Ford Dam, he said, officials worried that extra seepage they had observed could eventually lead to erosion and create sinkholes that could break it apart. Once they started digging to put in some drains, "We found a very large sinkhole already developing. . . . We worried it could happen and found it already had."

Marble said similar findings came in repairs at many dams. For example, at Porcupine digging showed that seepage and saturation was much more extensive than feared — and had saturated almost the entire dam. "It wasn't something that you could just look at the dam (from the outside) and see from a safety inspection," he said.

To help find hidden and unpleasant surprises among the many dams awaiting upgrades, Marble said, virtually all have added special equipment in recent years to help monitor interior saturation, seepage and dam movement. He said that helps give early warning if conditions are deteriorating and quick action is needed.

That is a vast improvement over conditions found back in 1988.

"In 1988, I would bet there were no more than 10 high hazard dams that were fully instrumented for performance evaluation," Marble said. "Now virtually all of the high hazard dams are instrumented."

Also of note, records show that all high hazard dams overseen by the state are being inspected every year now, which was not always the case back in 1988. However, Marble said, plans call for inspecting some rarely filled flood control dams every other year to allow more attention on higher risk dams that constantly store water.

Also, all but eight of the high hazard dams in Utah have completed "emergency action plans" — about how to handle emergencies and failures and whom to contact downstream. Few had them back in 1988, but they were later required by law. The only dams lacking them now have only recently been elevated to "high hazard" status, which triggers requirements for such plans.

Federal efforts

The federal government has also made big strides in recent years to upgrade the large dams it owns or inspects.

In 1988, more than half the federal dams were rated as poor or had their condition unknown. Now, all are considered to meet safety standards or are undergoing

construction to meet them, said Ed Vidmar, Resource Management Division director for the Bureau of Reclamation's Provo Area Office.

He added that all dams have an intensive "Comprehensive Facility Review" every six years, with major engineering studies conducted by Reclamation's Denver Technical Service Center.

At the midpoint between such reviews, engineers from the bureau's regional office in Salt Lake City perform a somewhat less intensive safety review. And once a year, inspectors from the bureau's Provo Area Office conduct safety reviews of dam exteriors and key features.

Some dams get even more attention. For example, the massive, 50-story Flaming Gorge Dam, the largest in Utah, receives exterior inspections monthly, said Walter Payne, a maintenance official in the bureau's Salt Lake City regional office.

Additionally, he said, "Measurement of movement (by the dam structure) is done monthly," as is measurement of movement of water under the dam. Also, he said, flows from drains are checked four times a year, as is seepage.

Some of the major ongoing work of federal dams includes upgrading the large Deer Creek Dam in Provo Canyon. Vidmar said once construction relocates roads and traffic off the top of that dam, the bureau plans spillway modifications to improve safety.

The bureau is also finishing a second set of modifications to the large Pineview Dam above Ogden. During one of the regular re-evaluations of that dam, Vidmar said, engineers found that earlier improvements in 1991 did not meet "new standards that came because of the Kobe, Japan, earthquake. Some of the materials used tend to liquefy (in an earthquake), so the standards were changed," he said.

2005 outlook

Utah has been in a long drought, which Marble notes means "spillways have not really been tested a lot in recent years." But with mountain snowpack heavier this year, long-forgotten concerns about dam safety are suddenly becoming more important.

One dam already partially failed this year. "Strates Dam in Sanpete County failed. It washed out (because of interior erosion) under the spillway. It was about 25 feet tall, and the top 7 feet of the reservoir came off," he said. That was a "moderate hazard" dam that did not threaten any populated areas.

Marble said, "The only area we're really keeping an eye on right now with concern for the spring is the Enterprise area" in Washington County.

Some tense moments came at the Lower Enterprise Dam there during flash floods in January. That concrete dam had water flowing over its top for a time, with its spillway unable to handle heavy rainfall that filled its reservoir to overflowing.

"It (the dam) actually performed fairly well. But there has been some damage, of which we are concerned, and which will require some remedial work," Marble said.

"While we are concerned, we are not alarmed. It is very important we do not raise a panic and make people think they need to evacuate," Marble said. "There are concerns, but we do not see anything at this point" to make officials believe the dam cannot handle spring runoff or that it needs to have its storage restricted.

While Marble said that "any of the dams that do not meet our current standards we would call unsafe," that is only for extreme events, such as heavy flooding or earthquakes.

He said most of the dams rated as "unsafe" can handle routine years and operations safely, or inspectors would take actions to close them. He does acknowledge, however, that some dams in the state "are leakers and saggies."

Still, Marble stressed that any dam in the state that inspectors believe could pose an immediate threat would face emergency actions, such as restricting storage. "If there is something we can see and determine that it's deteriorating, something that is an imminent safety concern, we can deal with that immediately."

He said the monitoring equipment at virtually all high hazard dams in the state should help residents feel more safe, as should the repairs and replacements of the most dangerous dams in recent years.

"For those who haven't had their dams fixed, I would emphasize again that . . . we are out there inspecting and monitoring these dams. We've got all the high hazard dams now instrumented. We are collecting that data. We are reviewing that data," Marble said.

"I can't say that's 100 percent sure, but we are doing all that is possible to address the safety concerns, even before they get fixed. If there is anything we can do to prevent a catastrophe, we will do that," he said.

Regional News 03/31/05

Western states to miss drought plan deadline

Proposal would determine Colorado River allocations in event of water-shortage declaration

By HENRY BREAN
REVIEW-JOURNAL

The seven Western states that depend on water from the Colorado River will not have a drought management proposal in hand by the Friday deadline set by the U.S. Department of the Interior, Nevada's top water official said.

No such proposal has been developed and representatives from the seven states are not slated to meet again until next week, said Pat Mulroy, general manager of the Southern Nevada Water Authority.

"I don't think we are any closer than we were," Mulroy said. "I think we're going to need more time."

In December, Deputy Interior Secretary Steven Griles called on the states to accelerate discussions on how they would divide up a shortage on the drought-stricken river. Griles used the same news conference at the Las Vegas convention of the Colorado River Water Users Association to announce the April 1 deadline.

Federal officials have never declared a water shortage on the Colorado, and no rules presently exist that spell out how the river allocations of Nevada and the six other states would be cut in the event of such a declaration.

Some experts were predicting that a shortage could be declared as early as 2006, but Mulroy said this year's record wet winter appears to have bought river users some time.

Most pressing now, she said, is for the states to reach a consensus about how much water to release from Lake Powell this year.

The upper basin states of Colorado, New Mexico, Utah and Wyoming want to reduce the 8.23 million acre-feet of water that traditionally is released from Powell each year to allow the lake to recover, Mulroy said.

Five years of drought, coupled with normal water deliveries downstream to Nevada, Arizona and California, have caused Lake Powell to shrink to about one-third of its capacity.

Mulroy said Nevada is agreeable to a reduced release from Powell, so long as the resulting drop in Lake Mead does not jeopardize the intakes Southern Nevada uses to draw about 90 percent of its drinking water supply from the lake.

Mulroy expects the states to agree on a preferred release from Powell by mid-April, before federal officials conduct their midyear review of the 2005 Annual Operating Plan for the Colorado River.

But complicating the interstate discussions is the weather. "Nobody knows if this is the end of a dry cycle or just a wet year in the middle of the cycle," Mulroy said.

As for the larger task of developing shortage criteria for the river, Mulroy predicted the process will take at least two years, with or without input from the basin states. "It's pretty academic. If the states don't do it, the (Interior) secretary will," she said.

Mulroy has said that Nevada's share of a shortage probably will be 12,000 to 18,000 acre-feet a year, though the state would be able to replace that lost supply with banked water here or from its recent water agreement with Arizona.

There are about 326,000 gallons in an acre-foot. The average Las Vegas Valley household uses slightly more than two-thirds of an acre-foot of water each year.

"Nobody wants to tackle these ugly issues until they absolutely have to," Mulroy said. "But the possibility of the lower basin going into a shortage within two years is real."

That's why the Interior Department came up with the April 1 deadline: to push the states into talks on shortage criteria, Mulroy said.

"And quite honestly, we're going to push back. I still want to know what, if anything, the federal government is doing to engage Mexico on shortage criteria. There is no way Arizona and Nevada can bear the brunt" of a shortage if Mexico doesn't take a hit, she said.

Under the terms of a 1944 treaty, the United States is obligated to allow 1.5 million acre-feet of Colorado River water to flow into Mexico each year. However, that obligation is not governed by the 1922 Colorado River Compact or subsequent federal laws that divvy up the river among the seven states.

Mulroy and her fellow basin-states representatives are slated to meet behind closed doors in Las Vegas on Monday.

Federal effort to ease Western tensions getting mixed reviews

April Reese, Greenwire Southwest reporter

An Interior Department initiative aimed at averting water wars in the West is getting mixed reviews as it heads into its third year.

Regional water managers praise "Water 2025" as an important first step toward easing tensions, but environmentalists largely dismiss the program for enhancing irrigation infrastructure while ignoring damage to rivers and other resources.

But the program's critics and backers do agree on one thing: Water 2025 needs more money.

With a budget that has grown from \$8.4 million in fiscal year 2004 to \$19.5 million in fiscal 2005, the Bureau of Reclamation program provides grants aimed at enhancing conservation, improving the efficiency of irrigation systems, and developing new technologies to increase water supplies. It has funded 19 projects so far -- ranging from lining irrigation canals to reduce seepage to creating a "water bank" to buffer against shortages.

The Bush administration is asking Congress for \$30 million for the initiative in fiscal 2006, and Avra Morgan, who directs the program, said the additional cash would be

welcome. The initiative received more than 100 applications for grants in fiscal 2004, but could award only 19 grants, she said. BuRec is expected to announce the next round of grant recipients by July 1.

Despite the relatively small number of projects funded so far, Morgan predicted that Water 2025 would prove its worth in water-shortage hot spots. "I do have confidence that these projects, once they're completed and under way, will help reduce tensions over water," she said.

But critics say the initiative is tantamount to putting Band-Aids on broken arms. Laura Ziemer, director of Trout Unlimited's Montana Water Project, called the program, which is implemented by the Bureau of Reclamation, a "lofty and noble endeavor," but one that puts too much emphasis on increasing efficiency of existing water-supply infrastructure and not enough on restoring rivers.

"I would broadly characterize it as a missed opportunity," Ziemer said. "It was a well-conceived notion and an opportunity ... for the bureau to take a broader view of what it means to have fundamentally altered many of the waterways of the West. Unfortunately, they've failed in taking that opportunity."

Interior launched the program in May 2003, seven months after farmers and other water users in Oregon's Klamath Basin clashed with federal agencies that sought to provide water for endangered fish during a drought.

"I think what they're trying to do is prevent any future Klamaths from sneaking up on them, because it was a black eye for the department," said Tom Donnelly, executive vice president of the National Water Resources Association, which advocates for rural and municipal water districts and supports the program.

Announcing the program's first round of challenge grants, Interior Secretary Gale Norton touted Water 2025 support for "realistic, cooperative approaches and tools that have the most likelihood of successfully addressing water challenges in basins where crisis and conflict are preventable."

Enviros want more attention for ecosystems

But environmentalists maintain that Water 2025 largely ignores the need for restoring the ecological health of river systems, which they say is essential for averting water conflicts. Ziemer said a Trout Unlimited project that would have created a reservoir to store wastewater to be used by irrigators on the Sun River in northwestern Montana was rejected by Water 2025 gatekeepers.

Most Water 2025 projects, which primarily involve improvements to irrigation systems, could have been funded through other means, such as the Reclamation Reform Act program, she said. "They're doing the same kinds of things they were doing before, and just calling it a new name," Ziemer said.

John Weisheit of the advocacy group, Living Rivers, based in Moab, Utah, said the initiative has proven itself to largely be a public relations exercise with few real results.

Water banking, farm-to-urban transfers, and irrigation efficiency projects will not be enough to prevent future water conflicts, he said, especially at current funding levels.

"We think it would definitely help, but it would require a lot of money," Weisheit said. "It's very limited funding."

Furthermore, Interior waited too long to come up with a plan to help address the West's water challenges, Weisheit added. "Unless they put lots and lots of money into this," he said, "it's a little too late."

Optimistic water managers hope for more federal cash

Tim Martin, executive director of Western Resource Advocates in Colorado, said the initial Water 2025 report was "a pretty good roadmap for how to move forward" but that the limited funding behind the initiative hinders its ability to achieve its stated goals.

"There's only so much you can do with the amount of money that has been allocated," Martin said.

Interior has targeted the basins facing the greatest risk of water conflicts, but critics say there is still not enough money to fund all of the ditch-lining, water banking and conservation projects that need to be done.

But Mark Limbaugh, deputy commissioner of BuRec, said a little can go a long way. "The reality is we're in tight times, the federal government is not going to come in and solve this all by itself," Limbaugh said. "I'd rather have some drops in the bucket than none at all."

Getting projects going on the ground can help build momentum and "start a healing process that helps people resolve conflict," Limbaugh said. "These are projects on the ground, working every single day to alleviate conflict to help these communities not have to go through what we've seen in the Klamath Basin."

The program focuses on irrigation systems because agriculture is the biggest water user in the West, Limbaugh said. And improving efficiency in agricultural systems can save water that can be left in the river to help increase flows, which benefits fish and wildlife, he said.

While Reclamation Reform Act funding does support efficiency improvements, those projects tend to be on a smaller scale than Water 2025 projects and are more directly tied to Reclamation-managed systems, Morgan added.

"I do believe," she said, "these are projects that would not be able to go forward without our Water 2025 funding."

A sampling of Water 2025 grants

Projects funded in part by Water 2025 include: * The San Juan River Dineh Water Users Association in New Mexico replaced three unlined canals with pipelines in an effort to reduce evaporation and seepage, providing a potential water savings of 5,600 acre-feet

per year, Morgan said. An acre-foot is about 325,850 gallons, a year's water supply for a family of four. Water 2025 picked up \$200,000 of the project's \$751,000 tab.

* The Central Oregon Irrigation District teamed with cities and tribes to create a water bank, a pool of donated or temporarily leased water that can be used to help meet demand during dry times, that could save up to 326,522 acre-feet of water a year, BuRec says. The bureau provided \$233,750 of the project's \$588,750 cost.

* The Medford Irrigation District in Oregon replaced 2,200 feet of open canal with a pipeline, saving about 94 acre-feet of water per year, BuRec says. The project will also remove three fish passage barriers and enhance habitat for federally protected coho salmon. Water 2025 grant will cover \$300,000 of the \$900,000 project.

LR Press Release 04/06/05

DOE: Announces preferred alternative to move uranium waste pile away from the Colorado River

April 6, 2005

For immediate release

Contact: John Weisheit - (435) 259-1063/(435) 260-2590

Sarah Fields - (435) 259-4734

Washington DC - The Department of Energy (DOE) announced today that their preferred alternative concerning the fate of the uranium waste pile adjacent to the Colorado River near Moab, Utah, is to move it to a location 30 miles away from the Colorado River. The location of this preferred waste storage facility is near Crescent Junction (the junction of Highway 191 and Interstate 70), which the Environmental Protection Agency recommended as a superior site in their comments to the DOE. This site is in the shadows of the Book Cliffs, which is considered a desirable place to relocate the pile because it is isolated, protected from potential flash floods, and where a thick layer of shale will better prevent the contamination of local ground water resources.

The alternatives not chosen as preferred include capping the pile in place; moving the pile to Klondike Flats, which is about 17 miles north of Moab and a popular place to recreate; and pumping the waste in a slurry via pipeline to a uranium processing plant near the White Mesa Ute Reservation, which is about 80 miles south of Moab.

"We are delighted with this announcement from the DOE about their preferred alternative," says John Weisheit from Moab, who is the conservation director at Living Rivers and the Colorado Riverkeeper. "This decision was not wholly unexpected considering the issue to move the pile to the north had overwhelming support from our city, county and tribal councils. A decision to the contrary would have started a

contentious situation from a determined local citizenry that considers the pile a threat to human health and endangered fish species."

Besides the local city and county representatives, the citizens of Moab, and concerned citizens of the White Mesa Tribe, other groups and agencies were also in favor of moving the pile away from the river.

"We are very happy to hear how the combined efforts of the communities down river, the State of Utah, federal agencies and our representatives in Congress, has resulted in sound decision by the DOE to remove the tailings from the floodplain of the Colorado River. We hope the final decision will include congressional action to appropriate all the necessary funds in a timely manner to remove the pile and remediate the local ground water," said Sarah Fields, who is the project coordinator for Living Rivers and the chair of the Nuclear Waste Committee, Sierra Club Glen Canyon Group.

April 6, 2005

DOE Announces Preferred Alternatives For Moab, Utah, Uranium Mill Tailings

WASHINGTON, DC - The U.S. Department of Energy today announced the department's preferred alternatives for remediation of the Moab, Utah, Uranium Mill Tailings Remedial Action Project Site: active groundwater remediation, and offsite disposal of the tailings pile and other contaminated materials to the proposed Crescent Junction disposal site.

These preferred alternatives will be included in the Department of Energy's Final Environmental Impact Statement (EIS). Previously, the department did not identify a preferred alternative, in its draft Environmental Impact Statement on the remediation of the Moab, Utah, Uranium Mill Tailings Remedial Action Project.

The preferred alternatives do not indicate that the department has reached a final decision on remediation of the Moab site. The department continues to review comments it has received from the public on the site.

A Final EIS on the Moab, Utah, Uranium Mill Tailings site and the remediation of the site is in preparation, and the final department Record of Decision will be issued following the release of the Final EIS for the Moab site.

Activists hail the proposal to move toxic tailings away

By Lisa Church
Special to The Tribune

MOAB - News that the Energy Department will move almost 12 million tons of radioactive waste away from the banks of the Colorado River brought tears to Bill Hedden's eyes.

The department said Wednesday that it will recommend in an upcoming final environmental impact statement that the Cold War-era uranium mill tailings be moved by rail to a site 30 miles north from where they now sit four miles from Moab along the bank of the Colorado River across from Arches National Park.

For Hedden, a former Grand County councilman, and other residents and government officials, the announcement was especially sweet after years of pushing to have the unsightly and unhealthy tailings moved away from this red rock tourist destination.

"I actually cried this morning when I got the call. I surprised myself with that reaction," said Hedden, now executive director of the Grand Canyon Trust, an environmental group that has lobbied Congress on the tailings issue.

"Our democracy works slowly sometimes, but frequently we end up in the right place. This was a roller coaster."

The decision is a victory long overdue for Western politicians, county officials and environmentalists who have argued for years that toxic chemicals leaching from the pile are contaminating the Colorado River, the major source of drinking water for about 25 million people in Utah, Arizona, Nevada and California.

"This just goes to show what a small town can do when people work together," Grand County Councilwoman Joette Langianese said of the Energy Department's decision. "The fact that we got this decision is amazing. Just a year ago, everybody was feeling like it wouldn't happen."

The relocation effort, which probably will take five years, also will bring jobs to Grand County, Langianese said. And many feel having the 130-acre site cleaned up will boost tourism.

"I'm looking forward to the time when we can drive down Moab Valley and see its beauty instead of seeing a toxic pile," Langianese said.

"This is a good day for Grand County."

Moab activist Sarah Fields, who spent years researching the environmental impact of the tailings, said pressure from other state and federal agencies made it almost

impossible for the Energy Department to recommend leaving the tailings at their current site.

"I'm sure the [Energy Department] felt they wouldn't have a leg to stand on," she said.

Ute Mountain Ute tribal leaders and residents of White Mesa, a small community in southeastern Utah, had opposed one cleanup alternative that would have transported the tailings to the White Mesa processing mill located on tribal lands south of Blanding.

"It took a tremendous amount of time and money to discuss the White Mesa alternative, even though it was a ridiculous idea," said Tom Rice, director of the Ute Mountain Environmental Department.

"We're pleased that the decision was made to move it to a less populated area."

Colorado River users at odds over flow

By Theo Stein
Denver Post Staff Writer Staff

The seven states that share the Colorado River are unlikely to agree on how much to refill Lake Powell this year, leaving the decision to Interior Secretary Gale Norton, Colorado's top water planner said Tuesday.

Five of the driest years on record have left Lake Powell, the giant impoundment on the Utah-Arizona line, two-thirds empty.

Meanwhile, record precipitation this winter has helped produce a dramatic rebound in Lake Mead, Powell's equally large downstream sibling, which is now nearly two-thirds full.

To help restore balance to the system, Colorado, Utah, New Mexico and Wyoming want the Bureau of Reclamation to capture more water than planned behind Lake Powell's Glen Canyon Dam. They plan to make that request next week.

"It's just common sense at this point," said Rod Kuharich, executive director of the Colorado Water Conservation Board.

But Kuharich said consensus among the seven states is unlikely by federal officials' Tuesday deadline.

That would leave Norton to make a decision in early May.

Upper Basin states such as Colorado want Lake Powell to fill because the lake plays a critical role in providing water for downstream users - especially during dry years.

If the lake empties, California, Nevada and Arizona, which have a senior claim on the Colorado River, would be able to take water from the river that Front Range residents now use.

"It's our protection," Dave Merritt, chief engineer of the Colorado River Water Conservation District in Grand Junction, said of Lake Powell.

The debate was cast last fall when officials, wary that the drought could deepen, agreed to an unprecedented midyear review of Glen Canyon's operations.

Lower Basin officials argue no change of course is needed. They point out that the reservoir's annual operating plan, which is set each September, assumed continued drought in the Upper Basin would reduce runoff into the reservoir to 77 percent of normal. Instead, runoff is forecast to be 107 percent of normal.

"That's 30 percent better than the estimate used in setting the operating plan," said Herb Guenther, director of Arizona's Department of Water Resources.

In addition, Lower Basin officials say, the two reservoirs are headed in opposite directions.

The runoff season, which is just starting, will raise Lake Powell's level to 49 percent of capacity by summer's end.

Meanwhile Lake Mead's level will drop to about 54 percent by the end of the year, officials said.

"So they'll be getting pretty close equalizing on their own," said Dennis Underwood, chief executive of Southern California's Metropolitan Water District, which serves Los Angeles and San Diego.

But Upper Basin officials are frustrated by the Lower Basin's reluctance to let Powell fill.

After all, they argue, Lake Powell's water is destined for California, Arizona and Nevada anyway. Refilling the reservoir means more reliable supplies to the lower basin if drought returns.

A fuller Lake Powell produces more power, and hence more revenue, from the turbines in Glen Canyon Dam.

And, because Powell is higher in elevation, the vast lake surface loses less to evaporation than Mead, they say.

Lurking below the surface is lingering uncertainty about what next year will bring.

"The drought in the Colorado River basin has eased," said Tom Ryan, a Bureau of Reclamation hydrologist.

"We can't say that it's over."

The issue

Should Interior Secretary Gale Norton reduce water released from Glen Canyon Dam to help Lake Powell refill more quickly?

Upper Basin states: Yes.

Norton should cut the planned annual release from 8.23 million acre-feet to perhaps 7.5 million acre-feet, Colorado, Utah, New Mexico and Wyoming say. That would allow Powell to capture an additional 730,000 acre-feet of water. An acre-foot is enough water to serve two average families for a year.

Lower Basin states: No.

California, Arizona and Nevada say runoff expected in the Upper Basin is greater than was anticipated when the 8.23 million acre-foot objective was set in September.

Biologists to see if latest experiment on Colorado River helped fish habitat

Deseret News

An experiment regarding fluctuating flows in the Colorado River below the Glen Canyon Dam ended last week.

Now, biologists will begin collecting data to see if the fluctuating flows actually helped the endangered humpbacked chub.

In November 2004, a second high-flow experiment, which involved the release of 41,000 cubic feet per second during an 60-hour period, was conducted in an attempt to scour the beaches and shorelines through the Grand Canyon, and to help the endangered humpback chub.

Scientists hoped to redistribute 800,000 metric tons of sediment through the Grand Canyon to create and resurface beaches, build substrate used by plants and backwaters and pools to help the fish breed. Then, from early January through April 8, flows were periodically changed, from roughly 5,000 cfs to 20,000 cfs.

Chubs, over eons of time, have adapted to the fluctuating flows of the Colorado River, while non-native species, such as trout, have not.

What biologists found after the high release of 41,000 cfs, however, was that there were 63 percent fewer juvenile chubs in the river than before the release.

The belief was that the fish were either washed downstream or were holding in areas not studied.

The chubs are the last of four endangered fish still living in the river running through the Grand Canyon.

Consensus was that fluctuating flows would keep the non-native fish, such as rainbow and brown trout, out of the river and holding in tributaries. This would stop the trout from competing against the chubs for food, and would stop the trout from preying on young chubs and eggs.

Biologists also believe that the fluctuating flows would thin the trout population, which is overgrowing the available habitat between the dam and Lee's Ferry, which is approximately 16 miles of very popular fishing waters.

Researchers have found that since 1991, when such fluctuations ended, the trout population dramatically grew at the probable expense of the native chub population.

Scientists are trying to determine if the fluctuating flows can keep the trout population in check by impacting their spawning and other aspects of their lifecycle

Additionally, another ongoing experiment has been the mechanical removal of non-native fish, primarily trout, near the confluence of the Little Colorado River and the mainstream Colorado River. The area is prime humpback chub habitat as the endangered fish move between both rivers. The removal effort, using electro-fishing techniques, reduces competition by physically removing trout. Early indicators from last summer's work have shown positive results.

The initial portion of the experiment was conducted this year from January through March and resulted in removing 7,573 fish, with 6,703 of them rainbow trout. There were also 130 brown trout and 135 common carp removed.

"Now we will have to monitor to determine if reduced non-native numbers result in a benefit to the humpback chub. That's why it is called adaptive management. You try something, if it works, you can repeat or expand the process to achieve greater results. If it doesn't work, you move on and try something else," said Steve Gloss, a scientist with the U.S. Geological Survey.

The endangered humpback chub is one of eight native fish species that were once abundant in the 277-miles of river flowing through the Grand Canyon.

The humpback chub is a "big-river" fish that grows to 20 inches. It is superbly adapted to survive in the wild and turbulent Colorado River that had historic flows ranging from 500 to 300,000 cfs.

As with earlier releases, biologists and scientists will now collect needed data to see if, in fact, the experiment worked.

Feds will referee Colorado River fight

Storm runoff ups ante for 7 states

Shaun McKinnon
The Arizona Republic

Winter storm runoff that should have eased fears of water shortages along the Colorado River has instead fueled new fighting among the seven states that use the river.

At issue is whether the states along the upper river - Colorado, Utah, New Mexico and Wyoming - can withhold water from the lower-river states of Arizona, California and Nevada, which benefited more from the winter storms.

What's really at stake isn't so much the water that flows downriver this summer - the storms ensured there would be no shortfall - but whether the seven states can agree on how to manage a resource that has steadily weakened under the pressures of growth and drought. advertisement

The federal government will be forced to settle the short-term question of how water from the river will be divided for the next six months. But fallout from that decision, expected by May 1, could sour longer-range discussions about the river's future and hurt Arizona's efforts to protect its supply during a drought.

"We've approached (the upper-river states) three times to get a consensus on this," said Herb Guenther, director of the Arizona Department of Water Resources.

"They've chosen to use it as bully pulpit against us. I think it's already kind of spoiled the atmosphere."

Representatives of the seven states will meet Tuesday in Las Vegas to discuss how much water should be released from Lake Powell downstream into Lake Mead this summer. They aren't expected to reach an agreement, leaving the final call to Interior Secretary Gale Norton.

Typically, the river's use is planned out one year in advance, from October to October, but because the drought had taken such a toll on Lakes Powell and Mead, the states agreed this year to revisit the numbers after six months. The two sides disagree on what the midyear numbers mean.

- The Upper Basin states say Powell, which is at 33 percent of capacity, needs help in recovering from the drought. They argue that Mead received extra water this year from the heavy winter runoff and want the secretary to reduce the water released from the reservoir downriver to Mead by 500,000 acre-feet or more, a reduction of about 6 percent compared with a normal year.

- The Lower Basin states say there's no reason to change the original plan because the upper river is set to receive more runoff than predicted last fall. Powell will rise by as much as 50 feet this spring and summer, they say, and won't need the extra protection sought by the upper-river states.

Both sides acknowledge that the drought has cut deeply into the West's water storage. Hydrologists say the river in 2005 should receive nearly normal runoff for the first time in six years, but by the end of the summer, Powell will still be less than half full and Mead will have settled just slightly above the half-full mark.

"From our perspective, we can see no reason why the secretary should make an adjustment when conditions are better than they were when the plan was agreed to by all the states," said Sid Wilson, general manager of the Central Arizona Project, which delivers Colorado River water to Phoenix and Tucson. "Colorado just seems hellbent on pushing those changes."

'Thinking about future'

The Colorado General Assembly has adopted a resolution calling on the Interior Department to reduce water deliveries from Powell, and state water managers are marshalling the other Upper Basin states to support that position.

"We're not thinking about this year, we're thinking about future years," said Eric Kuhn, general manager of the Colorado River Water Conservation District, which represents river users in 15 Colorado counties.

"This would give us more assurances down the road. We don't know what the future will bring."

Although it stores water for use by the Lower Basin states, Powell was built to help the Upper Basin states, which are required by the Colorado River Compact of 1922 to deliver water to the Lower Basin states each year. The Lower Basin states take their water from Powell, allowing the Upper Basin states to divert more of the river upstream.

Since Powell began operation more than two decades ago, the Upper Basin states have always released a minimum of 8.23 million acre-feet a year to the lower states. An acre-foot is 325,851 gallons, enough to serve one or two average households for one year.

But Upper Basin officials are now citing specific passages from the compact that say they are not bound to deliver that amount of water each year but rather a total of 75 million acre-feet over 10 years. Over the past 10 years, they say, total releases from Powell have topped 100 million acre-feet.

Extra water

The problem, those states suggest, is that the faster-growing lower states have grown accustomed to the extra water.

"In the long run, if things go dry again, the Lower Basin has a problem," Kuhn said. "It uses more water than it can rely on. The sooner the Lower Basin gets on to try to

address that problem, the better off we are." Lower Basin states are furious about what they describe as posturing by Colorado, which is fighting its own internal battles over how to meet increasing demands for water from the river.

"For the Upper Basin states to dig their heels in and demand some token reduction this year is distracting and is jeopardizing the long-term discussions we need to have," said Pat Mulroy, general manager of the Southern Nevada Water Authority. "This is all about posturing, and that's where the frustration sets in for the Lower Basin. This is a position we did not want to be in."

For Norton to withhold water based on the river's current condition would be difficult, Lower Basin officials say, because there are no immediate risks to water users or power producers.

"The midyear review was to see if conditions got worse," Guenther said. "They didn't. They got better, so there's no need to make an adjustment."

The dispute has slowed work on a plan to manage drought-related shortages on the river, although the Lower Basin states are prepared to submit a preliminary plan to Norton, who had set an April deadline. The Interior Department is now ready to begin work on the shortage plan with or without the states' involvement.

Arizona's interest in resolving supply-related issues is especially keen: If the Interior secretary was ever to declare a shortage on the Colorado, the Central Arizona Project Canal would lose its entire supply before any other user suffered. State officials are working to protect the CAP in case the drought deepens.

The Bureau of Reclamation will begin seeking public input next month and hopes to include as much from the river states as possible.

"We would definitely like to have a consensus from the seven states," said Bob Johnson, commissioner of the Bureau of Reclamation Lower Colorado Region. "We would prefer to hear them speaking with one voice. But the reservoirs are low, and even with a normal year, the drought's not over. We need to move ahead."

States fail to agree on drought rules; Norton takes over

Feds to map river plan

By Jerd Smith, Rocky Mountain News

LAS VEGAS - Seven Western states failed to reach agreement Tuesday on how to manage the mighty Colorado River in times of drought, an impasse that means the federal government will begin crafting its own plan May 1.

"We've tried to come to a consensus, but it hasn't been possible for us to do that," said Larry Anderson, director of the Utah Division of Water Resources.

Anderson and more than 40 other water officials met in Las Vegas in a last-ditch effort to meet an April 30 deadline imposed by U.S. Secretary of the Interior Gale Norton. Norton wanted the states to come up with at least the rudiments of a drought-management plan for the river and its two main reservoirs - Lake Powell and Lake Mead.

A key issue has been the request by Colorado and three other states to hold more water in Lake Powell this year to help it recover from the drought.

But weeks of talks leading up to the final meeting Tuesday failed to deliver any consensus on how the river could be equitably shared if shortages arise, or whether releases from Lake Powell to Lake Mead should be reduced this year.

Norton will decide by the end of the week whether to alter releases from Lake Powell, but she plans to spend much of the next two to three years holding public hearings to build a federal drought-management plan for the river.

"The idea was that the states would develop some middle ground," said Tom Weimer, assistant secretary overseeing water issues at the U.S. Department of Interior.

"We clearly didn't get there. So we'll begin briefing the secretary tomorrow and we'll continue briefing her Thursday and Friday until she's prepared to make her decision."

Riding on Norton's drought-management plan are potentially historic new legal precedents in Western water law and millions in recreation dollars and electric power sales from Glen Canyon Dam at Lake Powell and Lake Mead's Hoover Dam.

Under a 1922 compact, Colorado River water is divided equally between the Upper Basin states, Colorado, Wyoming, Utah and New Mexico, and the Lower Basin states, California, Nevada and Arizona. Each basin gets 7.5 million acre-feet.

Last December, John Keys, commissioner of the U.S. Bureau of Reclamation, warned the seven states they needed to begin resolving long-standing differences to get at a potentially bigger issue: how some 25 million people who depend on the river can share its waters if chronic drought becomes the norm, as it has been for the past five years.

As part of the drought talks, the Upper Basin states sought a reduction of as much as 700,000 acre-feet in the amount of water released from Lake Powell this year to help it recover from the drought. The giant storage pond on the Utah-Arizona border is just 34 percent full, its lowest level since 1969.

If the lake drops too low, Colorado and the other Upper Basin states might have to deliver more of their own supplies to ensure that cities such as Phoenix, Las Vegas and Los Angeles get their fair share under the 1922 compact.

Such a situation, though unlikely, has Colorado water officials scrambling to figure out how they would cope with such a demand for extra supplies.

The headwaters of the Colorado River occur high in the Never Summer Mountains in Rocky Mountain National Park and supply about half the water used on Colorado's Front Range.

Colorado's General Assembly and the state's congressional delegation have also weighed in, asking Norton to protect Lake Powell's supplies until it can recoup some of its losses.

"We think it is definitely within her authority to make a modification in the release," said Randy Seaholm, a manager at the Colorado Water Conservation Board, who has been representing Colorado in the talks.

But officials from California and Nevada on Tuesday, though tight-lipped, made clear they were unwilling to go along with anything that would reduce their share of river water this year.

"We in the Lower Basin states believe the hydrologic conditions do not justify any change in the release," said Gerald Zimmerman, a representative from California.

Norton turns down proposal for Powell

Upper Basin states hoped to hold more water in reservoir

By Jerd Smith
Rocky Mountain News

Secretary of the Interior Gale Norton on Monday rejected a plea to hold more Colorado River water in drought-stricken Lake Powell this year, dealing a blow to the efforts of Colorado and three other states to shore up the giant holding pond on the Utah-Arizona border.

"It's disappointing, but I feel as if we got a very fair hearing from the secretary," said Russell George, executive director of Colorado's Department of Natural Resources.

Last December, Norton warned Western states that they must come up with a drought plan for managing the Colorado River and Lakes Powell and Mead or the federal government would develop a plan for them.

But last week the seven Colorado River basin states acknowledged that they could not reach a consensus on long-term drought issues or, in the short term, whether deliveries from Lake Powell should be reduced this year. That failure opens the door to creation of a federal drought plan for the river.

George and other Colorado water officials refused to class Norton's Lake Powell decision as a defeat, saying it was only the first round in what will become historic talks on how to manage the Colorado River in times when water is scarce.

"This thing is way too complex to be thinking in terms of winning or losing at this point," George said.

Even as she rejected the request to hold more water in Lake Powell, Norton said that she would review the situation again next year, in case the drought worsens and stored water supplies continue to drop.

About 25 million Americans rely on the Colorado River, from Wyoming to California. In Colorado, it supplies nearly half the drinking water for the Front Range, keeps snowmaking machines going from Winter Park to Vail, and irrigates peach orchards and wineries along Colorado's western border.

Under the 1922 Colorado River Compact, the river's water is divided equally between the upper basin - Colorado, Wyoming, Utah and New Mexico - and the lower basin states of Nevada, Arizona and California.

According to the compact, the Upper Basin gets to keep at least 7.5 million acre-feet of water annually and must deliver another 7.5 million acre-feet to the Lower Basin states.

In addition, the Upper Basin states deliver another 730,000 acre-feet from Lake Powell each year to help meet the Colorado River's obligation to Mexico, bringing total minimum deliveries from Powell to Lake Mead to 8.23 million acre-feet. Lower Basin states contribute water to Mexico, as well.

Until the current drought struck, enough water has been stored in Lakes Powell and Mead to ensure that Nevada, Arizona and California and Mexico get their share, even in dry years.

But if the reservoirs' stored supplies continue to shrink, greater pressure will be put on Upper Basin states to provide more.

Last fall, as worrisome forecasts showed storage at Powell continuing to shrink - it now stands at just 34 percent of capacity - the Upper Basin states asked Norton to slash deliveries to help the lake recoup water supplies lost to the drought.

But forecasts improved dramatically over the winter, showing that for the first time in five years Lake Powell would see above-average inflows.

"I don't think it's a devastating blow," Eric Wilkinson, manager of the Northern Colorado Water Conservancy District, said of Norton's decision. "But if this downward trend continues, we'll be asking her to do the same thing next year."

In Los Angeles, Dennis Underwood, manager of the giant Metropolitan Water District of Southern California, struck a conciliatory tone, saying the need to cooperate in the drought talks was more important than winning or losing the first round.

"This was an operational decision for 2005," he said. "This is the first time in history we've had the reservoirs where they are. We've never had to look at 'is there a better way to operate.' But there is no victory here."

In a letter to the seven basin-state governors on Monday, Norton restated her concern about the lingering drought and the need to develop new drought rules for the river to ensure that all seven basin states have adequate supplies.

Norton said Monday she wants the drought plan done in 30 months - by the end of 2007 - and she wants meetings to begin by May 31.

Norton's decision on Lake Powell is "understandable . . . but we'd hoped to keep more water in the Upper Basin," said Scott Balcomb, a Glenwood Springs water attorney who represents Colorado on the Upper Basin Commission and in talks among the seven basin states.

Norton's decision, however, didn't sit well with a Lake Powell boating enthusiast, one of thousands who live in Colorado.

"They had a chance to get some capacity in Powell and you'd have thought she'd be all for that," said Dave Dunder, of Grand Junction, part-owner of a houseboat. "So the water will keep dropping so all those folks in Arizona and California can keep their swimming pools full. It's not right."

Water Wars Move Underground

Los Angeles Times

Cities seek to refill aquifers emptied by extensive pumping. But another agency claims control over reserves.

By Jia-Rui Chong, Times Staff Writer

Since Southern California was settled, communities have lived and died on their access to water, fighting mercilessly for their rights to pump it. Now, the focus has shifted as cities see the depleted underground aquifers as a potentially valuable resource.

A group of cities in southeast Los Angeles County, including Downey and Lakewood, are asserting their rights over the vast aquifers and hope to eventually use the porous sediments to store portions of their water supply. They believe they can save money by pumping imported water into the ground rather than pay for expensive water storage facilities and pipelines.

Water storage can be expensive: The Metropolitan Water District, the region's main water wholesaler, spent \$2 billion completing Diamond Valley Lake, a reservoir that holds 800,000 acre-feet of water and required flooding a valley in Riverside County. An acre-foot is enough water to supply two average families for a year.

"I could spend a lot of money, find land, build a pipeline to that land because there's no land around here, but it would be very expensive," said Desi Alvarez, the director of public works in Downey. "Why would I give up a relatively inexpensive resource right under our jurisdictional boundaries?"

But exactly who controls the valuable aquifers is a matter of dispute. The Water Replenishment District of Southern California also claims authority over what happens in the aquifers. The district was formed in 1959 because local agencies had drawn out so much water that the aquifers were dangerously low. It was charged with refilling the aquifers so that agencies with rights to the water could continue pumping.

Water district officials fear that cities or other groups with water rights, such as private water companies, want to use the fragile water system to generate revenue. They worry about the aquifers being leased out to the highest bidder or agencies that will distribute the water elsewhere. That, they said, could result in misuse of the system.

"It's like deregulating energy," replenishment district General Manager Robb Whitaker said. "You saw what happened. If people put water in whenever they want to put it in and we have no ultimate authority over what occurs, we'd be left to clean up the mess."

Aquifers form when water saturates loose layers of earth - sand and gravel in the Los Angeles Basin - that are separated by dense silt and clay. Under certain conditions, water percolates from the surface into these underground reservoirs. Some aquifers lie just below the surface and others spread out at a depth of about 1,000 feet. Cities and water agencies drill wells to recover the water.

Not all areas have aquifers. Bedrock underlies San Diego, for example, so not enough water can accumulate to supply the county.

In the Los Angeles Basin, much of the natural water had been drained from the wells by the 1960s. In the decades after that, no one really sought to use empty space in the aquifers.

But that changed a few years ago.

Voters passed ballot initiatives in 2000 and 2002, making millions of dollars available for local groundwater storage projects. Underground storage is attractive not just because of the lower costs but because less water evaporates than in a surface reservoir.

In southern Los Angeles County, geologists believe the 10 aquifers that spread underground from Manhattan Beach to Whittier could safely store 450,000 acre-feet of water. That's enough to fill more than half a million Olympic-sized swimming pools.

The region's main importer of water, the Metropolitan Water District, has already joined water officials in Orange County to slowly fill aquifers with about 60,000 acre-feet of imported water. In exchange for the storage space, the MWD used the bond money and its own construction funds to pay for new pipes to bring the water into the Orange County Water District's system.

The eight cities participating in the project will also get free wells so it is easier to draw the stored water. The cities could draw the water as soon as 2007, officials said.

Cities in Los Angeles County are now talking about reserving a portion - perhaps half - of the aquifers beneath their own communities.

They would use the space to capture additional storm runoff and store imported water, a move they said would save them the cost of contributing to big water storage projects.

In drier years, the cities would still have to import water from sources in Northern California and the Colorado River, among others, to put into storage. But they could take advantage of natural aquifers, instead of paying a water wholesaler to build its storage systems. With plenty of water in hand, the cities could also avoid surcharges the wholesalers sometimes add in times of drought.

Several cities said they had no immediate plans to sell off that storage space to other counties and funnel the money back into police departments or other city services.

But, Alvarez, of Downey, added: "I see nothing wrong with that."

Flaming Gorge test flow blamed for flooding crops

April Reese, Land Letter Southwest reporter

A test flow unleashed by the Bureau of Reclamation in late May to aid endangered fish in the Green River flooded farms along its banks, prompting an angry backlash from farmers and local government officials that may culminate in legal action.

The razorback sucker, humpback chub and Colorado pike minnow -- all listed under the Endangered Species Act -- have been in decline for decades, and biologists say Flaming Gorge Dam, completed in 1962 as part of the Colorado River Storage Project, is partly to blame.

But the Fish and Wildlife Service and the Bureau of Reclamation, which operates the dam, have come up with a plan to recover the fish while keeping the dam in place. The key, they say, may be experimental, increased flows from the dam that mimic historic flows on the Green River, which is fed by the free-flowing Yampa River in Dinosaur National Park. At the behest of FWS, BuRec launched a test flow in late May, allowing a

torrent of water to surge downstream for several days in hopes that the flows would help create sandbars and side channels, which serve as nurseries for the fish.

But officials in Uintah County, Utah, and some area farmers say the experiment, which boosted flows to 19,500 cubic feet per second near the confluence of the Green and Yampa rivers, flooded farmland and destroyed crops. Some farmers along the river have had to pull their irrigation pumps, said Mike McKee, a Uintah County commissioner.

"We have some real concerns about how this has affected farmers," McKee said. "To spend hundreds of thousands of dollars and have this kind of thing happen ... taxpayers should be pretty frustrated right now."

The county argues that a smaller test flow would have been just as beneficial to the fish. Their requests to ratchet down the flows went unanswered, McKee said.

"This whole flooding tragedy could have been avoided," McKee said.

But Beverly Heffernan, an environmental specialist at BuRec's Provo, Utah, office, said the test flows are no higher than flows during wetter years in the basin. In 1996, 1997 and 1999, flows exceeded 20,000 cfs -- less than the peak of the test flow.

"It seems bigger to everyone because we've had 6 years of drought," she said.

And the test flows are required under a 1992 biological opinion from the Fish and Wildlife Service that calls for boosting flows for at least a week every spring to help recover the fish, Heffernan added.

After receiving complaints from Uintah County, BuRec asked FWS for approval to decrease the flows, but the service said the flows had to be in keeping with the requirements of the biological opinion, Heffernan said.

Furthermore, without the dam in place, flows would be higher, she noted.

"There's a reason it's called a flood plain," she said. "They're saying we're causing an unnatural, high flow, but actually it's an unnatural low flow compared with what it would be like if the dam weren't there."

When asked why the county has allowed farming and development on the banks of the river, McKee said it's difficult to determine where to draw the line in a flood plain to protect property.

"The problem is, what is a flood plain -- is it 500 years, 100 years?" he said, referring to the frequency of floods that is often used to characterize a flood plain. "How far do you go?"

Uintah County likely will file suit against BuRec for losses incurred by farmers during the test flows, McKee said.

BuRec and FWS have gotten flack over the test flows from environmental groups as well, which say the influx of water is unlikely to help endangered fish.

"I'd like to see them doing something as positive as experimental flows are supposed to be to help recover fish," said John Weisheit, conservation director for Living Rivers in Moab, Utah, which has advocated for the removal of Flaming Gorge Dam.

Water expert warns Colorado River shortages may be inevitable

ASSOCIATED PRESS

BOULDER, Colo. – Water shortages in the Colorado River are almost inevitable by 2011 and could force feuding Western states to cooperate on managing the river, an expert said.

"All the states are at risk," said Jim Lochhead, former executive director of the Colorado Department of Natural Resources. "And when all parties are at risk, there is potential for a mutually beneficial (resolution)."

Lochhead spoke Wednesday at a University of Colorado symposium on the river's problems.

A long drought has left Lake Powell and Lake Mead, the river's two major reservoirs, dangerously low. Abundant snow last winter will raise both reservoirs, but not enough to replace what the drought and a booming population have drained.

"We wiped out the bad year of 2004 by having a wet 2005," said Terry Fulp of the U.S. Bureau of Reclamation. "But there is still an impetus to get some agreement."

The 1922 Colorado River Compact divides the river's water between the Upper Basin states – Colorado, New Mexico, Utah and Wyoming – and the Lower Basin states – Arizona, California and Nevada. So far, the river has been able to satisfy the demand, but population growth is expected to outstrip the available water, officials said.

The Interior Department has begun writing a drought management plan for the river after the seven states failed to reach an agreement. The plan is expected to be finished by December 2007.

Meetings to focus on Colorado River water pact

Comments will lead to seven-state sharing agreement

By Jerd Smith, Rocky Mountain News June 16, 2005

Federal water officials, hoping to break a seven-state impasse over a new drought plan for the Colorado River, will launch the first round of public meetings in Utah and Nevada next month on what such a plan should contain.

Late last year, federal officials warned the states that if they couldn't agree on a drought plan, the U.S. Bureau of Reclamation would do it for them.

"The drought has placed a lot of pressure on everybody," Bob Johnson, director of the Lower Colorado Region at the U.S. Bureau of Reclamation, said Wednesday. "Now decisions have to be made."

U.S. Interior Secretary Gale Norton has said she wants the water-sharing agreement finished by the end of 2007.

In April, the seven states that comprise the Colorado River Basin missed the deadline to come up with their own plan.

Today the stalemate continues as states from Wyoming to California contemplate a future of shrinking water supplies.

"Now it's who blinks first," said Herb Guenther, director of Arizona's department of water resources.

Tensions rose in May when Norton refused to hold more water in Lake Powell this year, as Colorado and others had requested.

Any new drought plan is likely to include triggers for determining when releases from Lake Powell to Lake Mead, the river's two main storage banks, can be reduced.

But that's something Arizona and other states have vigorously opposed because it means they would have to get by on less water.

Under the 1922 Colorado River Compact, the river's water is divided between the Upper Basin states - Colorado, Wyoming, Utah and New Mexico - and the three Lower Basin states - Nevada, Arizona and California.

Lake Powell holds extra water generated in the Upper Basin until it is needed farther downstream in Lake Mead. But if Lake Powell drops too low, Upper Basin states such as Colorado could be forced to cut back their own take from the river to ensure those farther south get their legal share. The river provides about half the water used on the Front Range.

In the past, there always has been enough extra water to satisfy growing demands on the river. But the recent drought has shown all of the states how difficult it is to manage when the river's supplies are short.

Water officials estimate that the Upper Basin states did without more than 400,000 acre-feet of Colorado River water - enough for more than 800,000 households - during the dry spell that began in 2000.

Even if the drought ends and there is a return to wetter weather, the need to provide drinking water to millions of new residents throughout the West will strain the river to the breaking point, water officials say.

The main problem: Writers of the 1922 compact believed the river produced, on average, nearly 17 million acre-feet of water, more than enough to supply the Upper Basin and Lower Basin with 7.5 million acre-feet each.

Now, water officials believe the river produces much less - from 13 million acre-feet to 14.5 million acre-feet.

"The river has been overdeveloped based on the water supply we now know is there," said Scott Balcomb, Colorado's representative on the Upper Colorado River Commission and a negotiator in the seven-state talks.

Last week, at a University of Colorado conference on the river, several Western water officials said the only way to break the deadlock is to find new water supplies, using such techniques as cloud seeding to produce more snow or desalination plants on the West Coast.

How to comment

Public hearings on the Colorado River Drought Plan:

- July 26: Henderson, Nev., 10 a.m to noon (PDT), Henderson Convention Center, 200 S. Water St.
 - July 28: Salt Lake City, 10 a.m. to noon, Hilton Hotel, 255 South West Temple St.
 - Officials will take written comments through Aug. 31 for the Lower Colorado region at Strategies@lc.usbr.gov, or by fax at 702-293-8156.
 - For the Upper Colorado region, the e-mail address is Strategies@uc.usbr.gov, or fax 801-524-3858.

APS dam removal releases Fossil Creek

Central Ariz. plant closures let stream flow again

Mary Jo Pitzl The Arizona Republic Jun. 19, 2005 12:00 AM

FOSSIL CREEK - It started as a trickle, a small finger of water stretching across a sunbaked slab of granite. But it had the force of a flood, heralding a historic event and the beginning of a new era for this central Arizona stream.

At high noon Saturday, Arizona Public Service Co. abandoned the dam that has held back Fossil Creek for nearly a century and let the water flow unabated. advertisement

It marks the first time in anyone's memory that an Arizona dam has been taken out of commission in the name of restoring a river. On Fossil Creek, the water had been diverted to power two hydroelectric plants run by APS.

"This represents a watershed event," said Andrew Fahlund, vice president for protection and restoration at American Rivers, a conservation group. "To do something like this in Arizona is extraordinary." It's extraordinary for a number of reasons, as speaker after speaker said during a creekside ceremony that marked APS' retirement of the Childs and Irving hydroelectric-power plants northwest of Payson.

"This is just another benchmark in the long history of Fossil Creek," said Jack Davis, president and chief executive officer of APS. When future generations come to Fossil Creek, he said, "they'll remember that short period of time - 100 years - when Fossil Creek was used for economic development."

"APS gave Fossil Creek a gem," said Duane Shroufe, director of the Arizona Game and Fish Department. The creek is one of the few perennial streams in Arizona, running even on hot summer days. The water is rich in calcium carbonate, which will grow into travertine formations under the force of the increased water flow, creating pools and basins reminiscent of those found at Havasu Falls.

Hiking enthusiasts will have a 14-mile waterway to follow on hikes along the tree-lined stream, and wildlife is expected to be drawn to the once-again flowing creek.

Fossil Creek also is on the brink of becoming a prime spot for native fish, such as the humpback chub, the speckled dace and the longfin minnow.

State and federal fishery officials airlifted native fish to ponds along the creek last fall, and the ensuing months have been productive.

"There's lots of little fish that spawned," reported Dave Weedman, an aquatic-habitat specialist with Game and Fish.

But don't grab your fishing pole just yet. Game and Fish wants to give the fish at least two years to establish a healthy population before opening the area to anglers.

Saturday's event was highlighted by Davis and representatives of six other groups flipping a symbolic switch to turn "off" the dam.

This triggered dam operators to open the gates on the dam, several miles upstream. Two hours later, the first trickles of Fossil Creek flow reached the grounds of the Irving power plant. Plant operators figured it would take four hours for the full force of the 43 cubic-feet-per-second flow to reach the plant, and estimated it would raise the creek 10 inches.

Davis said the shutdown of the only two hydropower plants in its network wouldn't cause a ripple in APS' power supply. Combined, the plants were producing less than 1 percent of APS' total electricity. The return of water to Fossil Creek came about through an unusual alliance between the utility company, various environmental organizations and the Yavapai-Apache Nation.

In 1999, APS decided to drop plans to recommission the power plants.

Tribal Chairman Jamie Fullmer fought back tears as he contemplated the significance of Saturday's event.

"To us, water is sacred," Fullmer said. "And with the water now flowing, it will bring back a new energy to our community in the Verde Valley and to Arizona." Just as the power plants were key to Arizona development, their decommissioning also plays a big role, he said.

The Childs plant was built in 1909, Irving in 1916. Both were powered by an above-ground pipeline that channeled the force of Fossil Creek to produce power for central Arizona mining operations. Later, some of the power was directed to Payson and Phoenix.

Robin Silver of the Center for Biological Diversity put in a plug for the National Environmental Policy Act, which he said gave environmental groups the right to speak out against continued damming on the creek. The law is currently the subject of congressional scrutiny, including a public meeting Saturday in Show Low.

"The two laws that made this happen are being destroyed," he said referring to NEPA and the Endangered Species Act, which protects the habitats of endangered plants and animals.

The creek's restoration puts more pressure on officials with the Coconino and Tonto national forests, where the creek runs, to manage the people that are expected to visit the area.

Long-term planning will start soon, said Nora Rasure, the Coconino superintendent. And in the short term, some hiking trails may be closed as APS deconstructs the power plants.

The utility plans to leave a section of the flume and one or two structures at the Irving plant; everything else, including a new temporary bridge, will be dismantled and removed.

Perhaps the looming threat to Fossil Creek is that it will be loved to death, proponents say.

But U.S. Sen. John McCain, R-Ariz., plans to introduce legislation that would include Fossil Creek in the Wild and Scenic Rivers system, providing federal protection and dollars.

Scientists investigate Colorado River paleoflood deposits

The Times-Independent
Moab, Utah

Fieldwork for Phase 2 of a Living Rivers uranium waste research project was recently completed along the banks of the Colorado River. Living Rivers is a Moab-based non-profit river restoration organization that is conducting the study with a grant from the Department of Energy's Citizens Monitoring and Technical Assessment Fund.

This project was completed with the cooperation of three professors of geomorphology at the University of Arizona, namely John Dohrenwend, Victor Baker and Noam Greenbaum. The purpose of this work is to provide sound scientific evidence to describe the nature of past floods along the Colorado River and how such floods, if they occur again, could potentially lift the pile into the river, thereby causing serious contamination problems for all downstream users for generations to come.

Dr. John Dohrenwend, who assessed that the Colorado River was migrating towards the Moab Mill site, conducted the first study last winter. The results of Dohrenwend's findings were published with much detail in the Times-Independent.

See: [Times-Independent.pdf](#) [7.2 MB File]

The second study was conducted in the last four weeks under the direction of Dr. Noam Greenbaum, who is currently on a sabbatical at the University of Arizona. Dr. Greenbaum is a professor at the University of Haifa, Israel, and an expert in the study of paleofloods.

A paleoflood refers to a past or ancient flood event that occurred prior to the time of human observation or direct measurement by modern hydrological procedures. Such floods usually leave evidence along the margins of watercourses that include sediment deposits, driftwood lines, and buried organic material.

In late March an excellent study site was discovered across the river near the BLM boat launch along Highway 128 near milepost 10.3. The site included surface driftwood, imbricated rocks (rocks stacked like shingles by moving water), and high water flood deposits.

"For the purposes of this study it was critical to find a pristine site close to the Moab Mill downstream of the Dolores River," said Dr. Greenbaum. "To discover such a potentially productive site was indeed a very fortunate occurrence for us."

The site is located in Arches National Park and the permit to begin investigative work was issued by the park superintendent. During the excavation of 14 test pits (up to 2 meters deep), which were dug by hand by the staff of Wildland Scapes, a certified archeologist was present to ensure that no cultural properties were jeopardized at the work stations – which fortunately was the case.

Of the 14 pits that were carefully examined, described and sampled, 13 pits provided evidence of several large floods that have occurred on the Colorado River. The findings in the pits include also four samples of organic material that will be analyzed by the University of Arizona for Carbon 14 radiometric dating. These samples will provide ages of at least 4 paleofloods. Additionally, sediment samples were also collected to undergo another dating process called Optically Stimulated Luminescence.

Another phase of the second project included measuring the river geometry including 25 cross-sections, longitudinal profile and elevations of flood deposits with a total station – an instrument that uses a laser range finder to accurately record the maximum stages of these historic floods. Approximately three miles of the Colorado River segment was sufficiently measured, starting downstream from Sandy Beach.

Said Dr. Greenbaum on the extent of the flooding, "We hope to produce a public report of our findings this fall. In the meantime, we feel confident in our preliminary findings to conclude that part of the floods we are currently analyzing were much bigger than the historic flood of 1884, which was measured at Loma, Colorado at a discharge of 125,000 cubic feet per second."

The final report will be submitted to all the management agencies that utilize the resources of the Colorado River, especially the Department of Energy as it relates to the mitigation of the Moab Mill tailings pile. It is the intention of this report to provide information to aid the DOE concerning their pending Record of Decision and to encourage Congress to provide the necessary funding to move the pile in a timely manner. This report should also provide the people of Moab and other settlements along the Colorado River a long-term and more reliable flood frequency analysis to improve flood risk assessment for any engineering design along the Colorado river.

"What is really exciting about this project was the filling of a scientific void through the initiative of citizens of Moab and Grand County. This study will in turn benefit all the people downstream who depend on the Colorado River for sustenance," says John Weisheit who is the conservation director at Living Rivers and the Colorado Riverkeeper of the Waterkeeper Alliance.

Says Professor Victor Baker, "We thank the citizens of Moab for their persistence to get this work done. It is our hope that Dr. Greenbaum's study will initiate further funding to investigate the paleoflood deposits of the Green and San Juan rivers as well. By doing this, agency managers will have much needed information to safeguard public resources and private property along the Colorado River."

Two-hour comment period on river set up

LAS VEGAS SUN

The federal government is providing two hours Tuesday for Southern Nevada residents to contribute their thoughts toward what ultimately would be a new policy governing shortages along the Colorado River, the source of 90 percent of Southern Nevada's drinking water.

The Interior Department and the Bureau of Reclamation are working to design rules to govern how the seven states along the Colorado River would share the pain from cuts to the river resource if the volume of water in the river continues to fall.

The impetus for the rule-making process has been more than five years of drought that caused water supplies in the river to drop to about half of what it has been in wet years.

Although last winter's relatively wet season helped the Colorado River recover somewhat, the volume is still just 56 percent full. Regulators worry that an extension of the drought could require cuts for the states that use the river water, among them Nevada, Arizona and California.

Before drafting the rules for "shortage criteria," the Bureau of Reclamation is working to define how the rule-making process should go forward. The meeting from 10 a.m. to noon at the Henderson Convention Center, 200 S. Water St., is one of the first steps toward setting the process. A second meeting will be Thursday in Salt Lake City.

People will be able to submit written or verbal comments at the public meeting.

Robert Walsh, a bureau spokesman, said despite the narrow, two-hour period for the public meeting, people will have ample opportunity to comment.

"This is a scoping process," he said. "We have left that period open to the end of August. People can send us a letter. They can fax us information. They can send us e-mails. There's full opportunity to participate even if they can't attend the meetings."

As the policy is constructed over the next several years, there also will likely be other public meetings, Walsh said.

"There will probably be other opportunities for input and comment," he said.

One group that promises to attend the two-hour meeting is Living Rivers, which is dedicated to conserving the Colorado River. The group is probably best known for advocating the removal of Glen Canyon Dam, which spans the river from Utah to Arizona and forms Lake Powell.

Although Nevada and federal water officials have said Lake Powell has been a critically important upstream reservoir, Living Rivers members argue that Lake Powell has led to an unsupportable loss of water from the Colorado River system because of evaporation.

The main concern of the group is that the two-reservoir system with Lakes Powell and Mead is contributing to the demise of endangered species along the river.

"The Grand Canyon ecosystem is falling apart," said John Weisheit, Living Rivers conservation director. "They are sacrificing the Colorado River, is what they are doing."

Doug Hendrix, a spokesman for the Bureau of Reclamation's division that manages the upper Colorado River, including Lake Powell, said the upcoming meetings will not address the long-simmering debate over Glen Canyon Dam. Hendrix noted that operation of the dam and Lake Powell is congressionally mandated "for the long term use by the states that depend on that water."

He said the upstream reservoir with Lake Mead have been very important in regulating the water supply on the river. Southern Nevada and its neighbors have had a reliable source of water despite severe drought, he said.

"They have certainly proven their worth over the last five consecutive years of drought," Hendrix said. "That's what they were designed to do."

The Southern Nevada Water Authority, the water wholesaler for the region, also will have officials attending the meeting, said Vince Alberta, Water Authority spokesman.

He said the economies of all seven basin states, from Wyoming to California, depend on effective management of the river.

"The primary objective in developing these guidelines must be the conservation of the water supply, consistent with the purposes for which Mead and Powell were authorized by Congress," Alberta said.

For information about the development of strategies to manage shortages in Lake Mead and Lake Powell, call Bureau of Reclamation at 293-8156.

LR Press Release 07/25/05

The One-Dam Solution: Hoover Dam alone the solution for managing dwindling Colorado River water.

Report calls for decommissioning Glen Canyon Dam as the primary action needed to reduce current and future economic and ecological impacts of dam operations to the Southwest.

Contact:

John Weisheit - (435) 259-1063/Mobile: (435) 260-2590

David Haskell - (928) 567-9873

As the Bureau of Reclamation begins developing plans for re-operating the nation's two largest dam and reservoir complexes with public meetings at Las Vegas and Salt Lake City this week, a new report released by Living Rivers reveals that Southwestern water users and the ecological health of the Colorado River would both be better served if one dam were removed.

"Hoover and Glen Canyon Dams may have been icons of 20th century civil engineering, but continuing to operate them in their present fashion is wasting water that could support more than six million people. In addition, Glen Canyon Dam is devastating the ecological integrity of the Grand Canyon and is creating a dam safety problem due to advancing sedimentation in Lake Powell," says John Weisheit, Living Rivers conservation director.

The analysis reveals that increased water use and decreasing supplies raise questions about the need for both dams, especially in light of their tremendous evaporation losses. The report concludes that it would be more efficient to eliminate Glen Canyon Dam from the system and utilize Hoover Dam and adjacent underground storage to capture the limited amounts of surplus water that may be available in the future.

Key findings of the 24-page The One-Dam Solution include:

More efficient water storage strategies are needed.

When Glen Canyon Dam was built, nearly 2.6 million acre feet (MAF) of surplus water flowed into Lake Powell annually, allowing the reservoir to fill in 17 years. However, increasing demand upstream has nearly eliminated these reserves. Demand has risen 100 percent since the dam was built and is projected to increase another 23 percent by 2020--placing demand well above the rivers' 13.5 MAF average annual flow.

Since 1979 there have been warnings that the Colorado River would fail on the supply-side because 11 percent more water has been allocated than the river can historically provide. Even more problematic is that Department of Energy research forecasts that climate change will cause Colorado River flows to decline 18 percent by 2040.

Precious water is being lost from the system

On average, Lake Powell and Lake Mead lose 1.3 MAF of water annually to evaporation, nearly ten percent of the river's annual flow.

It was not until the Autumn of 2004 that Lake Powell's storage actually factored into the water usage of people downstream. Prior to this time it caused the loss of 36 MAF due to evaporation and to seepage into the surrounding sandstone. Underground Storage should be more widely utilized

Depleted groundwater aquifers along the Colorado River represent a storage solution that could eliminate much of the water now being lost. In California and Arizona alone it is estimated that suitable sites containing a total of 41 MAF of storage are available along the system, and potentially another 46 MAF nearby. Aquifer recharge infrastructure in place now have the capacity to recharge 1.4 MAF of Colorado River water annually.

There is one dam too many in the Southwest desert.

Removing Glen Canyon Dam from the system, using Hoover Dam to capture annual flows while expanding groundwater storage could recover 810,000 acre feet annually now being lost to evaporation. This is enough water to support 1.6 million households of four people each.

The Destruction of Grand Canyon Resources must be stopped.

More than \$200 million has been spent in failed efforts to halt the demise of Grand Canyon National Park's river ecosystem due to the impacts of Glen Canyon Dam. Four native fish are now extinct, one is in jeopardy and another is of special concern. Glen Canyon Dam has trapped the sediment necessary to maintain habitat and beaches for wildlife and recreation, as well as the stabilization of archeological sites.

Accumulating Sediment Presents a Serious Looming Problem.

Sediment is a major unresolved problem threatening the long-term operations of both Hoover and Glen Canyon Dams. Ultimately, sediment will have to be removed from one or both of these reservoirs. Removing sediment from Lake Mead rather than Lake Powell is the most feasible and least expensive likely alternative. While original estimates projected that sediment would not effect the safe operations of Glen Canyon Dam for another 60 years, scientists now warn that major problems could occur sooner.

Hydropower and Recreation are Incidental Benefits

Lower reservoir levels have already resulted in reducing Glen Canyon's power production by 40 percent. This loss has been seamlessly absorbed elsewhere in the energy market. The same is true of recreation, which at Lake Powell has dropped 50 percent in the past 15 years. Such uses were deemed "incidental" to water management when these dam were authorized, and should be treated similarly as new management strategies are developed.

"There will be no efficient solution to managing the growing crisis in Colorado River water management without seriously rethinking how these dams are used, or not," adds Weisheit. "And when doing so, it's clear than when it comes to saving precious water, and restoring Grand Canyon in the process, one dam is better than two."

Boulder City, NV 89006-1470

Mr. Rick Gold
Regional Director
Bureau of Reclamation, Upper Colorado Region
Attention: UC-402
125 South State Street
Salt Lake City, Utah 84318-1147

Dear Mr. Johnson & Mr. Gold,

Living Rivers, Colorado Riverkeeper, and the 144 undersigned organizations submit the following report, The One-Dam Solution, as scoping comments for the development of management strategies for operations at Lake Powell and Lake Mead, on the Colorado River, under low reservoir conditions.

With current demand for Colorado River water nearly at the river's historical annual flow of 13.5 million-acre feet (MAF) and rising, and government-sponsored scientists anticipating average annual flows to decline 18 percent by 2040, the prospect of ongoing low water conditions for Colorado River reservoirs is a near certainty. The average flow of 60 percent into the system for the past six years is firm evidence of this.

For more than 25-years, government scientists and administrators have warned that shortages would be occurring now. This action is the first to reexamine the flawed operational strategies that have been in place as far back as 1922 when the Colorado River Compact allocated 11 percent more water than the Colorado River has to give.

Reexamining these two reservoirs is critical, as they constitute more than two-thirds of the system's storage capacity, which with declining inflows and increased demand are proving excessive.

Meanwhile, these two reservoirs can cause the loss of upwards of ten percent of the river's average annual flow due to evaporation—valuable water for critical habitats and water users downstream.

Furthermore, the challenges facing the future operations of these reservoirs go beyond water allocation and storage inefficiencies. Sediment entering Lake Powell will eventually compromise Glen Canyon Dam's safety. Despite recent warnings that this could happen sooner than the 40-year-old estimate of 2060, there has been no comprehensive monitoring or analysis conducted to address this inevitable problem.

Lastly, despite more than \$200 million already spent, no gains have been made to restore the critical habitat for endangered species in Grand Canyon National Park impacted by Glen Canyon Dam's operations. The mandates of the Grand Canyon Protection Act and the Endangered Species Act in particular are being ignored to maintain Lake Powell even though it is proving to be both wasteful and unnecessary for water storage.

It is therefore critical that the Bureau of Reclamation broadly reexamine the operations of these facilities in accordance with preparing an Environmental Impact Statement to address the following:

- 1) Pursue transfers of Lake Powell and Lake Mead storage to groundwater aquifers.
- 2) Develop a sustainable sediment management program for Lake Powell and Lake Mead.
- 3) Determine the costs and benefits of decommissioning Glen Canyon Dam to restore natural flows through Glen and Grand Canyons.
- 4) Identify new water allocation guidelines to reflect the amount of water the Colorado River actually provides, how it should be distributed and what amounts are needed to protect critical habitats in Grand Canyon and elsewhere.

A water management crisis is looming on the Colorado River. The federal government, as Water Master, has the responsibility to help avert this. Most of the issues addressed in the attached report are not new, but continuing to ignore them will only worsen the impacts once the crisis arrives.

Thank you for the opportunity to submit these comments. We look forward to assisting the Bureau of Reclamation in developing this Environmental Impact Statement concerning the protection of water resources from the Colorado River in times of shortage.

Sincerely yours,

John Weisheit Conservation Director, Living Rivers Colorado Riverkeeper

Future of Colorado River subject of meeting

Utah environmental group seeks dismantling of Glen Canyon Dam, proposes pumping reserve water into aquifers

By HENRY BREAN LAS VEGAS REVIEW-JOURNAL

The Bureau of Reclamation will hold a public meeting in Henderson today on the future of the Colorado River, and a Utah environmental group plans to be there to call for an end to North America's second largest man-made reservoir.

Moab-based Living Rivers wants the federal government to tear down Glen Canyon Dam and allow Lake Powell to drain downstream, a move the group argues would save water and revitalize the Grand Canyon.

"We've got to do something because it's obvious the Colorado River doesn't have any more to give," said John Weisheit, Living Rivers conservation director.

But state and federal water officials insist the dam and the reservoir behind it are far too important to simply dismantle.

"The groups out there are free to have their own suggestions and their own opinions, but from the bureau's perspective, it is not an issue we have under consideration," said Doug Hendrix, spokesman for Reclamation's Upper Colorado Regional Office. "The intent of the reservoir is to provide long-term carry-over storage for Colorado River water users."

Lake Powell has served that role well in recent years, said Vince Alberta, spokesman for the Southern Nevada Water Authority.

"The value of Lake Powell has never been more significant than over the last six years, when the Colorado River has been dealing with the worst drought on record," Alberta said.

"Without Lake Powell, Lake Mead would have been pretty close to empty before this in-flow year," Hendrix said.

Today's meeting is scheduled for 10 a.m. to noon at the Henderson Convention Center on Water Street. The bureau will hold a second meeting from 10 a.m. to noon Thursday in Salt Lake City.

Reclamation officials are seeking public input as they prepare to consider new management strategies for Lake Mead and Lake Powell, where water levels have dropped in the face of drought and increased demand by water users.

Interior Secretary Gale Norton has called on the Lower Colorado River Basin states of Nevada, Arizona and California and the upper basin states of Colorado, New Mexico, Utah and Wyoming to adopt new management strategies for the lakes.

Norton has also directed the states to agree for the first time on rules for dividing a shortage on the river.

She wants both issues decided by the start of 2007, or the federal government will impose a solution of its own.

About 90 percent of Southern Nevada's drinking water comes from the Colorado River.

In a 24-page report titled "The One-Dam Solution," Living Waters argues that decommissioning Glen Canyon Dam is necessary to restore natural habitat along the Colorado and protect wildlife, recreation and cultural resources within the Grand Canyon.

The move also would save water, since about 6 percent the Colorado River's annual flow is lost to evaporation and seepage from Lake Powell, which straddles the Utah-Arizona border at the northeastern end of the Grand Canyon.

Instead of storing water in the giant, open-air reservoir, the Living Rivers report released this week recommends pumping the water into depleted groundwater aquifers along the Colorado River, where it could be stored with comparatively little evaporation.

According to the report, there is enough aquifer space in California and Arizona alone to store almost twice as much water as Lake Powell can hold when it is full.

But Alberta called the Living Rivers plan "cost prohibitive."

"The spike flows on the Colorado River would make it extremely difficult to make an artificial recharge system large enough to accommodate the volume of water over the run-off period," he said. "Lake Powell has risen more than 50 feet over last few weeks alone."

One way or another, Glen Canyon Dam will not last forever, Weisheit said. Unless something is done, silt carried by the river will build up at the base of the dam until it endangers the structure.

"This is going to happen anyway," Weisheit said of losing the dam. "Why are we putting this off?"

The Bureau of Reclamation will accept public input through Aug. 31 on how the Colorado River should be operated during low reservoir conditions.

Comments can be sent by fax to 702-293-8156, by e-mail to strategies@lc.usbr.gov, or by surface mail to Regional Director, Bureau of Reclamation, Lower Colorado Region, Attention: BCOO-1000, P.O. Box 61470, Boulder City, NV 89006-1470.

Draining Lake Powell not an option, federal water officials say

By KEN RITTER
ASSOCIATED PRESS

HENDERSON, Nev. (AP) - Decommissioning Glen Canyon Dam and draining Lake Powell is not an option for managing the Colorado River during years of drought, federal officials said Tuesday.

"Our direction from Congress has been, 'Don't study that,'" Terry Fulp, Bureau of Reclamation Lower Colorado area manager, said of a proposal by a Moab, Utah-based environmental advocacy group.

Millions of gallons of water lost to evaporation could be saved by removing the dam in Page, Ariz., the Living Rivers group said in a report outlined for bureau officials.

Water managers took public testimony Tuesday as part of Interior Secretary Gale Norton's command to establish rules to limit interstate squabbles while managing the river during shortages.

A 1922 agreement allocating Colorado River water does not specify how it should be shared during drought. Norton in May rejected a request by four states in the river's upper basin - Colorado, Utah, Wyoming and New Mexico - to reduce releases of water from drought-depleted Lake Powell to more quickly refill the reservoir.

The decision was seen as a victory for California, Nevada and Arizona - three lower basin states that rely on allocations from the downstream Lake Mead reservoir. But Norton made it clear she wanted the states to find a way to share the water without federal involvement.

"This boils down to how we deal with droughts in the future," said Ken Albright, an official with the Las Vegas-based Southern Nevada Water Authority who said he was speaking for the seven Colorado River basin states. "We'll do it, or they'll do it for us."

"Today we have no answers," Fulp said. "We're only trying to get questions and comments about where we're headed."

Another session is scheduled Thursday in Salt Lake City.

The information-gathering process may lead to one or more environmental studies before yielding a December 2007 report, Fulp said.

Nine people spoke Tuesday at the Henderson Convention Center. Some acknowledged the rapid growth of cities such as Denver, Salt Lake City, Albuquerque, Las Vegas and Phoenix was increasing pressure to rewrite river allocation rules drawn up decades ago to serve agricultural needs. Mexico also has a stake in Colorado River flow south of the border.

"You're basically going to be in permanent drought," said Michael Jackson, a lawyer representing a farm family in California's Imperial Valley. "There's not going to be water to fill those reservoirs because of demand."

David Weisheit and David Haskell, Living Rivers officials, said they accelerated the release of a report calling for the decommissioning of the Glen Canyon Dam to coincide with the Bureau of Reclamation review.

They contended that lakes Powell and Mead, the largest of the more than 40 reservoirs in the Colorado River basin, lose 1.3 million acre-feet of water a year to evaporation - or about 10 percent of the annual river flow. An acre-foot equals 325,851 gallons, enough to serve one or two households for one year.

Haskell said capturing water at upstream reservoirs or letting it seep into the ground to recharge underground aquifers would be more efficient.

Rapid silt buildup also could render the Glen Canyon Dam ineffective faster than builders projected, they said.

The dam, which they said contributes to ecological damage in the Grand Canyon downstream, was completed in 1963. Lake Powell, when full, covers 266 square miles, mostly in Utah.

"Somebody's got to be looking out for the future," Haskell said.

Draining of Lake Powell urged

Group cites loss to evaporation

The Arizona Republic

By MARK THIESSEN
Associated Press Writer

SALT LAKE CITY (AP) - A Utah environmental group on Thursday renewed its call for Glen Canyon Dam to be decommissioned and Lake Powell drained to stop the massive yearly evaporation of stored Colorado River water, saying there is a better use for it in the water-starved West.

"We believe 800,000 feet of water could be available to the lower basin," said John Weisheit, with the Moab-based Living Rivers group. "We think that is a significant amount of water."

The group issued a 24-page report - titled the [One-Dam Solution](#) - this week ahead of two federal Bureau of Reclamation meetings seeking comment on plans to manage Lake Powell and Lake Mead during drought.

By having only Hoover Dam in Nevada capture water and using extensive underground storage, enough water could be saved to support 1.6 million households of four people each, Weisheit said at Thursday's meeting here.

When Weisheit spoke at a similar meeting Tuesday in Henderson, Nev., he was told the bureau has been directed by Congress not to study that.

"Living Rivers thinks it's highly undemocratic that we are not allowed to discuss and debate the study of the facility that uses public money," Weisheit said Thursday. "If Glen Canyon Dam is needed, the studies will prove that. If it is not, then that will be the case, too, and we should let science decide what is best for the resources of the Colorado River."

There was no debate Thursday as water managers only took testimony for review. More hearings may be held before the bureau's management report is issued in December 2007.

This week's meetings were part of Interior Secretary Gale Norton's command to establish rules to limit fights among states while managing the river during shortages. A 1922 agreement allocating Colorado River water does not specify how it should be shared during drought.

Norton in May rejected a request by four states in the river's upper basin - Colorado, Utah, Wyoming and New Mexico - to reduce releases of water from drought-depleted Lake Powell to more quickly refill the reservoir.

The decision was seen as a victory for California, Nevada and Arizona - three lower basin states that rely on allocations from the downstream Lake Mead reservoir. But Norton made it clear she wanted the states to find a way to share the water without federal involvement.

Nine people testified Thursday, some urging the government not to ignore the financial rewards from recreation and tourism at both lakes and nearby recreational areas.

Fourteen million visitors annually result in direct and indirect economic benefit to the economy, said Kitty Roberts, superintendent for the Glen Canyon National Recreation Area.

But five years of drought "has negatively affected recreation use and likely caused significant changes to the local and regional economies," she said.

The National Park Service has spent more than \$20 million over the past three years responding to the drought, with the money being used for things like closing or extending launch ramps, moving or adjusting docks.

She urged bureau officials to establish critical water levels on both lakes so recreation services won't have to be curtailed.

Steve Ward, president of Friends of Lake Powell, asked the bureau to consider adjusting water depending on conditions to stabilize the lake's level.

"More efficient reservoir operation would help prevent overflowing spills in the wet years and slow the drawdowns during severe droughts that can jeopardize hydroelectric power production," he said. ---

Arizona braces for water war

\$1.5 million sought to fight Colorado River lawsuits

Shaun McKinnon
The Arizona Republic

Arizona has created a legal defense fund to protect its Colorado River allocation in the event a simmering dispute among other states flares into a regional water war.

The state hopes to raise at least \$1.5 million in the coming months to prepare for possible lawsuits, though officials admit costs could climb many times higher if the dispute spills into a courtroom.

At stake is Arizona's ability to grow. A worst-case loss in court could force the state to give up half of the water that flows through the Central Arizona Project Canal and leave it in reservoirs to benefit upstream users or satisfy a treaty with Mexico.

Most of that water is now reserved for cities in Maricopa, Pima and Pinal counties or set aside to settle claims with Indian tribes.

Representatives from all seven Colorado River states will meet today in San Diego to consider a plan that might solve some of the issues without legal action. The plan is aimed at wringing every possible drop from the river even if it means punching holes in clouds.

The states hope to submit their proposals to Interior Secretary Gale Norton next week as part of a larger effort to create a long-term drought plan for the Colorado. Drought and growth have pushed the river past its limits and renewed tensions among the states, whose bickering dates back decades.

Without a workable plan, "litigation is inevitable at some point," said Herb Guenther, director of the state Department of Water Resources. "We've been staring at it for a long time. But we're trying to avoid the head-on collision and see if we can't work together on these issues."

Guenther's agency ponied up the first \$200,000 for the defense fund, and the state will ask boards governing the CAP and Salt River Project to contribute similar amounts. Guenther said a fund-raising committee will then seek donations from others with a stake in the river, including cities and home builders.

The state has also retained a lawyer who specializes in water to help with legal research and planning.

The decision to begin raising money for legal action pushes Arizona further into a battle that it had largely avoided in recent years, though the state is certainly no stranger to river wars. Arizona vs. California, a landmark case that helped define the way the Colorado is managed, grew out of Arizona's refusal to ratify the original river compact.

"The Colorado River is extremely important to the state of Arizona," said John Sullivan, associate general manager of SRP's water group and a member of the fund-raising committee. "When other states begin to make noises about threatening Arizona's supply, I think the whole state needs to get involved."

The threat stems from arguments over how the river and its tributaries are divided among users. In states along the upper river, which include Colorado, Wyoming, New Mexico and Utah, water taken from tributaries is counted against the states' shares.

In states on the lower river - Arizona, Nevada and California - tributaries are not included in the accounting. That means Arizona, the primary beneficiary to the difference in rules, can use water from the Salt and Verde rivers, for example, and still take its full share of the Colorado.

Arizona won the tributary issue during negotiations over the original Colorado River compact, the set of laws and agreements that governs the river. But, in recent years, Colorado and other upper river states have argued that the lower river states have abused the rule and, as a result, take more than they should.

What may force the argument to the table is a plan by Nevada to divert water from the Virgin River to thirsty Las Vegas, which has exhausted its Colorado River allocation. The Virgin flows into the Colorado at Lake Mead.

Officials from Colorado and Wyoming protested the proposal, telling federal regulators it would rob the Colorado River of a significant amount of water. Those states say that, because the Virgin flows into the Colorado, any water taken from it should be counted against Nevada's share.

Arizona officials fear that, if the dispute over the Virgin River lands in court, the upper river states could demand that other states account for water taken from their tributaries. In addition, the upper river states could ask the court to force the lower river states to deliver all the water that Mexico gets from the Colorado, an obligation all seven states now share.

State officials believe as much as 750,000 acre-feet could be lost. Because the CAP holds the most junior rights to the river, the water would be taken from the canal, leaving it at half-strength. (An acre-foot covers an acre to the depth of 1 foot, or 325,851 gallons. It would meet the needs of a family of five for a year.)

CAP officials believe the seven states can forge an agreement and avoid court, but they acknowledge the risk.

"We all have something at risk when we litigate," said Sid Wilson, the CAP's general manager. "If we could work together on a program of management, we could all be winners for a good long while."

The plan under consideration today would focus on augmenting the river's flow, adding water by seeding clouds, removing non-native vegetation such as salt cedar, adding storage on the lower river and simply managing the water more efficiently.

Wilson said he is confident such an approach could add 1 million acre-feet of water or more per year, easing the pressure on the lower river states.

Pat Mulroy, general manager of the Southern Nevada Water Authority, said what is happening now could be "a lot of saber-rattling," but she said Nevada can't just do nothing.

"It would show a real failure on everyone's part if we end up in court," she said. "If we're pushed, we may not have a choice. Given what our resource picture is, we have no choice but to be dogged."

Colorado created its own legal fund earlier this year and staked out its position that the lower river states, Arizona in particular, have taken more than their share of Colorado River water. Officials there have softened their public stance and have pledged to work on a cooperative plan.

"We believe that we water professionals should be able to do a better job of managing the river than leaving it up to a judge or a court," said Scott Balcomb, Colorado's representative on the Upper Colorado River Commission. "Our thrust right now is to attempt to get some kind of a seven-states agreement in place"

"(Still), I don't blame Arizona for being concerned about the situation that is unfolding," he said.

"My boss was quoted in the Colorado papers indicating that if we needed to, we would have our own legal defense fund ready. Being ready to litigate, if that turns out to be the only option, is only prudent. None of us is gambling on an agreement."

Glen Canyon Dam set for flow test to revive habitat

New twist: Officials will reduce high-low water fluctuations in hopes of restoring the environment for native fish species

By Joe Baird
The Salt Lake Tribune

They will be slowing the flow at Glen Canyon Dam this week, the latest installment in a series of attempts to analyze and ultimately revive the habitat for endangered native fish species in the lower Colorado River.

Beginning Thursday and continuing through Saturday, the Bureau of Reclamation - which operates the dam - will start reducing Glen Canyon's high-low water fluctuations to roughly half of what they have been this month. The lower flows will continue for the following three weeks, then bureau officials will smooth the releases to a steady level before resuming the reduced fluctuations in October.

The flow adjustments are all part of a larger scheme by federal officials to restore the Colorado River to something closer to its natural habitat in the Grand Canyon, with the goal of reviving fish species such as the humpback chub. This week's flow test follows a Glen Canyon release last November in which flows were substantially increased in a bid

to wash sediments down the river to create the sandbars and backwaters that young native fish need to survive. This time around, bureau officials and scientists will be assessing water temperature changes and the food sources that come downstream in the course of the river fluctuations.

Water flowing naturally downstream warms during the summer, but the water released from Glen Canyon Dam is typically much colder because it comes from the deep recesses of Lake Powell. The new twist, according Dennis Kubly, manager of the bureau's adaptive management plan, is that because of the drought and the reservoir's depleted supply, the water released from Glen Canyon is currently warmer than usual - providing bureau analysts with an opportunity. "There is strong evidence that these fish will grow faster in warmer water than colder water," Kubly said.

"They'll be larger at the end of the year; they'll have a better chance of survival than the smaller fish."

But as has been the case with the bureau's other flow test experiments, this latest release is drawing flak from some environmental groups, who argue that the experiments have been a failure. "What they're trying to do is artificially create a natural river habitat with the dam, but that can't be done," said John Weisheit, conservation director of the Moab-based Living Rivers organization. "That 700-foot dam is trapping all the sediment in Lake Powell, and along with it all the nutrition - carbon, trees, driftwood - which creates food base for these fish."

Weisheit says the humpback chub has re-established itself in the Little Colorado River, which feeds into the Colorado. What the bureau is attempting to do, he says, is create a second stronghold - which is a worthy goal, in and of itself.

"But it's not working," he added, "because the sediment continues to be pushed downstream because of the normal fluctuating flows from power generation." Bureau manager Kubly says it is too early to begin making those kinds of assessments.

"People want to reach conclusions quickly," he said. "But sometimes they do it before the evidence comes out in the science."

Beginning Thursday, Glen Canyon Dam's August flows, which have ranged from 10,000 to 18,000 cubic feet per second (cfs), will be reduced to 6,500 to 9,000 cfs. Those daily fluctuations will be adjusted to a steady 8,000 cfs beginning Sept. 21, with the reduced high-low flows resuming from Oct. 8 through the end of the month.

Normal dam operations will resume on Nov. 1.

Regional News 09/11/05

The Colorado River system: Dams and drought

John W. Keys III
Salt Lake Tribune

Note: this opinion piece is longer available on the Salt Lake Tribune's web page.

The numbers are in and the winners are - the more than 25 million people who depend upon the Colorado River system for their daily water supply.

After serving the people of Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming through the worst five-year drought in 100 years of record-keeping, the Colorado River system is recovering and recharging. In doing so, immediate needs and obligations will continue to be met while we regain storage for the next dry period.

My views on the Colorado River system are shaped by two equally important vantage points. I'm writing this from my desk in the Interior Department in Washington, D.C., where I am commissioner of the Bureau of Reclamation, the agency entrusted by the Interior Department to manage water in the West.

Equally, I also feel that I am writing from my back porch in Moab, Utah, where my home is. You see, I am also one of those 25 million people who keep a careful eye on the Colorado River as it rolls past our towns and farms.

All across the Colorado River Basin, the smaller water projects that Reclamation has constructed over the years refilled. As the drought persisted, those reservoirs were taxed to the maximum. Many were drawn down to near bottom. Without them, cities and farms alike would have been bone dry years ago.

Looking at Lake Powell behind Glen Canyon Dam, I really understand the foresight of those in Congress and past administrations who formulated the Colorado River Storage Project. They envisioned that a long-term drought would develop at a point in time when growing populations and water demands would run head-to-head with a drought-starved water supply.

Over the past five years, Lake Powell went down by two-thirds of its capacity, but in doing so it insured that Lake Mead behind Hoover Dam would stay viable. Without Lake Powell, there would have been no Lake Mead. Without the two dams, Arizona, California and Nevada and Mexican water users would have had serious troubles.

I can't overstate the importance of storing spring runoff. The Colorado River is one driven by winter snowfall, spring melt and high runoff, and then low summer and fall flows. Unlike the great rivers in the eastern states, it is not heavily influenced or served by summer rainfall. Here we must take what Mother Nature gives us in snowmelt, conserve it, and carefully release it throughout the rest of the year.

So, in a few words, why is Lake Powell so important? Why does it stand out from all the other storage on the Colorado River?

Lake Powell gives us the long-term storage capacity to ride out droughts and to deal with the increasing demands that come with the phenomenal economic growth in the Southwest. Naysayers who question Lake Powell's relevance somehow believe that because the Southwest will continue to grow, further taxing the water supplies, that becomes the reason to do away with Lake Powell.

The logic escapes me. We need to be stewards of our stored water, the Bureau of Reclamation working with the states. As I've said time and again, the keys to viability and survivability for the Southwest come in balancing growing demands for water, respecting state water laws and the treaty with Mexico, and stretching limited supplies through inevitable prolonged drought conditions.

We are doing that today and we will continue in generations to come.

When I think of Lake Powell, I really do think of Secretary Gale Norton's "4 C's" credo that guides the Department of the Interior. It goes like this: Consultation, cooperation, and communication - all in the service of conservation. We are truly attempting to consult, cooperate, and communicate to conserve the single greatest resource we have in the Colorado River Basin - our water supply.

John W. Keys III is commissioner of the U.S. Bureau of Reclamation.

[Living Rivers letter to Salt Lake Tribune](#)

LR Letter 09/12/05

Response to Commissioner John Keys' 9/11 Opinion

Editor,

It's appalling that in the wake of Hurricane Katrina, that Bureau of Reclamation Commissioner John Keys peruses the same public relations' strategy as FEMA Director Michael Brown.

In Keys' opinion piece ["The Colorado River system: Dams and drought"](#) he celebrates that people along the Colorado River are "winners" because reservoirs like Lake Powell kept water supplies flowing these past few years while the region experienced below average precipitation.

But just like FEMA's Brown, what Commissioner Keys continues to ignore are the findings of government scientists and Congressional investigators, who for nearly 25 years now have been warning that disaster is on the way.

- 1) That 11 percent more Colorado River water has been promised to the American people than the Colorado River has historically provided, leading to supply problems as states now edge toward using their full allocation.
- 2) That lower snow pack is likely to be the norm due to climate change, and that water managers should be planning for ongoing flow reductions of 18 percent over the next several decades.
- 3) That Lake Powell and Lake Mead lose to evaporation annually ten percent of the Colorado River's annual flow, whereas this water could be stored underground without such waste through the minimal use of Hoover Dam alone.
- 4) The unnecessary use of Lake Powell is causing the near collapse of the river ecosystem in Grand Canyon National Park.
- 5) That despite sediment forcing the closure of Lake Powell facilities and heading toward the dam, Keys has no plan for this looming safety problem.

But given how the Bush Administration is so fond of telling the truth, I guess we should not be surprised when Commissioner Keys' states "the logic escapes me" as to why we should be looking toward draining Lake Powell as a cornerstone of more efficient and environmentally sound means toward protecting scarce Colorado River water.

The party will soon be over on the Colorado River, but instead of too much water from Katrina, the people of the Colorado will find they don't have enough.

Who will be the winners then Commissioner Keys?

John Weisheit
Conservation Director
Living Rivers & Colorado Riverkeeper
Moab, Utah

["The Colorado River system: Dams and drought"](#), by John Keys Commissioner of the Bureau of Reclamation.

Salt Lake Tribune, Saturday, September 11, 2005

LR Press Release 09/12/05

Colorado River water users beware

Bureau of Reclamation Chief follows in FEMA's footsteps

While the public continues to wrestle with the Bush administration's disregard for the truth in acknowledging that a Katrina-like event would eventually strike New Orleans,

the Bureau of Reclamation Commissioner is denying nearly three decades of warnings that water shortages are imminent for Colorado River water users.

In his opinion piece, ["The Colorado River system: Dams and drought"](#) published in the Salt Lake Tribune on Sunday, Bureau of Reclamation Commissioner John Keys stated that despite several years of reduced flows, all is well again for the 25 million people reliant on Colorado River water.

"After serving the people of Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming through the worst five-year drought in 100 years of record-keeping, the Colorado River system is recovering and recharging. In doing so, immediate needs and obligations will continue to be met while we regain storage for the next dry period," wrote Keys.

Such logic runs contrary to the advice of government scientist and Congressional researchers. Since 1979 there have been warnings that the Colorado River would fail on the supply-side because 11 percent more water has been allocated than the river can historically provide. Even more problematic is the Department of Energy research forecast that climate change will cause Colorado River flows to decline 18 percent by 2040.

"It's terrible what has happened on the Gulf Coast and while we are fully sensitive to all those affected by Katrina, there's another kind of lack of preparedness prevailing along the Colorado. But instead of too much water, there will be too little, " says John Weisheit, Conservation Director for the Utah-based Living Rivers & Colorado Riverkeeper.

"Science and common sense tell us that recent reductions in river flows were not some hundred-year aberration, as Commissioner Keys claims. But should instead be viewed as a stern warning that increased demand and decreased supply have taken root in the Colorado River watershed and we are unprepared for the repercussions," Weisheit adds.

The only attention the Bureau of Reclamation has given to Colorado River water shortages began in July—a [two-year study](#) on reoperating the Colorado River systems two largest reservoirs, Lake Powell behind Glen Canyon Dam and Lake Mead behind Hoover Dam, when low water levels occur.

In response to the proposed reoperation, Living Rivers and 85 other groups from across the country demanded that a much broader approach be taken. In their report "The One-Dam Solution" they highlighted how the Bureau must prepare for much lower flows over time, and be more efficient in how it stores scarce Colorado River water.

"Moving minimal water from one dam to the next will be of little value to those without water," continues Weisheit. "They must address the fundamental problem that there will no longer be enough water to go around, and that these dams themselves are part of the problem."

A key finding of "The One-Dam Solution" is how evaporation from these two reservoirs causes the loss of ten percent of the Colorado River's annual flow every year. By eliminating the use of Glen Canyon Dam and using Hoover Dam alone for capturing snowmelt, then routing water to more efficient underground storage, enough water for six million people could be saved.

Commissioner Keys ignores such evidence, stating in his opinion piece, "the logic escapes me," as to why one might consider removing Glen Canyon Dam from the system.

"Maybe because it's not needed and is destroying Grand Canyon's ecosystem downstream," concludes Weisheit. "But the real problem is so much bigger than this dam, and that like Katrina, the Administration is ignoring that soon Colorado River water users won't have the water Commissioner Keys has promised."

Grand Canyon Restoration Program, a Failing Grade Government to release scorecard

For immediate release

Contact: John Weisheit, 435-259-1063; Cell: 435-260-2590

PHOENIX - On the occasion of the tenth anniversary of the federal program established to reverse the ecological impacts of Glen Canyon Dam's operations on Grand Canyon's Colorado River corridor, government scientists will release an internal analysis of their progress.

"The State of the Colorado River Ecosystem in Grand Canyon" report will be presented and discussed at a three-day symposium which begins here on Tuesday.

"Their primary objective was to stop Grand Canyon's endangered native fish from going extinct and to help recover those species already lost, but after \$200 million spent, one more species has disappeared and another now hangs in the balance," says Living Rivers conservation director John Weisheit.

Living Rivers own assessment (below) of the Glen Canyon Dam Adaptive Management Program's 12 goals reveals that no progress is being made on eight. Two areas where progress can be claimed, hydropower production and preservation of non-native trout habitat, happen to be in conflict with the core objectives of native habitat restoration. The only other area of progress has been not to impinge on river recreation opportunities.

These program goals were rooted in recommendations of an Environmental Impact Statement (EIS) completed in 1995 to comply with the Grand Canyon Protection Act passed by Congress three years earlier. "All the past decade has taught us is that the findings and assumptions of the EIS were insufficient," adds John Weisheit. "The declining state of the ecosystem proves the program has been a failure and it's high time for a new EIS to be undertaken that reflects this new reality."

What Living Rivers and more than 200 other organizations have been calling for is the implementation of management strategies that will restore the natural processes that have been lost during the four decades since Glen Canyon Dam has been in operation, including:

- * A water temperature regime that fluctuates seasonally from near freezing to 80 degrees Fahrenheit, not the year-round dam releases of 47 degrees.
- * River flows that fluctuate seasonally from 3,000 to 100,000 CFS (cubic feet per second), not daily between 8,000 and 20,000 CFS.
- * The return of the sediment required to maintain sandbar habitat and supply nutrients to the food web.
- * The removal of non-native fish that inhabit the post-dam environment and compete with the native fish.

"This ten-year masquerade of a recovery program must come to an end," stresses Weisheit. "The habitat can no longer absorb this kind of help, and it's time to revert back to what nature intended by examining the benefits of decommissioning of Glen Canyon Dam."

###

Living Rivers Scorecard

Ten-Year Assessment of Glen Canyon Dam Adaptive Management Program Goals

0=Failing; 1=Unacceptable; 2=No Effect; 3=Potential Progress; 4=Achieving Goal

1. Protect or improve the aquatic food base so that it will support viable populations of desired species at higher trophic levels.

An ongoing decline in composition, diversity and biomass of the native food base continues in the Colorado River, which will be modified further as low reservoir levels at Lake Powell change the downstream thermal regime which will result in additional chemical and biological changes to occur. (Score 0)

2. Maintain or attain viable populations of existing native fish, remove jeopardy from humpback chub and razorback sucker, and prevent adverse modification to their critical habitat.

Humpback Chub populations have declined 67 percent since the program began, and continues to be threatened with extinction. In November 2004 the AMP sponsored a beach rebuilding event in the Grand Canyon which resulted in documented significant losses to the remaining humpback chub populations. The razorback sucker is now confirmed to be extirpated from Grand Canyon. (Score 0)

3. Restore populations of extirpated species, as feasible and advisable.

There has been little effort, and no success, in establishing a second humpback chub population in the river's main stem as required by the program, nor has there been efforts to recover any extirpated species. The AMP focus appears to be concentrated primarily on the removal of trout which is a temporary Band-Aid as long as trout are allowed to remain above Lees Ferry. The AMP program primarily funds the continued monitoring of the demise of the species rather than focusing on specific actions that would support the recovery of the humpback chub. The US Fish and Wildlife Service has failed in its responsibility to recover and protect the listed fish species in the Grand Canyon. (Score 0)

4. Maintain a naturally reproducing population of rainbow trout above the Paria River, to the extent practicable and consistent with the maintenance of viable populations of native fish.

Trout populations have been preserved, but there has yet to be the establishment of viable populations of native fish which are prey to the trout, an appropriate balance, if indeed possible, has also yet to be achieved. The maintenance of the trout fishery above Lee's Ferry severely limits any potential action that can be taken to support the native fish species. (Score 2)

5. Maintain or attain viable populations of Kanab Ambersnail.

Attempts have been made to establish new wild populations of Kanab Ambersnails in three additional natural springs along the Colorado River. These sites are located above the historic high water mark, so that the new populations will be protected from the experimental scouring floods. (Score 3)

6. Protect or improve the biotic riparian and spring communities including threatened and endangered species and their critical habitat.

Marshes, riparian plant communities and sandy beaches are essential to maintain the diversity of wildlife, enhance visitor use and preserve cultural resources. Without sediment and nutrient replacement and effective exotic plant removal programs these resources will continue to degrade. Dam controlled releases and the lack of sediment input to the Grand Canyon ecosystem limits the extent of any protection or improvement effort. Again, the ongoing AMP program is oriented to the continued monitoring of the demise of the ecosystem. (Score 0)

7. Establish water temperature, quality, and flow dynamics to achieve the Adaptive Management Program ecosystem goals.

First proposed ten years ago, progress continues to be nothing more than talk in achieving temperature regimes or flow dynamics beneficial to native fish recovery. No actions have been taken to augment changes that are ongoing in the reservoir. Lack of action by the AMP to thoroughly evaluate changes in water chemistry, sediment supply and thermal regimes indicates that the program is more interested in maintaining the status quo than looking for solutions to the environmental problems below Glen Canyon Dam. (Score 0)

8. Maintain or attain levels of sediment storage within the main channel and along shorelines to achieve the adaptive management program ecosystem goals.

Despite several attempts to utilize specialized dam operating techniques to conserve sediment, such practices have proven not to achieve lasting results. Operations to periodically stir up the sediments in the Grand Canyon do not address the real problem of the lack of sediment supply. Without an aggressive approach to the management of sediment which includes the movement of sediment around Glen Canyon Dam, long-term solutions cannot be achieved. The proposal to augment the system with sediment from outside still continues to be nothing more than a ten-year discussion item. (Score 1)

9. Maintain or improve the quality of recreational experiences for users of the Colorado River ecosystem, within the framework of the adaptive management program ecosystem goals.

By in large, the "quality" of the recreational experience in the river corridor has not been unduly compromised by the program. However, this experience remains inconsistent and violates the basic precepts of the protection of the National Park and makes a travesty of the National Park Service Organic Act. The AMP program is keeping the status quo while allowing visitors to experience an ecosystems but violates the intent and purpose of the providing and environment that has been left 'unimpaired' for future generations. (Score 4)

10. Maintain power production capacity and energy generation, and increase where feasible and advisable, within the framework of the adaptive management program ecosystem goals.

Glen Canyon Dam power production has continued, and has at times has been modified to allow for scientific experimentation. However the intent of the AMP is to keep the power system functioning at all costs. Power production has been modified, but at times of year that are conducive to minimize power impacts instead of focusing on completing the studies during periods of the year that would show the most scientific value. Fulfilling this objective has significantly restricted options toward achieving the broader goal of ecosystem restoration. (Score 4)

11. Preserve, protect, manage and treat cultural resources for the inspiration and benefit of past, present and future generations.

Archeological resources along the river continue to be threatened by the lack of sediment to continuously rebuild and stabilize the banks. As a result, artifacts must be removed, as opposed to be protected in-situ as prescribed by historic preservation legislation. Native American tribes continue to have their programs reduced and their involvement limited to periodic river trips and occasional consultation. (Score 1)

12. Maintain a high quality monitoring, research, and adaptive management program.

The program has been plagued by staff turnover, the removal of staff and consultants whose findings may be disagreeable to water and power interests, and has abandoned the policy of obtaining peer review of their protocols and findings. Further the lack of following the intent of the National Resource Council recommendations and continuing the focus on monitoring and data management limit the intent and objectives and requirements of the Grand Canyon Protection Act. (Score 1)

Dam still injuring Grand Canyon

Geological Survey study: The restoration picture is not encouraging for the Colorado River ecosystem

By Joe Baird
The Salt Lake Tribune

Thirteen years of effort and millions of federal dollars have not been enough to stave off the deterioration of the Colorado River's ecosystem below Glen Canyon Dam, according to a new report released Wednesday.

In the most extensive assessment of river conditions in the Grand Canyon since the creation of the Grand Canyon Protection Act in 1992, the U.S. Geological Survey study says endangered native fish species are still struggling, while sandbars and backwaters that serve as habitat for the fish as well as anchors for vegetation, havens for cultural resources and campsites for human visitors continue to decrease.

The report, produced by the agency's Grand Canyon Monitoring and Research Center, stopped short of calling federal attempts to restore the river and its shorelines a failure. But it makes clear there is still a long way to go to bring the environment back to anything close to what it looked like before Glen Canyon Dam and Lake Powell were created some four decades ago.

"We've learned a helluva lot, but we've also learned is that this is really, really hard," said Jack Schmidt, an aquatic, watershed and earth resources professor at Utah State University, who attended a symposium in Phoenix unveiling the study. "It's a real challenge to adaptively manage the river [and restore habitat] while also focusing on producing electricity and providing water for California. It's just damn hard."

Others were more blunt. At least one environmental group labeled the report proof that efforts by the Bureau of Reclamation - which manages Glen Canyon Dam - to revive the Colorado River below the dam have been a flop.

"When you add up all the numbers, over \$200 million has been spent on this, and 13 years after all this money has been spent, they have absolutely nothing to show for it," said John Weisheit, conservation director of the Moab-based Living Rivers, which has called for the decommissioning of Glen Canyon Dam. "The Grand Canyon, in my opinion, is worse off. There's less fish. Less sand. Fewer archaeological resources. The dam has become more of a liability than an asset."

Attempts to reach Bureau of Reclamation officials for comment were unsuccessful Wednesday. Built in 1963, Glen Canyon Dam has provided water and power for the West, but also transformed the Colorado River below it from muddy and warm to clear and cold, and altered and moderated its natural flows. The long-term results have been a gradual disappearance of sandbars and backwaters throughout the canyon, as well as the decline of native fish species, such as the humpback chub, and the emergence of new, non-native fish such as rainbow trout.

The Geological Survey study focused on efforts by federal managers since the creation of the Grand Canyon Protection Act, and specifically the establishment of the Glen Canyon Dam Adoptive Management Program - an attempt to reintroduce beaches and other native fish habitat into the Grand Canyon's bottom. The focus of those efforts: a series of high-flow test experiments, the most recent last November, that were designed to push more sediment downstream.

The big picture is not encouraging. According to the report, sandbars "continue to erode," and new sand brought downstream by the test flows have not accumulated in the main channel. Likewise, the humpback chub's population has decreased between 30 percent and 60 percent. Now on the endangered species list, it is one of four native fish species that survive in the Colorado River below the dam out of the original eight. But there also have been positive signs. Warmer water coming out of Lake Powell - depleted because of the drought - combined with a program to eradicate non-native fish from the river has resulted in an increase in juvenile humpback chubs, though it's unclear now how many will make it to adulthood. And last November's flow test, which came following heavy October rains, succeeded in pushing more sediment and creating sandbars in the upper reaches of Marble Canyon, even though it was shorter in duration than previous flow tests.

"We saw a limited restoration scenario in an area that had been subject to significant erosion," said Ted Melis, executive director of the Grand Canyon Monitoring Center. "We didn't see a larger impact because of the limits in sand, but with more supply, we might have seen more restoration throughout the system. That's a real positive outcome."

All sides agree on one point: The sediment issue will have to be resolved - both because its need in the Grand Canyon, and because the buildup of sediment in Lake Powell will eventually threaten the reservoir. A sediment pipeline, or dredging Lake Powell, could be in the offing at some point.

Temperature controls at the dam could also become a fixture, if they are proven to enhance native fish populations without introducing new problems.

"It might be hard and it might be costly," said Schmidt, the USU professor. "In fact, it might be so costly that the public might decide that we shouldn't try. Maybe we should tell the public that the cost of providing water and power is the decline of the Grand Canyon and the public will accept that. But the public might also say the Grand Canyon is too important and we should spend whatever it takes."

Grand Canyon health report

- * The Grand Canyon ecosystem hasn't been repaired despite a long, costly effort.
- * The disappearance of sandbars and native fish declines haven't been reversed by experimental releases from Glen Canyon Dam.

LR in the News 10/28/05

Scientists still unsure of how to protect river in Grand Canyon

By the Associated Press

PHOENIX — Scientists say they still don't know how to protect the Colorado River in the Grand Canyon without disrupting water and power production upstream.

Despite a decade of trying, few attempts have succeeded in trying to mimic the natural conditions erased by construction of Glen Canyon Dam, which supplies water and electricity to millions of people.

Endangered fish continue to disappear, habitat erodes almost as fast as it is rebuilt and interloping fish and plants find new ways to thrive.

The river's health as it courses through the Grand Canyon is the focus of a 10-year-old program created after environmental studies uncovered deteriorating conditions caused by Glen Canyon Dam.

The giant structure cooled the river, stripped it of sediment and nutrients and tamed its seasonal flows, which helped keep wildlife habitat vital.

Scientists admit that reversing the damage from 40 years of unnatural river flows could take decades and cost hundreds of millions of dollars.

Living Rivers, a conservation group, claims the best solution is to decommission the dam and return the river to its historic flow all the way through the canyon.

“We're sacrificing the Grand Canyon for that dam,” said John Weisheit, Living Rivers' conservation director.

“We just don't need it.”

Glen Canyon Dam, completed in 1963, supplies power across the West and stores water that eventually serves users in Arizona, Nevada and California.

Other restoration efforts also are under way, including a \$600 million lower-Colorado habitat-conservation program adopted this year by Arizona, Nevada and California.

But Weisheit said the government should stop spending money on ideas that will never solve the entire problem.

“They've spent \$200 million and there's been no improvement,” he said. “Nature's been doing this for millions of years for free.”

Dam has hurt the Colorado

River study yields few positives

Shaun McKinnon for the The Arizona Republic

Oct. 28, 2005

After more than a dozen years of trying, scientists still don't know how to protect the Colorado River in the Grand Canyon without disrupting water and power production upstream.

Few attempts have succeeded in trying to mimic the natural conditions erased by construction of Glen Canyon Dam, which supplies water and electricity to millions of people. Endangered fish continue to disappear, habitat erodes almost as fast as it is rebuilt and interloping fish and plants find new ways to thrive.

Even faint signs of progress may be as much the work of nature as the ongoing experiments on the river, according to information presented at a science symposium this week in Tempe. An increase in the number of endangered humpback chub occurred at the same time drought conditions warmed the temperature of water released from Lake Powell, creating better surroundings for the tiny fish.

The river's health as it courses through the Grand Canyon is the focus of a 10-year-old program created after environmental studies uncovered deteriorating conditions caused by Glen Canyon Dam. The giant structure cooled the river, stripped it of sediment and nutrients and tamed its seasonal flows, which helped keep wildlife habitat vital.

Although scientists tried to find reasons for optimism, they admitted that reversing the damage from 40 years of unnatural river flows could take decades and cost hundreds of millions of dollars. Some of the work will never end, they said, and some of the damage will go unrepaired as a trade-off for the benefits from the dam.

A river conservation group produced its own report card on the restoration studies and pronounced the effort a failure. The government-led program missed the mark on eight of its original 12 goals and achieved progress on two - power production and non-native fish habitat - that clash with true resource protection, according to Living Rivers.

The best solution, the group argues, is to decommission Glen Canyon Dam and return the Colorado River to its historic flow all the way through the Grand Canyon, an idea already rejected emphatically by government and business leaders. "We're sacrificing the Grand Canyon for that dam," said John Weisheit, Living Rivers' conservation director. "We just don't need it."

Glen Canyon Dam supplies power across the West and stores water that eventually serves users in Arizona, Nevada and California. The U.S. Geological Survey's report assumes the dam will remain in operation and focuses on issues ranging from endangered fish and plants to lost recreational opportunities along the river and in the canyon.

"Not everything in the report says what we're doing is working," said Denny Fenn, director of the USGS Southwest Biological Science Center, one of the agencies involved in the long-term studies. "But we're making progress."

The sheer size of the problem accounts for the slow work, scientists said. Glen Canyon Dam, completed in 1963, permanently transformed the Colorado from a wild river that

fluctuated with the seasons to a carefully controlled waterway that ebbs and flows based on water and power demands.

After environmental studies identified the changes to the river ecosystem, federal officials created the adaptive management program to study the problems and look for solutions that can be integrated into the operations of the dam and the river. This week's report examined several key problems:

- Sediment and erosion.

Before the dam was built, the Colorado moved about 29 million tons of sand and sediment through the Grand Canyon each year. The constant flow rebuilt beaches and sandbars as others washed away. The dam captures almost all of the upstream sediment, leaving only what flows from tributaries like the Paria and Little Colorado River.

In an effort to rebuild beaches and mimic the fluctuations of the old river, scientists have tried twice to create artificial floods by releasing extra water from the dam for several days. A 1996 flood produced mixed results, but a smaller experiment last November was more promising.

"There were clear indications of restoration," said Ted Melis, acting chief of the Grand Canyon Monitoring and Research Center. The question is whether there is enough sediment to sustain artificial floods.

Fenn said the goal is to hand over the flood and sediment experiment to the U.S. Bureau of Reclamation, which would incorporate the high flows into the dam's regular operations.

- Endangered fish.

The cooler water provided a poor environment for native fish like the humpback chub and razorback sucker, which hasn't been seen since about 1992. But the river is now ideal for such non-native species as rainbow trout, which prospered and quickly turned into a chub predator, eating newborns.

Chub numbers have fallen by as much as 67 percent. Scientists don't think the fish will turn extinct, as several other native species have, but a Canadian researcher at the symposium predicted the long-term numbers will remain below the recovery goals.

To help the chub and other native fish, scientists have removed trout from stretches of the river, but recent events suggest that water temperature may have more to do with the chub's long-term survival. The drought lowered water levels at Lake Powell, which raised the temperature of the river downstream. In surveys this past summer, the number of newborn chub rose significantly, said Lew Coggins, a fishery biologist at the research center. That's no guarantee they'll survive until adulthood, he said, and the warm waters aren't a perfect solution.

"There are risks because the warm water could allow for more expansion of non-native fish, and that could be an even bigger threat," he said.

- Drought.

At least half the study period occurred during a serious drought on the Colorado, and that may have colored some of the findings.

In addition to making it difficult to tell whether management or nature contributed to the higher number of newborn chub, the drought also limited the amount of sediment and sand carried toward the Colorado by the tributary rivers, said Fenn of the USGS. That forced the agencies to delay some of the flood experiments.

"It's clear that nature always plays a role and drought can compound the results," he said. The study released this week won't end the adaptive management work, Fenn said.

Other efforts are also under way, including a \$600 million lower-Colorado habitat-conservation program adopted this year by Arizona, Nevada and California. Weisheit, of Living Rivers, said the government should stop spending money on ideas that will never solve the entire problem.

"They've spent \$200 million, and there's been no improvement," he said. "Nature's been doing this for millions of years for free."

Regional News 10/31/05

Experts worry about Colorado River estimates

By Associated Press October 31, 2005

GRAND JUNCTION, Colo. — Some Colorado River experts worry a new federal process aimed at figuring out how to operate Lake Mead and Lake Powell in times of drought is being overly generous in its assumptions of how much water is available.

They caution the overestimate could cause problems in the future, echoing the mistake the West's water honchos made in the early 1920s when they divided up the river's water during a time of plenty.

Years after the 1922 Colorado River Compact, the document that divided the water among seven western states, officials discovered the allocation was much higher than the river's historical flow. The result was a serious water deficit that left water lawyers in the 21st century to figure out the mess.

"They knew they were overdeveloping the system back then, and they left us to deal with it," said Jim Lochhead, an attorney in Glenwood Springs who represents a group of Colorado cities and water districts in system discussions.

Officials with the Colorado River Water Conservation District don't want to repeat the past mistake.

The U.S. Bureau of Reclamation is working on a series of models that analyze a number of scenarios for operating Lake Powell and Lake Mead in tandem, eventually calculating how much water should be released from Lake Powell during dry spells to satisfy users downstream.

Feds hope the process will be completed by 2007, with the goal of minimizing water shortages to the Lower Basin states of California, Arizona and Nevada. The Upper Basin states of Colorado, Wyoming, Utah and New Mexico also hope their water shortages will be minimal.

Eric Kuhn, general manager of the Colorado River Water Conservation District in Glenwood Springs, said the bureau's current modeling looks at the period from 1906 to 1995 to calculate the reservoir scenarios.

"The future may not look like the recent past," he said. "Using the entire 1906 to 1995 period understates the probabilities of shortage in today's current climate conditions."

Kuhn worries the bureau's hydrology could lead this round of Colorado River Compact negotiators down the same slippery slope their ancestors sent them hiking to, setting up even more problems for the future.

There's not enough worst-case scenario thinking, he said.

But the bottom line for Upper Basin states is that many of the operating scenarios put Lake Powell in the shallow end of the pool.

"A lot of options on the table right now benefit the Lower Basin, and most of them reduce water in Lake Powell," Kuhn said.

Some of the scenarios even bring water levels at the reservoir below minimum power pool, eliminating the ability to create hydropower at Glen Canyon Dam.

"It's one of the proposals on the table, but I don't know if it's serious," he said.

All seven basin states have agreed that strategies should be in place to delay the extent of water shortages to the Lower Basin during drought, but the Upper Basin doesn't want to increase its own risk in the process.

Hydropower, recreation on the popular Lake Powell and a host of side issues keep the process as complicated as ever.

As a result, discussions have become a tennis match of wish lists.

Scott Balcomb, the water attorney appointed by the governor to represent Colorado in the basin state discussions, said the basins were slowly working toward consensus.

"We're trying to process each other's issues, concerns and wishes," he said.

"Colorado wants to keep all of our water and learn to operate the system more efficiently."

The basin states have agreed to some vague ideas of how to minimize shortages on the system, pushing ideas such as conservation, tamarisk removal and the potential to exchange desalinated water into the Colorado River system.

But it's Nevada, a Lower Basin state, that has led the charge in generating wish lists, offering an array of unconventional ideas for solving its own water woes.

The state receives one of the smallest apportionments from the river, but Las Vegas, the main recipient of the water, has only enough water to continue its current rate of growth until 2013.

Pat Mulroy, Nevada's representative to the negotiations, has suggested diverting water from the Virgin and Muddy rivers east of Las Vegas to the city, but both rivers are tributaries to the Colorado River.

Colorado and the other Upper Basin states argue those rivers, and others like them in the Lower Basin, should be considered part of the Colorado River.

They contend that Lower Basin states are using the tributary water illegally when Upper Basin tributaries, such as the Gunnison River, already are calculated in Compact deliveries.

Colorado has threatened in the past to sue to bring tributary water in the Lower Basin into the Compact's jurisdiction.

Nevada presented the idea of diverting the Virgin and Muddy tributaries again during a meeting of the basin states in Denver on Friday.

"Nevada is pressing ahead on all of its options, including the Virgin and the Muddy," Balcomb said.

"They don't believe they have another choice."

Nevada did, however, back off a previous proposal to buy water from other states in the Upper Basin.

Utah has expressed an interest in the idea, but Colorado has remained vehemently opposed.

"Nevada knows that is one place we in Colorado will not go," Balcomb said.

"They know bringing up that concept again does not further any opportunities to truly discuss these new management scenarios."

For now, basin state representatives will continue to gather and peruse graph after graph of hydrological information, trying to come up with future reservoir operations from the Bureau's assumptions.

"It's a fairly complex process on a tight timetable," Lochhead said. "The issues are framed, but now is the hard part, talking about them."

Take Action 11/01/05

Comments needed to halt the operation of Glen Canyon Dam

Submit Comments by: Wednesday, November 30, 2005

The Bureau of Reclamation is accepting public comments on the reoperation of the nation's two largest reservoirs, Lake Powell and Lake Mead. Your voice is needed to demand that they examine the viability of permanently ceasing operations at Lake Powell and employing just one reservoir to capture and manage the bulk of Colorado River flows.

Join in calling for the [The One-Dam Solution](#) as outlined in Living Rivers' new report prepared for the reoperation public scoping process.

Let the Bureau of Reclamation know that:

1. No longer a need for a single-use dam at Glen Canyon It was not until the fall of 2004, more than 40 years after Glen Canyon Dam began impounding Lake Powell that Lake Powell water storage actually augmented water storage downstream. But with climate change already causing long-term flow reductions, and water consumption levels near the river's historic average flow and rising, it's unlikely that Lake Powell will fill again. The surplus water that filled it during 17 years the first time is no longer there to build a storage cushion. Even should surplus water accumulate, Lake Mead on its own could accommodate it.
2. It's time for more efficient storage With Lake Powell and Lake Mead losing to evaporation upwards of 17 percent of the water that flows into them, it's time that more efficient means be explored for storing this precious water. Vacant space in underground aquifers on, or accessible to, existing Colorado River infrastructure could accommodate more water than these two reservoirs combined—and with far greater efficiency. Upwards of 810,000 acre-feet of water annually—enough water for 1.6 million households of four people each—could be saved by eliminating Lake Powell and operating Lake Mead principally for distribution to groundwater recharge facilities.
3. Revive Grand Canyon Between Lake Powell and Lake Mead lies one of the world's most famous and geologically and ecologically unique river canyons, Grand Canyon National Park. The operation of both these reservoirs has impacted the Canyon, but Glen Canyon Dam has been far more devastating. Since its completion four of eight native fish have gone extinct and the dam has trapped the sediment necessary to maintain habitat and beaches for wildlife and recreation, as well as the stabilization of archeological sites.

4. Manage the sediment Sediment is a major unresolved problem threatening the long-term operations of Lake Powell and Lake Mead. Ultimately, sediment will have to be removed from one or both of these reservoirs. Removing sediment from Lake Mead rather than Lake Powell is the most feasible and least expensive likely alternative. While original estimates projected that sediment would not effect the safe operations of Glen Canyon Dam for another 60 years, scientists now warn that major problems could occur sooner.
5. Revise the Colorado River Compact The Colorado River Compact of 1922, which largely governs the discharge of flows from Lake Powell to Lake Mead, cannot meet its intended purpose of sharing Colorado River water equitably between the Upper and Lower Basin states. The Compact allocated 11 percent more water than the river has to give, and affords the Lower Basin 20 percent more water than the upper basin. With river flows expected to decline 18 percent by 2040, this inequity will worsen as the Upper Basin is required to deliver to the Lower Basin its full share regardless of declines in river flow.

Grand Canyon Fish v. Glen Canyon Dam

Living Rivers and the Center for Biological Diversity today notified the Bureau of Reclamation and Fish and Wildlife Service of their intent to sue over violations of the Endangered Species Act resulting in the demise of endangered native fish in Grand Canyon National Park.

For more than a decade the Bureau of Reclamation has been required to modify the operations of Glen Canyon Dam on the Colorado River to reverse the dam's downstream impacts on Grand Canyon's famed river ecosystem. However, as outlined in a letter sent to Department of Interior officials today, these efforts have failed.

"Since the Fish and Wildlife Service issued its Biological Opinion on the dam's operations in 1994, the Bureau of Reclamation's actions have merely made things worse," says Living Rivers Conservation Director John Weisheit. "One more fish species is effectively extinct in the Canyon, and another is on the verge."

Just eight native fish species once lived in Grand Canyon's desert river corridor, six of which could not survive anywhere else in the Colorado River. Now only four species remain, one of which, the Humpback Chub, has declined to just a few thousand fishes.

In 1992 Congress passed the Grand Canyon Protection Act to reverse this decline. Following the completion of an Environmental Impact Statement, three years later, the Glen Canyon Dam Adaptive Management Program was established to guide the Bureau of Reclamation in implementing recovery guidelines set forth by the Fish and Wildlife Service.

Now, some 13 years later, the United States Geological Survey has evaluated this program and has confirmed what many scientists have been saying for years, that recovery is not being achieved. Released on October 25, their 220 page "The State of the Colorado River Ecosystem in Grand Canyon" report states:

"...it is clear that the restrictions on dam operations since 1991 have not produced the hoped for restoration and maintenance of this endangered species

"Overall, about 15% - 20% of the adult humpback chub are dying each year. If this mortality rate and the dramatically reduced recruitment rate of young chub experienced since the early 1990s remain unchanged, there will be a decline in the adult population

of humpback chub from the present 3,000 - 5,000 fish to a level of 1,500 - 2,000 adult fish over the next 10 - 15 yr.

"...the MLFF [Modified Low Fluctuating Flow] operating alternative has not effectively mitigated the influence of regulation with respect to either the thermal and hydrologic changes or the fine-sediment supply limitation of the downstream ecosystem."

"It's outrageous that the public has invested more than \$200 million to help the Bureau of Reclamation restore the river habitat in Grand Canyon, and all they have to show for it is fewer fish." says Dr. Robin Silver, Board Chair of the Tucson-based Center for Biological Diversity. "It's time they re-tool their strategy before Grand Canyon's river ecosystem is lost forever."

The groups are demanding that in light of the mounting evidence of no progress, the Fish & Wildlife Service is compelled by law to immediately reinstate consultation and devise a new strategy to ensure recovery of Grand Canyon native fish, particularly the Humpback Chub. Key issues that must be addressed are:

- * Restoring a water temperature regime that once fluctuated seasonally from near freezing to 80 degrees Fahrenheit, but now is a constant 47 degrees year-round.
- * Restoring river flows that fluctuated seasonally from 3,000 to 100,000 CFS (cubic feet per second), but now can fluctuate daily from 8,000 to 20,000 CFS.
- * Restoring the sediment and nutrients that nourished Grand Canyon's aquatic habitat, 95 percent of which is now trapped by the dam annually.
- * Controlling non-native fish which have flourished in this new environment, competing with, and preying on, the native fish.

"The Colorado River through Grand Canyon is one of this planet's most precious gifts, but the Bureau of Reclamation remains hell-bent on destroying it," adds Weisheit. "This ecosystem may not survive much longer with that dam in operation, but we could certainly survive were that dam not there."

More than 200 groups from across the country now advocate the decommissioning of Glen Canyon Dam as the best alternative for restoring the river ecosystem in Grand Canyon National Park.

Enviro groups issue notice to sue over declining Grand Canyon ecosystem

April Reese, Land Letter Southwest reporter

Two weeks after scientists released a report critical of federal efforts to improve the flagging health of the Grand Canyon ecosystem downstream from Glen Canyon Dam, two environmental groups have filed notice that they plan to sue to force the agencies involved to reconsider their management approach.

Calling the Bureau of Reclamation and Fish and Wildlife Service's program for reversing the decline of the endangered humpback chub and other canyon resources a "failure," the Center for Biological Diversity and Living Rivers notified agency officials Tuesday they plan to file suit to nudge federal officials toward conducting a new analysis of how dam operations are affecting the fish. The groups also want BuRec to take a new look at how to operate the dam to reverse the decline of the chub, razorback sucker, bonytail and Colorado pikeminnow -- the four remaining native fish species of the eight that once inhabited the Grand Canyon.

The groups say new information presented in an Oct. 25 report from the U.S. Geological Survey requires the agencies to retool their management plan for the fish and other Grand Canyon resources.

The report found that the low fluctuating flow regime that federal water managers and biologists have been using for the past decade to help improve conditions for endangered fish the canyon is not working. About 15 percent to 20 percent of adult humpback chub are dying each year, while populations of non-native fish are on the rise. If that mortality rate continues, the adult humpback chub population will plummet

from current population levels of between 3,000 and 5,000 fish to between 1,500 and 2,000 fish over the next 10 to 15 years, the report says.

There is "evidence that dam operations during the last 10 years ... have not restored fine-sediment resources or native fish populations in Grand Canyon," the report states. Scientific information collected over the last decade contradicts the projections for habitat improvement outlined in a 1995 environmental impact statement for modified flows, the USGS scientists concluded (Greenwire, Oct. 25).

The construction of the dam in the early 1960s trapped sediment that once moved down the river, providing sandbars and pools important for fish in the Grand Canyon.

Under the Grand Canyon Protection Act of 2002, the federal government must protect downstream resources in the park from the effects of Glen Canyon Dam.

"New information reveals effects of 'adaptive management' and the [low fluctuating flows] operational scheme are harming the humpback chub, its critical habitat and the Grand Canyon in a manner and extent not previously considered," the groups wrote in their notice.

"The scientists have shown pretty compelling evidence that not enough is being done to save Grand Canyon," said John Weisheit, conservation director for Living Rivers.

"It's outrageous that the public has invested more than \$200 million to help the Bureau of Reclamation restore the river habitat in Grand Canyon, and all they have to show for it is fewer fish," added Robin Silver of the Center for Biological Diversity.

The groups argue that FWS's 1994 biological opinion on the effect of dam operations on endangered fish requires the agency to reassess those effects if new information -- such as the USGS report -- suggests it should do so.

Decommissioning Glen Canyon Dam is the only way to restore the Grand Canyon ecosystem and recover the fish, Weisheit said.

Sam Spiller, lower Colorado River coordinator for FWS, said he could not comment on the group's notice because of an agency policy that prevents employees from discussing pending litigation with the press. Reclamation officials also declined to comment.

Federal biologists and water managers have found some hope in the preliminary results of an experimental flood conducted in November of last year that they say appears to have resulted in some habitat improvements, but more high flow tests are necessary before recommending any changes in dam operations, agency officials said (Greenwire, Oct. 26).

Southwest reporter April Reese is based in Santa Fe, N.M.

LR Press Release 11/10/05

Profits to Trump Saving Grand Canyon Ecosystem, Recommends National Park Service

For immediate release

Contact: John Weisheit 435-259-1063

Cell: 435-260-2590

Despite decades of compelling scientific evidence concerning the deteriorating biological integrity of Grand Canyon Park, the National Park Service's Final Environmental Impact Statement released Thursday, concludes that virtually no changes should be made to its Colorado River management activities.

Cascading 250 miles from just below Glen Canyon Dam to Hoover Dam's Lake Mead, the Colorado River through Grand Canyon National Park is one of the world's most sought after river recreation adventures. This ecosystem is also one of the most threatened in the National Park system. The proposed Colorado River Management Plan is intended to guide new strategies for achieving the Park Service's dual missions of providing visitor access while preserving Grand Canyon's natural integrity for future generations.

"From dams to inflatable aircraft carriers, a journey through Grand Canyon now has nothing to do with Theodore Roosevelt's intentions when creating the Park 86 years ago," says Living Rivers conservation Director John Weisheit. "It's become a motorized, ecological funeral procession marketed as a six-day E-ticket Disneyland ride, and this new plan is doing nothing to change that."

Indeed, the plan emphasizes alterations in the allocations of visitor activity on the river with very little attention to managing the ecosystem. It's preferred alternative is designed to satisfy demands from the public boating sector without impacting the commercial. Another way of assessing this preferred alternative is: as the resource degrades, visitation increases.

"The plan says nothing about how the Park Service will meet it's obligation to recover the ecosystem that has seen half it's native fish species disappear, along with otters and muskrats, and it's entire aquatic food base devastated due to dams above and below," continues Weisheit. "It's all about preserving a \$30 million outfitting industry and \$110 million worth of hydropower, not the priceless ecosystem they are required by law to protect."

Although most of the land emanating from the banks off the Colorado River to the Grand Canyon's rim is designated Wilderness, thus subject to the most stringent federal ecological and human management practices, the new plan would not recommend the need the river itself to managed Wilderness in kind. Such designation has been fought

extensively by the Grand Canyon River Outfitters Association, a lobbying group for the Grand Canyon river companies.

The Plan also side steps issues pertaining to the impacts of Glen Canyon Dam, stating that the dam is outside its jurisdiction, and under the management of another Department of Interior agency, the Bureau of Reclamation. Such issues did not come into play ten years ago for Everglades National Park, which found its ecological integrity degraded by Army Corps of Engineers projects outside the Park. A \$10 billion restoration programs along the Kissimmee River which feeds the park is now well underway.

"The bottom line is that the current leadership in the Department of Interior considers Grand Canyon to be no different than an oil field or a coal mine, and could care less whether the Grand Canyon is there to be enjoyed by future generations," concludes Weisheit.

LR in the News 11/10/05

New plan should allow more people to tour Grand Canyon by boat

Associated Press Nov. 10, 2005 04:11 PM

More people would be able to tour the Grand Canyon by boat each year, but they'll go in smaller groups under final river management plans released Thursday by the National Park Service.

The plan for Colorado River use in the Grand Canyon would shift more travelers into the fall, winter and spring months, while cutting the number of daily summertime launches of motorized and non-motorized commercial rafts.

It trims the maximum number of passengers in groups by about 10, to 32 for both types of boats, but increases the number of private launches in the summer.

The result would be more tourists overall.

In the lower Colorado River from Diamond Creek to Lake Mead, the number of pontoon boat tours would go up, from 130 passengers daily to 480 each day. But jet boat tours would be banned entirely. Existing operations that use large jet boats to meet rafts above Lake Mead would still be allowed, however.

The final plan, technically a final environmental impact statement, comes after four years of study by a group of scientists, park service managers and other professionals, with input from tour operators, Indian tribes and members of the public.

Nearly 25,000 public responses were taken during the public comment periods, and at more than a dozen public meetings around the country from 2002 to 2004, said Jeffrey Cross, the project manager for the Colorado River Management Plan.

"We listened, we talked to people, they submitted information and we looked at it," said Cross. "We've tried to address the comments and concerns. That's the best that we can do. We will never satisfy everyone who wants to go down the Grand Canyon."

The plan could still be revised by the regional director of the park service, but that's not likely. Plans are to publish a final version in about two months, and have it in force by 2007.

It wasn't met with glowing reviews by environmental organizations.

John Weisheit, conservation director for the river restoration group Living Rivers, said the park service didn't even consider a wilderness designation that would have increased protections.

"I'm very, very disappointed but I'm not surprised," Weisheit said. "Even though their own surveys have indicated a strong preference for a wilderness designation, they don't do it because they don't want to upset the tour operators."

Meanwhile, the Hualapai Indian Tribe, which runs the lower river pontoon trips, disputed the government's legal ability to limit its operations.

"From our tribal perspective, there's a question of whether or not they have the jurisdiction to impose this on the tribe," said Charlie Vaughn, the tribe's chairman.

"There was no limitation on us in the lower gorge prior to this plan - and we don't feel we have increased to our capacity and there's no allowance for that in the plans.

The 2,300-member tribe's reservation spans 1 million acres bordered on the north by 108 miles of river.

The Hualapai had wanted to increase the number of daily pontoon boat passengers to about 1,000.

Superintendent Joe Alston of Grand Canyon National Park said the law is clear that the entire river is subject to federal government oversight.

"Our simple answer to this is it doesn't really matter where the Hualapai boundary is, Congress established where the Grand Canyon is - and it is the south side of the river," he said.

For adventurers trying to raft the river on their own, the biggest change will be in the system used to allocate the limited number of slots.

Currently, a waiting list system is used, but it is overloaded.

There are now about 7,000 people on the waiting list, 1,700 of whom have spent from 11 to 15 years in line. It's been frozen to new signups since 2003.

That system will be replaced with a lottery, Cross said. Those who has been waiting the longest will get preference during the first years of operation, but no guarantees of receiving a permit.

More trips will be moved to the wintertime as well, he said. Those trips are given more time, so that visitors can hunker down if needed and wait out stormy weather.

Despite that, the plan was a huge disappointment for some noncommercial users.

"We want it to be fairly allocated. Right now we've got concessionaires that can't fill their seats, and yet here we are with this huge pool of demand that's not going to be met," said Jo Johnson, co-director of River Runners for Wilderness, which advocates fair access and wilderness protection for the canyon. "This plan was our last best chance to get that."

River use had to be cut back during peak times for several reasons, Cross and Alston said. The biggest is the loss of beaches.

About half of the large beaches used for camping have been lost since the 1964 completion of the Glen Canyon dam cut off sediment flow, leading to crowding and competition for the best spots.

The other reason is driven by the intent to give visitors as true a "wilderness experience" as possible.

During peak months now, as many as 300 rafters can be stopped at well-known scenic spots at any one time, Cross said. By lowering the number of people per raft and cutting the number of daily tour departures, visitors will meet fewer people.

The director of the association representing tour operators said the park service appears to have done a good job balancing the competing interests of many users.

"The bottom line is we believe that one of the purposes of the plan was to reduce the amount of use happening at one time, to spread that use out over a broader period of time," said Mark Grisham, director of the Grand Canyon River Outfitters Association. "Our initial read of the plan is they've done a pretty decent job under a lot of competing demands."

Report sees decline of up to 30% by 2050, cites warming

Snowmelt may dwindle

By Jerd Smith, Rocky Mountain News
November 17, 2005

Colorado and other Western states dependent on snowmelt could see a 10 percent to 30 percent reduction in annual runoff by 2050 as the Earth's atmosphere warms, according to a report in the journal Nature.

Such a change would have severe consequences for water supplies in regions such as the seven-state Colorado River Basin and other parts of the world, including southern Europe and the Middle East, the report said.

Even a 10 percent reduction in the Colorado River's flows, for instance, would mean a drought-like existence for the historic stream, with annual flows equal to those of the recent five-year dry spell, said Andrew Gilmore, a hydrologic engineer for the Bureau of Reclamation in Salt Lake City.

During that time, flows averaged 10.1 million acre feet, well below the 98-year average of 15.1 million acre feet, Gilmore said.

Other parts of the world, such as eastern equatorial Africa and Eurasia, could see stream runoff increase as global temperatures rise, the report says.

The new research marks an expansion of what scientists have been able to determine to date about the effects of climate change.

Until now, much of the analysis done on the complex interrelationships between temperature and climate have indicated that winter snowpacks are likely to melt earlier, that more rain and less snow will fall, but that overall amounts of precipitation would stay about the same in the West.

But the new findings indicate that there will be a marked decrease in the total amount of water in streams in some regions, said Christopher Milly, an author of the Nature report and a research hydrologist for the United States Geological Survey in Princeton, N.J.

"It's taken us a while to tease out a way to look at this," Milly said. "But the results of this study will increase the degree of confidence that scientists put in water resource

projections. . . . We know there are certain areas of the Earth that are systematically projected to dry."

The precision is thanks largely to new international data collection and coordinated international modeling efforts. That work has resulted in much more reliable global and regional analyses.

Milly said it isn't entirely clear why runoff is shrinking in some regions, but he believes that one plausible explanation for its occurrence in the West is this: As the atmosphere warms above the ocean, it is able to hold more water.

As these warm ocean winds blow across the hot, semi-arid West, they warm even more, holding more water and ultimately carrying that water out of the region rather than allowing it to fall.

Those findings don't necessarily conflict with a recent report by Boulder climate researcher Gerald Meehl, who published a paper in September indicating that total annual precipitation in Colorado would change little over the next century.

But even a slight decrease in precipitation can trigger a much more dramatic decrease in runoff, Milly said.

Meehl said the new modeling being done is allowing scientists to connect more data and better data than before.

How similar data can be used in real life river-management tools isn't clear yet.

"It's one thing to say we think the climate is warming," said Rick Clayton, a hydrologic engineer for the U.S. Bureau of Reclamation. "It's another thing to say we think the Colorado River is drier. That's quite a leap."

Still, Clayton and Gilmore said that the bureau is searching for ways to include climate-change projections in their existing analysis to better understand how the river will respond to dramatically lower flows.

"We get asked this question all the time," Gilmore said. "And we need a better answer than we have."

Regional News 12/07/05

Salt in Colorado River concerns USGS

Donna Gray Post Independent Staff

By the time they reach Mexico the waters of the Colorado River are so laden with salt as to be a danger to crops.

"About 9 million tons of salt passes Lees Ferry (on the Colorado River in Arizona) every year," said Paul Von Guerard, office chief of the U.S. Geologic Survey in Grand Junction.

Since the 1970s, the seven states through which the river flows have agreed to control that burden of salt as much as possible. The USGS monitors the salinity of the river, which has its source in Colorado.

Thursday, members of USGS in Grand Junction brought the Energy Advisory Board up to date on efforts to monitor salt in the Colorado reaches of the river.

The Colorado, as it flows through the state, picks up a significant amount of salt that is augmented as it is carried downstream, Von Guerard said.

"Salinity is a major water quality concern in the Colorado River," Von Guerard said.

Salt dumps into the river from a variety of sources, among them irrigation of agricultural lands, the Mancos shale geologic formation and the hot springs around Glenwood Springs, Von Guerard said.

About 47 percent of the salt in the river comes from natural sources such as hot springs and erosion of soil and the rest is from human actions. Salt causes about \$300 million in damage to crops, water pipes and hot water heaters in the lower Colorado River Basin in California and Nevada, as well as in Mexico, Von Guerard said.

While the survey has a number of monitoring stations along the river and its tributaries, there is a gap between Glenwood Springs and Grand Junction.

"We don't have a good handle on the discharge from Glenwood Springs," he said.

About 47 percent of the salt load that goes through Colorado passes the Cameo monitoring station on the west side of DeBeque Canyon just east of Grand Junction, Von Guerard said. But only 18 percent of that load comes from the river above Glenwood Springs, according to data from a station just upstream from the city. The rest of that salt comes from sources between Glenwood and Grand Junction, he said.

The USGS needs to monitor that load with at least one new monitoring station between Glenwood and Grand Junction, at a cost of \$25,000. Because of flattened funding in the last few years, USGS is seeking to find financial support from local towns and cities in that reach of the river to install a station, Von Guerard said.

"We are working with the (Colorado River Water Conservation District) on funding," he said. The district also suggested the USGS appeal to the energy companies operating in the county for financial support.

Alan Lambert, an Energy Advisory Board member and a Rifle city councilman, agreed salinity is a problem and municipalities need to push for minimum stream flows in the Colorado in order to protect their infrastructure.

"We have a salinity problem in the water treatment plants," he said.

LR in the News 12/11/05

Lake Powell still a glass half-empty

By Kim McGuire Denver Post Staff Writer

Flows into Lake Powell were slightly above average this year, but the giant reservoir in Utah remains far from full, officials with the Bureau of Reclamation say.

In 2005, flows into the reservoir were about 105 percent of average.

Even with that increase, Lake Powell is only about half- full, holding 12 million acre-feet of water.

One acre-foot of water is about 326,000 gallons.

"There were increases in both content and elevation in both Lake Powell and Lake Mead this year that were about the same in the water year 2003," said Rick Clayton, a hydrologist with the Bureau of Reclamation. "Another way to look at that is what we saw this year was the equivalent of rolling back one year of drought."

The drought of 2002 decimated Lake Powell, which acts like a water bank for the upper basin states of Colorado, Wyoming, New Mexico and Utah, releasing water to Lake Mead for distribution to the lower basin as required under the 1922 Colorado River Compact.

Flows in Lake Powell in 2002 were 25 percent of average - the lowest they had been since the completion of the Glen Canyon Dam in 1963.

Clayton declined to say how long he thought it would take for Lake Powell to refill.

"That would be speculation," he said. "But I think it's safe to say it's trending in the right direction."

Some Western environmental groups are skeptical about the chances of Lake Powell ever refilling again.

They say the insatiable thirst of booming cities in Arizona, California and Nevada will outweigh any gains in flow the reservoir may experience.

"When the demand equals the supply, it seems highly unlikely Lake Powell will fill again," said John Weisheit, conservation director for Living Rivers, a Moab- based

group that supports decommissioning the Glen Canyon Dam. "It might happen. But let's put it this way: It's more likely to be empty than full."

This summer Interior Secretary Gale Norton rejected a request by Colorado and other upper basin states to help refill the depleted reservoir by reducing outflows from Lake Powell.

The move disappointed officials in the upper basin states who wanted Norton to send a message to California, Nevada, and Arizona that she could curb releases in times of drought.

Staff writer Kim McGuire can be reached at 303-820-1240 or kmcguire@denverpost.com

LR Testimony 01/01/06

144 NGOs Support The One-Dam Solution

November 30, 2005
Mr. Bob Johnson
Regional Director
Bureau of Reclamation, Lower Colorado Region
Attention: BCOO-1000
P.O. Box 61470
Boulder City, NV 89006-1470

Mr. Rick Gold
Regional Director
Bureau of Reclamation, Upper Colorado Region
Attention: UC-402
125 South State Street
Salt Lake City, Utah 84318-1147

Dear Mr. Johnson & Mr. Gold,

Living Rivers, Colorado Riverkeeper, and the 144 undersigned organizations submit the following report, The One-Dam Solution, as scoping comments for the development of management strategies for operations at Lake Powell and Lake Mead, on the Colorado River, under low reservoir conditions.

With current demand for Colorado River water nearly at the river's historical annual flow of 13.5 million-acre feet (MAF) and rising, and government-sponsored scientists anticipating average annual flows to decline 18 percent by 2040, the prospect of ongoing low water conditions for Colorado River reservoirs is a near certainty. The average flow of 60 percent into the system for the past six years is firm evidence of this.

For more than 25-years, government scientists and administrators have warned that shortages would be occurring now. This action is the first to reexamine the flawed operational strategies that have been in place as far back as 1922 when the Colorado River Compact allocated 11 percent more water than the Colorado River has to give.

Reexamining these two reservoirs is critical, as they constitute more than two-thirds of the system's storage capacity, which with declining inflows and increased demand are proving excessive.

Meanwhile, these two reservoirs can cause the loss of upwards of ten percent of the river's average annual flow due to evaporation—valuable water for critical habitats and water users downstream.

Furthermore, the challenges facing the future operations of these reservoirs go beyond water allocation and storage inefficiencies. Sediment entering Lake Powell will eventually compromise Glen Canyon Dam's safety. Despite recent warnings that this could happen sooner than the 40-year-old estimate of 2060, there has been no comprehensive monitoring or analysis conducted to address this inevitable problem.

Lastly, despite more than \$200 million already spent, no gains have been made to restore the critical habitat for endangered species in Grand Canyon National Park impacted by Glen Canyon Dam's operations. The mandates of the Grand Canyon Protection Act and the Endangered Species Act in particular are being ignored to maintain Lake Powell even though it is proving to be both wasteful and unnecessary for water storage.

It is therefore critical that the Bureau of Reclamation broadly reexamine the operations of these facilities in accordance with preparing an Environmental Impact Statement to address the following:

- 1) Pursue transfers of Lake Powell and Lake Mead storage to groundwater aquifers.
- 2) Develop a sustainable sediment management program for Lake Powell and Lake Mead.
- 3) Determine the costs and benefits of decommissioning Glen Canyon Dam to restore natural flows through Glen and Grand Canyons.
- 4) Identify new water allocation guidelines to reflect the amount of water the Colorado River actually provides, how it should be distributed and what amounts are needed to protect critical habitats in Grand Canyon and elsewhere.

A water management crisis is looming on the Colorado River. The federal government, as Water Master, has the responsibility to help avert this. Most of the issues addressed in the attached report are not new, but continuing to ignore them will only worsen the impacts once the crisis arrives.

Thank you for the opportunity to submit these comments. We look forward to assisting the Bureau of Reclamation in developing this Environmental Impact Statement concerning the protection of water resources from the Colorado River in times of shortage.

Sincerely yours,

John Weisheit Conservation Director, Living Rivers Colorado Riverkeeper

Groups Sue Feds Over Colorado River Fish

By AMANDA LEE MYERS Associated Press Writer © 2006 The Associated Press

PHOENIX — Five environmental groups filed a lawsuit against the federal government Thursday, saying it has failed to protect endangered fish in the Colorado River.

Because of the failure of the Interior Department and its Bureau of Reclamation to provide a more natural environment in the river, the humpback chub, razorback sucker, Colorado pikeminnow and bonytail chub are in danger of extinction, the suit alleges.

The suit, filed in U.S. District Court in Arizona, contends the government is violating federal law by operating Glen Canyon Dam in a manner that fails to protect the features of Grand Canyon National Park and Glen Canyon National Recreation Area.

The dam straddles the Arizona-Utah border, backing up the Colorado River to form Lake Powell. The suit contends the dam releases water at unnatural temperatures, quantity, quality and frequency, and deprives the Grand Canyon of sediment and needed nutrients.

The lawsuit asks the court to order Interior Secretary Gale Norton and the Reclamation Bureau to consult with the U.S. Fish and Wildlife Service over the effects of dam operations, and ultimately, provide a "more natural flow and water temperature regime" and "adequate downstream nutrients and sediment."

The species in the most danger is the humpback chub, the adult population of which declines between 15 percent and 20 percent each year, according to a 2005 report by the U.S. Geological Survey.

Currently, there are between 3,000 and 5,000 in the Colorado River, but that number could decline sharply to between 1,500 and 2,000 in the next 10 to 15 years if nothing is done.

"Arizona's native fish are overwhelmingly imperiled," said Robin Silver, conservation chair for the Center for Biological Diversity, one of the plaintiffs.

For years, officials have studied how to regulate the temperature of water released from the dam, said Barry Wirth, spokesman for the Bureau of Reclamation's Upper Colorado region. But change takes time, he said.

"There's a lot of things that come into play," he said. "We know the technology works. It's just not an off-the-shelf thing."

Wirth said programs such as reducing predators and water flow strategies help the humpback chub and other species.

Neither Wirth nor agency spokeswoman Trudy Harlow in Washington would comment directly on the lawsuit. The suit was filed by the Center for Biological Diversity, Sierra Club, Glen Canyon Institute, Living Rivers and Arizona Wildlife Federation. It followed another legal battle last month between the federal government and two environmental groups, Grand Canyon Trust and Earthjustice.

In that case, U.S. District Judge Frederick Martone ruled the U.S. Fish and Wildlife Service recovery plan for the endangered fish was ineffective. He ordered a new plan to include more specific goals and a timeline for recovery.

Although the ruling was a victory for the environmental groups, a better recovery plan won't save the fish unless the government acts on it, Silver said.

"A recovery plan does not save species because they're never obeyed," he said. "It won't cause anything to happen." ____

Roxane George, Sierra Club-Grand Canyon Chapter, Flagstaff 928-774-6514

Sandy Bahr, Sierra Club-Grand Canyon Chapter, Phoenix 602-253-8633

Phoenix, AZ—The Center for Biological Diversity, Arizona Wildlife Federation, Living Rivers, Sierra Club – Grand Canyon Chapter, and Glen Canyon Institute file suit in U.S. District Court in Arizona today against Gale Norton, U.S. Department of the Interior, and the U.S. Bureau of Reclamation on behalf of the humpback chub and the Grand Canyon. For more than a decade the Bureau of Reclamation has been required to modify the operations of Glen Canyon Dam on the Colorado River to reverse the dam's

downstream impacts on Grand Canyon's priceless river ecosystem. These efforts have failed to produce results. The agencies are in violation of the Grand Canyon Protection Act, the Endangered Species Act and the National Environmental Policy Act.

"The agencies have neglected their responsibilities to this incredible place. Arizona's native fish are overwhelmingly imperiled, and only four of eight native fish species continue to exist in the Grand Canyon. The humpback chub's decline is just another example of the federal government's complete disregard for native wildlife and the irreplaceable habitat they represent," said Robin Silver, Board Chair of the Center for Biological Diversity.

In 1992, Congress passed the Grand Canyon Protection Act to reverse the demise of the canyon and the decline of endangered native fish species such as the humpback chub. Following the completion of an Environmental Impact Statement (EIS) three years later, the Glen Canyon Dam Adaptive Management Program was established to guide the Bureau of Reclamation in implementing recovery guidelines set forth by the U.S. Fish and Wildlife Service (USFWS). The unsuccessful "Modified Low Fluctuating Flow Alternative" (MLFF) is the operational scheme enacted in the Adaptive Management Program which called for released flood flow events with the hope of improving habitat and restoring native fish populations.

"To date, the negative impacts of Glen Canyon Dam continue to lead to the continual decline of the humpback chub. Clearly the Adaptive Management program, as being implemented by the federal government, is not working," said David Wegner, Glen Canyon Institute.

"The Grand Canyon Chapter has long worked to protect the Grand Canyon and the Colorado River, plus the species which rely on this important system," said Sandy Bahr, Conservation Outreach Director, Sierra Club – Grand Canyon Chapter. "We have supported efforts to remove non-native fish species and previous efforts to operate the dam in such a manner as to promote recovery of the fishes and to rebuild the beaches which are also being decimated by the operation of the dam. Clearly, the federal government needs to make some changes to protect our native fishes and to protect the recreation that relies on the Canyon's beaches."

In October 2005, the U.S. Geological Survey released its evaluation of this program in a 220-page report, "The State of the Colorado River Ecosystem in Grand Canyon." This report confirmed what many scientists have been saying for years: that recovery of the humpback chub is not being achieved. According to the report, "...it is clear that the restrictions on dam operations since 1991 have not produced the hoped for restoration and maintenance of this endangered species."

"Since the Fish and Wildlife Service issued its Biological Opinion on the dam's operations in 1994, the Bureau of Reclamation's actions have merely made things worse," said Living Rivers Conservation Director John Weisheit. "One more fish species is effectively extinct in the Canyon, and another is on the verge."

Despite the ongoing detrimental effects of Glen Canyon Dam on the humpback chub, razorback sucker, Colorado pikeminnow and bonytail chub, and the failure of the Adaptive Management Program to address those impacts, the agencies have not reinitiated consultation with USFWS and prepared a supplemental EIS as required by law.

The groups' suit aims to protect the native fish and aquatic habitat of the Grand Canyon and Colorado River by stopping the ongoing destruction caused by the current operations of Glen Canyon Dam. The suit does not seek to decommission the dam. Matt Kenna, Western Environmental Law Center in Colorado, represents the organizations.

Lawsuit targets Arizona dam

Says native fish near extinction

Shaun McKinnon for The Arizona Republic Feb. 17, 2006 12:00 AM

Five environmental groups on Thursday accused the Interior Department of failing to protect native fish in the Grand Canyon and asked a federal court to order changes in how water flows into the Colorado River from Glen Canyon Dam.

Their lawsuit, filed in U.S. District Court in Phoenix, stopped short of demanding that the government decommission the dam, a drastic solution some activists say is the only way to restore the river's ecosystem.

Instead, the groups want the court to enforce an existing plan that calls for operating the dam in a way that will help the fish and other species downstream. The government has ignored that plan, the lawsuit alleges, and allowed some fish species to slide nearer to extinction. advertisement The suit could disrupt other attempts to control the river's flow

from Glen Canyon Dam, most notably the ongoing drought talks among the seven states that draw water from the Colorado. That plan could clash with some of the measures prescribed to help the native fish, whose populations have declined in the 40 years since the dam was built.

The groups want the courts to declare the Interior Department in violation of the Endangered Species Act and force the agency to conduct new environmental studies that would lead to changes in the dam's operations. The suit specifically says the groups are not seeking an injunction to stop or alter the flow of water from the dam.

In denouncing the government's efforts so far, the groups cite a plan released last year by the U.S. Geological Survey, which found little progress in species recovery or habitat restoration after experiments designed to mimic the river's pre-dam flows. That report noted trouble for at least four native species: the humpback chub, the razorback sucker, the Colorado pikeminnow and the bonytail chub.

"We waited patiently while they did their studies," said Robin Silver, board chairman for the Center for Biological Diversity, one of the groups that signed on to the suit. "It shouldn't be this way. The lawsuit should be unnecessary. But those agencies are not motivated to do what's necessary to make sure we get these species to survive."

Federal officials had not seen the full complaint Thursday, but it is likely to trigger a negative response from water managers in the seven Colorado River states, said Sid Wilson, general manager of the Central Arizona Project, which delivers water from the river to Phoenix and Tucson.

"If the environmental groups continue to push, you're going to have the seven states and the federal agencies and, frankly, the political officials from the seven states pretty united on all this," Wilson said. Because the states are working on their own plan to control flows from Glen Canyon Dam, any competing scheme could complicate work on the drought plan. Wilson said he has heard anecdotal evidence in recent months that some native fish populations are growing again, in part because of government-sponsored programs to remove non-native fish, such as trout, that feed on baby chubs.

"This suit is like anything else," he said. "If you want to discredit things, you can find them."

The complaint asks the court to force the Interior Department to revise an environmental impact statement written more than a decade ago after studies found evidence that the dam was harming the Colorado River ecosystem along the length of the Grand Canyon.

With the dam in place, the water that flowed into the Grand Canyon was cooler and clearer, creating conditions that are not friendly to the native fish. The dam also blocked seasonal floods and other fluctuations in the river's flow, which helped maintain beaches and other natural habitat in the canyon.

In 1992, Congress ordered the Interior Department to regulate the dam's flows in a way that would help restore the habitat and protect the native species. Two years later, the U.S. Fish and Wildlife Service found that the humpback chub and razorback sucker

were in jeopardy of extinction, triggering an adaptive management plan aimed at improving conditions.

One of the plan's most visible elements was a series of artificial floods designed to rebuild beaches. The first try in 1996 produced disappointing results, and later attempts were only slightly more successful. Future floods could be hampered by agreements among the seven states on how and when water is released.

"Their actions have merely made things worse," said John Weisheit, conservation director for the group Living Rivers. "One more fish species is effectively extinct in the Canyon and another is on the verge."

Weisheit's group has helped lead the charge to decommission Glen Canyon Dam and drain Lake Powell, restoring the river's natural flow through the Grand Canyon. That proposal has been widely discredited by water providers and federal agencies.

Rivers: a drying shame

We have used our engineering skills to harness the Earth's water systems. Now we are paying the price.

By Geoffrey Lean for The Independent (UK) March 12, 2006

The delta of the great Colorado River - where once it swept into the Gulf of California - used to be the most wonder-filled wetland in the whole North American continent. Some 400 species of plants and animals - including jaguars, beaver and the world's smallest dolphin- thronged its 3,000 square miles of wetlands, lagoons and tidal pools. The local people made a good living fishing its teeming waters. Now it has become a forbidding desert of salt flats and giant heaps of dead clamshells. The fishing boats have been long since beached; the destitute people have to seek what work they can in wheat fields and tortilla factories far away.

The reason for the transformation is not hard to find. Not a drop of the mighty river which once carved the Grand Canyon now flows through the delta to the sea. It has all been used upstream - to slake the thirst of cities such as Tucson, Arizona, feed fountains in Las Vegas, green golf courses and irrigate farmland. Such water as remains in the delta has flowed in from the sea.

It is much the same story in that other great river of the American south-west, the Rio Grande. This does not merely fail to reach the sea: it disappears for much of its length.

The atlases tell us it is one of the 20 longest rivers in the world, but in reality it stops some 800 miles inland at El Paso, Texas, which takes all its water. For the next 200 miles or so there is just a dribble of sewage in its old river bed, and even this often dries up in summer. Local people call it "the forgotten river". The dry channel does not come alive again until a relatively healthy tributary, the River Conchos, joins it from Mexico. For the rest of its length, as it forms the boundary between the two nations, it should, in justice, be called the Conchos, not the Rio Grande. But even this is quickly used up, mainly to irrigate farmland, and often fails to make it through to the Gulf of Mexico.

It is much the same story right across the world. China's Yellow River, the fifth longest in the world is in trouble at both ends. Its source in the Tibetan plateau is drying up - and for most of the past 35 years it has failed to reach the sea all year round.

Similarly, despite the words of the spiritual, the River Jordan is far from "deep and wide". In practice it ends at the Sea of Galilee, where Israeli engineers have blocked the outflow and piped the water to irrigate fields and supply Jerusalem and Tel Aviv.

Such water as flows down the Jordan valley again comes from a tributary, the River Yarmuk. But it cannot really do the job. In biblical times the valley carried a billion cubic metres of water every year; now it has to make do with less than a tenth of that. The ugly truth is that the river - sacred to Christians, Jews and Muslims - is now mainly made up of diluted sewage.

It is the same for river after famous river. The lower reaches of the Nile used to carry 32 billion cubic metres of water a year; now they are down to two billion. The Indus in Pakistan - "Asia's Nile" - similarly has lost 90 per cent of its water in the last 60 years. Australia's Murray River fails to reach the sea every other year.

Even in Europe, Germany's River Elbe has run so dry that it frequently becomes impassable to barge traffic for months at a time - and three years ago river traffic almost completely stopped on the Rhine. In Britain the Environment Agency regularly sounds the alarm about our chalk rivers and streams - which gave birth to the sport of fly-fishing. Dozens of them dry up every summer, and 40 of the 160 in the country are officially under threat.

The writer Fred Pearce, who has published a groundbreaking book on the crisis of the world's rivers, says: "The maps in an atlas no longer accord with reality. The old geography lessons about how rivers emerged from mountains, gathered water from tributaries and finally disgorged their bloated flows into the oceans are now fiction."

The UN-backed World Commission on Water for the 21st Century reported: "More than one half of the world's major rivers are being seriously depleted and polluted".

There are two main culprits; abstraction of water for rivers - usually after damming them - and global warming.

The world has, on average, built two giant dams a day, every day, for the past 50 years. Now 45,000 of them span the world's rivers. Every one of the world's 20 longest rivers is encumbered by them.

In many ways it all began on the Colorado, 70 years ago, with the Hoover Dam, the great symbol of Franklin Roosevelt's New Deal. Today, the dams intercept more than a third of the world's freshwater as it flows towards the sea and at any one time are holding back 15 per cent of it.

The UN's triennial World Water Development Report, published for a international conference in Mexico City this week, cautions that damming has "hugely changed the natural order of rivers worldwide." It goes on: "Humanity has embarked on a huge ecological engineering project with little or no preconception - or indeed full present knowledge - of the consequences. We have sought to redesign and impose a new order on natural planetary systems, built over aeons of time."

Dams waste massive amounts of water. In hot, dry regions, they lose about 10 per cent of their reservoirs to evaporation every year: much more is lost in irrigation. Global warming is making things even worse. The source of the Yellow River is drying out as glaciers retreat. And a great drought in the southwestern United States - so intense that even cacti are wilting - is exacerbating the crisis of the Colorado and the Rio Grande.

It is even endangering relatively healthy rivers. The Amazon, relatively unencumbered by great dams, was hit by the worst drought on record last year: water levels fell by 10 metres and boats were stranded. And salmon are endangered in Alaska's Yukon River because its waters are too warm.

This will only get worse as the world goes on heating up, making the desert delta of the Colorado just a foretaste of the rivers of the future.

RIVER REPORT

Amazon

Length: 4,000 miles

Famous as: Source of some of world's richest habitats

Problems: Depleted by a record drought last year. Widespread deforestation

Verdict: Largely undammed and rescuable

Yellow River

Length: 2,900 miles

Famous as: Carries most silt

Problems: Source is drying out and river now usually fails to reach the sea

Verdict: Attempts at rescue. Task immense

Jordan

Length: 104 miles

Famous as: Holy river

Problems: Effectively ends below the Sea of Galilee. Site where Jesus was baptised now a pool of sewage

Verdict: Hardly exists, damage seems terminal

Rio Grande

Length: 1,900 miles

Famous as: Border river
Problems: Now two rivers, split by 250-mile dry section
Verdict: Over-exploited

LR in the News 03/23/06

Plan for Grand Canyon use gets final approval

March 24, 2006 USA Today

PHOENIX (AP) - More people will be able to raft down the Colorado River each year, but visitors will be spread out over a longer period of time and will be forced to travel in smaller groups, according to a new plan the National Park Service formally adopted Thursday.

More rafters will be shifted to fall, winter and spring months while the number of daily summertime launches of both motorized and non-motorized commercial rafts will decrease.

The result will be more tourists overall.

The new plan also eliminates the current waiting list for those who want to raft the river in non-commercial boats, replacing it with a lottery system.

More than 7,000 trip leaders are on the waiting list, said Jeffrey Cross, project manager for the plan. Many people have been waiting to go on trips for more than a decade, he said.

"Their lives often changed," Cross said. "They had babies, they moved, they changed jobs."

The long wait resulted in a cancellation rate between 30 and 50 percent, Cross said.

In the next six weeks, the 600 people who have waited the longest will be assigned dates spread throughout the next five years. After that, those on the waiting list can combine their waits with the waits of friends, allowing the longest 600 of those waits to be assigned dates.

After that, everyone else will be in the computerized lottery. The first drawing will be in August and will take up the rest of the available 2007 dates.

Those who have already been assigned trips for the summers of 2006 and 2007 will not be affected, said Steve Sullivan, who manages the waiting list.

"We heard pretty strongly from members of the public," Sullivan said. "A waiting list was not working for the people."

Additionally, the number of non-commercial trips allowed annually will double by 2007, allowing 500 trips a year, up from 240, Cross said.

The lower Colorado River, from Diamond Creek to Lake Mead, will see pontoon boat tours go up, allowing up to 480 passenger per day, up from between 130 and 188 passengers, depending on the time of year.

Members of the Hualapai American Indian tribe, which runs the lower river tours, had requested allowing nearly 1,000 passengers.

The plan bans jet boat tours entirely, but commercial operators that use the craft to meet rafts above Lake Mead would still be allowed.

Additionally, the maximum number of passengers on commercial boats will be trimmed by 10 to 32.

The approval of the final plan comes after four years of study by a group of scientists, Park Service managers and other professionals, with input from tour operators, Indian tribes and members of the public. It will be in place for the next 10 years, but alterations can be made if necessary.

The plan is being met with wide support, including the Grand Canyon River Outfitters Association and the Grand Canyon Private Boaters Association, two difficult-to-please groups, Sullivan said.

"That's kind of amazing," he said. "Three years ago, I would have said that would be unlikely. It's a pretty major accomplishment."

But not everyone is pleased.

"We're pretty disappointed," said Owen Lammers, director of Living Rivers, a river restoration group. "It's completely shortsighted and completely negligent in terms of the Park Service mission. They're failing. They're completely derelict in their duties."

Lammers said the plan should have addressed the environmental affects of the Glen Canyon Dam on the Colorado River and banned motorized boats altogether because "they're not necessary at all."

"They spent how many millions of dollars on this when the end result is a lottery system instead of a waiting list?" Lammers said. "It would be OK if they labeled it a human resources plan. It's not a river management plan at all. The public is just being completely misled by the Park Service."

Cross said there are non-motorized boats on the river, as well, and that the Park Service is just trying to meet the demands of the public.

Groups Sue to Protect the Grand Canyon

Coalition effort to improve management of the Colorado River\

For Immediate Release: Tuesday, March 28, 2006

CONTACT:

John Weisheit
Living Rivers
435-259-1063
john@livingrivers.org

Jo Johnson, Co-director
River Runners for Wilderness
303-443-1806
jojohanson@rrfw.org

Marc Ross, Executive Director
Rock the Earth
303-454-3304
macr@rocktheearth.net

(Denver) A coalition of groups has announced their lawsuit (not a 60-day notice) challenging last Thursday's National Park Service decision to continue to allow commercial motorized rafting tours and helicopter passenger exchanges through Grand Canyon National Park. Since Grand Canyon's recommendation for formal wilderness designation three decades ago, the Park has neglected to remove motorized tour boats and helicopters, that, by the Park's own admission, do not conform to legal wilderness standards.

The groups, Rock the Earth, River Runners for Wilderness, Living Rivers and Wilderness Watch, are defending this crown jewel of the National Park system and every visitor's right to a pristine wilderness experience in the backcountry and on the river. The coalition is represented by Julia Olson of Wild Earth Advocates and Matthew Bishop of the Western Environmental Law Center.

"After consulting with a number of partners and citizen groups, we feel that the recent park service ruling fails to properly fulfill the National Park Service mandate that the Colorado River through Grand Canyon must be managed as wilderness," states Rock The Earth Executive Director Marc Ross, "We're fighting to make sure the National Park

Service does the duty all Americans entrust them with: protecting this beloved natural treasure.”

In addition to the Park Service’s failure to remove motorized tour boats and helicopters in a qualifying wilderness area, the agency’s decision to perpetuate the inequitable allocation of river running permits is also at issue. Currently, commercial tours receive priority over public opportunities for do-it-yourself rafting and kayaking in the summer.

“The distribution of use is so skewed that public river runners have little or no chance of ever gaining a permit through the proposed lottery. It is scandalous discrimination against those choosing to do their own trips while tourists can buy their way onto a high-priced tour almost immediately,” notes Jo Johnson, Co-director of River Runners for Wilderness.

A third concern of the group is the Park Service’s failure to properly address and mitigate degradation of the Grand Canyon’s ecosystem by human use and the ongoing depredations of Glen Canyon Dam, including the lack of planning for lower river flows caused by the continuing drought.

“Dangerous national precedents for the commercialization and privatization of public lands and wilderness areas are at stake here,” said Julia Olson, lead attorney. “We hope they finally address these vital concerns now that we’ve filed notice.”

Arizona goes on 'red' alert over drought

Shaun McKinnon for The Arizona Republic

Arizona turned red with extreme drought Tuesday after one of the driest winters on record left the state's high country draped with too much brown and not enough white.

The official drought monitor was moved from "severe" to "extreme" based on nearly non-existent snowpack and brittle soil and vegetation conditions. The recent rain and snow had little effect on a drought that is now entering its 11th year.

The new status won't trigger rationing or any other restrictions, but it comes with a lengthening list of things to do for state agencies and local government officials. Unless the governor declares an emergency, only those local officials can limit Arizonans' water use.

A map issued by the state drought-monitoring group Tuesday shows all but three counties colored bright red, indicating extreme drought. Mohave, La Paz and Yuma counties stayed at "severe."

This is the first time the state has used the drought monitor. If conditions worsen, the red could turn even darker, indicating the top category of "exceptional" drought.

Regional News 03/30/06

Groups sue over plan for Grand Canyon's river corridor

Land Letter on Thursday, March 30, 2006

April Reese for Land Letter Western reporter

Days after the National Park Service issued the final management plan for Grand Canyon National Park's river corridor, two environmental groups have filed suit seeking changes to the controversial plan.

The Colorado River Management Plan, which was codified in a record of decision issued March 23, is aimed at balancing public access to the 227-mile river corridor in the park with the protection of the canyon's natural resources. Thousands of rafters and kayakers ply the river's waters each year.

The 277-mile corridor of the Colorado River in the Grand Canyon is a popular destination for rafting enthusiasts.

But environmental groups and private river runners say the new plan favors commercial outfitters over private boaters.

Even though the new plan gives private boaters more access to the river overall, it relegates them largely to the off-season while allowing commercial, motorized trips in the popular spring and summer months. It also requires private boaters to complete their trips faster, giving them less time on the river, said Tom Martin, co-director of River Runners for Wilderness.

"It is scandalous discrimination against those choosing to do their own trips while tourists can buy their way onto a high-priced tour almost immediately," said Jo Johnson, co-director of River Runners for Wilderness.

"Dangerous national precedents for the commercialization and privatization of public lands and wilderness areas are at stake here," added Julia Olson, an attorney who is representing the groups in the case. "We hope they finally address these vital concerns now that we've filed notice."

Environmental groups also fear that the plan could hurt the river corridor's chances of being designated as wilderness, since it does not ban motorized boats. A long-standing Park Service directive requires the agency to manage the river to preserve its wilderness characteristics.

However, Linda Jalbert, a planner for Grand Canyon National Park, noted that allowing motorized rafting does not preclude the area from qualifying for wilderness designation. A provision in the Wilderness Act makes an exception for existing motorized use. The park recommended the river for wilderness designation in 1980, but Interior officials have not carried that request to Congress, Jalbert said. Under the plan -- itself a result of a lawsuit filed by environmentalists in 2002 over management of the popular canyon -- motorized and non-motorized use would be split into two periods, and river traffic would increase by about 2,200 boaters per year.

Motorized boating would be allowed during the main tourist season, from April 1 through Sept. 15, with non-motorized use primarily between September and March. Currently, the park allows boating nine months out of the year, and about 70 percent of permits go to commercial outfitters, with the rest going to private boaters. Under the park's new plan, the number of commercial trips would stay about the same, while access for private, noncommercial boaters would increase.

Overall, the new system would allow about 24,700 people on the river, up from 22,500 (Land Letter, Nov. 17, 2005).

The document also attempts to address the much-maligned permit system for non-commercial, private boaters, who currently must wait as long as a decade for a permit to float through the canyon. The park will now use a weighted lottery, where winners would be chosen each year for the following year's permits. Those who have waited longer for a river trip would be given more chances in the lottery.

Mike Denoyer, president of Grand Canyon Expeditions, said he believes the plan is fair to all concerned.

"They've made a very cooperative effort to make trips available to both the commercial and non-commercial sector," he said.

While the new plan will increase river traffic overall, it distributes launches more evenly throughout the year, lessening pressure on the river's resources and reducing crowding, Jalbert said.

"We were able to accomplish this balance by spreading the use out on a daily, weekly and even a seasonal basis," she said.

For instance, under the existing plan, up to nine trips could float down the river on a summer day, but the new plan allows only five to six trips per day in summer while increasing the number of allowable trips in the off-season, Jalbert said.

But critics said the plan does little to address beach erosion, degradation of cultural sites and other effects of those trips.

"Basically, instead of treating it as a wilderness resource, they're treating it like a water highway," said Sandy Bahr, conservation director for the Sierra Club's Grand Canyon chapter. "We think there will continue to be more damage to the vegetation, the beaches, and the cultural resources."

The Sierra Club has not yet decided whether to join the lawsuit, she added.

Conservationists sue to keep motors out of Canyon

By CYNDY COLE Sun Staff Reporter

Four environmental and river rafting groups are suing the National Park Service in an attempt to stop helicopter flights and motorized rafting in the Grand Canyon.

They want the park designated as wilderness and a recent decision that doubled river use for private boaters overhauled. It's the first lawsuit since the early 1980s to attack motorized rafting in the Grand Canyon, something the Park Service itself had recommended ending in the 1970s and '80s.

Motorized rafts and helicopters in the canyon have long been a target for some because of the noise they create. The Park Service itself decided repeatedly that motorized rafting was not in the best interest of the canyon's beaches, fish or visitors, the groups said in their lawsuit.

"We feel like we're going to battle on behalf of all American citizens. They deserve to have the Grand Canyon designated as wilderness," said Jo Johnson, co-director of River Runners for Wilderness.

But maybe extra federal protections for the canyon are a moot point.

Motorized rafting could be allowed even if the Grand Canyon and Colorado River were designated as wilderness, Park Service documents state.

Living Rivers, Rock the Earth and Wilderness Watch are the other plaintiffs. They say the Park Service failed to prove motorized commercial boating is necessary as required by law, failed to fairly distribute boating permits on the river and didn't analyze whether increasing boating by about 2,000 rafters annually will harm the ecosystem.

Of the 24,657 people to be allowed down the Colorado River next year under a new plan to reallocate time on the river, a third will be noncommercial boaters.

That's twice as many as previously allowed but still not enough, the plaintiffs said.

Between 40 percent and 60 percent of all trips on the Grand Canyon are motorized, giving time-starved customers a way to get down the river in a week instead of two, said Mark Grisham, director of the Grand Canyon River Outfitters Association, which represents commercial interests.

"If there weren't motorized trips, the majority of Americans would be deprived of the opportunity to see the Grand Canyon by river," Grisham said.

The groups suing have also argued that helicopter use to transport rafters in and out of the canyon should be illegal.

"The park believes that the final environmental impact statement and the record of decision represent a good balance of the many competing interests and we believe that the court will affirm our decision," Grand Canyon spokeswoman Maureen Oltrogge said.

Sen. Orrin Hatch, R-Utah, attached a rider to a 1981 bill that would block any federal funds from being used to support removal of motorized boats from Grand Canyon, even if they were only used for drawing up planning documents.

The Park Service reversed course on its mission to phase out motorized boating following Hatch's move and hasn't attempted again since.

A proposal to designate most of the Grand Canyon as wilderness was put forth by Grand Canyon managers in 1993 and has never been transmitted to Congress or any president since, as would be required, according to the Colorado River Management Plan.

The lawsuit is not expected to hold up river trips or permit lotteries for upcoming river trips, as the plaintiffs are not seeking an injunction.

National Geographic: Drought Drains Lake Powell--Uncovering the Glory of Glen Canyon

National Geographic on April, 2006

By Daniel Glick and photographs by Michael Melford

Excerpt

"Today, the fall of the lake has driven a rising debate about its future. Many scientists think Western droughts will intensify as the Earth's climate warms. Water will become even more precious-and reservoirs, which lose vast amounts through evaporation, will seem intolerably wasteful. Better, say many environmentalists, to exploit new technologies for storing water underground, decommission the dam, and let Lake Powell once again be Glen Canyon."

A DRY RED SEASON

A year ago Lake Powell reached its lowest level since Jimi Hendrix played Woodstock and Neil Armstrong made his giant leap onto the moon. A sustained drought had sucked out two-thirds of its water, exposing 140 vertical feet of once drowned cliffs. The dry spell temporarily turned the great reservoir back into a red-rock maze called Glen Canyon, stirring hopes that terrain whose grandeur rivals any on Earth may one day be revealed for good.

It also resurrected Tom McCourt's childhood.

McCourt holds forth on a newly exposed rock outcrop near the shrunken lake and reminisces about what was here 40 years ago: two small settlements flanking a vast floodplain cleaved by the Colorado River's milk-chocolate waters and guarded by fortress cliffs. His grandparents lived on this east side, in the town of White Canyon, before it was slowly inundated by the reservoir.

As a kid, he'd come regularly to visit, and he recalls the country as harsh and bountiful. "My grandfather told me it got so hot down here that the ravens left contrails because their feathers were smoking," McCourt says, a storyteller's glint in his eye. "The soil was so rich we couldn't grow watermelons, because the vines would grow so fast they'd drag the melons across the garden and wear them out before they could ripen."

On this early spring day, visitors representing three generations of two families with ties to White Canyon gather and bear witness to its unveiling. The water hasn't dropped enough to reveal the old landing strip or the site of McCourt's grandparents' house, but it's fallen more than enough to stir personal and collective memories.

McCourt's entourage includes his cousin Janis York, who lived here with her parents until she was five. York shyly approaches, moved to tears by swirling childhood memories. She used to sit on a hill behind her grandparents' house and pretend she was queen of the land. "There were rocks that sparkled," she recalls bits of glittering fool's gold. I used to call them my little jewels." After her family left and the waters rose, she says, I was brokenhearted."

York gazes out over the canyon and the years. "This is the heart of the whole world," she says. I remember telling my jewels I'd be back some day."

After Glen Canyon Dam closed its gates on the Colorado River near Page, Arizona, in 1963, the river's cargo of snowmelt and spring rain, gathered from much of the mountain West, hit the dam's concrete stopper and began to back up. The rising waters slowly transformed the lower reaches of the intricate, thousand-hued Glen Canyon into a monolithic blue-green reservoir, the country's second largest after Lake Mead, farther down the Colorado.

Aided by Lake Powell's aqueous bounty, Little League fields sprouted in Las Vegas, subdivisions multiplied in Los Angeles, golf courses carpeted Phoenix. As the reservoir waters rose, Glen Canyon drowned. This remote heart of the Colorado Plateau, dubbed "the place no one knew" in photographer Eliot Porter's ode to this lost landscape, gurgled underwater.

In unknown Glen Canyon's stead emerged the enormously popular Glen Canyon National Recreation Area-which quickly became a mecca for millions of houseboaters, water-skiers, and striped bass fishermen taking advantage of this watery miracle in the desert.

Then came the sustained drought that ushered in the 21st century, one of the region's periodic dry spells. For five years clouds yielded little moisture, even as the West continued to drink greedily. The Colorado River, lifeblood for seven states, dwindled. Lake Mead and Lake Powell, the river's massive catch basins, shriveled. No amount of hydro-engineering, cloud seeding, flow regulating, or other manipulation could change a simple fact: Not enough water was falling from the sky to keep the West's reservoirs full. Not with the increasing number of straws sucking upstream water to irrigate alfalfa fields, fill swimming pools, and sprinkle suburban bluegrass expanses.

Lake Powell's loss was and is Glen Canyon's unmistakable gain. People who were lucky enough to get a glimpse of Glen Canyon when they were young flocked to see it again, as if offered the chance to visit, after 40 years, a first love who had abruptly moved away. People who had only known the canyon through photos and descriptions-by John Wesley Powell, Wallace Stegner, Katie Lee, Eliot Porter, David Brower, and Edward Abbey-hurried for a first look.

The ancient Navajo sandstone itself shook off the water as easily as a dog emerging from a swimming pool. At an average rate of an inch a day, a lost sculpture garden of rock resurfaced, miraculously intact.

The uncovered slickrock sandstone told its astounding life story: of Sahara-size sand dunes marching across the landscape 190 million years ago; of three-toed dinosaurs that left tracks in damp spots between the dunes; of deep burial that slowly squeezed sand and mud into rock; of epic uplifts and tectonic shifts; of water and wind that carved slot canyons hundreds of feet deep.

Layers of human history saw the light again too: thousand-year-old petroglyph panels and cave dwellings of the Anasazi; artifacts from Navajo settlements; inscriptions left by 19th-century Mormon pioneers; equipment from uranium miners' camps of the 1950s; sunken boats and even a lost airplane of more recent vintage.

Desert varnishes, mineral-rich dust transformed by microbes and moisture, soon streaked the canyon walls. Vermilion, rust, beige, taupe, slate, maroon, cocoa, coffee, pale orange, and peach, they began painting over the lake-bleached bathtub ring left by high water. Streams rippled anew in the side canyons that branch out like arteries from the main stem of the Colorado to distribute lifemaidenhair ferns and coyote willow, soft-stem bulrushes and golden sedges in this arid land.

There was little soul-searching when Congress voted to euthanize this hidden world back in 1956, when Ike was President, the country poised to pave interstates coast-to-coast, and Sputnik was but a year away. Today, the fall of the lake has driven a rising debate about its future. Many scientists think Western droughts will intensify as the Earth's climate warms. Water will become even more precious-and reservoirs, which lose vast amounts through evaporation, will seem intolerably wasteful. Better, say many environmentalists, to exploit new technologies for storing water underground, decommission the dam, and let Lake Powell once again be Glen Canyon.

There's little chance of that for now. Lake Powell, however diminished, plays too important a role in the West's water supply, and its removal would mean rewriting complex water laws at a time of massive population growth. But even though slightly above-average runoff in the spring of 2005 raised the lake 53 feet from that year's historic lows, managers expect it to drop again, to perhaps 108 feet below full pool by this month. Another sustained dry spell would push the lake to new lows. And in the very long run, nature will defeat the dam. Over the centuries, Lake Powell will ultimately fill up with silt.

Let me get a little less disoriented here," says Bill Wolverton as he scrambles up a slickrock tower to gaze into Twilight Canyon. Wolverton, 57, has roamed this Glen Canyon backcountry for a quarter century, first as a furloughed railroad worker with time on his hands and a love of the desert, and for the past 18 years as a seasonal backcountry ranger and an ardent advocate for the canyon. On his days off he walks me up and down a half dozen remote canyons, observing what the reservoir wrought and the drought incrementally reversed.

In the lower reaches of each canyon, by the lake, we sink into giant pillows of sediment, deposited over the decades since high water flooded the canyon and stripped the banks of life. Wolverton calls this vegetation-free carpet of stinking mud the "death zone." At

one point I am in it up to my knees and elbows when solid-looking ground turns out to be quicksand.

Here gnarled gray hundred-year-old cottonwood branches beckon like skeletal hands from the mud. Detritus from boating trips—an anchor, the handle from a water-ski towrope, a swim fin rests forlorn in the sandbars. Fishing line trails from broken rods tangled in driftwood.

The reservoir's drop of 140 feet, stretched over the gentle gradient of a side canyon, can mean that two or three miles of terrain have been slowly unveiled over the past six years. By last spring more than 100 square miles of canyons had seen air for the first time in decades. We slither up one of Twilight Canyon's tributaries, a magnificent narrow slot that requires gymnastic moves to explore. Seeing it for the first time delights Wolverton, and he doesn't hide his desire that the waters keep receding. "It's knowing that places this special are underwater that makes me want the reservoir gone," he says.

The farther we hike from Lake Powell, the more signs of life reappear. Less than half a mile from the water, frontier willow colonies and tiny reeds clothe the banks, along with a host of invasive species. Tamarisk, tumbleweeds, and cheatgrass, all aliens, have seized an unnatural advantage, battling with the natives for the new territory. Farther upstream, spring floods since the lake receded have blasted a channel into the sediment, uncovering the bedrock and exposing swirling patterns on the sandstone canvas.

A mile or so up from the reservoir's edge, the canyon feels like it is breathing again. The descending plaintive warble of canyon wrens, which Wolverton describes as the "call you can hardly forget," echoes off salmon-hued walls. Sixfoot cottonwood saplings with fresh, electric green leaves sprout in the shadow of drowned, hulking snags. Cattails, horsetails, and black willows are revegetating the stream banks. On benches above the streambed, yellow and pink blooms of prickly pear cactus herald the spring. Gardens of monkey flower and cave primrose take tenuous hold in aired-out alcoves wet from seeps. Gambel oaks and box elders cluster above the high-water mark. We are struck by wafts of desert flower perfume, of sage aroma awakened by the sun, of moist sand and earthy oak and fleshy cottonwood bark.

"This dam won't work forever," Wolverton says, and he shows me why. We hike to the confluence of Coyote Creek and the Escalante River, a tributary of the Colorado. Where the clear water washing down Coyote Gulch meets the pea green water of the Escalante, we stare at a steady underwater parade of pebbles, sand, and silt moving downstream. "Budding a dam across sediment-laden rivers is like driving your car without ever changing the oil filter" he says. Sooner or later the marching sediment will have its day. "There's the answer right there," he says, pointing to the gravel on the march. "It's inexorable. This is the land of erosion."

Perhaps it all comes down to this place: a waterfall in a most unlikely location, a hidden cavern of mystical proportions aptly called Cathedral in the Desert. I arrive here alone by boat, following a sinewy side canyon, new desert varnish on its steep walls and the

chalky white bathtub ring nearly gone. The water is green, deep, still. The walls close in, the canyon narrows. Rounding one last turn, I eye a beach, cut the motor, and glide silently to shore.

Ahead, the canyon walls curve, rising hundreds of feet above me, overhanging to form a giant cavern, once drowned by Lake Powell. The waterfall drops 50 feet, bounding, bouncing, pulsing. It has left a splash of dark green on the wall. Water was at work here long before the dam and the reservoir, wearing a notch in the rock that now guides the stream the way a halved section of bamboo pipe funnels water in a Japanese garden. The cascade sounds eerily like the low murmur of a room full of people. Three hundred feet above, an opening frames a boomerang-shaped sliver of sky.

As I write this, the waters have risen again and put the waterfall at least temporarily back in the bottle. Somewhere, though, a canyon wren still warbles its haunting song. The warm desert wind rushes over the slickrock. Pebbles march toward the sea. And Glen Canyon abides.

End

Lake Powell may never be full again

New accord means it won't go so low,
nor reach full pool in future

By Joe Baird for The Salt Lake Tribune

The white band on the cliffs of Lake Powell shows a drop in the water level in March 2004. (Paul Fraughton/Tribune file photo)

After six years of drought and a drop to water elevation levels not seen in decades, Lake Powell began refilling last year. And it will continue to rise this spring and summer, owing to a second consecutive year of close-to-normal snowmelt in the upper Colorado River Basin.

For those who recreate on the huge reservoir that sprawls across the Utah-Arizona border, this comes as happy news. Powell dropped to a record-low elevation of 3,555 feet just over a year ago - about 33 percent of capacity - and is forecast to reach 3,622 feet this summer when the runoff reaches its peak in July. That's a jump of nearly 70 feet, and to about half of what the reservoir can hold. But for those who long for the day when Lake Powell will be replenished to the brim - about 3,700 feet - the wait could be a long one.

A nearly finalized agreement between the seven Colorado River Basin states regarding future management of the river calls for the joint, coordinated operation of Lake Powell in the upper basin and its sister reservoir, Lake Mead, downstream in the lower basin. The thrust of the idea is to ensure, as much as possible, that neither reservoir suffers at the expense of the other during future dry periods. The upside: Federal and state water officials believe that, barring a hydrological catastrophe, such a coordinated approach will prevent Powell from draining to the depths it reached during the drought. On the other hand, the deal - which probably will be incorporated into an ongoing federal environmental study of drought conditions on the Colorado River - will in most years prevent Powell from refilling to its historical high-water mark.

"This agreement really puts a cap on the reservoir unless we have some gangbuster [water] years," says Jack Schmidt, an aquatic, watershed and earth resources professor at Utah State University who specializes in Colorado River issues.

Water officials don't like the word "cap," but acknowledge that a less-than-full Powell will become the rule and a filled reservoir the exception under the new agreement.

"The first thing you have to remember is that reservoirs aren't meant to be full all the time," says Larry Anderson, the just-retired director of Utah's Division of Water Resources. "The second thing is, the upper basin still hasn't developed all of its water. As it does, there will be a greater drain on the reservoir.

"But now," he adds, "as we jointly manage these reservoirs, we won't run into the problem of one being too high and one being too low. That will protect the water users first and foremost, and recreation and hydropower."

Lake Powell is a hugely popular regional tourist destination, the Glen Canyon National Recreation Area drawing nearly 2 million visitors annually, largely for boating among the parts of the redrock canyons that rise above the water. The drowning of Glen Canyon, however, has been the long lament of American wilderness advocates who say the dam was not needed for water storage and who mourn the loss of one of the most beautiful and spectacular river canyons on Earth.

Under the terms of the recent agreement, when Powell's water level is up and Mead's is low, upper basin officials will have the discretion to release extra water to the lower basin, beyond the annual 8.23 million acre-feet they are committed to provide. Conversely, lower basin users will accept less than that amount if Mead is up and Powell is low.

Anderson says that extensive computer modeling established that 3,570 feet was Powell's baseline elevation for maintaining recreation opportunities - which translates into a huge chunk of the economy for southern Utah and northern Arizona.

Under the new management criteria, Bureau of Reclamation officials expect that Powell's median elevation will hover between 3,630 and 3,640 feet over the next decade. That's still 60 to 70 feet below the reservoir's full line, but still plenty of water for boaters to launch their craft and for marinas to operate.

"In the past few years, during the drought, we made a lot of effort to ensure the public had access to the reservoir," says Kevin Schneider, management assistant for Glen Canyon National Recreation Area. "We extended the launch ramps and made sure the [navigation] buoys were in the right places. The reservoir is designed to go up and down. Our management is also designed to adapt. Regardless of what the elevation is, the public will have the opportunity to enjoy the park."

Not everybody agrees with such optimistic assessments. Environmental groups clamoring for the decommissioning of Glen Canyon Dam and draining of Lake Powell say federal and state officials are ignoring long-term historical trends - at their peril.

"They're concentrating on a historic record based upon the 20th century. But those who study tree rings call it the wettest century in 1,200 years," says Jon Weisheit, conservation director of the Moab-based Living Rivers organization. "What we've lived through has been an anomaly. The whole thing is based on bad science, and this new agreement just basically maintains the status quo. They're ignoring the good work that's being done by climatologists, something they could use and benefit from."

Richard Ingebretsen, founder of the Glen Canyon Institute, a group that advocates draining Lake Powell to uncover the lost Glen Canyon, said that at the Bureau of Reclamation's projected median elevations, many of the side canyons, including much of the Escalante River, will be above water.

"A lot of the side canyons in the upper stretches will be out of water," he said. "Almost all of Cataract Canyon."

Ingebretsen agrees it is inevitable that upper basin states will develop more of their Colorado River allotment - Utah's planned Lake Powell pipeline being a prime example. But in addition, he predicts that lower basin states will want to buy more water and said that projections show as much as a 30 percent reduction in the flow of the river because of global warming.

"Lake Powell is going to go lower and lower," said Ingebretsen.

At the other end of the spectrum are those who believe not only will the new agreement stabilize Lake Powell's water levels, it will eventually top out again - and sooner rather than later.

"The seven basin states have modeled the heck out of this. With good hydrology, with a series of good water years, I think Powell will fill up again in the future," says Don Ostler

of the Upper Colorado River Commission. "But the bottom line is, this deal will allow Powell to fare better during the droughts."

And that, USU professor Schmidt says, is the central point of the proposed joint operations of the two reservoirs.

"The important thing that the public needs to understand is that the elevations of Lake Powell are only partially determined by nature and droughts," he says. "They will be determined most fundamentally by human decisions."

Park plan makes Grand Canyon river tours easier to get

USA Today

PHOENIX (AP) — More people will be able to raft the Colorado River through the Grand Canyon each year, but they will be spread out over more of the year and will travel in smaller groups, under a new management plan adopted by the National Park Service.

More rafters will be shifted to fall, winter and spring months while the number of daily summertime launches of both motorized and non-motorized commercial rafts will decrease.

The result will be more tourists overall.

The new plan also eliminates the existing waiting list for those who want to raft the river in non-commercial boats, replacing it with a lottery system.

More than 7,000 trip leaders are on the waiting list, said Jeffrey Cross, project manager for the plan. Many people have been waiting for more than a decade, he said, but the cancellation rate when their names finally reached the top was between 30% and 50%.

"Their lives often changed," Cross said. "They had babies, they moved, they changed jobs."

In the next six weeks, the 600 people who have waited the longest will be assigned dates spread over the next five years. After that, another 600 applicants will get assigned dates based primarily on how long they have waited.

But then, everyone else will be in the computerized lottery. The first drawing will be in August of this year and will take up the rest of the available 2007 dates.

Those who have already been assigned trips for the summers of 2006 and 2007 will not be affected, said Steve Sullivan, who manages the waiting list.

Additionally, the number of non-commercial trips allowed annually will double by 2007, allowing 500 trips a year, up from 240, Cross said.

The lower Colorado River, from Diamond Creek to Lake Mead, will see pontoon boat tours go up, allowing up to 480 passenger per day, up from between 130 and 188 passengers, depending on the time of year.

The plan bans jet boat tours entirely, but commercial operators that use the craft to meet rafts above Lake Mead would still be allowed.

The plan is supported by the Grand Canyon River Outfitters Association and the Grand Canyon Private Boaters Association. But the plan is being criticized by Living Rivers, a river restoration group, which feels motorized boats should have been banned entirely.

Climate change may shrink supply, hike demand in Denver

By Jerd Smith, Rocky Mountain News April 27, 2006

Denver Water could see its customers' thirst for water rise dramatically and its supplies shrink if Colorado's temperatures rise an average of 2 degrees, a scenario that is possible as climate change occurs, the agency says.

"The combination of lost supply and higher demand is a worst-case scenario worth worrying about," said Tom Gougeon, a Denver Water Board member.

Gougeon's comments came during a board briefing Wednesday on the agency's long-term water supply plans.

As part of that work, the agency analyzed the effect of various climate-change scenarios, both on its water supply and on how much water customers would need to maintain healthy landscapes in a warmer environment.

According to Denver Water's analysis, its supplies, derived largely from mountain snowmelt, could drop 12 percent or 45,000 acre feet, as customer demand rises 6 percent, or 23,000 acre feet each year.

That would be under a "moderate" climate change scenario in which temperatures rose 2 degrees.

An acre foot equals nearly 326,000 gallons, or about enough water to serve up to two urban households annually.

Denver Water, which serves about 1.2 million metro-area customers, is Colorado's largest municipal water utility.

The agency derives about half of its annual water supply from the headwaters of the Colorado River and the rest from the South Platte River.

A study by the United States Geological Survey published late last year indicates that higher temperatures could reduce the Colorado River's flows 10 percent or more and that could jeopardize Denver's share of the river.

One of the key issues the board is examining is how large a water reserve it should maintain.

The agency's system generates just over 325,000 acre feet of water annually. It maintains a reserve of 30,000 acre feet.

The reserve is designed to help the agency survive a multi-year drought or to cope with a major breakdown in its water supply system.

Now, climate change is being factored into the agency's reserve calculations.

"We don't know what's going to happen," said George Beardsley, another board member.

"But we don't have the luxury of waiting to find out."

Ruling Favors Rivers Over Power Dams

The Supreme Court says states may protect the waterways by requiring a steady flow at hydroelectric plants, which tend to harness it.

By David G. Savage, Times Staff Writer on May 16, 2006

WASHINGTON — The Supreme Court sided with the environment over electric power Monday, ruling that state regulators may require a steady flow of water over power dams to benefit fish and kayakers.

The unanimous decision holds that states may protect the health of their rivers, even though hydroelectric dams are regulated exclusively by the federal government.

The dispute arose over five small dams on the Presumpscot River in Maine, but the court's decision affects an estimated 1,500 power dams in 45 states. They include scores of dams on the Sacramento, Klamath and San Joaquin rivers in California.

Separately, the court agreed to take up an appeal from environmentalists who are seeking to enforce stricter clean-air rules against aging coal power plants. The justices said they would hear the clean-air case in the fall.

The ruling on rivers and dams resolved a clear conflict in the law. The Federal Power Act says hydro-power dams are to be regulated by federal authorities with the aim of producing electricity. But the Clean Water Act says those who "discharge" anything into a state's navigable waters must obtain a permit from the state.

Until recently, state officials believed they were entitled to protect their rivers by regulating the flow of water over and through dams.

But last year, the privately owned SD Warren Co., which produces hydroelectric power in Maine, won the Supreme Court's review of its argument that water flowing in and out of a dam is not a discharge.

Had the company prevailed, states would have lost their legal authority to protect their rivers and ensure a steady flow of water. Not surprisingly, officials of the power plants said that during dry seasons, they were more interested in holding back water so they could be assured of a steady flow over their generators to maintain power production.

In its opinion, the Supreme Court looked to the dictionary to decide the meaning of the word "discharge."

"When it applies to water, 'discharge' commonly means a 'flowing or issuing out,' " said Justice David H. Souter, citing Webster's New International Dictionary. Other judges and regulators have agreed with "our understanding of the everyday sense of term," he added.

Therefore, since water flowing over a dam is discharged back into the river, a state may regulate the operation of the dam, the court concluded in *SD Warren Co. vs. Maine*.

"This is a victory for rivers, for clean water and most of all for good common sense," said Rebecca Wodder, president of the environmental group American Rivers.

But environmentalists are anxiously watching two other Clean Water Act cases that are pending before the Supreme Court. Both from Michigan, they will determine whether federal regulators can continue to protect inland wetlands and small streams from development or pollution.

Private-property activists say the Clean Water Act protects only rivers and lakes where boats can float, not wetlands that are far inland. Decisions in those cases are due by late June.

Bush administration lawyers joined all three Clean Water Act cases on the side of the environmentalists.

The clean-air case to be heard in the fall, however, concerns a move by the Bush administration to relax a strict anti-pollution rule set by the Clinton administration.

Under that rule, aging power plants that expanded or modified their facilities were required to adopt modern anti-pollution controls in the process. This issue has drawn much attention in the states of the Northeast, including New York, which are downwind of coal-powered plants in Ohio and West Virginia.

The Duke Energy Corp. in North Carolina challenged the Clinton-era rules and won a ruling from the U.S. 4th Circuit Court of Appeals concluding that the Environmental Protection Agency had exceeded its authority in requiring such modifications.

In a separate lawsuit, several Northeastern states are challenging the Bush administration's move to relax the same rules.

Taking up the cause of clean-air advocates, lawyers for the nonprofit group Environmental Defense appealed to the high court. They argued it was the 4th Circuit Court that exceeded its authority.

The ruling will have a broad impact, environmentalists say.

"Over 160 million Americans, more than half of the country, live in communities out of compliance with the nation's health standards, and today the Supreme Court took a big step toward aiding those communities in their efforts to restore healthy air," Vickie Patton, an Environmental Defense lawyer, said on Monday.

UA tree-ring study could affect use of Colo. river water

By Eric Swedlund for Arizona Daily Star, Tucson, Arizona

A new UA study uses tree-ring data to reconstruct Colorado River flows over the past 500 years. The study could have a significant impact on water use in the West and further emphasizes the need for flexibility in managing the resources, according to scientists and policy experts who study the Colorado River basin. The study found several periods of more severe and longer-lasting drought than the region has experienced in the past century. The findings provide further indications that the data used for the 1922 Colorado River Compact overestimated the Colorado's average water flow, with water allocations to the seven Western states that share the river based on one of the wettest periods in the past 500 years.

"The long-term perspective provided by tree-ring reconstructions points to a looming conflict between water demand and supply in the upper Colorado River basin," the study said.

Updating the University of Arizona's groundbreaking 1976 study of tree rings in the Colorado basin, the new work reconstructed the river flows back four centuries before the gauge record and found eight periods of drought of equal or greater severity to the

most recent drought, roughly from 1999 to 2004, said Dave Meko, one of the study's authors.

"The other issue on the droughts is the tree-ring records show periods of dry conditions that lasted longer than the observed record," said Meko, an associate research professor of dendrochronology.

The 1922 Colorado River Compact between Arizona, California, Colorado, Nevada, New Mexico, Wyoming and Utah determined how much of the Colorado River water each state would get, dividing them between upper- and lower-basin states. The Boulder Canyon Project Act of 1928 ratified the compact and apportioned the lower basin's 7.5 million acre-foot annual share of the water. Arizona's share is 2.8 million acre feet, enough to meet the needs of 5.6 million four-person families for a year.

"For a long time, many of the states in the basin have assumed that just the historical gauge record is adequate for modeling purposes," said Brad Udall, managing director of the Western Water Assessment, which partially funded the study. "It's not adequate. We need to consider hydrological stresses on the system commonly like what we have just seen and expect those things are quite frequent."

The study, a collaboration between the University of Arizona's Laboratory of Tree-Ring Research, the National Oceanic and Atmospheric Administration, the U.S. Geological Survey and the University of Colorado, is published in this month's issue of *Water Resources Research*.

While the new reconstructions estimate the average water flow at 14.6 million acre-feet, compared to the 1976 study's estimate of 13.5 million acre-feet, the longer historical average remains below the 15.2 million acre-feet recorded by stream gauges from 1906 to 1995.

The researchers compared tree-ring widths from 1906 to 1995 with the stream flows recorded by gauges along the river as a way to calibrate the tree rings, then applied the statistical comparison to the tree rings dating back to the late 1400s.

The core samples used in the study were taken from about 1,200 trees in 60 areas throughout the Colorado River basin. The update of the 1976 study gives more precise results, filling in gaps to provide a more accurate picture overall of the Colorado region, Meko said.

The new work had 40 more years of tree-ring data to build a more accurate statistical model from comparisons to the gauge records, plus expanded tree-ring site coverage of the basin for a more reliable sample.

The study zeroed in on a drought period of about 20 years in the late 1500s, a much longer drought cycle than contained in the gauge records of last century. "There were much bigger swings in the reconstructed flows at some periods of the record than at others," Meko said. "We don't know if we're going to move into a really long-lasting dry period or if it may go back to more rapid switching back and forth between wet and dry periods."

The researchers are trying to reconstruct the water flows even further back into the past by expanding the tree-ring data to include core samples from dead trees, preserved pieces of trunks and standing snags known as remnant wood, Meko said.

The reconstruction has reached the limit of living trees, but using the evidence from remnant wood, researchers can see growth patterns about 200 years further into the past. The wood, however, is more difficult to find and will yield a spottier record.

"I think this paleo record is a good point to start to talk about stresses on the river greater than we've seen in the past," said Udall of the Western Water Assessment, a joint climate assessment venture between the University of Colorado and the National Oceanic and Atmospheric Administration.

"To date our reservoirs have been big enough to allow us to deal with these periods of time when we haven't had enough," he said. "There will come a time in the future that will not be true."

The West has to be prepared to modify its water use, shorting some things to allow more valuable uses to continue at times of drought, Udall said.

"There's a lot you can do actually," Udall said. "The true gauge of our future success in water management is how flexibly we design our water institutions." Fernando Molina, conservation program manager for Tucson Water, said he hadn't seen the study but that long-range planning is crucial to the agency.

Tucson Water uses about half its allocation from the Central Arizona Project, a 336-mile long system that brings Colorado River water to Pima, Maricopa and Pinal counties.

"On the user end, if we start look at shortages on the Colorado, if there's any cutbacks on there, we need to be prepared to deal with that," he said.

Tucson Water stresses conservation programming, Molina said, as well as looking into long-range supply alternatives including using groundwater from other areas, negotiating deals for a greater share of Colorado water and potentially using effluent as a potable supply.

LR Press Release 06/02/06

60-day notice filed to protect endangered species in Grand Canyon

Mitigation Mayhem in Grand Canyon's River Corridor
Stocking Fish Upstream, Shocking Them Downstream

For immediate release on Friday, June 2, 2006

Contact:

Living Rivers, John Weisheit: 435-259-1063

Center for Biological Diversity, Robin Silver: 602-246-4170

In an effort to resuscitate a long-deteriorating, artificial sport fishery below Glen Canyon Dam, Arizona Game and Fish is planning to stock non-native rainbow trout in the Colorado River just above its entrance into Grand Canyon National Park.

Seventy-five miles downstream from Glen Canyon Dam, the US Department of Interior has for three years been removing trout because these introduced fish prey on the larvae and young juveniles of the humpback chub, a native fish species whose numbers have dropped to potentially unrecoverable levels and is protected by the Endangered Species Act.

At a cost of \$800,000 annually, this trout removal process involves using electroshock to stun the fish, netting them by the boatload, then grinding them up for use as fertilizer.

"There are plenty of places where trout exist in their native habitat, and that are far more accessible to the average angler than below Glen Canyon Dam, that's not the case with the humpback chub," says Living Rivers Conservation Director John Weisheit. "If more aggressive action is not taken to protect them, the humpback chub will soon be the fifth of Grand Canyon's original eight native fish species to go extinct since Glen Canyon Dam's operations began in 1963."

Thirty years ago the artificial environment below Glen Canyon Dam supported one of the most famous blue-ribbon sport fisheries in the country. But with changes in dam operations the population shifted from one dominated by a thriving population of very large fish to a population of moderate-sized trout, little difference from what could be caught in thousands of streams around the country. As a result, angler interest declined considerably, especially as access to the fishery requires the use of powerboats.

With the advent of the recent drought the rainbow trout populations has been declining considerably due to rising water temperatures, lower oxygen content and lack of basic nutrients to support their food requirements. Fishing guides are reporting a 50 percent decline in business over the past five years, a further acceleration of the decline in angler activity that had already been underway since the mid 1980s.

"Putting in more fish when there's no food will merely force them to swim downstream to survive, potentially exacerbating the problems for the humpback chub," adds Weisheit. "There are so few fishing guides left anymore, and as they are the only ones who get people to the trout, why not just spread the restocking money among them as a direct subsidy, and focus on protecting the native fish that belong there."

The National Park Service, which itself once stocked trout in Grand Canyon tributary streams, has abandon this practice altogether, and has even erected weirs in an attempt to impede trout populations from spawning in these tributary streams. Additionally, more than \$200 million has been spent over the past 14 years by the Department of Interior to mitigate the impacts of Glen Canyon Dam's operations on

Grand Canyon's river ecosystem following the passage of the 1992 Grand Canyon Protection Act.

"It's unfortunate for the ecology of the Grand Canyon state that Arizona Game and Fish must prioritize efforts to prop-up a declining, artificial fishery over the preservation of endangered native fish," concludes Weisheit. "It's also unfortunate that the federal government, responsible for protecting the humpback chub, appears equally hamstrung in addressing this obvious contradiction in management objectives."

The Center for Biological Diversity and Living Rivers filed a 60-day notice today to stop this contradiction to the federal mandate of conserving the endangered fish species of Grand Canyon National Park.

Salt in the Colorado River

Are your dishes spotted? Your toilet choked? Your water heater dying a premature death?

Blame salt: City exploring ways to rid our water of destructive mineral

B. POOLE for The Tucson Citizen

We're getting more than water from the Colorado River.

We're also getting 100,000 tons of salts every year, most of it calcium carbonate - the cause of lime buildup. Like a silent plague, the salt creeps into our homes through faucets, washing machines and dishwashers and comes to rest where you have likely dealt with it.

That white film on your sink? Salt. The white spots on your clean dishes? Salt. The knocking sound in your water heater? The ring in your toilet bowl?

It's all salt, and it's costing us plenty. Salt from the Colorado River - about 9 million tons per year - causes an estimated \$300 million in damage annually in southwestern states, said Kib Jacobson, manager of a Bureau of Reclamation program aimed at keeping salt out of the river.

Most of that damage is in agriculture, but cities face their own problems. Over the past five years, Tucson Water helped fund a central Arizona salt study, because the salt content of our water is rising, said Karen La Martina, a Tucson Water management analyst.

"The things that they are beginning to explore and the things that they are experiencing now could be our future," La Martina said.

The study, due out this summer, recommends strategies Arizona cities can use to rid our water of salt. Salt assault

Maricopa, Pinal and Pima counties accumulate 1.75 million tons of salt per year from the Colorado, Salt and Verde rivers. Southern Arizona's share will rise to about 200,000 tons when the city ramps up to full use of its Central Arizona Project water allocation over the next few years, according to a draft report of the Central Arizona Salinity Study.

The Colorado River gets much of its salt when farmers irrigate crops and the water washes into the river through underground calcium deposits. The Salt River sends sodium salt - the kind in your salt shaker - to Phoenix from springs in the White Mountains, said Thomas Poulson, the Bureau of Reclamation's manager of the study.

"Originally those salts would have been carried out to the ocean," he said.

Tucson and Phoenix also import sodium through tens of thousands of water softeners, which keep calcium salt from clogging appliances but dump sodium salt into sewers. In Phoenix, 26 percent of the salts in wastewater is from home water softeners, the study found.

Sewers get another dose from household cleaners and cooling tower backwash.

Salt, which is in Tucson groundwater, though in much lower levels than Colorado River water, is a familiar nightmare for homeowners.

We spend money avoiding it with bottled water, filters and water softeners. It forces us to buy extra cleaners (which are less effective because of the hard water). Salt buildup from landscape watering can eventually poison soil. Salt cuts the life of coffee makers, dishwashers, showerheads, faucets, sinks and swamp coolers.

Water heaters are especially vulnerable because heat causes calcium to build up faster, said Kevin Cummings, owner of Cummings Plumbing, 1050 S. Park Ave.

When you turn on a water heater, the white, rock-hard calcium carbonate starts collecting on every surface in the tank. After a year, electric heating elements are usually coated, and after two or three they burn out. The buildup eventually cuts capacity, Cummings said.

"We've seen them half full," he said.

After five years, most electric water heaters here have hit retirement age, often because of reduced capacity.

"In other parts of the country they last 10 or 15 years," he said.

Gas water heaters last more than 10 years on average because they have no heating elements. In a gas heater, the calcium can't settle in the bottom, because the water there is boiling. Bouncing chunks of calcium eventually develop, creating a knocking sound that hints it's time for a new heater, Cummings said.

Calcium can also destroy the internal parts of toilets and clog jets around the inside of the bowl. If your toilet flushes slowly, poking a wire coat hanger into each jet can get it flowing properly again, he said.

Tankless water heaters and filters can help, but tankless heaters cost three times the \$500 to \$600 price of a traditional heater, and whole-house filters start at about \$2,800. In addition, tankless heaters generally require new gas or electric lines, which can add another \$500 to \$1,000. The costs outweigh the benefits for most of us, Cummings said.

"I wouldn't recommend those for the average homeowner," he said.

Cummings also doesn't recommend water softeners because of the salt they add to sewers. The answers

The most cost-effective way to deal with salt is to prevent it from getting into water, the salinity study says.

Since 1973, the Colorado River Basin Salinity Control Program, a collaboration among federal agencies, Colorado River states and farming interests, has been keeping salt out of the Colorado through improved irrigation, crop management and diversion of salty groundwater.

Though the program keeps an estimated 1 million tons of salt out of the river annually, it needs more money, the study says.

The program this year got about \$30 million through the Bureaus of Reclamation and Land Management and the Department of Agriculture. The request for next year is to add \$13 million, Jacobson said.

Blocking salt before it gets into the river costs about \$30 per ton of salt blocked. Salt removal can cost more than 20 times that. The salt-prevention program is a bargain, considering the \$112 in damage caused by each ton of salt, Jacobson said.

"This is one of many answers. Right now it's the cheapest answer," he said.

Public awareness campaigns, another suggestion in the study, can reduce salt in sewers by educating the public on water softener settings or offering rebates for high-efficiency softeners. Specifics would have to be created for each community, based on circumstances, the study says.

The study also urges cities and water providers to research reverse osmosis (see related story), or pushing water through membranes to screen out minerals. The current technology is costly and wastes about 20 percent of the water, the report says.

"The water loss is the real key for places like the Southwest, where we just don't have the source water," Poulson said.

Tucson Water recommends that the city not desalinate drinking water. Because we blend groundwater at an average of 280 parts per million dissolved solids with water from the CAP canal, which has 650 ppm dissolved solids, our drinking water will eventually stabilize between those levels without treatment.

But growth is increasing the amount of salt we dump in sewers, and salinity rises again by about half during treatment at wastewater plants. Tucson will eventually have to desalinate wastewater if we intend to turn it into drinking water, which Tucson Water recommends we do in coming decades, La Martina said.

Activists fight trout stocking at Lees Ferry

By CYNDY COLE, Sun Staff Reporter

Although rainbow trout are down by at least half at Lees Ferry, two environmental groups are planning to sue Arizona Game and Fish to prevent proposed stocking at the world-renowned fishery.

Utah's Living Rivers and the Center for Biological Diversity of Tucson have given notice they will sue on behalf of declining populations of native humpback chub and three other endangered fish under the Endangered Species Act if Game and Fish adds more rainbow trout, believed to prey on native fish downstream.

Game and Fish wants to stock tagged, mostly sterile trout for catching at Lees Ferry and to track them to see whether they make it 60 miles downriver to prey on chub and other native fish. Rainbow trout populations are about 50,000 less than normal.

Experimenting with a population of 4,500 or 5,000 chub by adding predators is too dangerous and shouldn't be considered before studies are conducted in public, Center for Biological Diversity's Robin Silver said.

Three of eight fish species native to the river have already been exterminated, U.S.G.S. studies have found.

But there may be two problems with the environmental groups' arguments.

First, chub populations might not be declining. They might have actually made a turnaround in the last three years because of warmer water or trout-removal operations, according to U.S.G.S. research.

Although the chub population was slated to decrease from a range of 3,000 to 5,000 to around 1,500 or 2,000 in the coming decade, the population is now up around 4,500 or 5,000, more recent research from the Grand Canyon Monitoring and Research Center shows.

"It looks like the humpback chub population is no longer on a straight projection down, but is stabilizing," said Matthew Andersen, biology program manager at the Grand Canyon Monitoring and Research Center.

Second, there is no direct evidence that the rainbow trout eat chub, according to U.S.G.S. and Game and Fish.

But biologists do believe rainbow trout compete with chub in other ways, such as eating their food, according to data from the Fish and Wildlife Service and other scientific papers.

It's the brown trout populating Bright Angel Creek and the Colorado River -- which Game and Fish doesn't stock -- that have certainly been found to eat chub, including some fish caught with chub in their mouths.

Experimenting with a population of 4,500 or 5,000 chub by adding predators is too dangerous and shouldn't be considered before studies are conducted in public, Center for Biological Diversity's Robin Silver said.

Game and Fish last stocked Lees Ferry in 1998. More recently, the same agency has been killing mostly rainbow trout by the thousands 60 miles downstream where the humpback chub live.

"It's a ludicrous program. On one hand you're trying to remove trout in the Grand Canyon and electrofishing them out ... and on the other hand you're adding them near the dam," said Dave Foster of Marble Canyon Outfitters at Lees Ferry.

Some anglers are concerned the trout population won't bounce back without human intervention.

"It's bad. It's really bad. People that I know from Flagstaff, they don't fish up there anymore. They know there's hardly any fish up there," said Mark Steffen, who

represents the Federation of Flyfishers/Northern Arizona Flycasters and makes fishing poles in Flagstaff.

Yet commercial fishing Web sites still sometimes boast that the fishing is legendary these days, Steffen concedes.

That's because commercial fisherman with powerful boats and deep knowledge of the river aren't having as hard a time as the private boaters, he said.

There are supposed to be 100,000 rainbow trout 2 years old or older between Lees Ferry and the Glen Canyon Dam, according to management plans for the river, Game and Fish fisheries branch chief manager Larry Riley said.

The actual population is half of that or less now, he said, and rainbows haven't been reproducing much in the past three years.

Both trends are attributed to a November 2004, flood experiment, higher-than-average water temperatures and low oxygen absorption into the water.

There's also a tiny New Zealand snail that can reproduce quickly without a mate that has made it into the river. The snail competes with the trout for food, Andersen said.

Ultimately, the trout question becomes a divisive issue on the Colorado River, Andersen said.

On one side, anglers say the industry at Lees Ferry is an economic engine for northern Arizona and one of the state's best fishing areas.

But others, including some anglers, seem to support propagating the remaining native fish that live in the Grand Canyon.

It would be possible to put trout into the river on one end and kill any that make it 60 miles downstream, Andersen said.

"At this time, in 2006, it might be possible to strike a balance," he said.

LETTER TO THE EDITOR

In regard to article "Activists fight trout stocking at Lees Ferry" by Cyndy Cole:

The reporter is correct that the population of humpback chub seems to have stabilized after a long period of decline. However, it is illogical and incorrect to assume that this means rainbow trout are not a threat, or that the abundance and distribution of humpback meet the agencies objectives for this endangered fish population.

When agencies behave more like bean counters and not as ecologists, it suggests that all they are really interested in is avoiding lawsuits over dubious compliance actions and not about the true measure of actual recovery for our endangered creatures.

The agencies are not correct that there is no evidence that rainbows eat humpback. A 1997 peer-reviewed research paper (Marsh, et al.) describes rainbow predation on humpback chub. Several studies have also documented trout predation on threatened native fish, such as speckled dace and bluehead sucker. In January 2003, the mechanical removal crew caught a rainbow with a flannelmouth sucker in its mouth. http://www.usgs.gov/newsroom/article_pf.asp?ID=200

The agencies assert that the real problem is brown trout predation on humpback chub. Although an individual brown trout is more likely to include fish in its diet than an individual rainbow trout, there are so many more rainbow trout that they exert a higher overall impact on humpback chub. Estimates suggest that prior to recent trout removal near the Little Colorado River confluence, there were about 35 times more rainbow trout than brown trout.

Perpetuating the convenient fiction that rainbows do not emigrate from Glen Canyon and prey on humpback chub is not helpful to the commons. Suggesting the stocking of rainbows at Lee's Ferry and then killing those that emigrate to the mouth of the Little Colorado River, is neither logical nor fiscally responsible. This strategy would undoubtedly cause a negative impact to humpback chub and other native fish. Under National Park Service policy, management for native and endangered species has precedence over recreation. Secondly, the cost of continuous trout removal would be astronomically high.

We strongly suggest an Environmental Impact Statement be conducted to develop and analyze the management alternatives.

John Weisheit

Below-normal flows projected for Colorado River

June 16, 2006 at 17:51:19 PDT ASSOCIATED PRESS

LAS VEGAS (AP) - Light snow falls and an early, warm spring have federal officials predicting below-normal flows into the Colorado River this year.

"We didn't get quite as much snow as we'd hoped, and it got very warm, very quickly in the upper basin, so snow melted very rapidly," said Terry Fulp of Bureau of

Reclamation, the agency that oversees management of the river. "That means we lost more water to evaporation and seeping into the ground."

Fulp presented the projections Friday at the first of three meetings in which representatives from state water agencies and power, tribal and environmental interests compile an annual Colorado River operating plan to be submitted to the Interior Department in September.

Fulp said the National Weather Service is projecting runoff from the snow melt at 72 percent of normal levels in the April to July period. Forecasts for the "water year" of October to September call for similar levels.

The numbers are down from last year, when water levels rose after five years of record drought and flows came in above normal. Officials caution one good year doesn't end a drought.

"My answer when people ask, 'Is the drought over?' is 'We still don't know,'" Fulp said. "We had a better year last year, but then again we've had a sub par year this year. We don't know where we are in the drought sequence."

Fulp said the projected levels will not likely force changes in the river's management plan because there is still enough water in storage. The system is at 59 percent of capacity, and is expected to fall to 58 percent by the end of September.

Officials predicted a slight increase in the water level at Lake Powell by the end of the water year and slight decreases for the system's other major reservoir, Lake Mead. Lake Powell is projected to be 52 percent full in September, Lake Mead is forecast at 54 percent capacity.

Parties agreed on river plan lawsuit process

<http://www.grandcanyonnews.com/main.asp?SectionID=7&SubSectionID=7&ArticleID=6170>

By Jackie Brown

Grand Canyon News Editor

Parties in a lawsuit challenging portions of the Colorado River Management Plan came to an agreement last week on how the case will proceed.

In a meeting last week, both sides agreed to conduct the case in two phases – one to determine the merits of allegations that NPS violated the law in its development of the CRMP, and a remedy phase to discuss relief if plaintiffs prevail. The civil suit was filed last March after the CRMP was finalized. In it, the plaintiffs – River Runners for

Wilderness, Rock the Earth, Wilderness Watch and Living Rivers – say that officials violated several laws when developing the plan, including the National Environmental Policy Act, National Park Service Organic Act and the National Park Service Concessions Management Improvement Act.

Defendants named in the suit are Superintendent Joe Alston, NPS Director Fran Mainella, former Secretary of the Interior Gayle Norton and the U.S. Department of the Interior. It is being heard by David G. Campbell, U.S. district court judge for the District of Arizona.

According to attorney Julia Olson, plaintiffs are challenging the CRMP on several grounds. One is that by allowing motor boat and helicopter use in a proposed wilderness area, it violates NPS policy.

"The coalition is seeking to require the National Park Service to fulfill the park's mandate that the Colorado River through Grand Canyon be managed as wilderness," Olson said.

Also, the plaintiffs charge that the Park Service did not comply with the law in how it determined appropriate amounts of commercial use and that it gives concessioners preferential treatment.

"The amounts of use allocated to commercial purposes is not necessary," Olson said. "The wait to go on a Colorado River trip is much longer if you choose to do a non-commercial trip."

They also maintain that the process of determining long-term impacts was flawed and failed to properly address impacts from human use, ongoing drought and from Glen Canyon Dam.

She said the case will likely go forward by early next year. "Things are moving forward," she said. "There won't be a decision until next spring or early summer."

The Grand Canyon River Outfitters Trade Association has requested to legally intervene on the side of the defendants in the litigation. Judge Campbell will review this request. Olson said that the Havasupai tribe was also considering joining as an intervenor on the plaintiff's side, "but their issues are slightly different than ours."

According to Park Public Affairs Officer Maureen Oltrogge, the Park Service will not comment on ongoing litigation.

Grand Canyon humpback chub population 'stabilizing,' USGS says

April Reese, Land Letter Western reporter

The Grand Canyon's long-suffering population of humpback chub appears to be stabilizing, according to new findings from federal scientists.

According to data released by the U.S. Geological Survey last week, the canyon's adult humpback chub population increased to 5,000 fish between 2001 and 2005, up from about 3,500 in 2002. Scientists also found more juvenile and newly hatched fish in 2005, suggesting that the fish are successfully reproducing, according to the report.

"The possible stabilization of adult fish numbers is exciting news for the recovery effort because it means that conditions exist in Grand Canyon that allow young fish to reach reproductive age," said Matthew Andersen, supervisory biologist with the survey's Southwest Biological Science Center.

"Before the upswing, the Grand Canyon population was steadily declining, with adult fish dying at a rate of 15 to 20 percent a year," Anderson said. Young fish were not surviving in great enough numbers to replace the dying adult fish.

Fish biologists are hoping the new findings suggest the fish, which was listed as endangered in 1967 under a precursor to the Endangered Species Act, can be recovered despite the ecological changes wrought by Glen Canyon Dam upstream.

Sam Spiller, Lower Colorado River coordinator for the Fish and Wildlife Service's Southwest region, called the findings "exciting," adding that he is hopeful the new data will attract greater attention -- and support -- to recovery efforts.

Several factors may have contributed to the population increase, according to USGS. Drought has helped warm the waters of the Colorado, which have been too cold in most parts of the river for the chub to successfully reproduce since the dam was built. In 2005, water temperatures in the Colorado River near the confluence with the Little Colorado River reached almost 61 degrees -- the warmest the river has been since the reservoir filled behind the dam in 1980.

Efforts to remove large numbers of non-native fish, such as rainbow and brown trout, which compete with the chub for food and prey on their young, may also have helped the fish. And a 2000 experiment in which dam operators released steady flows of 8,000 cubic feet per second during the summer, with two high flow releases to enhance habitat, also likely had a beneficial effect on the population, USGS concluded.

The endangered humpback chub, which once numbered in the tens of thousands and thrived throughout the Colorado River Basin, now occupies only the lower basin, primarily in a small area within Grand Canyon National Park near the confluence of the Little Colorado River and the mainstem river.

Nikolai Ramsey of Grand Canyon Trust said that while the new numbers are encouraging, the fish have a long way to go before they can be considered a healthy population.

"We're pleased to see this bump up, but they haven't stabilized," Ramsey said. "Five thousand fish is insufficient for recovery. The best available science suggests that at least 10,000 fish are needed for recovery."

FWS is completing new recovery goals for the chub, the result of a successful court challenge by the Grand Canyon Trust (Land Letter, Feb. 2). Previous recovery goals called for establishing a minimum viable population at 2,100 fish, which Ramsey called "ludicrous."

And it remains to be seen whether the population will continue to grow, particularly when -- and if -- the drought breaks, added John Weisheit, conservation director for Living Rivers.

"You would like to think it's because of our management actions, but it's because of the drought," Weisheit said. "Mother Nature helped save the fish."

Weisheit is hoping the findings will convince the Adaptive Management Working Group, the stakeholder group that helps decide how to operate the dam to meet objectives for both hydropower and park resources, to recommend a flow regime more like the 2000 experiment. A report released in 2004 by the technical arm of the group concluded that the flow plan advocated by the Bureau of Reclamation, which calls for daily fluctuations in flow, has been a "failure" (Greenwire, July 26, 2004).

Power generation tied to supplies of water

By Cyndy Cole

Arizona Daily Sun (Flagstaff); Tucson, Arizona | Published: 08.14.2006

As interstate disputes over the Colorado River and other water fights loom large in future years, power-supply problems promise to be twice the headache.

People are moving into arid Arizona and Nevada quickly enough to make them the fastest-growing states in the nation. The demand for power across the Southwest is expected to roughly double by 2025.

And that power is coming, by and large, from electricity producers across the West that rely on water.

That's 650 million gallons of water per day for power generation, said Gary Deason of Northern Arizona University's Center for Sustainable Environments. NAU, in Flagstaff, hosted a recent summit on sustainability, where the people charged with providing water and power across the nation looked toward the future, trying to solve problems they'll share.

Among them was Mike Hightower of Sandia National Laboratories, a group that studies threats to the nation's water and power supplies for Congress.

While 70 percent of the water in the West goes to irrigation for farming, electricity generation is also still largely water-related, Hightower said.

Add climate change, drought, population booms in arid areas, microclimates that keep cities such as Phoenix hot and more energy spent pumping water from deeper in aquifers, and you have a "potential train wreck," Hightower said.

Speakers at the conference focused on big-picture solutions.

Biofuels can't save the day en masse, Hightower said, because of the amount of water needed to irrigate the vast cropland that would be required.

Hydroelectric power can be a problem during drought.

Hydrogen power requires substantial water availability. And desalination of seawater requires a lot of power.

"The issues of water availability are not just a Western issue," Hightower said. "They're becoming a national issue."

The solutions, in his view, might involve placing power generation next to water-treatment facilities and giving special tax credits or other incentives to water-efficient renewable forms of energy that don't use water, such as wind power.

LR Press Release 09/01/06

Scientists reveal a higher discharge and frequency of extreme floods along the Colorado River

Utah's uranium waste pile is at risk while funding for removal stalls in Congress

For immediate release on September 1, 2006

Contact: John Weisheit 435-259-1063
Cell: 435-260-2590
Sarah Fields: 435-259-4743

In an effort to better understand the impacts from extreme floods on the infrastructure and water resources of the Colorado River corridor, Living Rivers, supported by a grant from the Citizens' Monitoring and Technical Assessment Fund, commissioned two flood studies in Utah near the town of Moab.

Two critical issues were examined:

- 1) River migration adjacent to the second largest uranium waste pile in the United States
- 2) The magnitude and frequency of large floods along the Colorado River

These investigations were performed by two professors of geology from the University of Arizona: John C. Dohrenwend and Noam Greenbaum. Victor Baker, a pioneer in the field of flood research, reviewed their findings.

The report on river migration by Dohrenwend emphasized how previously contracted investigations by the Department of Energy (DOE) failed to provide reasonable assurances that this radioactive waste pile in Utah was safe from probable maximum floods within the next 1,000 years, a reclamation standard the DOE is required to fulfill under Environmental Protection Agency regulations.

Dohrenwend also announced to the DOE that a paleoflood study would help to remove the uncertainty, and that a professional investigation would be conducted. Paleoflood studies are detailed examinations of flood sediments and organic deposits--the remnants of huge floods that once tumbled down the Colorado River before modern-day instruments began to measure stream flow. This was to be the first study of its kind for the Colorado River upstream of Arizona.

The results of the paleoflood study were completed in June 2006 by Greenbaum, who provided physical evidence to support a conclusion that floods occurring at 100- and 500-year intervals in the Colorado River Basin are not yet properly understood.

It is generally accepted by resource managers that a 100-year flood on the Colorado River has a peak discharge of about 100,000 cubic feet per second (cfs), and that a 500-year flood has a peak discharge of about 120,000 cfs. The limit of a maximum flood is considered to have a peak discharge of 300,000 cfs and occurs around intervals of 10,000 years.

Greenbaum's preliminary findings indicate that these conventional flood estimates are vastly underestimated by a factor of five times. His data shows that over the past 2000 years, at least 20 floods have matched or exceeded the 500-year estimate, and that five probable maximum floods have also occurred in the same time period. Greenbaum also discovered the possibility that two floods may have exceeded 350,000 cfs.

Says Greenbaum, "This study shows that catastrophic floods can occur with much greater frequency than originally speculated, and such floods could happen, quite frankly, sooner as opposed to later."

"Such floods are induced by springtime storms that drop warm rain on mountainous snow packs," added Victor Baker from Tucson.

The scientists recommend additional investigation be undertaken to better understand the potential for severe flooding along the Colorado River above Glen Canyon Dam.

"These preliminary results of high magnitude floods occurring at greater frequencies spotlight future vulnerabilities for the entire Colorado River watershed," says John Weisheit, conservation director of Living Rivers. "This paleoflood study provides useful information for all resource managers of the Colorado River, so that they can take action to reduce the hazards associated with catastrophic floods."

The findings of Dohrenwend and Greenbaum are contained in the recently published report by Living Rivers, *The Moab Mill Project: A technical report towards reclaiming uranium mill tailings along the Colorado River in Grand County, Utah*.

Supplemental information

Two years ago it seemed likely that the uranium waste pile (the former Atlas Corporation uranium processing facility) along the Colorado River near Moab, Utah, would remain in place with nothing to protect it from large flood events other than a veneer of clay and large rocks.

Instead, the Department of Energy (DOE), the agency designated by Congress in 2000 to reclaim the site and remediate the groundwater, issued a Record of Decision in 2005 announcing that the pile would be moved 30 miles to the north and out of harm's way.

The Colorado River supplies water for metropolitan areas such as Phoenix, Las Vegas, Los Angeles, and San Diego, as well as much of the region's agricultural industry. Other river resources at risk of radioactive contamination include the riverine ecosystems of national parks, such as Grand Canyon and Canyonlands.

On July 17, at a public meeting in Moab, it was disclosed that DOE's funding cycle for the next five-years will be insufficient to remove the pile as scheduled. Instead, DOE documents reveal that continuing site remediation and incremental preparatory work is

anticipated, until which time a committed appropriation for removal by Congress is approved.

Since taking over responsibility of the pile in October of 2001, the DOE and the project contractors have expended in excess of \$23.5 million at the end of the first quarter for year 2006. For the next five years, it is projected they will spend about \$136 million, with no financial guarantee that the next five-year cycle will mean the actual removal of the pile.

How the West Was Sold

Auctioning off government land and giving the money to communities robs the federal treasury and could waste natural resources.

July 31, 2006

NOT EVERY IOTA OF FEDERALLY owned land is an environmental treasure crying out for protection. Some portions would be better sold for private development. That's especially true within the vast Western holdings of the Bureau of Land Management.

The federal government owns about two-thirds of the land in Utah and more than 80% of Nevada, a product of Western states' history - they were federal territories before they were states. Some isolated communities, surrounded by these protected swaths of unused land, cannot respond to the pressures of growth because they have nowhere left to grow.

Selling off chunks of fenced-off land makes sense. But new proposals to auction BLM property near these towns come with a troubling twist: The money, which could easily run into the billions, wouldn't go to the Treasury to pay down the deficit or otherwise benefit U.S. taxpayers. Instead, a hefty portion would be directed to the communities to build local projects, such as water lines, roads and schools. The rest would be used for federal programs, but only near where the land was sold.

Using federal lands as a piggybank for local projects is a waste of national resources, and as a result might earmark hundreds of millions in federal funds for what won't be the most worthy or urgent public projects. Worse, it gives local communities a strong incentive to pressure the federal government to sell land that might otherwise be preserved for good reason. How about that new highway you've been wanting but haven't been able to afford? Just get the feds to sell off some nearby land and give you the proceeds.

The run on national resources for local profit started with legislation forcing the BLM to sell land around Las Vegas and give the money to Sin City and the state of Nevada. The latest target is Washington County, Utah, near Zion National Park. County officials there lust after 25,000 acres of BLM land, in part so that the popular area can expand, but also to help pay for a \$500-million water project they have in mind. They are supported by Utah congressmen from both parties.

President Bush was stymied last year when he rightly tried to direct more of the \$4 billion from the Vegas sale to the Treasury. As The Times' Julie Cart reported last month, Western legislators are now lining up with similar proposals for Idaho and New Mexico.

There's nothing wrong with the federal government helping long-pressed areas build public projects. But converting federal resources into local windfalls, at the expense of taxpayers nationwide, is a way to squander money while carving up protected land.

###

NY TIMES

True Wilderness, and False

Published: September 4, 2006

Under the radar, Congress has been quietly adding to the nation's inventory of protected wilderness. In three bills approved by both houses and signed by President Bush, the 109th Congress has awarded wilderness designation to 11,000 acres of canyonland and desert in New Mexico, 10,000 acres of rain forest in Puerto Rico and 100,000 acres in the Cedar Mountains of Utah.

Four more wilderness bills have cleared one house or the other, and when approved will add an additional 750,000 acres of wilderness in California, Idaho, Oregon and Washington. More such bills are waiting in the Congressional wings.

The Wilderness Act of 1964 prohibits all commercial activity — roads, buildings, logging, drilling — in areas designated as wilderness, the highest level of protection given to any public lands, including the national parks. Congress has designated roughly 106 million acres as permanent wilderness, more than half of it in Alaska.

Measured against this number, the latest designations may seem like small change. Yet they reflect rare moments of bipartisan cooperation at a time when Congress seems polarized on just about everything, not least conservation issues. They also reflect well on local groups that have worked long and hard to find common ground between

environmentalists and commercial interests. And while Mr. Bush seems as determined as ever to open up chunks of the public estate to commerce, especially for oil and gas drilling, like other presidents before him he finds it impossible to resist grass-roots ideas that have been so thoroughly debated in advance.

This is not to say that all wilderness bills are free of low motives and commercial intent. One particularly distasteful example is a bill introduced by Senator Robert Bennett and Representative Jim Matheson of Utah. It would sell off 40 square miles of federal land to private developers in Washington County, the fifth-fastest-growing county in the country and already something of a monument to suburban sprawl and strip development. In exchange, it offers wilderness protection to about 220,000 acres.

Wilderness bills often involve land swaps — small amounts of land for commercial purposes in exchange for lots more permanent wilderness — and the Utah deal would seem to fit the pattern. It doesn't. First, about half the proposed wilderness is already protected. Second, some of the proceeds would go not for local conservation projects but for off-road vehicle trails and, most alarming, for a 120-mile pipeline to draw water from Lake Powell, which is already stressed by undisciplined development. Third, there has been little public input. Finally, there appears to be plenty of private land available to satisfy Washington County's insatiable needs.

This is, in short, a raid on national resources aimed at helping private developers. It is the worst sort of Congressional earmarking. And it gives true wilderness bills a reputation they do not deserve.

###

SALT LAKE TRIBUNE

Bigger pants: Washington County bill is on backwards

You are honest enough with yourself to note that you are gaining weight. You can start to eat more wisely and get some exercise. Or you can buy a bigger pair of pants. The Washington County Growth and Conservation Act is a bigger pair of pants.

The bill introduced by Utah's Sen. Bob Bennett and Rep. Jim Matheson is represented as an overdue way of managing the colossal growth of St. George and the surrounding area. But, despite some reasonable provisions that set up planning and preservation activities affecting both the urbanizing areas and nearby Zion National Park, the guts of the bill are just bad news.

It is simply - no, astoundingly - unwise to begin what will be a complicated and controversial planning process by giving the Bureau of Land Management, which holds title to large swaths of southern Utah, direction to sell as much as 24,300 acres of federal land.

Some 4,300 acres of that land have already been identified, in a process that even some environmentalists accept, as land that isn't worthy of federal protection. But the other 20,000 acres is no more than a figure pulled out of the air and imagined as some

kind of a relief valve for the urbanization that is already swallowing up most of the privately owned land in and around St. George.

There's a grain of sense in that. It is entirely possible that some land now in private hands should and could be preserved, either as park land or for agricultural use, just as some federal land could become homes, shops and golf courses. The net effect could be positive for all concerned.

Or it could be seen as a final word - an act of Congress, by gum - that 24,000 acres is going to be released for development - common sense and environmental responsibility be hanged.

Unless the Vision Dixie smart-development program is allowed to work its difficult magic first, and concludes with binding guidelines, such a land rush would be the logical outcome of this bill's passage.

Bennett and Matheson are hoping the bill can be passed this year, probably as a rider on some bigger piece of legislation. Bennett certainly has the clout and the skill to insinuate it into some other act while no one is looking. He will claim that he is doing his constituents a favor.

He wouldn't be. This bill should wait.

###

BOSTON GLOBE
A ruinous land rush
August 16, 2006

NEAR THE majestic canyons of Zion National Park in southern Utah is the fifth-fastest-growing county in the United States, a monument to suburban sprawl and strip development. To help Washington County grow even faster, one of Utah's senators, Republican Robert Bennett, is sponsoring a bill that would sell off a parcel of federal land almost as large as the city of Boston to developers. Some of the proceeds would go not for conservation but to such local projects as an off-road-vehicle trail and a water pipeline.

The bill has set off alarm bells all over the West for the worrisome example it sets. Because Utah was originally a territory, the federal government owns about two-thirds of it, and the Bureau of Land Management periodically sells off properties. The money from the sale is supposed to be spent on conservation projects in the affected state. Instead, this bill encourages the wasteful use of land.

It specifically earmarks money for an off-road-vehicle trail, which would destroy fragile desert habitat, and for a portion of the cost of a \$500 million, 120-mile pipeline to draw water from Lake Powell in Arizona. Getting a straw into Lake Powell would spur further growth in Washington County, a center for resorts and retirement homes.

A spokesman for Bennett points to a similar federal land sale in Nevada as a precedent for this kind of allocation of land-sale funds. Conservationists say the Utah proposal is worse than the Nevada one because the proceeds would directly benefit local government, giving local officials a strong incentive to push for the sale of lands that would be better left under the protection of the federal government.

Critics also say there was too little opportunity in Washington County or elsewhere in Utah to debate the legislation. Officials held two open houses with poster boards and draft maps and comment sheets for the public to fill out, but many of those who attended complained they did not have the chance that a genuine public hearing would provide to discuss the bill's pros and cons with its government supporters.

The Bennett bill follows an attempt by the Bush administration to sell off national forest lands to raise money for rural schools and to sell Bureau of Land Management land to reduce the federal deficit. That proposal set off overwhelming bipartisan opposition and was dropped earlier this year. The public properly recoils when it sees its birthright put on the auction block to offset the government's profligate fiscal policies or to advance private development projects. If the Senate does not reject the Bennett bill, it invites a proliferation of proposals in the West to use land sales to finance not conservation but the despoliation of the public's land.

New Environmental Study on Grand Canyon's Native Fishes and Habitat — Impacts of Glen Canyon Dam

Center for Biological Diversity
Living Rivers/Colorado Riverkeeper
Arizona Wildlife Federation
Sierra Club – Grand Canyon Chapter
Glen Canyon Institute
Western Environmental Law Center
For Immediate Release: September 5, 2006

Contacts:

Robin Silver, Center for Biological Diversity 602-246-4170
John Weisheit, Living Rivers 435-259-1063

David Wegner, Glen Canyon Institute 970-259-2510
Sandy Bahr, Sierra Club-Grand Canyon Chapter, Phoenix 602-253-8633

Phoenix—The U.S. Bureau of Reclamation will conduct further environmental studies on the impacts of Glen Canyon Dam on endangered fish of the Colorado River according to a recent settlement agreement. The agreement specifies that the Bureau, in consultation with the U.S. Fish and Wildlife Service, will prepare a supplemental environmental impact statement by October 15, 2008.

The Center for Biological Diversity, Arizona Wildlife Federation, Living Rivers, Sierra Club – Grand Canyon Chapter, and Glen Canyon Institute filed suit in U.S. District Court in Arizona earlier this year against the Bureau of Reclamation on behalf of the Humpback Chub and the Grand Canyon. The groups charged the Bureau with violations of the Grand Canyon Protection Act, the Endangered Species Act and the National Environmental Policy Act.

In the settlement recorded by the Court on September 1, the Bureau agreed to assess the impacts of current and modified operations of Glen Canyon Dam on the Humpback Chub, Bonytail Chub, Razorback Sucker, and Colorado Pikeminnow—all native fishes to the Colorado River.

“We’re pleased that the agencies will be conducting the studies without a protracted lawsuit. Arizona’s native fish are overwhelmingly imperiled, and only four of eight native fish species continue to exist in the Grand Canyon. The Humpback Chub will fail to recover and likely go extinct if action isn’t taken to reverse the degradation posed by Glen Canyon Dam,” said Robin Silver, Board Chair of the Center for Biological Diversity.

For more than a decade the Bureau of Reclamation has been required to modify the operations of Glen Canyon Dam on the Colorado River to reverse the dam’s downstream impacts on Grand Canyon’s priceless river ecosystem. These efforts have failed to produce results.

In 1992, Congress passed the Grand Canyon Protection Act to reverse the demise of the canyon and the decline of endangered native fish species. Following the completion of an Environmental Impact Statement (EIS) three years later, the Glen Canyon Dam Adaptive Management Program was established to guide the Bureau of Reclamation in implementing recovery guidelines set forth by the U.S. Fish and Wildlife Service (USFWS).

The unsuccessful “Modified Low Fluctuating Flow Alternative” (MLFF) is the operational scheme enacted in the Adaptive Management Program which called for released flood flow events with the hope of improving habitat and restoring native fish populations.

“To date, the negative impacts of Glen Canyon Dam continue to jeopardize the Humpback Chub. Clearly the Adaptive Management program, as being implemented by the federal government, is not working,” said David Wegner, Glen Canyon Institute.

“The Grand Canyon Chapter has long worked to protect the Grand Canyon and the Colorado River, plus the species which rely on this important system,” said Sandy Bahr,

Conservation Outreach Director, Sierra Club – Grand Canyon Chapter. “We have supported efforts to remove non-native fish species and previous efforts to operate the dam in such a manner as to promote recovery of the fishes and to rebuild the beaches which are also being decimated by the operation of the dam. Clearly, the federal government needs to make some changes to protect our native fishes and to protect the recreation that relies on the Canyon’s beaches.”

In October 2005, the U.S. Geological Survey released its evaluation of this program in a 220-page report, “The State of the Colorado River Ecosystem in Grand Canyon.” This report confirmed what many scientists have been saying for years: that recovery of the humpback chub is not being achieved. According to the report, "...it is clear that the restrictions on dam operations since 1991 have not produced the hoped for restoration and maintenance of this endangered species..."

"It is past time for a new assessment on the dam's operations. At least now the issue will be reopened for public review," said Living Rivers Conservation Director John Weisheit. "The hope is that the Humpback Chub can be rescued from imminent extinction and that the ongoing destruction caused by the current operations of Glen Canyon Dam on the Grand Canyon and Colorado River will be stopped."

Matt Kenna, Western Environmental Law Center in Colorado, represents the organizations.

Droughts and reservoirs: Finding storage space underground

Press Release: Geological Society of America
Longmont, Colorado and Conference of September 19-20, 2006

"Managing Drought and Water Scarcity in Vulnerable Environments: Creating a Roadmap for Change in the United States"

Droughts and reservoirs: Finding storage space underground

Odd as it sounds, in some places the smartest way to safeguard the water supply is to let it drain out of the reservoirs and soak into the ground. That's what been discovered in local water shortages in Kansas, Oklahoma, and New Mexico – all of which could be microcosms of water shortage issues looming throughout the Western U.S.

In these three cases – Cedar Bluff Reservoir (Hays, KS), Optima Lake, (Guymon, OK), and Storrie Lake (Las Vegas, NM) – water losses from evaporation are so high that they can accelerate water supply emergencies for farms and cities, explains Tom Brikowski, a professor of hydrology at the University of Texas at Dallas. Brikowski and Wayland Anderson, a Denver engineer, are presenting their work at the Geological Society of America conference on Managing Drought and Water Scarcity in Vulnerable Environments: Creating a Roadmap for Change. The meeting takes place 18-20 September at the Radisson Hotel and Conference Center in Longmont, Colorado.

In the case of the City of Hays, the trouble starts 20 miles upstream at the Cedar Bluff Reservoir. Because of changes in farming practices, the reservoir gets only half the inflowing water it did when built in 1949. It now loses 75 percent of its inflowing water to evaporation. As a result, water losses most years now equal or exceed inflows. Reservoir releases were cut in 1979.

"You get to the point where you can't afford to lose that much water," said Brikowski, "and your only other alternative is to store it underground."

But how do you do that? In the case of Hays, nature had already provided for underground storage in the form of the Smoky Hill River aquifer. The aquifer has provided half the city's water supply for decades. Since the building of the Cedar Bluff reservoir, however, stream flow on top of it has dropped by 50 percent. That stream water recharged the wells, which, in turn, kept alive the town of Hays, Brikowski explains.

At the behest of the City of Hays, Brikowski and Anderson created a detailed three-dimensional model of the sandy, gravelly ("alluvial") ground beneath the Smokey Hill River. Anderson analyzed the water balance of the reservoir. Next they simulated what had happened to the dropping water table, how much groundwater the aquifer could store, and how long a drought it could endure.

"It's a clear case that the shut off of water (by the reservoir) limited how much water Hays could pump," said Brikowski. It also showed that by releasing water from that same reservoir they could kill two birds with one stone: recharge the aquifer and reduce the evaporation loss rate. According to Brikowski, "It was pretty hard to argue with the conclusion."

They also found that by releasing reservoir water to recharge the Smoky Hill River aquifer, users could survive even the worst recorded drought with full production from municipal wells.

"I think the City as a whole was quite happy," said Brikowski. By getting a better understanding of their water, the city can now avert seasonal water emergencies and no longer have to consider building hundreds of miles of pipeline to get water from other river basins.

This story could replay in other places as well – especially where reservoirs are getting less inflow due to changing water uses or climate change.

There's the city of Las Vegas, NM, only months away from evacuations this year after lack of snow over the winter left streams dry. It was only the annual monsoon season that saved them this year, said Brikowski. The water crisis is becoming an almost annual event as winter snow packs shrink and melt sooner each spring, probably as a consequence of global warming.

"More efficient storage, perhaps in alluvial aquifers, represents the only real hope for a solution," Brikowski said.

The same may eventually be the case for most of California, which relies heavily on the melting of snow pack high in the Sierra Nevada to feed streams and rivers through the summer. Global warming is expected to raise the snowline on those mountains and has already pushed spring earlier in the year. This means there is generally less snowmelt and it may not last the whole summer.

The Optima Reservoir of the Oklahoma Panhandle is an extreme example. A dry lake, it loses 100 percent of its inflowing water to evaporation. Converting to subsurface storage may be the only way to store water.

"It's not that in any of these places they've done anything wrong," Brikowski said. Rather, situations change and water management has to keep up to avoid supply problems. Underground storage, he said, is something to add to the water management toolbox.

Regional News 09/20/06

Scientists have grim drought forecast for West

Expert says some could be worse than Dust Bowl

By Jim Erickson, Rocky Mountain News on September 20, 2006

LONGMONT - Future Western droughts could last an average of 12 years, spanning half of the region and severely reducing Colorado River flows that supply millions of people, according to climate projections from a Boulder scientist.

Eighteen of the world's most powerful computer climate models were used in the study, presented Tuesday by Martin Hoerling, of the National Oceanic and Atmospheric Administration.

Hoerling said he was startled by his own findings. But he cautioned that his results are preliminary and have not been published in a peer-reviewed scientific journal.

"The numbers are pretty striking," he said Tuesday at a drought conference sponsored by the Geological Society of America. "Climate change is moving us in the direction of a perpetual state that is of the Dust Bowl type."

The models forecast a temperature increase of 5.4 degrees Fahrenheit by 2060 in the interior West, largely because of the buildup of heat-trapping gases emitted by fossil-fuel combustion.

But little or no precipitation increase is foreseen in the West. The result: Increased evaporation and drier soils, leading to more severe and frequent droughts, Hoerling said.

How severe? Some droughts could be 25 percent worse than the 1930s Dust Bowl, Hoerling said.

How frequent? On average, half of the interior West will suffer from severe drought each year, he said.

But several other scientists said that Hoerling's projections should be taken with several grains of salt, even though previous studies have concluded that more frequent and severe droughts are likely in a warming West.

"Past studies have shown smaller changes, not on the order of what Marty is showing," said Brad Udall, director of the Western Water Assessment at the University of Colorado.

"The (climate) models have a lot of problems," Udall said. "They get a lot of things right, and they're really good at the global level. But they're not so good when you try to step them down into the regional level."

Hoerling found that the Upper Colorado River Basin is likely to take the hardest hit from an increase in drought severity and frequency.

Currently, 13.5 million acre feet of Colorado River water are consumed each year. About 9 million acre feet are used by the Lower Colorado River Basin states: Arizona, California and Nevada. About 4.5 million acre feet go to the upper basin states: Colorado, Utah, Wyoming and New Mexico.

The dividing line between the two basins is at Lees Ferry, near the Utah-Arizona border, just below Lake Powell.

Hoerling's computer simulations show that the flow at Lees Ferry could drop to 6 million acre feet by 2050, creating huge problems for water managers trying to meet obligations to the Lower Colorado River Basin.

"The decrease in runoff at Lees Ferry is pretty dramatic," said Connie Woodhouse, NOAA paleoclimatologist. "If he's right, we're going to have to rethink how we use water in this area."

But Woodhouse cautioned that other studies of future Colorado River runoff are in the works, and that preliminary results from one of them show "not as sharp a decrease" in runoff as Hoerling found.

Denver Museum of Nature & Science geologist Bob Reynolds echoed Udall's concerns about the uncertainties of climate models. But he said he was alarmed by Hoerling's findings.

"It's something to be concerned about, but it's not something to be scared of," he said. "We're going to have to adapt our survival strategies to coping with less water."

Last year in the journal *Nature*, a team led by U.S. Geological Survey hydrologist Christopher Milly used 12 state-of-the-art climate models to study global-warming associated reductions in river runoff worldwide.

Milly and his colleagues found that by 2050, drier conditions could lead to a 10 to 20 percent drop in runoff from rivers in the U.S. West.

Milly said Tuesday that his results appear to jibe with Hoerling's findings.

"I think those drought numbers that he's giving you are probably realistic numbers," Milly said in a telephone interview. "What he's saying does not seem far-fetched."

NOAA researcher Jon Eischeid collaborated with Hoerling on the study.

Drought becoming norm, experts say

Sept. 30, 2006 12:00 AM

By Shaun McKinnon for THE ARIZONA REPUBLIC

Everything you think you know about water in the West is about to change.

Scratch that. It's changing now.

The drought that's squeezing Arizona and the Colorado River? It could be the new normal. The warming temperatures that seem to start earlier and linger later? A shift in climate that already has stolen runoff in some parts of the Northwest. advertisement

Scientists met in Colorado last week for a conference on drought and water scarcity and there was no missing the theme of change in their messages, swathed as they were at times in dense, geologic research papers.

" . . . the natural snow pack reservoir is getting smaller and smaller," said Richard Palmer, who teaches water resource management at the University of Washington.

"In the winter of 2005, we had the smallest snow pack on record. That's a real wake-up call for us that something is changing."

An Australian scientist urged Americans to treat drought as constant rather than an emergency: In her country, "drought is no longer considered a disaster," said Linda Botterill, who teaches at the Australian National University in Canberra. "We have one of the most variable climates on earth. We really don't have a 'normal' climate. Therefore it's absurd to treat every drought as an emergency."

Changing ideas about climate and rain and water are nothing new in the arid West. It hasn't been that long ago - the middle of the 19th century - that respected leaders subscribed to a theory called "rain follows the plow." The theory gained prominence as homesteaders began moving into the Great Plains and the edge of the West and found that they couldn't rely on rain to water their crops.

Leaders of the time, fearful of the economic effects of a stalled expansion, convinced farmers that if they would only plow their fields and plant crops, the rain would follow. They found scientists who swore that plowing field would release moisture into the air and create rain; some even suggested the vibrations from all the building and digging and tromping around would drum up storms.

The whole scheme is widely blamed for early dry farming failures.

As late as the early 1900s, leaders of the seven Colorado River states apportioned water based on what turned out to be some of the wettest years in centuries. The river is now overallocated.

Botterill and others say we should consider drought the baseline condition here and the wet years part of the dramatic variability in climate.

"Drought is always out there," said Donald Wilhite of the National Drought Mitigation Center in Lincoln, Neb. "It's always affecting some part of the country." Reacting to droughts is far more expensive than planning for them, he said. Climate change and growth will only worsen our plight if we don't shift our thinking.

In other words, the drought we're surviving now in Arizona might flatten us in 30 or 40 years, when climate change has cut into runoff and our population has doubled again.

Evidence is accumulating that warming temperatures will affect mountain snows in the West, reducing runoff into reservoirs. Several studies suggest the Colorado River could shrink by 30 percent or more over the next half-century.

Warmer conditions eat away on several fronts: Less snow falls, resulting in less runoff. Rain falls at the wrong times of year, when reservoirs can't contain it. Warmer temperatures increase demand for water sooner in the season, tightening the supply further.

In studies of the Seattle and Portland areas, the UW's Palmer estimated that the amount of water available in the high-demand months will decrease 6 percent a year, 24 percent by 2040. Some of the water that arrives as rain in the winter will seep into the aquifers for pumping later, but it changes the equation in an area so reliant on runoff.

Efforts may help get more water from Colo. River

Shaun McKinnon for The Arizona Republic

The Colorado River will undergo a series of experiments in the coming year aimed at squeezing from it even more water to meet the growing demands of Arizona and six other Western states.

Among the experiments, most of them intended to reduce wasted water: a three-month test of the Yuma desalination plant, expansion of a pilot program that pays farmers not to plant crops and construction of a small reservoir near the river's end to catch unused water before it reaches Mexico.

The U.S. Bureau of Reclamation, which oversees the lower Colorado, outlined the programs in the river's annual operating plan, a document that includes water-supply estimates along with management strategies. A draft version was presented to representatives from the seven river states last week. It takes effect Sunday.

The experiments won't free up much water right away, nor will they end disputes among the seven states about how to deal with drought. But officials believe the ideas could

help avoid future water shortages and help the states find ways to better manage the overworked river.

For Arizona, which relies on the Colorado for more than one-third of its water supply, any saved water could help protect it from losses if a river shortage is declared. Under the river's governing laws, Arizona must give up as much as half of its allocation before any other state is affected, part of a deal struck to win approval of the Central Arizona Project canal.

Key proposals in the plan:

- Restart the Yuma Desalting Plant. The bureau would run the mothballed plant at 10 percent capacity for about 90 days, then evaluate it as a way to cut losses from agricultural runoff. The test also would examine ways to lessen environmental damage from the plant's operation.
- Build a reservoir. The bureau will work with several water agencies to start construction next year on a small reservoir about 25 miles west of Yuma in California along the All American Canal. The reservoir could prevent the loss of as much as 26 billion gallons of water a year.
- Pay farmers not to farm. The bureau will contribute money to a program started by a California water agency that pays farmers near Blythe, Calif., to leave land fallow. The unused irrigation water remains stored in Lake Mead, available for later use.

"Some of these things will be a big part of the future," said Larry Dozier, deputy general manager of the CAP, which delivers Colorado River water to Phoenix and Tucson.

"What we're seeing this year are just start-up programs, but if you don't start, you won't finish."

The proposals, whose total costs have not yet been released, are mostly aimed at more efficiently operating the river from Lake Mead to the Mexican border. A study several years ago found that the United States was losing 500,000 acre-feet or more in some years to waste and flawed delivery procedures. The water flowed into Mexico, which used it without counting it against its share of the river.

An acre-foot is 325,851 gallons, enough to serve a family of five for a year.

Changes to the system have reduced the losses in recent years, but as much as 100,000 acre-feet still flows into Mexico annually. That translates into a 1-foot drop in water levels at Lake Mead, the giant reservoir that stores water for Arizona, Nevada and California. Lake Mead's level is important because it is used to determine whether there is a shortage on the river.

Desalination restart

Arizona views restarting the Yuma desalter as a critical step in averting shortages. The desalter was built in the early 1990s to remove salt from agricultural runoff as it enters

Mexico, but it was operated for only a few months before it was shut down, in part because high flows on the river diluted the salt content naturally.

Restarting it, even just to run tests, marks an important step for Arizona, Dozier said. The test run will fit into plans developed more than a year ago to operate the desalter without damaging the Cienega de Santa Clara, a wetland south of Yuma that survives on farm runoff from Arizona.

"It's not very much, a minimal amount of water, but it's significant in that it will let us test the system," he said. The CAP has agreed to help fund an \$80,000 water-monitoring program during the test run to see how the wetland is affected.

Running the desalter full time would cost tens of millions of dollars, but the bureau agreed to run the test as part of a broader water-savings plan.

"We do think there are some benefits to do a test, to better understand how it might work," said Jayne Harkins, deputy director of the bureau's Lower Colorado Region. "We haven't run it in a long time, so the test will let us study what it's going to take to replace that water that's lost."

New reservoir savings

Another significant source of lost water has been the changing needs and conditions among the hundreds of farmers who take water from the river.

When a farmer or irrigation district orders water, it is released from Lake Mead and takes several days to reach diversion points downstream. In the meantime, rainy weather might mean the farmer doesn't need the water after all, but because it has already been released, it flows into Mexico.

To solve that problem, the bureau will back a plan to build a small reservoir west of Yuma along the All American Canal, which moves water from the river to the Imperial and Coachella valleys of California. The reservoir will hold only about 8,000 acre-feet of water - by contrast, Lake Mead can store 28 million acre-feet - but the water won't stay more than a few days. It will be put back in the system when it's needed.

The reservoir, scheduled for completion in 2009, would benefit all the states on the river, said Tom Carr, assistant director of the Arizona Department of Water Resources. The water saved will stay in Lake Mead, raising overall storage.

Under a plan endorsed by the states, Nevada offered to pay for construction of the reservoir, Carr said. If that happens, Nevada will earn access to extra shares of the saved water.

Farming for water

Arizona won't participate in the farm-fallowing programs in the coming year, Carr said. The Metropolitan Water District of Southern California, which serves Los Angeles and surrounding cities, will continue paying farmers near Blythe to leave some ground unplanted. The water saved will remain in Lake Mead.

As part of next year's pilot program, the bureau will contribute money to the program and will seek other water users for future following projects. Water stored in federally funded programs will be used on behalf of all users.

The seven basin states also are working with an independent consultant to find other ways of conserving water or adding it to the river. The Southern Nevada Water Authority paid for the \$750,000 study, which is expected to yield a list of ideas soon.

Arizona, California and Nevada will contribute money this winter to boost cloud seeding along the upper Colorado.

The states also are working on a long-term drought plan. Their first set of ideas is under review by the Interior Department, which will issue a draft proposal at the end of the year and choose a plan in 2007. The plan is expected to change the way Lake Mead and Lake Powell, on the Arizona-Utah line, operate and will spell out more specifically how water shortages will affect the river's 25 million users.

LR Press Release 10/13/06

CRSP 50th anniversary: no cause for celebration

For Immediate Release:

Contact: John Weisheit 435-259-1063

Cell: 435-260-2590

On the occasion of the the 50th anniversary of the Colorado River Storage Project Act (CRSP) next Thursday, the Bureau of Reclamation will host a private celebration at Glen Canyon Dam.

Wrought with technical, economic and environmental controversy from the start, the massive reservoirs authorized by the CRSP have now entered a new era of conflict as increased water demand and climate change induced flow reductions have reinforced 50-year old arguments that these projects are not sustainable.

The scheme's cornerstone and nation's second largest reservoir, Lake Powell behind Glen Canyon Dam, now sits at less than 50 percent full. The Department of Energy forecasts that it and its companion projects upstream will soon not be able to guarantee delivery of the full allocation of water to the states of California, Arizona and Nevada.

"Instead of a celebrating, the Bureau of Reclamation should be performing a wake for the pending funerals of the communities that will run out of water once these reservoirs bottom out and the rivers run dry," said John Weisheit of Living Rivers. "Its time to develop a new project, the Colorado River Survival Project."

Climate specialists warned Reclamation ten years ago (the aftermath of the 1989-92 drought) of the consequences that climate change would have on the supply of the Colorado River, but the message went unheeded. In 2000, as the worst drought to hit

the system began to take hold, they were instead putting the finish touches on a management plan now known as "Surplus Criteria."

It was not until 2002 that Reclamation began to publicly recognize the potential for scarcity, but instead of developing a solid plan to prudently conserve, it's "2025 Plan" focused more on public relations and plans for water desalinization. Not until last year did it take it's first baby steps to actually address reduced water flows though the implementation of what they call "Shortage Criteria."

"But these plans may, at best, only ensure supplies through a small drought. They cannot guarantee survival through the severe and prolonged droughts that all of us are about to face," adds Weisheit, "We are not talking about the daily weather forecast here. This is a situation about a changing climate of warmer temperatures that is going to hang around for a very long time."

The climate professionals have been successfully modeling Colorado River flow based on the warming trends of the atmosphere and the oceans. Their peer-reviewed reports say the consequences of global warming include a lengthening of the growing season, increasing surface water evaporation, drier soils, and, most importantly, it will rain more than it will snow--the snow that reservoirs need to refill when it melts each spring.

"The CRSP is a water project that was never needed. It is apparent that all it does right now is waste water and money, degrade the water quality, and destroy the national park values of Grand Canyon. The first step to survive the water scarcity situation we now face is to decommission the dam that was never needed in the first place--Glen Canyon Dam," concludes Weisheit.

Glen Canyon still a lightning rod

By Nancy Perkins for Deseret Morning News

Fifty years after the first explosive blast signaled the beginning of construction on Glen Canyon Dam and its mission to store and manage millions of gallons of water from the Colorado River, critics of the massive federal project are calling for its demise while other experts say it's vital to the West's water-storage system.

"Glen Canyon Dam is a boondoggle," said Richard Ingebretsen, president of the Glen Canyon Institute in Salt Lake City. "It has wreaked havoc on the ecosystem of a beautiful river. Of all the dams that are useless, this place, Glen Canyon Dam, is the worst."

On Thursday, the Bureau of Reclamation will host a 50th anniversary celebration of the Colorado River Storage Act of 1956 at Glen Canyon Dam. The act also authorized the construction of Flaming Gorge Dam. Mark Limbaugh, assistant secretary of water and science for the Department of the Interior, is scheduled to speak at the invitation-only event.

Dennis Strong, director of the Utah Department of Water Resources, said Glen Canyon Dam is fulfilling its purpose, not only as a critical piece of the West's vast water storage program but in its role as a hydroelectric power plant producing electricity for nearly 6 million customers.

"There will always be a conflict between those who think we should let water run down the river and those who think we should manage it as a resource," Strong said. "Glen Canyon Dam and Lake Powell have functioned exactly as they were designed to do. They have allowed the upper Colorado basin states to deliver water to the lower basin states and fulfill their contract."

In 1956, Congress passed the Colorado River Storage Project Act, or CRSP, which authorized the initial construction of four large dams and reservoirs, including Glen Canyon Dam and Flaming Gorge Dam on the Green River tributary, to help tame and store 34-million acre-feet of water from the turbulent Colorado River.

Seven states — Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming — and Mexico all claim various complicated legal water rights in the Colorado River.

At the time of its passage, the act generated controversy because of its massive scope. Environmentalists argued the giant reservoirs would waste water through evaporation and seepage, and that the salt content in the water would rise. Sediment that normally flowed unimpeded down the Colorado River, they argued, would eventually clog the system and ruin the comprehensive system of dams, reservoirs, spillways and other measures taken along the length of the river.

"Now that 50 years have passed since the arguments were first made, the warnings have turned into fulfilling prophecies," said John Weisheit, conservation director of Living Rivers in Moab. "Instead of celebrating, the Bureau of Reclamation should be performing a wake for the pending funerals of communities that will run out of water once these reservoirs bottom out and the rivers run dry. It's time to develop a new project, the Colorado River Survival Project."

Don Ostler, executive director of the Upper Colorado River Commission in Salt Lake City, takes exception, saying CRSP projects such as Lake Powell have proven their worth.

"The construction of Glen Canyon Dam and other CRSP projects by the Bureau of Reclamation have been a lifesaver already for the people who use this water because of the recent drought," said Ostler. "I say we're not finished with the drought, either, with six out of the last seven years of precipitation below normal."

Even though both Lake Powell and Lake Mead, located further downstream near Las Vegas, are currently less than 50 percent full, the two reservoirs are meeting their obligations, he noted.

"If we didn't have Lake Powell, Lake Mead would have been empty by now," Ostler said. "We could not have supported the needs of the people without these two reservoirs. They are critically important and will become much more important in the future."

Lake Powell first reached capacity in 1980 and has had its ups and downs since then, although it was considered to be at its full capacity in 1999. Several states, including Utah, have initiated conservation measures aimed at curbing water use at every level.

"I'm darn proud of what Utah has done in reacting to a campaign of wise water use," Strong said. "I know we've been aided by the drought; that's certainly speeded up conservation. Six years later, we have a 13 percent reduction statewide in water use, and that's pretty amazing."

The challenge for water managers, Strong said, is to learn how to improve on the systems that are now in place.

"Society's needs change and as we learn more, we need to make adjustments," he said, adding one of the biggest challenges could be changing the attitude most people have when it comes to water conservation.

"As I look out my window here in Salt Lake City I can see green trees around the Capitol and barren mountains in the distance," he said. "We have an ethic in this state of being green. Conservation is going to have to play a larger role."

Add to that the alarm sounded by scientists around the world that global warming is shifting the Earth's climate, and the astounding population surge in cities throughout the west and "water wars" are bound to occur, Ingebretsen said.

"When are we going to stop building these megacities in the Mohave Desert?" he asked. "The Colorado Plateau is an extremely fragile ecosystem and my big plea to developers and the Bureau of Reclamation is to consider the animals, plants, reptiles and other creatures that live here. Somehow we've got to teach people that we cannot grow at the expense of other species."

Basin river projects saluted

Dignitaries gather to mark 50th anniversary of the Colorado River Storage Project Act

By Mark Havnes for The Salt Lake Tribune

Article Last Updated:10/20/2006 01:13:05 AM MDT

GLEN CANYON DAM - Gazing into Glen Canyon back in 1858, Army Lt. Joseph Ives predicted the river-sliced gorge and surrounding red-rock desert would be a "profitless locality . . . forever undisturbed and unvisited."

Wrong.

Instead, Glen Canyon Dam and its sister dams along the Upper Colorado River Basin have pumped nearly \$4 billion into the economy. They quench the water needs of 25 million people and generate 4.1 billion kilowatt hours of electricity annually. And visitors? Try more than 2 million a year at Lake Powell alone.

On Thursday, dignitaries gathered at Glen Canyon Dam - 710 feet above the Colorado River just south of the Utah line in northern Arizona - to mark the 50th anniversary of the Colorado River Storage Project Act, which gave birth to the dam and three others.

"It was an engineering marvel," Utah Lt. Gov. Gary Herbert told the crowd amid heavy security. "From a Utah perspective, we are an arid state, averaging 13 inches of rain a year. We know the challenge from our pioneer heritage that dictated they make the desert bloom like a rose. Their vision literally made it blossom."

Herbert urged current stewards to show the "same kind of vision" to ensure that today's quality of life continues tomorrow.

Not everyone is celebrating. The dams swallowed up scenic wonders and ignited an environmental uproar that echoes to this day.

John Weisheit, conservation director of Moab-based Living Rivers, said officials are miscalculating the true nature of the 1922 Colorado River Compact - which allowed for the storage and distribution in seven Western states of water in the Colorado River Basin - by elevating hydropower production above the original intention of providing clean, healthy water for people and the environment.

"It [hydropower] became the funding mechanism for the dams," Weisheit said from Moab.

He maintains that instead of farmers paying for the dams, as originally planned, the government changed the law so it could go into the power business. Now, rather than paying back the U.S. Treasury, the money is being tapped to mitigate problems caused by the dams.

"It's not about water anymore, it's about keeping it ticking," Weisheit said. "They've stretched water supplies to the limit. It [the water] is too salty and is being wasted in reservoirs because of evaporation.

"They should rename the Colorado River Storage [Project] Act the Colorado River Survival Project."

The four dams - Flaming Gorge on the Green River in eastern Utah, Glen Canyon on the Colorado River in northern Arizona, Navajo Dam on the San Juan River in New Mexico and the Wayne N. Aspinall Dam on the Gunnison River in west-central Colorado - together store 30.6 million acre-feet of water and help irrigate 2 million acres of farmland.

"It's hard to think these days they knew when they put the Colorado River Compact together, the impact they would have on the economic development in the upper states," said Mark Limbaugh, assistant secretary of the interior.

Rick Gold, regional director of the Upper Colorado Basin, told the crowd the dams allow for long-term storage so allocations can be met for compact states.

"The system is a gift to us all in this part of the world."

mhavnes@sltrib.com --- * JOE BAIRD contributed to this story * Paved the way for the construction of four dams on the Upper Colorado River Basin, Glen Canyon Dam being the largest. * Cost \$760 million, with \$145 million going toward construction of Glen Canyon Dam. * Provides an average of 30.6 million acre-feet of water. * Irrigates 2 million acres of farmland. * Meets water needs of 25 million people. * Generates 4.1 billion kilowatt hours of electricity a year.

The 1956 Colorado River Storage Project Act Source: U.S. Bureau of Reclamation

As Utah and Nevada fight over water, some worry the West will turn into a new dustbowl

By Ted McDonough for Salt Lake City Weekly

To get to Snake Valley in Utah's west desert, find a road less traveled and drive west. Then keep on driving. Past the last paved road, past swirling cyclones of dust, past the once vast Sevier Lake drained dry by farms of the earliest settlers and now usually marked by 200 square miles of white salt.

Keep driving past the point where dust coats your teeth and eyes, past any sign of human habitation to the very west end of the state. There, smack on the border with Nevada and seemingly rising out of nowhere, you'll find some of the highest peaks in Utah—the Deep Creek Mountains—and the Snake Valley stretched out below.

The Deep Creeks are 12,000-foot-high collectors of water, and home to seven creeks that flow year round, giving the mountains their name. Isolated since the Pony Express stopped passing through in the 1860s, the Snake Valley is thought by some to be one of few places left to search for the liquid gold needed to satisfy the thirst of the West's growing population. It's also here that Las Vegas is digging for water.

It's on the Nevada side of the mountains that Las Vegas is planning hundreds of wells and a 285-mile-long pipeline that will move the Deep Creeks' water to Las Vegas. A total of 200,000 acre-feet of water—that's 65 billion gallons—would be shipped from rural Nevada to Las Vegas each year under the plan. Nine of the wells are planned just five miles from the Utah border in a valley straddling the Utah-Nevada line. Las Vegas' water officials have targeted the Snake Valley to produce up to 50,000 acre-feet of water per year, pumping water into Nevada that would otherwise flow into Utah's Great Basin. Not all of those 50,000 acre-feet would have flowed into Utah. Nevertheless, those who populate one of the sparsest corners of Utah warn that such a massive transfer of water will cause irreparable environmental damage.

The vast valley floor appears deserted, but if you know where to look, you can find a handful of ranchers determined not to let Vegas have its way. They are few, but a tough bunch.

George Douglass moved his family to the base of a Deep Creek canyon on the Utah side 30 years ago. At the time, he thought civilization was about collapse and wanted to live where he could concentrate on becoming self-sufficient.

"It hasn't collapsed yet, so I'm really disappointed," Douglass says with a chuckle. "I'll tell you what, my two daughters never let me live that down." Douglass' wife Ronnie thinks Vegas will be disappointed if it goes looking for water in this part of the desert. After seven years of drought, the family no longer grows crops. George must travel to make a living. Ironically, he's currently working in Cedar City, drilling wells for that fast-growing town.

Ronnie spends her days petitioning Utah's congressman and state water officials.

She said she fears removing any water from the valley will ruin the already tenuous existence of Snake Valley's ranchers and the unique animals and plants that call the area home. The Douglass ranch is home to wild Mustang, pronghorn antelope and the Bonneville cutthroat trout, a species that was near extinction until the Douglasses created a fish hatchery on their ranch preserving the native fish.

The small trickle of water that flows on their property feeds not alfalfa but a series of small fish breeding ponds that are primarily responsible for repopulating east slope Deep Creek streams with Utah's state fish thought extinct just 40 years ago.

Like George Douglass, many of the ranchers of Utah's west desert would prefer to be left alone. But trouble keeps invading their solitude. In the late 1970s, they fought plans to put the MX Missile on their valley floor.

Their new fight may be as difficult. It pits them against Las Vegas developers and against Harry Reid, Nevada's powerful U.S. senator. Reid has close ties to Sin City developers but also strong pull with Utah's politicians. They will need the Senate minority leader's help if the Beehive State's own plans for massive water projects are to become reality. It's Sen. Reid who holds many of the cards, by way of his various committee memberships at the federal level, to water that would enrich Utah's St. George area, and some worry Utah can't afford to anger him by opposing the Las Vegas pipeline.

The Las Vegas pipeline is just one of a series of massive Western water projects planned on a scale not seen since Lake Powell and Lake Mead were created to tame the Colorado River. Utah's plans include a pipeline to bring Lake Powell water to St. George, the nation's fastest-growing metropolitan area. A second project on Utah's books would take water from the Bear River to feed the growing thirst of the Wasatch Front, portions of which are projected by state water officials to run short of water at mid-century. Private speculators are even getting in on the act. One Colorado investor, Aaron Million, has proposed a pipeline from the Flaming Gorge reservoir to Denver.

With the Colorado River no longer able to keep up with water demands of Western states, everyone is getting desperate. Some proposed solutions sound like science fiction. Las Vegas has funded studies to determine if the Pacific Ocean could be made drinkable by removing its salt. Then, the thinking goes, California wouldn't need its share of Colorado River water, which could instead be sent to Nevada. But any such massive ocean desalinization programs are decades into the future.

And as Western states gear up for huge water projects, scientists warn increasingly that they are digging for fool's gold. The water, some say, simply isn't there. And squeezing the last drops out of the turnip could cause unprecedented environmental disasters, from the dust bowl Douglass fears to the environmental devastation of one of the Western Hemisphere's most important breeding grounds for migrating birds—the Great Salt Lake.

Environmentalists warn the West is undergoing a massive conversion of public land to private homes too rapidly to foresee the consequences. This summer, 80 environmental organizations called for a moratorium on Western land privatization laws moving through Congress.

Janine Blaeloch, with the Seattle-based Western Lands Project, heads the opposition, noting that both the Nevada and Utah pipeline proposals have been helped along by federal legislation she criticizes as giveaways of public land to private development.

Utah Sen. Bob Bennett and Rep. Scott Matheson are sponsoring a law that would sell off 24,000 acres of land for private development around St. George while setting aside rights of way for water from the Lake Powell pipeline. Similarly, a Nevada land privatization bill sponsored by Sen. Reid gave free rights of way over federal land for the pipes to bring Snake Valley water to Las Vegas. Sen. Reid's connections to the pipeline are personal. The project was redesigned in January so water could be shipped not just to Las Vegas, but also to a vast dry area one-hour northeast of the city known as Coyote Springs. There, casino lobbyist Harvey Whittemore—a heavy donor to Reid's campaigns who also employs one of Reid's sons as his personal lawyer—is planning a development described as one of the largest since the founding of Vegas itself: 159,000 homes and 16 golf courses on 43,000 acres of what's now bone-dry ground.

A second Reid son sits on the board of the Southern Nevada Water Authority, the Las Vegas water supplier proposing the pipeline project. Proponents of the federal land-trading bills deny it, but Blaeloch predicts much of the cash raised by selling off public lands will end up funding the massive water projects.

"Growth is putting so much pressure on public lands, there really is a huge impetus to privatize more land to make way for retirement communities, second homes and the normal population," she said. "And this incredible growth is in the West, where you have a huge amount of pressure on water supplies and not a whole lot of forethought on whether the water is going to be there to supply the development that is occurring." Blaeloch lumps proposed development of St. George and Las Vegas into the same basket as "unsustainable." Which means, quite simply, that if huge amounts of water must be shipped to develop land, maybe it shouldn't be developed at all.

"If you have to build 450 miles of pipeline to bring water to your community, there's a problem there."

Snake Valley rancher Cecil Garland puts it another way. "We ain't got water for Las Vegas," he says.

The 79-year-old Garland was one of the leaders in the campaign against the MX. Now he's determined to fight the Las Vegas pipeline. He lives in what was once the post office of the tiny Utah town of Callao, settled as a stop in the Pony Express route. His wife is the town schoolteacher.

Garland moved to Callao 30 years ago following a stint in Las Vegas where he claims to have dealt cards to Bugsy Siegel, the mobster often credited with the idea of a building

a wide-open city in Nevada's desert. Seventy percent of the Snake Valley is located in Utah, Garland notes, and Utah ranchers have historically used most of the area's water.

"If they build the pipeline, they'll get the water," said Garland. "They've got enough money to buy the ranches, the farms, everything else."

Where springs once bubbled from the surface of his ranch, today there are dry scars, the result, Garland says, of pumping by him and his neighbors during times of drought. Some climate scientists say the drought conditions Garland complains of might now be a permanent feature of the West.

Marty Hoerling, meteorologist with the National Oceanic and Atmospheric Administration's Earth System Research Laboratory in Boulder, Colo., recently examined temperature data collected by the world's climate scientists for a new assessment of climate change due out next year. His analysis focusing on Utah and Colorado, predicts a 5-degree rise in temperatures by 2050, perhaps as early as 2020. That means less snow pack, the area's primary means of storing water, and more evaporation. For the Colorado River, Hoerling predicts the change will mean a decrease in annual river flow to 10 million acre-feet, barely enough to meet current demand of California, Arizona and Nevada.

Years of drought have already robbed the Colorado River of much of its water. When the river was divided between Western states, it was thought to have a yearly flow of more than 16 million acre-feet. The flow in the last decade has measured about 13 million acre-feet. That level just matches current demand, Hoerling noted. "If flow is to decline because of climate change, it will move below current demand, let alone any growth in demand for water that some states have in mind," he said. The Southern Nevada Water Authority claims there is a lot of unclaimed water deep beneath the valleys on either side of the Deep Creek Mountains. The authority says it won't pump more than will be replaced each year by mountain runoff.

"There have been lots of claims that [Las Vegas] just wants the water, and they are going to take it. That's not at all how we are going about doing this," said Scott Huntley, water authority spokesman. "Our plan is based on the idea of doing this in a sustainable manner."

Garland has his doubts. "This was once a huge Ice Age lake," he said, noting scars left by the ancient Lake Bonneville on surrounding hills. "What makes them think it will recharge?"

Scientists with the Utah Geological Survey are busily trying to determine recharge rates for area underground aquifers but say too little is known about area geology to say for sure how water flows in the Snake Valley. And the Las Vegas pipeline project is moving through the permitting process ahead of ongoing federal studies aimed at determining how much water is available. Stefan Kirby with Utah Geological Survey agrees with the Southern Nevada Water Authority that there is significant water under the Snake Valley but said the water might not replace itself if taken out. The water now being pumped from deep wells may have been put down in prehistoric times, he said. And it's possible

the area's complex rock structure now carries mountain runoff sideways miles away before going to ground.

Kirby is performing Carbon-14 dating—the same process used to date dinosaur bones—on samples of water taken from area wells to determine how much of the water rolling off of the Deep Creeks actually makes it into the deepest underground aquifers. What Utah scientists believe they do know is that Nevada's wells will be placed precisely at the point where water from mountain creeks slips underground and makes its way into Utah. A 2005 Utah Geological Survey study found water currently flows from Nevada into Utah and predicted the Las Vegas pipeline would cause well levels in Utah to drop more than 100 feet, possibly drying up springs 30 miles into Utah. In a worst-case scenario, Nevada's pumping could cause water flow in the entire Great Basin to reverse direction. Instead of flowing from Nevada into Utah, water would be sucked from Utah into Nevada. Garland worries that reversal could suck brackish water near the Salt Flats onto his land, destroying forever its ability to be cultivated.

Utah ranchers plan to ask Utah's Legislature in January for \$1 million to fund test wells to monitor ground-water levels. They also want Utah to demand that Las Vegas switch off the pumps if those wells turn up signs that Utah's water is being impacted.

Responding to those calls, the Legislature's Natural Resources Agriculture and Environment Committee this summer passed a resolution asking Utah water officials to hold off signing the Snake Valley water agreement with Nevada until studies of area groundwater have been completed. Committee members hope to have the full Legislature pass the resolution in January—if, that is, it isn't too late.

Utah and Nevada water officials are on track to complete the Snake Valley water agreement by the first of next year. Utah's director of Natural Resources Mike Styler said he wants an agreement in place soon to protect Utah ranchers. He said the agreement he's negotiating calls for monitoring and other safeguards ranchers want.

All this hand-wringing may be in vain, Styler said. As part of negotiations, Utah and Nevada water officials estimated how much of the valley's water is already being used. The answer, Styler said, appears to be all of it.

"The amount of water available is so limited I think it will be marginal for southern Nevada to put a pipeline in [to Snake Valley]," he said. "One thing we've always said is any water right that belongs to Utah or could be used by Utah, we're not going to give up."

Ranchers point out they aren't the only ones using water in the west desert. On Dean Baker's ranch at the south end of Snake Valley, Baker points to a hole in the ground where a spring used to be. Animals, probably coyote, have dug a hole to reach the water now several feet underground, he said.

Today, without springs, the hundreds of antelope that range Baker's property drink from his irrigation ditches to quench their thirst.

Gandy Spring, a short drive from Baker's ranch, is home to the "least chub," a tiny prehistoric fish left behind in shallow pools when Lake Bonneville receded at the end of the Ice Age that is found almost nowhere else. Fish Spring National Wildlife Refuge and Great Basin National Park are also located in the area.

Don Duff, the man who in the mid-1970s discovered surviving populations of Bonneville cutthroat trout in two high Deep Creek streams and worked with the Douglass family to restore the fish, worries Las Vegas' pipeline could ruin his life's work. Overpumping of ground water, he notes, has been known to cause mountain streams to dry up.

"We can't have expanded growth without impacts in the environment," said Duff, a retired Forest Service aquatic ecologist who runs the Trout Unlimited chapter in Baker, Nev. "Once there are impacts shown, you've already lost. How do you shut the pumps down to a multibillion-dollar project? You can't pump water back into the basin."

Utah environmentalists share similar fears about their state's pending water projects. The Utah Rivers Council recently released a report asking Utah water officials to examine alternatives to developing water from the Bear River, noting the Bear provides 60 percent of the surface water to the Great Salt Lake. The lake and the river delta around it, including the Bear River Migratory Bird Refuge, are recognized as one of the most important refuges in the Western Hemisphere for migrating birds. Utah water officials say water would be taken only during high winter runoff, but the Rivers Council complains the lake is so shallow that small changes in water can have dramatic effects.

The Las Vegas pipeline project also could impact lake levels. Water flowing out from the Snake Valley is thought to contribute around 10,000 acre-feet per year to the Great Salt Lake.

Standing at the edge of his property where years of drought have killed even the tenacious plants that hold the desert together, Garland picks up a fistful of fine sand, then lets it fall through his fingers. Two years ago, before the worst of the recent drought abated, Garland said he witnessed clouds of dust 500 feet in the air. He predicted the result of Las Vegas pumping will be clouds thousands of feet high moving to Salt Lake City.

Garland isn't a man who shies from exaggeration. If the Las Vegas pipeline isn't stopped, he predicts the land will become, "New Orleans in reverse." But his vision of a new dust bowl isn't that far fetched. It happened before, not too far away, in California's Owens Valley, a one-time farming community at the base of the Sierra Nevada Mountains.

At Garland's invitation, attorney Greg James, the former water department director for Inyo County in Owens Valley, visited Callao this summer to speak to visiting lawmakers from Utah and Nevada. James told of Los Angeles raids on Owens Valley water beginning at the turn of the century and expanding through the 1970s. First the springs went dry. By the mid-1920s, the valley's entire river had gone to Los Angeles. Then a lake dried up.

By the time James got to Inyo County, Los Angeles had purchased all of the valley's farms and ranches for water rights, and Owens Valley had become the world's largest source of dust. The Clean Air Act eventually gave James some leverage to force Los Angeles to begin repairing the damage. Still, after decades of lawsuits, Owens Valley has managed to get back only about half the water.

"The lesson from L.A. is they came to the valley saying, 'Don't worry. It's very safe. We are going to take a little bit of water,'" James said. "But as the city continued to grow, they couldn't stop."

Global Warming Could Devastate Economy

BY THOMAS WAGNER FOR ASSOCIATED PRESS LONDON (AP)

[Stern Report](#)

[Stern Report Executive Summary](#) [1m PDF File]

Unchecked global warming will devastate the world economy on the scale of the world wars and the Great Depression, a British government report said Monday, as the country launched a bid to convince doubters that environmentalism and economic growth can coincide.

Britain hired former Vice President Al Gore, who has emerged as a powerful environmental spokesman since his defeat in the 2000 presidential election, to advise the government on climate change - a clear indication of Prime Minister Tony Blair's dissatisfaction with current U.S. policy.

Blair, President Bush's top ally in the Iraq war, said unabated climate change would eventually cost the world between 5 percent and 20 percent of global gross domestic product each year. He called for "bold and decisive action" to cut carbon emissions and stem the worst of the temperature rise.

"It is not in doubt that, if the science is right, the consequences for our planet are literally disastrous," he said. "This disaster is not set to happen in some science fiction future many years ahead, but in our lifetime."

The report emphasized that global warming can only be fought with the cooperation of major countries such as the United States and China, and represents a huge contrast to the Bush administration's wait-and-see global warming policies.

Sir Nicholas Stern, the senior government economist who wrote the report, said that acting now to cut greenhouse gas emissions would cost about 1 percent of global GDP each year. He recommended a "low-carbon global economy" through measures including taxation, regulation of greenhouse gas emissions and carbon trading.

"That is manageable," he said. "We can grow and be green."

Bush kept America - by far the biggest emitter of carbon dioxide and other gases blamed for global warming - out of the Kyoto international treaty to reduce greenhouse gases, saying the pact would harm the U.S. economy. The international agreement was reached in Kyoto, Japan, in 1997 and expires in 2012.

Blair made his displeasure with U.S. environmental policy clear when he signed an agreement this year with California Gov. Arnold Schwarzenegger to develop new technologies to combat the problem. The measure imposed the first emissions cap in the United States on utilities, refineries and manufacturing plants in a bid to curb the gases that scientists blame for warming the Earth.

The prime minister and the report also said that no matter what Britain, the United States and Japan do, the battle against global warming cannot succeed without deciding when and how to control the greenhouse gas emissions by such fast-industrializing giants as China and India.

Stern's 700-page report said evidence showed "that ignoring climate change will eventually damage economic growth."

"Our actions over the coming decades could create risks of major disruption to economic and social activity, later in this century and in the next, on a scale similar to those associated with the great wars and the economic depression of the first half of the 20th century," he said.

The report said at current trends average global temperatures will rise by 3.6 to 5.4 degrees within the next 50 years or so, and the earth will experience several degrees more of warming if emissions continue to grow.

It said such warming could have effects such as melting glaciers, rising sea levels, declining crop yields, drinking water shortages, higher death tolls from malnutrition and heat stress, and widespread outbreaks of malaria and dengue fever. Developing countries often would be the hardest hit.

The report acknowledged that its predictions regarding GDP relied on sparse data about high temperatures and developing countries, and placed monetary values on human health and the environment, "which is conceptually, ethically and empirically very difficult."

Treasury Chief Gordon Brown, who is expected to replace Blair as prime minister next year, said Britain would lead the international effort against climate change, establishing "an economy that is both pro-growth and pro-green." He called for Europe to cut its carbon emissions by 30 percent by 2020 and 60 percent by 2050 - and Blair's government on Monday said it would propose a British law to that effect.

Under the 1997 Kyoto accord, 35 industrialized nations committed to reducing emissions by an average 5 percent below 1990 levels by 2012.

But Britain is one of only a handful of industrialized nations whose greenhouse gas emissions have fallen in the last decade and a half, the United Nations said Monday.

The U.N. said Germany's emissions dropped 17 percent between 1990 and 2004, Britain's by 14 percent and France's by almost 1 percent.

Overall, there was a 2.4 percent rise in emissions by 41 industrialized nations from 2000 to 2004, mostly because former Soviet-bloc countries, whose emissions declined in their economic downturn of the 1990s, increased emissions during the recent four-year period by 4.1 percent.

The British government is considering new "green taxes" on cheap airline flights, fuel and high-emission vehicles.

States to begin augmentation study to prepare for water scarcity

Excerpt: "The Colorado River Basin States are currently collaborating on a system-wide study examining augmentation options, such as desalination, weather modification and other emerging technologies."

Press Release

Source: Southern Nevada Water Authority

Interior Secretary Kempthorne, Colorado River Water
Users Discuss Drought Management

Tuesday October 31

LAS VEGAS, Oct. 31 /PRNewswire/ -- Secretary of the Interior Dirk Kempthorne met yesterday (Oct. 30) with representatives from the seven states that share the Colorado River's flows to discuss water management issues related to the drought-plagued river.

"The key issue for this river system, as it is for many other river systems around the West, is the competition and demand for a limited resource, and the need to find solutions to this demand that will meet both current and future needs," Kempthorne told the representatives. "This is a tough job, and I look forward to working with you to find consensus solutions to these issues."

Among the items discussed were shortage sharing arrangements associated with persistent Colorado River drought conditions and potential options for augmenting the river system's flows. The Colorado River Basin States are currently collaborating on a system-wide study examining augmentation options, such as desalination, weather modification and other emerging technologies. The results of the study are scheduled for release next summer. An Environmental Impact Statement related to managing the river system is also being developed.

Representatives from the Colorado River Basin States expressed that Kempthorne's visit underscored his commitment to working proactively and collaboratively on difficult Colorado River issues such as shortage management. The meeting was productive and set a positive tone for the critical times ahead.

This was Kempthorne's first opportunity to meet collectively with officials from the Colorado River Basin States. The Secretary, who was appointed in May 2006, recently made an aerial tour of the Colorado River. Attending the meeting were representatives of all seven Basin States: Wyoming, Colorado, Utah and New Mexico (Upper Basin); and Arizona, California and Nevada (Lower Basin). Interior Assistant Secretary for Water and Science Mark Limbaugh, Bureau of Reclamation Commissioner Bob Johnson, Upper Colorado Regional Director Rick Gold and Lower Colorado Acting Regional Director Jayne Harkins rounded out the Interior team.

LR Testimony 11/01/06

The Moab Mill Project: A Technical Report Towards Reclaiming Uranium Mill Tailings

[This report](#) about the Department of Energy's (DOE) reclamation of uranium waste along the Colorado River, is a project supported by a grant from the [Citizens' Monitoring and Technical Assessment Fund](#).

The report includes two studies related to the behavior of the Colorado River in the vicinity of the Moab where DOE is carrying out the remediation of the former Atlas Corporation Uranium Mill, pursuant to federal law.

The first study, by Dr. John C. Dohrenwend, is "A Review: Department of Energy's Assessment of Potential Flood Hazards at the Moab Project Site (Atlas Tailings Pile)," January 2005.

The second, by Dr. Noam Greenbaum, is "Paleofloods in the Upper Colorado River near Moab, Utah," May 2006.

The first report was submitted to the DOE as comment on the Draft Environmental Impact Statement for Remediation of the Moab Uranium Mill Tailings. Dr. Dohrenwend's review was one of the studies relating to the potential long-term impact of the Colorado River should the estimated 16-million tons of uranium mill tailings be left on site.

It was one of the studies that the DOE took into consideration when the Record of Decision determined that the Moab Mill tailings should be moved from the floodplain of the Colorado River to a site at Crescent Junction, 30 miles north.

The second report is the result of a paleoflood study carried out upstream of the Moab site. The study, based on fieldwork carried out in the summer of 2005, brings forth a whole new set of data related to the flood behavior of the Colorado River within the past several thousand years.

Most significantly, the study provides new information that alters previous determinations of the flood discharge rates for the 100-year and 500-year floods and the probable maximum flood (PMF).

This new data must be considered and further investigations initiated.

Additional copies of this report can be obtained by contacting:

Reclamation announces new EIS for Glen Canyon Dam

First posted on November 3, 2006

The Bureau of Reclamation today announced it will begin to develop an Environmental Impact Statement (EIS) on the implementation of a Long-Term Experimental Plan (LTEP) for operational activities at Glen Canyon Dam and other management actions on the Colorado River.

This EIS is in response to a settlement agreement in the 9th District Court by the plaintiffs: Center for Biological Diversity, Living Rivers, Sierra Club Grand Canyon Chapter, Glen Canyon Institute and the Arizona Wildlife Federation.

In that agreement, Reclamation committed to further NEPA and Endangered Species Act compliance activities, in concert with the Adaptive Management Program, which began in 1996 following the completion of the first EIS, which began in 1989.

The development of the present EIS continues the efforts of the Adaptive Management Program and created to protect the resources of Grand Canyon National Park below Glen Canyon Dam.

A component of that program has been the work of the Adaptive Management Working Group (AMWG) and the Technical Working Group (TWG) through adaptive management and scientific experimentation.

The AMWG provides the Secretary of the Interior with recommendations on the development and review of science-related work and changes to management practices.

Since its inception in 1996, the AMWG and the TWG have been working to develop long-term planning and monitoring through structured experimentation related to operations of the dam (flow) and other management actions (non-flow).

The EIS on the Long-Term Experimental Plan will rely on the extensive scientific studies that have been undertaken by the U.S. Geological Survey's Grand Canyon Monitoring and Research Center (GCMRC).

The AMWG will inform Reclamation of options for a long-term experimental plan during the EIS process and will also have the opportunity to recommend other experiments related to the plan.

The public has the opportunity to provide oral and written comments to Reclamation on options and experiments until the last day of February 2007.

The AMWG will hold a public meeting December 5, 2006, in Phoenix, Ariz., at the Fiesta Inn at 2100 S. Priest Drive, Tempe, Arizona.

The Bureau of Reclamation will hold two public meetings:

January 4, 2007 at Phoenix, Arizona, Embassy Suites Phoenix Airport at 44th Street (Cholla room), 1515 North 44th Street. Meeting time: 6:00 p.m. - 8:00 p.m.

January 5, 2007: Salt Lake City, Utah, Hilton Salt Lake City Center, (Salon 1), 255 South West Temple. Meeting time: 6:00 p.m. - 8:00 p.m.

These meetings will provide an opportunity for public input on the Long-Term Experimental Plan. An agenda for the meeting, including projected times for the discussion of this action, has been posted on the Upper Colorado Region's web page at www.usbr.gov/uc. Click on the Adaptive Management Program listing for details.

The Department of Interior anticipates publishing a draft EIS in the spring of 2008.

THE COMMENT PERIOD ENDS FEBRUARY 28, 2007

Stegner Center 12th Annual Symposium: The Colorado River

Location: University of Utah / S.J. Quinney College of Law / Sutherland Moot Courtroom

Date: Friday Mar 2, 2007 (7:00 AM) to Saturday Mar 3, 2007 (5:00 PM)

Contact: 801.585.3440 [Link to the Stegner Center](#)

The Wallace Stegner Center's 12th annual symposium will explore issues of Colorado River management, focusing on the seven-state Colorado River Compact and other aspects of the "Law of the River," the complex set of laws, treaties, cases, regulations, and other documents that govern use and management of the Colorado River. The fundamental question to be explored in this two-day symposium is whether the 1922 Compact is resilient enough to meet the environmental needs and to withstand the hydrological, climatic, economic, and other real-world changes of the next century, or whether significant changes to the compact or other laws are necessary.

The Stegner Center will be joined by policy analysts, water users, scientists, economists, political leaders, environmental advocates, and others to consider whether the Colorado River Compact needs to be refashioned. Critical issues include how Colorado River water might be re-allocated among the Upper and Lower Basin states, Native American tribes, Mexico, and instream environmental uses, and what effect this might have on the ecological health of the river as well as surrounding communities and other users of Colorado River resources.

The goal for this year's symposium is to promote understanding of the cultural and historical forces that shaped the Colorado River Compact and how the realities of the New West, including the urbanization of the region, population growth, environmental damage, and increased water demands, along with a changing environmental ethic, might suggest a need to reconsider something as fundamental as the 1922 Colorado River Compact.

The symposium will feature the following speakers:

Robert Adler, Associate Dean for Academic Affairs and James I. Farr Chair in Law and Professor of Law, University of Utah S.J. Quinney College of Law

Niklas Christensen, Water Resource Engineer, Herrera Environmental Consultants

Steven E. Clyde, Shareholder and Managing Director of Clyde Snow Sessions & Swenson, P.C.

Karl W. Flessa, Professor of Geosciences, University of Arizona

Justice Gregory J. Hobbs, Jr., Colorado Supreme Court David H. Getches, Dean and Raphael J. Moses Professor of Natural Resources Law, University of Colorado School of Law

Richard J. Ingebretsen, MD, PhD, Professor, University of Utah Department of Physics and Clinical Instructor of Medicine, University of Utah School of Medicine

Robert W. (Bob) Johnson, Commissioner of the Bureau of Reclamation (invited)

Patty Limerick, Faculty Director and Chair of the Board, Center of the American West

Pat Mulroy, General Manager, Southern Nevada Water Authority

Don A. Ostler, Executive Director, Upper Colorado River Commission

Jennifer Pitt, Senior Resource Analyst, Environmental Defense

John (Jack) C. Schmidt, Professor, Department of Watershed Sciences, Utah State University

Tom Till, Nature Photographer and Author; Fellow of the North American Nature Photography Association

Susan M. Williams, Owner/Partner, Williams & Works, P.A.

David S. "Sid" Wilson, Jr., General Manager, Central Arizona Project

Connie A. Woodhouse, Associate Professor in Geography and Regional Development, University of Arizona

J. Francisco Zamora-Arroyo, Project Manager, Colorado River Delta, Sonoran Institute

Jerry Zimmerman, Executive Director, Colorado River Board of California

The Stegner Center will begin accepting registrations in January 2007. Registration fees are \$110 if received by February 16; \$140 if received on February 17 or later. Seniors and university and college faculty and staff are \$65 if received by February 16; \$90 if received on February 17 or later. Students are \$50 if received by February 16; \$75 if received on February 17 or later. Continental breakfast and lunch is included. Thirteen CLE credits are available for \$15.

Please contact the Stegner Center at 801-585-3440 or

LR Press Release 01/05/07

Federal study launched to mislead the public into supporting failed efforts to recover endangered species

January 5, 2006

For Immediate Release:

Contact: John Weisheit 435-259-1063

Cell: 435-260-2590

Grand Canyon Cover Up

Federal study launched to mislead the public into supporting failed efforts to recover endangered species

(Phoenix, AZ) While native species continue to decline within one of the world's most famous river corridors, federal officials are soliciting public comments for remedies without acknowledging the problem, nor their intent to continue with the same failed strategies exacerbating the losses.

"The main problem in Grand Canyon is the loss of endangered species due to failure to operate Glen Canyon Dam according to the mandate of the Grand Canyon Protection Act," says John Weisheit, from Living Rivers. "Yet now that an out-of-court settlement has forced this new study on the operations of the dam, the public is not being informed of these impacts, nor that Grand Canyon is the principle victim of their mismanagement policies."

The launch of this new Environmental Impact Statement (EIS) comes after more than three decades of studies and experimentation, Congressional interventions, and millions of taxpayer dollars invested principally to reverse the decline of endangered species in Grand Canyon National Park.

The most egregious errors have come over the past ten years during the implementation of an extensive adaptive management and research program. Annual program reports repeatedly show that these efforts have not been sufficient to improve a single threatened natural or cultural resource.

Under adaptive management, one more fish species has gone extinct, the razorback sucker, and another, the humpback chub, has dwindled to just a few thousand fish. Additionally, Native American archeological sites that were to be protected, have either suffered further damage, or required emergency stabilization.

Despite this lack of progress, Bureau of Reclamation briefing materials introducing this new EIS, ignore any mention of endangered species, archeology or, with one minor exception, the Grand Canyon itself.

"If the Bureau won't honestly describe the problem, how can the public have faith that they are seriously interested in developing a solution," adds Weisheit. "The ten-year experimental plan they intend to develop demonstrates that nothing has changed and the Bureau of Reclamation remains intent on administering to the slow demise of the Grand Canyon."

Fight brewing over endangered fish

By GARY HARMON

The Daily Sentinel Sunday

The federal government is spending millions of dollars in Colorado to save endangered fish that, according to one organization, it's allowing to dwindle in the Grand Canyon.

The U.S. Bureau of Reclamation is embarking on a two-year process of putting together an environmental impact statement for a long-term experimental plan for operation of Glen Canyon Dam.

That study, said a Moab, Utah-based organization, Living Rivers, is a "cover-up" launched to mislead the public into supporting failed efforts to recover endangered species.

It is, actually, said Reclamation official Dennis Kubly, the beginning of an effort to balance management of Glen Canyon Dam with the needs of people and other species.

The idea, Kubly said, is to balance the operations of the dam with a multitude of needs, including the requirements of Colorado and other Upper Colorado River Basin states to deliver set amounts of water to the lower-basin states, the need for electrical generation, and the scenic needs of the Grand Canyon, as well as those of its fish.

"There are big stakes here," Kubly said. "Let's take the time to do it right and hopefully we won't have to do it over."

Reclamation, however, has a clear mission under the Endangered Species Act and the Grand Canyon Protection Act, said John Weisheit of Living Rivers.

The launch of the environmental impact statement follows three decades of studies and experimentation, Congressional interventions and millions of taxpayer dollars invested

principally to reverse the decline of endangered species in Grand Canyon National Park, Weisheit said.

Under the adaptive-management program used by Reclamation, the razorback sucker has become extinct in the canyon, and another, the humpback chub, has dwindled to just a few thousand fish.

"We're thinking the razorback never had very high numbers in the Grand Canyon," Kubly said, and the population of the "primary fish of interest," the humpback chub, has stabilized at about 5,000 adults after a decline.

"We hope we're turning the corner and getting some things right here," said Kubly, chief of the adaptive management group of Reclamation's Upper Colorado regional office in Salt Lake City.

The razorback and humpback, as well as the Colorado pikeminnow and bonytail chub, are the species targeted for recovery in the management of the Colorado River and its tributaries through Colorado, including the Grand Valley, and Utah.

Weisheit said the agency has ignored any mention of endangered species and archeology.

"Their attitude is that it's more important to make electricity to pay for the cost of the dams" than to meet the requirements of the law, Weisheit said.

The agency, however, needs time to experiment, Kubly said.

Reclamation hopes to complete its process by the end of 2008, then begin an estimated 10-year experimental flow program.

Take Action 01/18/07

Stop Congressional Ban on Studying the Decommissioning of Glen Canyon Dam

Every year, since 1998, there has been a section of the Department of Interior Appropriations' bill forbidding any study of decommissioning Glen Canyon Dam on the Colorado River. Your help is needed now to get this ban lifted.

The region's climate change is illustrating how irrelevant Lake Powell reservoir is for water storage, and the dam's mounting impacts on Grand Canyon's Colorado River ecosystem are becoming more devastating.

Congress is poised to take-up this legislation again and your help is needed now to ensure that federal studies on the future of Glen Canyon Dam can proceed unencumbered.

PLEASE CALL AND WRITE your representatives in Congress

Urge them to support an amendment to the Interior Appropriations Bill, to negate the language that bans the use of federal funds to study the decommissioning of Glen Canyon Dam.

POINT OUT THAT:

- Climatic changes in the Colorado River watershed reinforce the need for evaluating more efficient water storage options. The 24 million acre-feet that Lake Powell has stored for the present drought came with a cost of 40 million acre-feet of Colorado River water lost to evaporation and seepage since Glen Canyon Dam was built. This is valuable water that could be used by the environment and communities in the states of Arizona, Nevada, California and Mexico. We need to explore other ways to store water and create energy. Storing this same water in underground aquifers, a strategy proliferating across the southwest, has a 99 percent recovery rate. Glen Canyon Dam is wasting valuable water. It's time to evaluate the dam's decommissioning so this water can be efficiently managed.
- The dam blocks the flow of the Colorado River killing Grand Canyon National Park's famed river ecosystem below the dam. This damage continues despite more than \$200 million invested in federal efforts to alter Glen Canyon Dam operations in an attempt to comply with the 1992 Grand Canyon Protection Act. Studies must be allowed to evaluate the dam's decommissioning as a principle option for saving the Grand Canyon.

Sediment accumulation in the reservoir is steadily reducing the storage capacity and will eventually lead to failure of the dam, spillway erosion and collapse. The cost of managing this sediment must be addressed.

THE LANGUAGE WHICH SHOULD BE OMITTED from the upcoming Interior Appropriations Bill.

No funds appropriated for the Department of the Interior by this Act or any other Act shall be used to study or implement any plan to drain Lake Powell or to reduce the water level of the lake below the range of water levels required for the operation of the Glen Canyon Dam.

SAMPLE LETTER

Dear Representative xxx
Dear Senator xxx

Please support eliminating, from the Interior Appropriations Bill, the ban to study Glen Canyon Dam decommissioning.

Please support an amendment to negate this ban so that the government can seek the best solutions for conserving precious Colorado River water and restoring critical river habitat in Grand Canyon National Park as called for in the Grand Canyon Protection Act.

The present drought situation reveals that Lake Powell reservoir is not the most efficient means for storing surplus Colorado River water. This drought is also coinciding with mounting evidence that the department of Interior's decade-long program to mitigate the impacts of Glen Canyon Dam on the resources within Grand Canyon National Park has been a failure. To aid in developing sound water use policy in the Colorado watershed, its critical that Congress allow the re-examination of how and if Glen Canyon Dam should remain operational.

Save Water for the Colorado's Future

Diverting water and storing it in underground aquifers represents the foundation for efficient Colorado River water storage, and should be vigorously pursued. It has become clear that above ground reservoir storage in the hot, arid desert is wasting vast amounts of precious water to evaporation. In addition the porous sandstone absorbs a lot of water that is not retrievable. We need to utilize underground storage in the places already proven feasible. Underground water banking programs can achieve up to 99 percent efficiency as compared to the 38 percent experienced with Lake Powell.

Assure Grand Canyon's Recovery

Since the 1992 passage of the Grand Canyon Protection Act more than \$200 million has been spent on mitigation efforts, but it isn't working. Glen Canyon Dam continues to devastate Grand Canyon's ecosystem.

The failure of this program to meet the goals of the Act was documented in the 2002 Bureau of Reclamation Report to Congress: Operations of Glen Canyon Dam Pursuant to the Grand Canyon Protection Act of 1992. More recent results of scientific studies

evaluating the Adaptive Management Plan have been even more disappointing. A review of their efforts to recover the endangered humpback Chub revealed that the Chub are spiraling toward extinction, declining by an average of 14 percent each year. We've already lost four of the eight fish species in Grand Canyon's river corridor and otters, muskrats, reptiles, insects and plants. It is critical that we now seek mechanisms that will actually comply with the Grand Canyon Protection Act.

Sediment Problems

Sediment accumulation in the reservoir is steadily reducing storage capacity and will eventually lead to failure of the dam, spillway erosion and collapse. In fact a high flow event occurring via monsoon or rapid snow melt could cause dam failure and disaster by moving the now high and dry exposed sediment, and the sediment in tributaries and depositing all of it at the face of the dam.

The cost of managing this sediment has not been addressed, nor have the effects of the absence of sediment in the Grand Canyon ecosystem been thoroughly analyzed. This too needs to be understood as we look toward a sustainable path for Arizona's water management.

As with the 84th Congress which allowed the creativity to design what was then felt optimal for Colorado River water management, so too must the 110th Congress allow federal water resource planners the same flexibility in guiding the Colorado's future. The public is ill served by banning analysis that could vastly improve both water storage efficiency on the Colorado, and a restored Grand Canyon river ecosystem.

Sincerely,
Your name and address

Save Grand Canyon from Glen Canyon Dam

New Environmental Impact Study Underway on Glen Canyon Dam Operations

Comments needed to demand that Bureau of Reclamation focus on actions for endangered species recovery in Grand Canyon National Park, not more experimentation for the

preservation of Glen Canyon Dam.

Submit by: Tuesday, February 28, 2007

In an attempt to comply with a settlement agreement reached last September between environmental groups and the Department of Interior, the Bureau of Reclamation has begun the scoping process for an Environmental Impact Statement on the operations of Glen Canyon Dam called the Long-Term Experimental Plan.

As presently conceived, this EIS will deliver nothing more than a continuation of studying Grand Canyon to death.

Your voice is needed to expose this fallacy and redirect the EIS away from experimentation aimed at preserving the operations of Glen Canyon Dam, and toward the principle objective of restoring and preserving Grand Canyon's unique river ecosystem.

Background

For more than four decades the world-renowned Colorado River ecosystem in Grand Canyon National Park has been [deteriorating due to the upstream operations of the 700-foot-high Glen Canyon Dam](#). Beaches, endangered native fish and archeological sites have all disappeared as cold, nutrient-depleted water is released at the whims of dam operators on a daily basis, replacing the gradual seasonal fluctuations consistent with the Colorado River's natural hydrology.

Within ten years of the dam's completion, strong public outcry forced the Bureau of Reclamation (BoR) to begin exploring mechanisms to alter Glen Canyon Dam's operations to reverse its detrimental effects on Grand Canyon National Park. Despite hundreds of millions of dollars invested, major studies completed, and new laws enacted by Congress, BoR has continued to drag its feet citing an ongoing need for more studies. As a result, the damage persists.

One more endangered fish has become extinct in Grand Canyon, another has seen its population decline to just a few thousand, while non-native fish now flourish in the artificial environment created by the dam. In total, four of eight native fish species have gone extinct, otters and muskrats have disappeared, and the riparian ecology has been dramatically altered--from the river's native food web to the proliferation of non-native plants throughout the canyon.

Only through the public intervention yet again, has BoR been forced to re-examine the operations of Glen Canyon Dam due to its lack of compliance with federal environmental laws. But this exercise is already shaping-up to be nothing more than a continuation of the stall and divert tactics in BoR's ongoing effort to study the dam's impacts until there's nothing left of Grand Canyon's native riverine environment to protect.

There already exists an abundance of scientific understanding regarding how dam operations must change if Grand Canyon's river ecosystem is to be protected, much of it stemming from the first Glen Canyon Dam Environmental Impact Statement completed in 1995. The problem is that these recommendations are not being followed by the stakeholder group put in charge of implementing these regulations, The Glen Canyon Dam Adaptive Management Program.

Dominated by water and power interests, this group of advisors to the Secretary of the Interior has continuously sidestepped its directives as outlined in the 1995 EIS. They have failed to develop a recovery plan for the endangered razorback sucker or a second population of the endangered humpback chub. They have failed to augment the water temperature or to restore sediment. And despite ongoing declines in native fish, they have failed to implement river flows consistent with the river's natural hydrograph as also called for.

Additionally, this long-term experimental operating plan, which is to be the subject of this EIS represents the pieces of another failed effort by the AMP that was supposed to be completed two years ago.

The problem is not knowing what to do-the problem is actually doing it. The lack of commitment to the scientific mandate has lead many quality researchers to abandon the program. Others who have endeavored to remain, but challenged the AMP's lack of commitment to its mandate have seen their recommendations suppressed, and their contracts cancelled.

This direction of this EIS initiative itself is further evidence of these misplaced priorities. The ingredients for the restoration of the Colorado River through Grand Canyon must be evaluated independently of interests in Glen Canyon Dam operations, not the other way around. Furthermore, as has already been illustrated by Living Rivers and others, there are numerous arguments for evaluating the decommissioning the dam entirely, beyond those benefits which would accrue to Grand Canyon's river ecosystem.

It is therefore mandatory that independent scientific and economic guidance be employed to advise policy makers on the recovery and preservation strategy for the Colorado River corridor in Grand Canyon National Park, and no longer the AMP.

There are many alternatives to meeting the theoretical water storage and energy benefits provided by Glen Canyon Dam, there are however no substitute for the recovery and protection of Grand Canyon's unique riverine ecosystem.

###

Sample scoping comments' letter to Bureau of Reclamation for its EIS on the Long Term Experimental Plan for the Future Operations of Glen Canyon Dam

Submit on or before Tuesday, February 28, 2007

To send via email: GCDExpPlan@uc.usbr.gov To send via fax: (801) 524-3858

Mr. Rick Gold
Regional Director, Bureau of Reclamation
Upper Colorado Region
Attn: UC-402
125 South State Street
Salt Lake City, Utah 84138-1147

Dear Mr. Gold,

Thank you for the opportunity to submit the following scoping comments for the Environmental Impact Statement on the Long-term Operations for the Future Operation's of Glen Canyon Dam. The river ecosystem in Grand Canyon National Park has suffered immensely over the past forty years due to the operations of Glen Canyon Dam, and it's vital that a fresh look at the problem be undertaken. I have concerns, however, that the EIS as envisioned is destined to fail in this regard unless a number of critical issues are addressed.

First, I would like to express my tremendous dismay with the Department of Interior's mishandling of the recovery efforts in Grand Canyon National Park over the past 40 years, and that the information presented so far by the Bureau of Reclamation indicates that this EIS promises more of the same.

While new plans for ongoing investigation and experimentation can be beneficial, they are useless amidst a backdrop where the commitment to implement those plans is virtually non-existent. We've already experienced this with the completion of the first EIS twelve years ago, and there's nothing outlined in the purpose and need for this EIS process to indicate things will be any different once this process concludes. For this

exercise to yield any meaningful outcome, the EIS process must be reconceived incorporating the following:

1. Restructuring the focus of the EIS on the recovery.

The principal objective should not be the long-term operation of Glen Canyon Dam, but the ingredients necessary to bring about the recovery and preservation of endangered species within the Colorado River corridor of Grand Canyon National Park. While such objectives may not be mutually exclusive, this has yet to be proven, and as such, one should precede the other. The focus must first address the ingredients necessary to restore the natural process to Grand Canyon's river ecosystem, and secondly how, and at what costs, can the Glen Canyon Dam/Lake Powell reservoir system be operated in order to achieve this. The restoration ingredients must include:

- The return of river flows consistent with the Colorado River's natural discharge into Grand Canyon.
- The re-establishment of a water temperature regime consistent with seasonal temperature variations of the Colorado River in Grand Canyon.
- The re-establishment of sediment inputs into Grand Canyon consistent with the amount that would be received in a dam-free environment.
- The elimination of non-native species, which have taken hold in the artificial riverine environment created by Glen Canyon Dam operations.

2. Evaluate the Decommissioning of Glen Canyon Dam.

The no-dam alternative must be evaluated as one means of achieving the restoration of the natural process necessary for the recovery and preservation of endangered species in Grand Canyon's river corridor. The no-dam alternative provides a valuable base line from which to evaluate other operational alternatives. Additionally, in light of the climate and human induced changes affecting flows into Lake Powell, and thus the viability of the dam to meet perceived water supply and hydroelectric benefits, BoR has additional incentive to examine a decommissioning or no-dam alternative consistent with the Council on Environmental Quality guidelines.

3. Replace the Working Groups of the Adaptive Management Program.

Despite being given specific instructions twelve years ago as outlined in the 1995 EIS on Glen Canyon Dam operations, the Glen Canyon Dam Adaptive Management Program (AMP) has failed to deliver in almost every aspect, causing Grand Canyon's river ecosystem to endure further damage. Many of AMP's failings were spelled out in the United State's Geological Survey's SCORE Report of October 2005. It was precisely these failings that have compelled BoR to undertake this new EIS process as part of its settlement agreement with environmental groups last year. Absent any structural changes to the AMP, any recommendations coming out of this EIS process will be of little value, as there are no mechanisms to ensure they won't be ignored as were those from the EIS twelve years ago.

Dominated by water supply and hydroelectric power interests, it's not surprising that the AMP has been intransigent toward addressing the true needs for endangered species recovery in Grand Canyon. Scientific, not political and commercial interests, should be the sole advisors to the Secretary of Interior on how Grand Canyon's river ecosystem should be studied, monitored and managed consistent with the recovery objectives.

Therefore, the AMP should be replaced by an open source and independent body of research and advisory scientists, where the monitoring and research data are consistently and thoroughly peer-reviewed prior to formulating any recommendations to the Secretary of Interior.

We're closing in on 50 years of ecological destruction in Grand Canyon National Park due to the operations of Glen Canyon Dam. For much of this time the public has been asking that this be remedied. We continue to lose valuable time and species as the BoR procrastinates and resists the public's mandate to put the resource first. While there are plenty of substitutes to achieve the benefits Glen Canyon Dam may provide, there will never be another Grand Canyon. It's time for the BoR to stop thwarting the public's interest to protect it.

Sincerely,

Regional News 02/16/07

Dams could contribute to climate change

Photo caption: A "mud volcano" emitting methane and hydrogen sulfide gases through the exposed reservoir sediment of Lake Powell in Cataract Canyon and Narrow Canyon above Hite Marina.

LOS ANGELES, Feb. 16 (UPI) -- Dams may contribute to global warming instead of being the clean energy source many have long thought, the Los Angeles Times reported Friday.

Greenhouse gases are emitted during construction and when the land behind a dam is flooded and vegetation rots, causing carbon dioxide and methane gas to be released, the report said. Additional emissions result as the dams operate, including when water is released and a pressure drop frees gases locked within it.

"If these are going to be built as a response to climate change, you at least need to convene some people to study the effect it will have," Danny Cullenward, a research associate at the Program on Energy and Sustainable Development at Stanford University, told the Times. "The facts are in that it's not a zero-impact source from an emissions standpoint."

Cullenward said methane from reservoirs alone could boost global inventories 20 percent.

"When you look at this on a global level, this actually is a really, really massive impact," he told the newspaper. "I would say, right now, this is totally under the radar."

Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability

From the National Academy of Sciences

FOR IMMEDIATE RELEASE

Tree-Ring Data Reveal Greater Variations in Colorado River Flows Than Previously Assumed

Extended Droughts Are Recurrent, May Become More Severe Because of Higher Temps

[Download Report](#)

LAS VEGAS -- Tree-ring based reconstructions of the Colorado River's flow over hundreds of years show that average annual flows vary more than previously assumed and that extended droughts are not uncommon, says a new report from the National Research Council. Future droughts may be longer and more severe because of a regional warming trend that shows no signs of dissipating, the report adds. It also states that a preponderance of evidence suggests that rising temperatures will reduce the river's flow and water supplies. Coping with water shortages is becoming more difficult because of rapid population growth, and technology and conservation will not provide a panacea for dealing with limited water supplies in the long run, the report warns.

The Colorado River basin covers 240,000 square miles and extends over seven states and a portion of northwestern Mexico. The river's annual average flow of roughly 15 million acre-feet of water is used by tens of millions of Americans for drinking and other

household uses, agriculture, landscape irrigation, hydroelectric power, and rafting and other recreational activities. The river also is home to diverse ecological habitats and is central to hundreds of miles of beautiful vistas that it carved out over millions of years, including the Grand Canyon.

Exceptionally dry conditions in much of the Colorado River basin in recent years, along with new streamflow reconstructions based on tree-ring data, prompted the Research Council to convene a committee to examine how hydroclimatic trends might affect the river's future flows.

For many years, understanding of the river's flow was based primarily on records from stream gages. But the tree-ring data is transforming that understanding by demonstrating that the river occasionally shifts into decades-long periods in which average flows are lower, or higher, than the 15 million acre-feet average of the gaged record. In particular, the tree-ring reconstructions show that the years 1905-1920 were exceptionally wet, which is significant because the Colorado River Compact that governs the allocation of water between upper and lower basin states was signed in 1922, when it was assumed that annual average river flow was closer to 16.4 million acre-feet. Tree-ring data also indicate that extended droughts are a recurrent feature of the basin's climate.

The tree-ring reconstructions, coupled with temperature trends and projections, suggest that extended droughts will recur and may be more severe than recent droughts, the report says. Many different climate models point to a warmer future for the Colorado River region, the committee noted, although projections of future precipitation are more uncertain. Significant warming in the region over the past few decades is shifting the peak spring snowmelt to earlier in the year and contributing to increases in water demands, especially during the summer, the committee found. Warmer temperatures also result in more water being lost to evaporation.

The committee also looked at how a steadily rising population and related increases in water demand will affect Colorado River water management. The population across the western United States has grown rapidly in recent decades. Arizona saw a roughly 40 percent rise in population since 1990, for instance, while Colorado's population grew by 30 percent in the same period. Despite some successful water conservation efforts, urban water use in the region has increased significantly along with the expanding population. For example, water consumption in Clark County, Nevada, which includes Las Vegas, doubled between 1985 and 2000.

Increasing urban demands for water are often met through sales, leases, or transfers of water rights from agricultural users. Although 80 percent of available water in the West is devoted to agriculture, this allocation is finite, the committee warned, and water transfer agreements will be limited in their ability to satisfy growing, long-term demand. In addition, such agreements may be inhibited by their potential effects on third parties, such as downstream farmers or ecosystems. Technology and conservation measures are useful and necessary for stretching existing water supplies, the committee

acknowledged, but any gains in water supply will be eventually absorbed by the growing population.

The combination of limited water supplies, rapidly increasing populations, warmer regional temperatures, and the specter of recurrent drought point to a future in which the potential for conflict among existing and prospective new water users will prove endemic, the report concludes. This will inevitably lead to increasingly costly, controversial, and unavoidable trade-offs among water managers, policymakers, and their constituents.

It was therefore a welcome development when the seven Colorado River basin states presented preliminary proposals for managing water shortages in a letter last February to the U.S. secretary of the interior, the committee said. Such interstate cooperation will prove increasingly valuable, and likely essential, in coping with future droughts and water demands. Likewise, a commitment to two-way communication between scientists and water managers will be critical. In addition, the federal government should ensure that the U.S. Geological Survey has the resources to maintain and expand the Colorado River gaging system, which collects streamflow measurements essential for sound water-management decisions.

Many water managers in western states and cities have developed innovative programs and policies for extending limited urban water supplies, but there have been few attempts to synthesize the results from these efforts across the region, the committee noted. And despite advances in understanding of the basin's hydrology and climate, knowledge is lacking on other important topics, such as the environmental effects of water transfers and how best to forecast water demand. The committee noted that urban water demands are far more prominent today than in earlier eras when the compact and other agreements, treaties, and laws governing the river were forged.

The committee called for a collaborative, comprehensive basinwide study of urban water practices and pressing issues in water supply and demand, which should be used as a basis for action-oriented water planning. The collaboration involved in preparing such a report could also promote better communication among federal agencies, states, and municipalities. The proposed study could be conducted by the Colorado basin states, federal agencies, universities in the region, or some combination thereof. The basin states should work with Congress on a strategy to commission and fund the study.

The Research Council study was sponsored by the National Academies, U.S. Bureau of Reclamation, California Department of Water Resources, Metropolitan Water District of Southern California, and the Southern Nevada Water Authority. The National Academies is made up of the National Academy of Sciences, National Academy of Engineering, Institute of Medicine, and National Research Council. They are private, nonprofit institutions that provide science, technology, and health policy advice under a congressional charter. The National Research Council is the principal operating agency of the National Academy of Sciences and the National Academy of Engineering. A

committee roster follows.

Necessity of new reservoirs debated

Some say climate trends argue against building more dams

News source: NOAA

By Deborah Frazier, Rocky Mountain News

February 22, 2007

Climate change may mean less water in Colorado rivers and streams, but experts can't agree on whether building more reservoirs is a wise investment or a waste of billions.

A series of recently released studies on climate change in the West predict more drought, warmer weather and greater water loss because of evaporation.

"The future doesn't portend a new abundance of nature's water. Rather, nature will be taking more water than it's now delivering," said Martin Hoerling, of the National Center for Atmospheric Research in Boulder.

Hoerling's research focused on the Southwest and the Colorado River, which originates in the Rocky Mountain snowfields.

Denver, Aurora, Colorado Springs, Fort Collins and other cities tap the Colorado River in western Colorado and move about 500,000 acre-feet to reservoirs that serve the Front Range.

An acre-foot, 325,800 gallons, supplies one to four families for a year depending on lawn size and landscaping.

Hoerling and other weather researchers said that climate trends argue against building more reservoirs that rely on the Colorado River. "If you add reservoirs, you are not going to fill them," he said.

The Colorado River serves seven states - Colorado, Wyoming, New Mexico and Utah in the upper basin and Arizona, California and Nevada in the lower basin.

When the 1922 Colorado River Compact divided the water among the states, the annual flow was estimated at 15 million acre-feet.

Hoerling said that the recent annual flows are about 13 million acre-feet, but by 2050, climate change may drop that to about 10 million acre-feet - less than what is currently used by all of the states. That could mean there would be no extra water to store in Colorado, which hasn't claimed it's full share of the river, he said.

"You can build all the reservoirs you want, but there are no existing surplus flows to fill them," he said.

That's not the conclusion that Chips Barry, manager of Denver Water, draws from the studies. Denver Water supplies 1.2 million homes in Denver and the suburbs. "It's a powerful argument for building more storage," Barry said. "More storage is one of the ways to adapt to climate change."

Barry said the climate studies also found a trend toward episodic periods of heavy precipitation with earlier and heavier runoff seasons.

"When you have a highly variable precipitation pattern, you store as much water as possible in times of plenty," he said. "That's the lesson of the West. You need more storage for the swings."

That doesn't mean a revival of the big dam building era that started in the 1960s after the devastating droughts of the 1950s.

Barry said that the best dam sites - mountain canyons - already have reservoirs. Environmental issues, political conflicts and costs make new reservoir construction difficult, he said.

That includes a reservoir that Denver Water wants to build near Wolcott in Eagle County. Denver Water owns enough water rights to fill a new reservoir, but a federal mediator is trying to resolve conflicts with western Colorado interests who want to keep the water there.

Despite the opposition, Barry said that Denver Water will pursue the project. The reservoir's size hasn't been determined, he said. "I can't afford to wait to fix global warming," Barry said. "And, you can't conserve your way out of global warming."

Neil Grigg, a civil engineering professor at Colorado State University and a water resources consultant, said that smaller projects may be the future.

Blue Mesa Reservoir near Gunnison is the state's largest storage project, at 940,000 acre-feet. Denver's Dillon Reservoir holds 252,000 acre-feet.

"If you built a large project and climate change diminished the water supply, it would never fill," Grigg said. "You'd have a failure."

Smaller reservoirs store up to 200,000 acre-feet, he said.

Large reservoirs at lower and warmer elevations also lose more water to evaporation - up to 30 percent of the stored supply in the southwest, officials said.

Grigg and others said that projects with smaller reservoirs that capture water from several river systems will be the most effective.

The Northern Colorado Water Conservancy District, which serves Fort Collins, Greeley and other towns in Larimer, Weld and Boulder counties, is studying several new storage projects.

"As we look at the forecasts for less runoff and most of it coming down all at once, we think we need to grab it as fast as we can," said Brian Werner, the district's spokesman.

The district is studying a 500,000 acre-feet reservoir near Maybell in northwestern Colorado to capture the Yampa River flows, he said. The Yampa River flows into the Colorado River, so the project would claim part of the state's share of the river.

The project could bring water to the South Platte, where farmers have had irrigation wells shut off, and to the south metro suburbs, Werner said.

The climate change projections make the project, estimated at up to \$4 billion, more attractive, Werner said. "While the drier years will get drier, those few wet years will be wetter. In those high years, you need the largest vessel possible," he said.

Chuck Howe, an economics professor at the University of Colorado who specializes in water supply, agreed. "The runoff will come earlier and faster and you'll want to catch it," he said.

But Howe added a warning. "There are places where additional storage ought to be considered, but one has to consider whether they will fill."

Nolan Doesken, the state's climatologist, said that the recent studies have shifted the discussion from whether there was climate change to "what do we do about climate change?"

"We know we are grateful for the water-storage projects we have now, but will new ones be cost effective? I have no idea," he said.

"That decision is the greatest challenge for the combination of science and policy that our part of the country has seen in a long time."

Scientists fear shortages could hit Colorado River earlier

Associated Press

Feb. 26, 2007 07:59 AM

TUCSON - Scientists and public officials fear water from the Colorado River will run short more quickly than previously predicted because of booming population growth and drought.

There's a 10 percent chance of shortages in four to five years, and a 25 percent chance the river will run short between 2020 and 2025, according to two prominent water officials in Arizona.

"I have no doubt that within the next five to 10 years, we will be in a shortage," said David Modeer, Tucson Water's director and a member of the three-county board that manages the Central Arizona Project, which diverts water from the Colorado River to Arizona.

"It does not look good," Modeer said.

Larry Dozier, general manager of the Central Arizona Project, said when the shortages happen, they would not reduce water deliveries to cities.

Rather, he said it would primarily affect non-American Indian farms that are lower on the pecking order for getting water from the Central Arizona Project.

But Dozier said the pain from shortages should be eased, if not eliminated, because the state has been buying excess Central Arizona Project water and storing it in the ground for the past decade.

Originally, scientists who conducted a 1995 federal study predicted states would lose no more than 3 percent of their river supplies even in the worst drought year.

Instead, in the time since the study, Lake Powell and Lake Mead carried less water than had been predicted for the worst possible drought, users took more water than expected, and the river's flow was weaker than expected.

Ben Harding, an engineer and one of the authors of the 1995 study, said the Colorado River's woes are a "system drought," caused by the huge scale of the Colorado's reservoir system that 25 million people rely on for water, and by population growth that has come to rely on it.

"The bigger the reservoirs that you build, the bigger the system you build, the more sensitive it becomes to droughts (and) the longer it takes to recover," Harding said. "You have a bigger hole to fill."

Harding said the study's authors assumed the worst-case drought would be a very rare event and probably many years off and that the high cost of pumping water 300 miles uphill to Tucson from the Colorado would reduce the demand for the project's water.

"The current drought, however, has caught water managers unprepared," Harding wrote.

LR Letter to Secretary Kempthorne: LTEP EIS

[Living Rivers Press Release on LTEP EIS](#)
[Download letter](#) [350k PDF File]

February 28, 2007

Honorable Dirk Kempthorne
Department of the Interior
1849 C Street, N.W.
Washington DC 20240

Sent Via Fax: 202-208-6950

Re: Environmental Impact Statement for the Long-Term Experiment Plan for the future operations of Glen Canyon Dam

Dear Secretary Kempthorne,

Living Rivers & Colorado Riverkeeper, and the Center for Biological Diversity request your immediate intervention into the Bureau of Reclamation's (Reclamation) Environmental Impact Statement for the Long-Term Experiment Plan for the future operations of Glen Canyon Dam (LTEP EIS).

While this National Environmental Policy Act (NEPA) process on Glen Canyon Dam's operations is long overdue, we fear that absent some significant retooling, Interior's approach to this EIS will only bring further damage to critical habitat and archeological sites within the Colorado River corridor of Grand Canyon National Park and Glen Canyon National Recreation Area.

As presently conceived this EIS does not sufficiently focus on the fundamental objective of recovering downstream resources. Nor does it appear this EIS will address the longstanding stumbling blocks to the successful implementation of any preferred recovery alternative, which to this day continue to thwart valuable recommendations made in the past.

For more than three decades the public has been demanding that Reclamation aggressively respond to the devastating impacts Glen Canyon Dam's operations have brought to Glen, Marble and Grand canyons. This EIS itself is the result of the continuation of these efforts: part of the settlement agreement between the Center for Biological Diversity, et al., and yourself, is to address Reclamation's demonstrated lack of progress in achieving compliance with numerous federal environmental and resource management laws and statutes associated with Glen Canyon Dam's operations.

Our organizations had hoped that this agreement would have compelled Reclamation to finally address these matters through a comprehensive EIS process committed to recovery. However, it is clear from the scoping process underway to date, that Reclamation's interests lie more with going through the motions of compliance with the settlement agreement, and not resolving the issues underlying it.

With the exception of accumulating additional evidence to substantiate further litigation, as it now stands, this EIS will be yet another waste of the public's resources in support of Reclamation's ongoing failure to implement an actual recovery plan for this critical piece of the world's natural heritage being destroyed by the operations of Glen Canyon Dam.

We therefore request that you instruct Reclamation to restructure this EIS process in accordance with the recommendations below. This EIS process should then be re-launched to allow the public to be properly informed of the issues being addressed, and inviting them to contribute to something truly meaningful.

1. Accurately Represent the Baseline Issues

Reclamation must accurately articulate the severity of the issues at stake with this EIS to enable the public to adequately respond. This must include describing the nearly complete loss of the natural and cultural resources in Grand Canyon's Colorado River corridor as a result of the operations of Glen Canyon Dam, and Reclamation's failed efforts to comply with federal mandates to rectify them. This is the background and baseline situation that forced the initiation of a new EIS process, thus must be presented to the public for the NEPA process to be credible. Reclamation's omissions not only mislead the public about the issues in which they are being asked to comment, but help to reinforce a proposed action which only appears rational when viewed through such tainted lenses.

Although the impacts on Grand Canyon National Park are the sole impetus, and thus intent for this EIS, one is hard pressed to develop any grasp of these issues through Reclamation's materials. Reclamation also appears to actively avoid mentioning Grand Canyon whenever possible, preferring instead the term—"downstream resources."

This is far from a trivial matter. At best, it illustrates an ongoing pattern by Reclamation to shield the public from knowing the true impacts of Glen Canyon Dam, and at worst, reveals a fundamental disconnect within Reclamation and Interior as a whole—as to what the real issues are, and how they should be addressed.

The superlatives associated with Grand Canyon are extensive. As such, Grand Canyon is one of Interior's most featured national parks. The ecology of its river corridor, too, was once unparalleled, as was acknowledged by your predecessor, Secretary Norton:

"The native fish community in the Colorado River in Grand Canyon was once one of the most unique in the world, supporting eight species that occurred nowhere else. Of the eight native fish species, three (Colorado pikeminnow, roundtail chub, and bonytail chub) have been extirpated from Glen and Grand Canyons; one – listed as endangered (razorback sucker) – has not been observed in the system since 1991; one (humpback chub) is listed as endangered; one (flannelmouth sucker) is a candidate for listing; and the remaining two (bluehead sucker and speckled dace) appear to be doing reasonably well in the Grand Canyon although much remains to be learned about their ecology and population dynamics." (2002 Report to Congress, page 23.)

Glen Canyon Dam's role in this demise of the Canyon's native fish is unquestioned. Be it the release of water of unnatural temperature, quantity, quality, and frequency; depriving Grand Canyon of sediment and nutrients needed for natural beaches and wildlife habitat; or so severely altering the aquatic ecology of the Colorado River allowing nonnative species to displace native species. Glen Canyon Dam has become a death sentence for the main artery that nourishes Grand Canyon National Park.

Such impacts clearly run contrary to the National Park Service Organic Act which compels Interior “to conserve the scenery and the natural and historic objects and the wildlife therein and to provide for the enjoyment of the same by such means as will leave them unimpaired for the enjoyment of future generations.” The dam’s operations also run afoul of the Endangered Species Act of 1973. This is precisely why, in 1992, Congress passed the Grand Canyon Protection Act (GCPA) and forced Reclamation to complete its first EIS on Glen Canyon Dam’s operations (1995), and established a monitoring and research program with a specific mandate that Reclamation alter dam operations to reverse this decline and work to recover all native fish species in Grand Canyon National Park.

But ten years after the GCPA was passed, Secretary Norton reported to Congress that Reclamation’s efforts have failed to stem the population decline of the principle species it was mandated to protect:

“The first population estimate of humpback chub in the Grand Canyon suggests that in 1982 there were 7,000 to 8,000 humpback chub larger than 200 millimeters. Approximately ten years later, in 1992, it was estimated that there were approximately 4,000 to 5,000 humpback chub larger than 150 millimeters. In 2001, there were approximately 2,000 to 3,000 humpback chub larger than 150 millimeters. While there is some question over the accuracy of the absolute numbers, there is little question that the population of humpback chub in the Grand Canyon has declined over time. The decline in the abundance of fish larger than 150 millimeters appears to be the result of a sustained decline in recruitment beginning in 1992.” (2002 Report to Congress, page 25.)

The failure of Reclamation’s recovery efforts were further documented three years later by the United States Geological Survey’s “State of the Colorado River Ecosystem in Grand Canyon” (SCORE Report) of October 2005.

“Overall, about 15%–20% of the adult humpback chub are dying each year. If this mortality rate and the dramatically reduced recruitment rate of young chub experienced since the early 1990s remain unchanged, there will be a decline in the adult population of humpback chub from the present 3,000–5,000 fish to a level of 1,500–2,000 adult fish over the next 10–15 years.” (Page 45.)

“[D]am operations during the last 10 years under the preferred alternative of the MLFF have not restored fine-sediment resources or native fish populations in Grand Canyon, both of which are resources of significant importance to the program.” (Page 208.)

“At the same time, nonnative fish have increased in both diversity and abundance. The reasons for the decline of native fish are commonly cited to include dramatic changes in the thermal, sediment, and hydrologic regimes of the river because of the construction and operation of numerous dams in the basin, the introduction of nonnative predatory and competitive fishes, and the introduction of diseases and parasites.” (Page 208.)

“[I]t is clear that the restrictions on dam operations since 1991 have not produced the hoped-for restoration and maintenance of this endangered species. During the MLFF,

basin hydrology has varied from drought to wet conditions and then back to drought conditions. Through these conditions, the decline of the humpback chub has continued. This trend leads to questions about whether daily, monthly, or even annual patterns of dam operation alone are relevant to native fish recruitment or whether changes in the sediment and thermal regimes of the river imposed by regulation have had the greatest influence on native fishes. Further, the issue of nonnative fishes and their potential to limit recruitment of native fish through predation and competition (although highly suspected by scientists as a significant factor) remains unresolved in Grand Canyon." (P. 208.)

"[T]he relatively stable habitat conditions created under the MLFF during protracted drought conditions, coupled with a coarsening of substrate in the river channel, appear to have greatly favored rainbow trout (*Oncorhynchus mykiss*), particularly in the Lee's Ferry reach, as reflected in their increasing numbers during the last decade." (Page 214.)

"Research and monitoring have conclusively demonstrated a net loss of fine sediment from the Colorado River ecosystem under the MLFF. Closure of Glen Canyon Dam eliminated about 84% of the sand that historically entered Grand Canyon." (Page 214.)

It's now been 15 years since the GCPA was passed, and Reclamation's dam operations have made no gains in recovering a single fish species in Grand Canyon. They have only reinforced what federal scientists already had told them: that without efforts to restore natural flows, water temperature gradients and sediment transport through Grand Canyon, there is no reason to believe that recovery can occur.

Despite the compelling evidence of poor performance, you yourself stated in December 2006, that the Glen Canyon Dam Adaptive Management Program (AMP) "is a cutting edge solution that provides an effective framework and process for integrating dam operations, downstream resource protection and management, and monitoring and research. We also are able to better safeguard natural resources and improve recreational opportunities at Glen Canyon National Recreation Area and Grand Canyon National Park."

The outreach materials also use the phrase "significant progress" when describing the AMP. However, when it comes to actually achieving what the principle objective of recovering endangered species, none of this is true. The public needs to know what the true state of play is in Grand Canyon, what cultural and ecological resources that have been lost due to the operations of Glen Canyon Dam and asked if they want to see it completely destroyed through continued implementation of activities such as those contemplated by the Long-Term Experimental Plan. If the public feels such losses are acceptable then end this fabled recovery exercise altogether. If not, then Interior must become serious about implementing an EIS that will achieve that result.

2. Accurately Assess the Failed History

A. Faulty Flows

Your positive spin on the AMP notwithstanding, the fact that this EIS process is underway at all is indicative that there must be problems with the program. As such, the EIS process must first conduct an independent audit to analyze how the performance of the AMP measures with the expectations of the GCPA and the AMP's charter and strategic plan.

One of the most critical aspects of the Grand Canyon Protection Act was to modify flows from Glen Canyon Dam to improve habitat conditions for native fish. Since the Act was passed, however, both Reclamation and the AMP have demonstrated resistance to implementing the flows and other recommendations from the US Fish and Wildlife Service (FWS) to achieve this objective. Even with a demonstrated reduction in native fish populations, Reclamation and AMP have been unwilling to implement a flow regime reflecting the river's natural hydrology, known as Seasonally Adjusted Steady Flows (SASF).

"It is my biological opinion that the proposed operation of Glen Canyon Dam according to operating and other criteria of the MLFF, as described in the Draft EIS and further modified by Reclamation's June 17, 1994, memorandum, is likely to jeopardize the continued existence of the humpback chub and razorback sucker and is likely to destroy or adversely modify designated critical habitat." (Biological Opinion, page 3.)

"Operate Glen Canyon Dam according to operating and other criteria of the SASF alternative. Draft EIS Elements common to all alternatives, habitat and maintenance flows, and elements two through seven of the Reasonable and Prudent Alternative would be part of this recommendation. The SASF has been analyzed as completely as any other alternative in the Draft EIS and would not require any additional analysis." (Biological Opinion, page 42.)

Reclamation defended its position to ignore this recommendation in its 1996 Record of Decision on the Final Glen Canyon Dam EIS stating:

"...the benefits from the Seasonally Adjusted Steady Flow Alternative were uncertain given the improvement in habitat conditions for nonnative fish this alternative would provide. Seasonally adjusted steady flows also would create conditions significantly different from those under which the current aquatic ecosystem has developed in the last 30 years and would adversely affect hydropower to a greater extent than the other two alternatives. The Modified Low Fluctuating Flow (MLFF) could substantially improve the aquatic food base and benefit native and nonnative fish. The potential exists for a minor increase in the native fish population." (1996 Record of Decision, Appendix G-12.)

The principle objective of most recovery strategies is to attempt to restore native habitat conditions, in this case stream flow, for the affected species. It was precisely the conditions of the previous three decades that had brought about this decline, yet Reclamation felt compelled to preserve as many of the unnatural conditions it created during this blip in history, as opposed to initiate flows more consistent with those of the previous three million years during which these species evolved.

While Reclamation argued that it wished to be cautious and not aggressively stress the system, they had already taken a significant step in altering Glen Canyon Dam's operating regime with the MLFF preferred alternative. The modifications to the hourly up and down ramping of river flows into Grand Canyon to meet the demands of the Western Area Power Administration (WAPA) had already somewhat altered the unnatural conditions of the past 30 years. What Reclamation and WAPA were not willing to do was support further flow restriction that would compromise hydroelectric revenue streams by an estimated 25 percent should the SASF be implemented as the preferred alternative.

While the Biological Opinion noted that during periods of high water, elements of MLFF may be appropriate to the extent they were consistent with the natural hydrograph, it was unambiguous regarding what to do during low water years, as has been experienced in the Colorado River for the past seven years.

"A program of experimental flows will be carried out to include high steady flows in the spring and low steady flows in summer and fall during low water years (releases of approximately 8.23 maf) to verify an effective flow regime and to quantify, to the extent possible, effects on endangered and native fish. Studies of high steady flows in the spring may include studies of habitat building and habitat maintenance flows. Research design and hypotheses to be tested will be based on a flow pattern that resembles the natural hydrograph, as described for those seasons in the SASF." (Biological Opinion, page 35.)

"If sufficient progress and good faith effort is occurring towards initiating experimental flows, implementation of experimental flows may occur later in 1997. If the Service believes there is not sufficient progress, Glen Canyon Dam would be operated as SASF flows during spring through fall (April to October) beginning in 1998." (Biological Opinion, page 32.)

In the last two FWS responses to Reclamation regarding sufficient progress on achieving this specific element of the Reasonable and Prudent Alternative (RPA) contained within the Biological Opinion, FWS clearly stated that progress was not being achieved.

"This element has not seen sufficient progress. Other than the controlled BHBF in 1996, there have been minimum efforts to develop experimental flows for native fishes. (Review of Sufficient Progress, May 27, 1999, page 3.)

"This element has not seen sufficient progress. We agree with your assessment that the delay in developing this element is largely attributable to the to the program being part of the adaptive management process, where multiple objectives, research and work assignments compete for time and attention of AMWG members. However, given the documented decline of humpback chub in Grand Canyon, additional delays in developing a program of experimental flows for native fish should not occur. (Review of Sufficient Progress, June 13, 2002, page 3.)

In light of this lack of sufficient progress, and the fact that flows have not exceeded 8.23 MAF since 2000, the RPA further states that "...Glen Canyon Dam would be operated as SASF flows during spring through fall (April to October) beginning in 1998." (Biological Opinion, page 35.)

Further support for the urgency to embark on steady flows came in 2002 from Grand Canyon Monitoring and Research Center's (GCMRC) principle aquatic ecology partners:

"Descending hydrographs of spring and fall are the best periods for the growth of the aquatic food base. We recommend a decade of the SASF alternative, with spring beach building flows as the climate permits and unlimited hydropower ramping within 10% of the predicted seasonal mean. We feel these flows in combination with alien fish suppression and thermal modification of GCD could make Grand Canyon a sanctuary for native fishes of the Colorado River basin." (Benenati, et al., 2002, page 10.)

The frustration of FWS and others is far from surprising since there has been only one low and steady flow test carried out, that in the summer of 2000. Worse still, now seven years later, the analysis of this test has yet to be completed. This is very discouraging, as it has been 11 years since the first experimental test flow took place, and it was the 2000 experiment that demonstrated that humpback chub populations "may have benefited from substantial in-stream warming." (USGS Press Release, August 3, 2006.)

The 1996 test of a Beach/Habitat Building Flow (BHBF) at 45,000 cubic feet per second (cfs) was conducted with much fanfare, and is still highly promoted by Reclamation as a major accomplishment. However, as was reported five years ago by the American Geophysical Union concerning the experimental releases from Glen Canyon Dam to conserve sediment, "Work conducted since the 1996 controlled flood has shown that the multi-year accumulation hypothesis on which the EIS was based is false..." (Eos, American Geophysical Union, v. 83, no. 25, page 237.)

The winter fluctuating trout suppression flows of 2004 and 2005 were a hastily conceived action in response to new information about declining humpback chub estimates. As pointed out by Korman et al., June 2005, these experimental flows were proven to be ineffective and have been discontinued. Surprisingly, these flows have now been included as one of the four alternatives for the LTEP EIS submitted by AMP in December 2006. Constrained releases in the fall of 2004 and 2005 were used to test the conservation of sediment (6,500 to 9,000 cfs). This has proved useful to understand that sediment can be retained during low flows, but the experiment has not provided any direct evidence of habitat benefits to endangered fish.

In November 2004 a BHBF similar to what was undertaken in 1996 was carried out at 42,000 cfs to coincide with sediment inputs from the Paria River. This experiment was considered more successful than the 1996 BHBF experiment in distributing marginal amounts of sand, but still in insufficient quantities to have any lasting effect on critical habitat conditions. Moreover, the subsequent trout suppression flows removed any sediment gains that may have occurred.

Overall, AMP's flow experimentations have been ineffective and imbalanced, with most of the focus on failed efforts to conserve sediment. With the exception of a few months in the summer of 2000, Reclamation and AMP have ignored the principle directive by FWS to carry out steady flow experiments at various times throughout the year

To this day, when it is clear that some significant alteration of this failed flow regime must be implemented, there remains virtually no support from Reclamation or AMP to embrace establishing a flow regime consistent with the river's natural hydrology as was called for by the FWS 12 years ago.

In the AMP's "Assessment of the Estimated Effects of Four Experimental Options on Resources Below Glen Canyon Dam" (the alternatives submitted as scoping comments for this EIS on the Long-Term Experimental Plan), two of the four options would allow even less restrictions on dam operations than the current MLFF baseline. The other two would make only modest changes to the current practice, with just Option B mentioning the SASF alternative, and to be implemented for just one two-year period, and not beginning until August 2011.

B. Failure to Implement Selective Withdrawal

The 1994 Biological Opinion and the 1996 Record of Decision both stressed the need to implement a mechanism to warm the water released from Glen Canyon Dam (selective withdrawal or temperature control device). The water's constant 46 degrees (F) temperature is too cold for native fish, which evolved with an annual temperature gradient from near freezing in winter months to up to 80 degrees (F) in the summer.

In 1998 the AMP initiated environmental review for proposed modifications to Glen Canyon Dam's intake towers that would allow for selective withdrawal, but this was suspended without sufficient explanation. Parties concerned with the impacts warmer water may have on the nonnative trout fishery, as well as the project's overall costs, were seen as impeding the process. Public pressure and the continued decline of humpback chub numbers forced the NEPA process to be started anew in 2003. But here, too, the process became bogged down as cost concerns were again raised.

The situation which compelled selective withdrawal to be a core component of the AMP's strategic plan is only more serious now, but Reclamation and AMP have refused to complete the evaluation, much less get a temperature control device installed. The likelihood that such a capital investment would be required, and that warmer water may impact the trout population was known to both Reclamation and FWS when they included this common element in the ROD and RPA respectively, thus such concerns should not have impeded the implementation.

"Temperature modification has been identified as central issue to be resolved in order to develop a mainstem spawning population of HBC. ... Reclamation has been working diligently to accelerate the technical and administrative process necessary for construction of the selective withdrawal structure. ... Funding will be requested as a separate appropriation through the Federal budget process under Section 8 of the

Colorado River Storage Project Act.” (Reclamation Response to FWS Biological Opinion, April, 6, 1995, page 4.)

Only as a result of the recent settlement agreement is the temperature control device now slated to have its environmental review completed as part of the LTEP EIS.

C. Failure to Establish a Second Population of Humpback Chub

The RPA instructs Reclamation to establish a second population of humpback chub in the main stem Colorado River below Glen Canyon Dam, or in one of Grand Canyon’s tributaries. Obviously the habitat of the main stem provides the most diversity and is the logical choice. This habitat is wide and abundant throughout Marble and Grand Canyon, and much preferable to a small and isolated tributary stream.

No protocols have been fully developed for locating an appropriate site on the tributary streams for a second population. For example, the habitat conditions required, water quality, consultation with the Havasupai Nation (Havasupai Creek), and/or how modifications to the habitat will be implemented to achieve suitable habitat conditions. Nor have any studies been fully completed, or are past due, on the genetic differences between those near the Little Colorado River and other aggregations, as specifically requested by FWS.

D. Lack of Little Colorado River Management Plan

As the AMP has yet to recover habitat conditions in the main stem Colorado to allow for humpback chub to spawn, the Little Colorado River (LCR) remains their sole spawning habitat. As such, the RPA instructed Reclamation to develop a management plan for the Little Colorado River. While Reclamation claims the LCR lies outside its jurisdiction, this does not mean, as FWS has explained, that Reclamation could not have been instrumental within a 12-year period to ensure a plan is put in place.

E. Lack of Progress on a Management Plan for the Razorback Sucker

The Grand Canyon reach of the Colorado River was designated as critical habitat for the razorback sucker before 1995. FWS instructed Reclamation in the RPA to assist in developing a management plan to re-establish habitat to support viable populations in Grand Canyon National Park. While a workshop has been conducted, it did not, as FWS stated, provide sufficient information to aid in the development of a plan and Reclamation has not been responsive to helping to identify recovery sites that provide spawning, nursery areas, floodplain, temperature and other aspects for restoration potential.

The directives set forth by the Grand Canyon Protection Act, the ROD and the RPA were clear, as were those set out in the AMP’s charter and strategic plan, but Reclamation and the AMP refuses to work to meet even these basic benchmarks, much less exhibit the forward thinking and pro-active leadership to bring about resource recovery in Grand Canyon. How can the public expect that such resistance will be any less apparent in future management plans for operations at Glen Canyon Dam?

3. Failure of the AMP Administration and Science

A. Address the Lack of Appropriate Leadership

The ROD called for the establishment of the AMP as a stakeholder group to advise the Secretary of the Interior on implementation of Grand Canyon programs. Known as the Adaptive Management Working Group (AMWG), this group is dominated by representatives of the seven basin states, hydropower marketers and consumers, along with environmental and recreation interests. These representatives have no legal responsibility, but have been given de-facto decision-making authority for determining the fate of Grand Canyon's River ecosystem. While promoted as an all-inclusive mechanism to ensure everyone interested in Grand Canyon's recovery have their say, this big tent strategy has proven to be nothing more than a convenient buffer to defend Interior against critics who challenge the lack of progress on mitigating the impacts of Glen Canyon Dam.

As exemplified by AMWG's unwillingness to comply with RPA programs, the decline in humpback chub, the extirpation of the razorback sucker, continued loss of essential sediment, and accelerated degradation of archeological sites, the AMWG has clearly failed. After 12 years of squandering public funds at the expense of Grand Canyon's river ecosystem, AMWG's proposed action for the LTEP only further illustrates that the group is more focused on self-preservation than in the resource it is supposed to protect.

This EIS is the result of interventions by parties outside AMP, due to the AMP's lack of commitment to undertake their responsibilities as defined by their strategic plan, charter or the Grand Canyon Protection Act. There is no need for most of these "stakeholders" to have a seat at the decision-making table. The management process for the river corridor in Grand Canyon is guided by federal laws that are not in need of a stakeholder group's interpretation or obfuscation.

The primary interest in the preservation of cultural and natural resources downstream of Glen Canyon Dam resides with the National Park Service, the Fish and Wildlife Service, and the Tribes. Reclamation should have no role in the decision-making as it relates to GCPA compliance. This should have been quite evident as early as 1995 when Reclamation clearly stated it was not interested in recovery of endangered species, only removal from jeopardy.

"By definition, the elements of an RPA describe an alternative action, which will avoid the likelihood of jeopardy, as opposed to actions to achieve recovery. The elements of the RPA seem to be focused on recovery. ... Recovery actions should be included in the Opinion only as a conservation recommendation." (Reclamation Response to FWS Biological Opinion, April, 6, 1995, pages 2-3.)

"We fully recognize our responsibility under Section 7 of the ESA to not only avoid action which will result in jeopardy to listed species, but a Federal agency we are also directed to utilize resources in furtherance of the ESA through carrying out programs for

conservation of endangered species.” (Reclamation Response to FWS Biological Opinion, April, 6, 1995, page 3.)

This statement is farcical. Were it true:

- The Biological Opinion it refers to would have been completed several years earlier, as Reclamation would not have dragged its feet on completing the original EIS, which commenced in 1989. No, only as a result to an act of Congress, the GCPA itself mandating completion of the EIS, did Reclamation finally, “recognize its responsibility under Section 7 of the ESA.”
- Reclamation would not have been quibbling with FWS over if and where such recovery objectives should be contained in an FWS Biological Opinion, or later arguing about subsequent recommendations in FWS’s response to Reclamation’s insufficient progress to the RPA. No, Reclamation would be embracing FWS advice on how recovery can best be achieved.
- No settlement agreement mandating yet another EIS would have been required to resolve Reclamation’s continued failure to comply with Section 7 of the ESA, and no letter such as this would have had to be written outlining the obvious deficiencies with Reclamation’s recognition of its responsibilities under the ESA and GCPA.

It is long past due for Interior to remove Reclamation of any role relating to how Glen Canyon Dam will be operated to ensure compliance with the GCPA. You must immediately direct NPS and FWS to be Interior’s primary voices cooperating with scientists in advising you as to how Reclamation must operate Glen Canyon Dam, as the GCPA states, “[T]o protect, mitigate adverse impacts to, and improve the values for which Grand Canyon National Park and Glen Canyon National Recreation Area were established, including, but not limited to natural and cultural resources and visitor use.”

Reclamation and all as other parties are free to intervene as allowable by law, but they should no longer be utilized to create an unnecessary ad hoc group that has a proven track record of ineffectiveness and obstructionism.

B. Cease to Support the Competing Objectives

Since the time of drafting the first EIS for Glen Canyon Dam, completed in 1996, there have been two distinct forces working against recovery of native fish in Grand Canyon: hydropower generation and nonnative fish protection. Nowhere in the Grand Canyon Protection Act is there any direct or indirect reference to these interests, yet they have become a major force nonetheless. Both have representatives in the AMWG, and of the 12 goals in the AMP Strategic Plan, two accommodate these interests directly:

- Maintain power production capacity and energy generation, and increase where feasible and advisable, within the framework of the Adaptive Management ecosystem goals.

- Maintain a naturally reproducing population of rainbow trout above the Paria River, to the extent practicable and consistent with the maintenance of viable populations of native fish.

As noted above, one of Reclamation's primary rationales for adopting the MLFF was to preserve hydropower benefits that would have been lost had Reclamation followed the SASF recommendations of FWS. Nearly every issue affecting dam operations within the AMP program is heavily debated and influenced by hydropower interests. Whether it be a Beach/Habitat Building Flow (BHBF), that causes more water to pass through the dam in excess of what the generators can accommodate, or running low flows in the summer months far below what hydropower interests would prefer, hydropower interest represent a major stumbling block to independent scientific experimentation necessary to allow for species recovery in Grand Canyon National Park.

Efforts to find balanced flow regimes that benefits both endangered fish species and hydropower are irrational as the science shows clearly that steady-state water flows are more beneficial to native fish, whereas they compromise hydropower revenues. Additionally, as the primary source for AMP funding is to come from hydropower revenues, having these interests in the decision-making process regarding recovery management choices, adds further to this conflict of interest.

The Grand Canyon Protection Act clearly recognized that to achieve its objective of mitigating Glen Canyon Dam's impacts to achieve habitat restoration for endangered species, hydropower production and revenue losses would likely be incurred. Section 1809 of the Act, "Replacement Power," deals solely with this issue.

"...shall identify economically and technically feasible methods of replacing any power generation that is lost through adoption of long-term operational criteria for Glen Canyon Dam as required by Section 1804 of this title. The Secretary shall present a report of the findings, and implementing draft legislation, if necessary, not later than two years after adoption of long-term operating criteria. The Secretary shall include an investigation of the feasibility of adjusting operations at Hoover Dam to replace all or part of such lost generation. The Secretary shall include an investigation of the modifications or additions to the transmission system that may be required to acquire and deliver replacement power." (Grand Canyon Protection Act, page 5.)

Furthermore, while the GCPA makes specific references to preserving flows to meet water delivery allocations, it makes no such reference as regards to power generation. Therefore, the only responsibility power interests should have is to undertake their own necessary planning for power sales and distribution, based on mitigation strategies necessary to achieve compliance with the Act. They should have no role in determining how, when or if any such strategies are implemented.

The same holds true for the protection of nonnative fish. The AMP wants to protect rainbow trout populations in one section of the river, while it has spent upwards of \$800,000 annually to remove them downstream.

It is known that cold-water and warm-water nonnative fish, such as rainbow trout and catfish, predate on juvenile humpback chub. (Marsh and Douglas, 1997; Gorman, et al. 2005.) Other studies have documented trout predation on threatened native fish, such as speckled dace and bluehead sucker. In January 2003, GCMRC's mechanical trout removal crew caught a rainbow trout with a flannelmouth sucker in its mouth (USGS press release of 3/4/2003).

While some assert that the real problem is brown trout predation on humpback chub, since an individual brown trout is more likely to include fish in its diet than an individual rainbow trout, the higher concentration of rainbows over brown trout causes rainbow trout to exert a higher overall impact on humpback chub. Estimates suggest that prior to recent trout removal near the Little Colorado River confluence, there were about 39 times more rainbow trout than brown trout. (SCORE Report, page 48.)

The National Park Service, which itself once stocked trout in Grand Canyon tributary streams, has abandon this practice altogether, and has even erected weirs in an attempt to impede trout populations from spawning in these tributary streams.

As has been demonstrated during the recent drought, the warmer water, combined with low levels of dissolved oxygen, from Glen Canyon Dam releases have contributed significantly to reducing rainbow trout populations above the Paria River, so much so that Arizona Game and Fish had contemplated a restocking program prior to threatened litigation. Putting in more fish when there's no food will merely force them to migrate downstream to survive, potentially exacerbating the problems for the humpback chub.

Attempting to preserve this nonnative trout fishery stands in direct conflict with a principle requirement of the AMP: to implement the selective withdrawal program to increase the water temperature being discharged from the dam. Nonnatives have thrived in the cooler waters, while the natives continue to decline.

Such counterproductive objectives and stakeholders must be removed from the AMP process.

C. Address the Lack of Scientific Rigor A central component of the original AMP design was the development and administration of an independent, peer-reviewed science program. This program would carry out unbiased scientifically credible studies to inform the AMP's decision-making process. A small science staff (less than 12) was to administer the program through the competitive bidding process and to award research contracts to the most competent bidder. Both the bidding process and final reports were to be peer-reviewed to assure quality and non-biased reporting.

The GCMRC, the science management component of the AMP, is now operating much differently than established in the original guidelines set for this administrative component of the USGS. The science staff is very large and most programs are being done in-house with no independent peer-review.

Prior to the EIS the Glen Canyon Dam Environmental Studies program was seriously criticized by the National Research Council (NRC) for this same failure to meet

accepted methods to assure scientific credibility. An independent review of the current AMP science program would reveal a loss of integrity and standing when the original model was abandoned in favor of what currently exists today in the GCMRC.

At a time when the Grand Canyon is about to lose another native fish species, the AMP has cut back on scientific work, seemingly at the request of the Western Area Power Administration, whose hydropower revenues are used to fund the science. The research for the 2000 Low, Summer Steady Flow (LSSF) represents one of the most blatant examples of how the AMP science program has been affected. First, the experiment was fast tracked, with limited opportunity for outside input or competitive bidding for the monitoring. Pre-experiment flow data was not compiled and therefore the design of the experiment may not have been properly formulated. Scientists did not start collecting data on the river until after the first spike flow occurred. Although the design of the experiment was released for the competition, the one proposed by the contractor was not accepted. Also, this experimental flow was originally proposed to benefit native fish with relatively low, steady flows in accordance with the Biological Opinion, but the final experiment allowed for less than the recommended time.

The 1995 EIS assumed that experimentation and recovery efforts would be achieved with firm attention paid to proper scientific protocol and management of public funds toward endangered species recovery in Grand Canyon National Park. This is not occurring. In fact the opposite is true. The AMP has enacted budget reductions and caps without supplemental funds to adequately maintain and preferably improve monitoring and research in Grand Canyon National Park. Finally, AMP is not providing adequate management leadership while the USGS/GCMRC is not contributing credible independent data required by the mandates prescribed by the ROD, RPA and subsequent charters and guidelines.

It's unfortunate that the same weakness observed by the National Research Council in 1999, are still as relevant today: "The adaptive management chapters of the strategic plans suffer from the following weaknesses: (1) lack of clarity of the Center's roles within the Adaptive Management Program; (2) inadequate discussion of competing goals and "visions;" (3) lack of clearly-defined linkages between adaptive management, ecosystem management, and social learning; (4) disparate management objectives and information needs; (5) inadequate definition of the core adaptive management experiment; (6) insufficient contingency planning; (7) insufficient decision analysis; and (8) uneven progress toward independent program review." (Downstream: Adaptive Management of Glen Canyon Dam and the Colorado River Ecosystem, National Science Council, page 59.)

The AMP has run amuck with no clear leadership or direction. It's not that its mission has been unclear, but its structure is functionally incapable of achieving it.

Unless these shortcomings are addressed, revising its work plan through a new EIS will only exacerbate, not resolve, these problems. To that end, the AMP must discard AMWG and put in place an advice and decision-making apparatus based primarily on scientific principles. A wholly independent scientific body should be commissioned, that

works with the Park Service, FWS and Tribes to achieve the goals of the Grand Canyon Protection Act. Reclamation must no longer play any leadership or advisory role, in the AMP process, merely furnish any necessary information, and follow through on implementing operational changes at Glen Canyon Dam.

4. Must Revise the Proposed Action

Reclamation states that the, "Adoption of a Long-Term Experimental Plan is needed to ensure a continued, structured application of adaptive management in such a manner as to protect, mitigate adverse impacts to, and improve the values for which Grand Canyon National Park and Glen Canyon National Recreation were established." (Federal Register Notice of 12/12/2006.)

Given that no significant progress has been made, and neither Reclamation nor the AMP has demonstrated the willingness to carry out the structured application of adaptive management that has already been put before them, along with known contradictions and decision-making impediments, why would such a process be continued?

It should be noted that the LTEP being conceived through this EIS process itself is the result of the failure of the AMP to complete its assigned tasks. This plan was launched in 2004, with the goal of finalizing the plan in 2005. It was not to be taken on by Reclamation as a convenient mechanism under which to attempt to comply with the conditions of the 2006 settlement agreement.

Reclamation's proposal to undertake the LTEP only further illustrates its inability to address the totality of issues that Reclamation's policies are having on Grand Canyon National Park. While some experimentation may indeed need to continue, experimentation is merely a tool, and should not be an objective in and of itself. It is precisely such reasoning that has lead to the downward spiral of resources in Grand Canyon. So long as experimentation continues, Reclamation has felt that it has been fulfilling its duty to the public, although throughout this time the natural and cultural integrity of Grand Canyon's river corridor has only worsened.

The EIS's stated objective must be to develop alternatives that will bring about the preservation and recovery of the natural and cultural resources of the Colorado River corridor through Grand Canyon National Park and Glen Canyon National Recreation Area. To what extent Glen Canyon Dam's continued operations impedes or compliments this objective can then be evaluated through the standard practice of identifying the alternatives.

Further experimentation may or may not be warranted, but if so they should represent components of alternatives to achieve specific resource recovery and preservation objectives, not the objective of the EIS itself. Moreover, how and if the current elements and structure of the AMP are to be "continued" must be subject to the same principle: they must demonstrate how their continuation will help realize the successful implementation of the alternative, when history has proven otherwise.

5. Issues to be Addressed in the EIS

A. Reformulate the AMP's decision-making structure

To avoid repeating the past failings of the AMP, the EIS must contain an independent review of the AMP's progress to date in fulfilling its charter, strategic plan, the elements of the ROD and the RPA. This should include evaluating all experimentation to determine what baseline knowledge currently exists, and gaps if any need to be filled. All current and former GCMRC employees and consultants should be surveyed to determine their views on the efficiency and rigor of the experimentation to date and the leadership and follow through by GCMRC and the AMWG with regard to scientific findings. The review must address the issue of competing objectives, such as hydropower generation and exotic trout preservation, which have influenced management actions. How well the current AMP has addressed the 1999 National Research Council findings in Downstream: Adaptive Management of Glen Canyon Dam and the Colorado River Ecosystem should also be addressed.

These findings should be used in developing the framework for a new AMP decision-making structure to replace the AMWG comprised solely on those agencies with primary jurisdiction over the management of those downstream cultural and natural resources in Glen Canyon National Recreation Area and Grand Canyon National Park. The findings should also be used to establish a wholly independent GCMRC outside of the DOI to militate against agency bias in the quest for the best science to guide resource protection.

B. Consider climate variability and change

At an increasing rate, federal scientists are warning that DOI should prepare for flow reductions on the Colorado River in upwards of 10 to 40 percent as we continue through this century. The DOI must partner with National Oceanic and Atmospheric Administration to ensure the most up-to-date climate modeling is applied in evaluating each alternative's flexibility to climate variability. Particular attention must be given to evaluating alternatives against scenarios where Lake Powell reservoir has not only reached dead pool, but remains at dead pool over multiple years.

C. Identify appropriate timeframe

Based on the findings of the independent review, the EIS team should determine over what time frame, if any, the alternatives contained within this EIS should be implemented. Some proposals offered already for a ten-year timeframe are arbitrary, and are based on no scientific rationale as to whether or not certain outcomes may or may not be determined within such a period. The development of alternatives should focus first on determining what are the inputs necessary to achieve restoration and recovery, and then determine the appropriate timeline for delivery and evaluation.

D. Focus on native fish recovery

The EIS must identify specific baseline objectives for nonnative fish suppression, sediment and nutrient concentration, temperature gradients and flow characteristics that

are believed to stimulate recovery of critical habitat for Grand Canyon native fish. It must then evaluate how each alternative will achieve these objectives for the humpback chub population in the Little Colorado River, the establishment of a second humpback chub population downstream of Glen Canyon Dam, the establishment of razorback sucker habitat, and lastly, habitat for reintroduced bonytail chub, roundtail chub and Colorado pikeminnow.

E. Provide for flows that mimic the natural hydrograph

Flow decisions should be evaluated in accordance with how well they mimic the natural hydrograph. This is the principle behind the recommendations from FWS in their 1994 Biological Opinion, but has yet to be embraced by the AMP. As a result, all of AMP's flow recommendations should be rejected as none ensure that seasonally adjusted steady flows will be initiated any time soon. Steady flows will improve the productivity of the aquatic food base at higher trophic levels, and create the greatest opportunity for establishing a second population for the humpback chub, and create habitat for the razorback sucker as called for in the RPA and the Strategic Plan.

F. Address sediment augmentation

Much of AMP's focus has been on marginal to failing efforts to push small amounts of sediment and organic debris around Grand Canyon, while providing no demonstrated benefits for the habitat conditions of endangered fish. There is an urgent need for sediment and nutrients to be introduced back into the mainstem. The prospect of mechanical sediment augmentation, which would place Lake Powell sediment, carbon and other nutrients into the Colorado River below Glen Canyon Dam, has been discussed by AMP, but not acted upon. Implementing an immediate plan for sediment augmentation must be addressed by this EIS.

G. Recommend temperature control device for selective withdrawal

The EIS must recommend the installation of temperature control devices onto Glen Canyon Dam's intake structures. This project is already eight years behind schedule, despite being a top priority in both the ROD and RPA. Recent discussions have suggested that an alternative is being evaluated to construct devices on only two of the eight intakes. This would allow for only minimal changes to the temperature of the water, and will likely prove to have little value for experimental or habitat recovery purposes. Reclamation modeling also shows that the increase of temperature from a two-unit TCD is too modest, and insufficient for sustaining warm temperatures over time. The EIS must recommend that all eight penstocks be retrofitted at one time to maximize experimental flexibility, and thus the potential for achieving a positive result for native fish recovery.

H. Remove nonnative fish

The EIS should evaluate any and all reasonable mechanisms for nonnative fish suppression as necessary to improve habitat conditions for native fish. The EIS should

recommend that all stocking of nonnative trout cease below Glen Canyon Dam and that dam operations not be modified in any way to intentionally benefit nonnative fish habitat.

I. Address potential water quality impacts

With the probability of Lake Powell's conservation pool being exhausted during the timeframe of the proposed action, the potential for significant changes in the chemistry and quality of water flowing into Grand Canyon cannot be ignored. Anaerobic bacteria, hydrogen sulfide, and supersaline and metal-rich sediments are just some of the existing substances that could find their way through the dam's bypass tubes. The EIS must evaluate what these impacts might be, and how they would be mitigated.

For example, Reclamation was compelled to deal with low dissolved oxygen levels from the turbines at Glen Canyon Dam last winter. A plume of oxygen-depleted water reached the penstocks at the dam. The oxygen was depleted by decaying organic matter, because the Colorado and San Juan rivers are eroding into the exposed sediment deposits of Lake Powell due to the drawdown of the reservoir. The US Supreme Court has decided (*S.D. Warren v Maine*) that threats to water quality are the responsibility of the dam operators to mitigate. The EIS should also address the operational and safety impacts of coarse sediments flowing through Glen Canyon dam during low reservoir levels.

J. Establish sediment distribution to protect archeological resources

Archeological resources along the river continue to be threatened by the lack of sediment. The terraces of sediment that host hundreds of the cultural sites continue to slough off and move towards the river. As a result, artifacts must be removed, as opposed to being protected in-situ as prescribed by historic preservation legislation.

The EIS should mandate that a comprehensive cultural site degradation abatement program be established throughout the entire river corridor in accordance with NPS standards. To the extent high flows are implemented, they should be in a range that greatly exceeds 45,000 cfs, in order to provide the greatest opportunity for distribution of sediment to the affected archeology sites.

Many of the sites now suffering the greatest impacts due to erosion are those above the 120,000 cfs terrace, thus flows of this magnitude must also be accommodated.

Providing infill for the arroyos in the high benches of the river would be a great asset to the preservation of cultural sites. The benefits of sediment augmentation should also be examined to improve archeological resource stabilization.

K. Consider dam decommissioning

The most effective way to protect and restore the culture resources in Glen Canyon National Recreation Area and Grand Canyon National Park is to return all the natural processes which allowed these resources to evolve. The most effective way to achieve this is to decommission Glen Canyon Dam. As such, the decommissioning alternative must be evaluated.

L. Identify program funding sources

At current reservoir levels, it is possible that power generation, and thus CRSP and AMP revenue streams could be brought to a standstill by the time this EIS is completed. Two more years of flows at 50 percent of normal would lower Lake Powell to the point where power production is no longer possible. The potential for power revenue streams for AMP activities and research could be affected during the timeframe for the proposed action, thus the EIS must address how this may affect each of the alternatives. It must also address how funding will be made available for large capital expenses, such as selective withdrawal or sediment augmentation.

M. Establish a scientific baseline and conceptual modeling

There are currently no control sites for AMP experiments. In the book, *Downstream: Adaptive Management of Glen Canyon Dam and the Colorado River Ecosystem*, the National Research Council (National Academy of Sciences) has recommended that Cataract Canyon above Lake Powell would serve this purpose, but there has been no action on the part of the AMP or GCMRC to seize this opportunity. The EIS must mandate that establishing such controls be a top priority in further experimentation.

The EIS must also mandate the completion and implement a conceptual ecosystem modeling plan.

N. Complete a management plan for the Little Colorado River

Reclamation must ensure the development of a management plan for the Little Colorado River. This plan specifically should address a hazardous material component to protect humpback chub against toxic chemical spills. With the sole remaining Grand Canyon humpback chub population concentrated at the mouth of the Little Colorado River, they are particularly vulnerable to extinction should any water contamination accident or other stochastic event occur in this tributary. A chemical spill occurred at Lake Havasu last year affected the water of the reservoir.

Increasing the range of the critical habitat designation in the Little Colorado River should also be explored to further promote translocation programs for the humpback chub up this tributary.

CONCLUSION

The importance of an Adaptive Management Program to ensuring the future health and vitality of the globally significant Grand Canyon ecosystem cannot be overstated. However, growing evidence demonstrates not only an ongoing decline in many key indicators, but an inability of Reclamation and AMP to manage the recovery tasks asked of them. Without major changes in how this program is operated, the public should prepare itself for the ongoing declines in the cultural and natural resource base of Colorado River below Glen Canyon Dam.

The launching of a new EIS process on Glen Canyon Dam operations affords an excellent opportunity to deliver to reverse this trend. Unfortunately, the Long-Term

Experimental Plan proposed action illustrates that Reclamation is not yet serious about seizing this opportunity, but merely going through the motions in an effort to comply with the settlement agreement.

Grand Canyon National Park, and all those who cherish it, deserve better. The future of Grand Canyon is at a critical decision point. We hope you, as its principle steward, will take the corrective actions outlined above so that a truly valuable EIS process can get underway, and the Colorado River ecosystem through Grand Canyon can finally get on the road to recovery.

Sincerely yours,

John Weisheit, Conservation Director
Living Rivers & Colorado Riverkeeper

Michelle Harrington, Rivers Program Director
Center for Biological Diversity

Giving up on Grand Canyon! Groups Demand Interior Department Revamp Approach

For Immediate Release: February 28, 2007

Contact: John Weisheit, Living Rivers, (435) 259-1063, (435) 260-2590 (cell)
Michelle Harrington, Center for Biological Diversity, (602) 628-9909

MOAB, Utah— In a 21-page letter sent today to Interior Secretary Dirk Kempthorne, conservation groups Living Rivers/Colorado Riverkeeper and the Center for Biological Diversity demanded that the Secretary revise his plan to support a failing Colorado River restoration project in Grand Canyon National Park.

A 12-year-old program that was established to mitigate the impacts of Glen Canyon Dam, upstream of Grand Canyon National Park, is undergoing environmental review for a new set of experiments. The groups charge that continuing activities under the current

framework would be a death sentence for the remaining native species trying to survive the extensive ecological changes the dam's operations have brought to Grand Canyon.

"If their approach doesn't change, the end result will be more of the same," says John Weisheit, of Living Rivers. "Study after study clearly illustrates the current program is a disaster."

Citing findings from the National Research Council, U.S. Fish and Wildlife Service, U.S. Geological Survey and former Interior Secretary Gale Norton, the groups outline how the Glen Canyon Dam Adaptive Management Program has failed in its mission to reverse the decline of cultural and natural resources in Grand Canyon National Park as directed by the 1992 Grand Canyon Protection Act.

- Habitat conditions for endangered native fish like the humpback chub have not been improved, so its numbers have declined since the program began. Plans to reintroduce other endangered species lost to Glen Canyon Dam's operations have stalled.
- Requirements of the Fish and Wildlife Service to operate the dam more consistently with the river's natural water levels and rates of flow are repeatedly ignored .
- Hydroelectric-power interests override conservation objectives and hamstringing progress .
- Recommendations by scientists are ignored and critical studies, such as the 2000 low summer steady flow experiment, are left incomplete .

The main problem, the groups point out, is not how to mitigate the dam's impacts to allow Grand Canyon's recovery to begin, but the deeply flawed decision-making structure that impedes sound science from fulfilling the objectives of the Grand Canyon Protection Act.

"Glen Canyon Dam has caused the nearly complete loss of the natural and cultural resources in Grand Canyon's Colorado River corridor ," says Michelle Harrington with the Center for Biological Diversity. "The Adaptive Management Working Group has failed in its work and needs to be cut off."

Prior to Glen Canyon Dam, the Colorado River in the Grand Canyon supported one of the most unique fish communities in the world — eight species that existed together nowhere else on earth. Four are already gone, one has not been seen since 1992, and another, the humpback chub, has declined to the brink of extinction with just a few thousand fish.

This Environmental Impact Statement process was launched as part of a settlement reached in September 2006 between the Center for Biological Diversity, Living Rivers, Glen Canyon Institute, Sierra Club and Arizona Wildlife Federation, and the Department of Interior to address the worsening habitat conditions for endangered native fish in Grand Canyon.

“We chose to settle the lawsuit with the understanding that the environmental review would comprehensively address immediate recovery needs for endangered species in light of the documented failings of the Adaptive Management Program, but it appears Interior had no such intention,” adds Harrington.

The groups have asked Secretary Kempthorne to abandon the Environmental Impact Statement’s focus from a hastily conceived set of experimental options prepared by the Adaptive Management Working Group to a broad examination of the Adaptive Management Program process to date. They urge removal of the Bureau of Reclamation as an adviser on Grand Canyon issues, establishment of a truly independent scientific research and advisory mechanism to ensure ecological integrity, and a thorough examination of all options available to improve habitat conditions, including decommissioning Glen Canyon Dam.

“It’s time to stop pretending that this program can work,” concludes Weisheit. “Let’s either agree that the public does not care about Grand Canyon National Park’s unique river ecosystem, and spend these so-called conservation resources elsewhere, or get serious about reviving them as Congress mandated through the Grand Canyon Protection Act.”

[Living Rivers](#) is a nonprofit organization dedicated to the restoration of the natural hydrological and ecological processes within the Colorado watershed to protect native species and their habitats.

[The Center for Biological Diversity](#) is a nonprofit conservation organization with over 32,000 members dedicated to the protection of imperiled species and their habitats.

Regional News 03/01/07

Shortage Criteria: Reclamation announces publication of DEIS and public meetings

Public Hearings Scheduled in Nevada, Arizona and Utah

The Interior Department's Bureau of Reclamation today released for public review and comment a Draft Environmental Impact Statement (EIS) on proposed interim guidelines for managing the Colorado River Storage System under drought and low reservoir conditions.

When approved the guidelines would be used for determining shortages in the Lower Colorado Basin and coordinating operations for Lake Powell and Lake Mead reservoirs.

As part of its efforts to seek public input on the draft EIS, Reclamation has scheduled three public hearings to receive written or oral comments.

Meeting dates, times and locations are:

- Tuesday, April 3, 2007 – 6 p.m. to 9 p.m.
Henderson Convention Center, Sierra Room
200 South Water Street
Henderson, Nevada
- Wednesday, April 4, 2007 – 6 p.m. to 9 p.m.
Phoenix Airport Marriott, Buckhorn Room
1101 North 44th Street
Phoenix, Arizona
- Thursday, April 5, 2007 – 6 p.m. to 9 p.m.
Hilton Salt Lake City Center, Canyon Room A & B
255 South West Temple
Salt Lake City, Utah

New experimental plan for Glen Canyon Dam operations likely to fall short, critics say

April Reese, Land Letter Western reporter

The Bureau of Reclamation is putting together a long-awaited, revised plan to experiment with various flow regimes and other efforts to restore the Grand Canyon ecosystem downstream from Glen Canyon Dam. However, environmental groups that previously filed suit to force the agency to craft the new plan say preliminary environmental impact statement documents indicate that the agency is not committed to fully recovering the canyon's resources.

The groups, Living Rivers and the Center for Biological Diversity, say that there is really nothing new in the bureau's latest proposal, and that it fails to acknowledge the shortcomings of the current flow management program. In a 21-page letter sent to Interior Secretary Dirk Kempthorne last week, the groups urged Interior to reassess its approach.

"As presently conceived, this EIS does not sufficiently focus on the fundamental objective of recovering downstream resources," the groups wrote.

The groups cited drafts of an environmental scoping report that is expected to be released later this month.

According to the Bureau of Reclamation's scoping announcement for the EIS, issued last November, the proposed plan would lay out a "structured, long-term program of experimentation" that could include altering dam operations, modifying intake structures in the dam, and removing non-native fish species below the dam.

For the past 11 years, Reclamation has been working under a dam operations plan from 1996 but is required under the Grand Canyon Protection Act to make sure operations are adequately protecting Grand Canyon resources. Under the 1996 plan, Reclamation has been operating the dam to create "modified low fluctuating flows," an approach that environmentalists and some scientists have criticized as insufficient to protect endangered fish and other downstream resources.

The agency, under the guidance of the Glen Canyon Adaptive Management Program, which involves various agencies and stakeholders and aims to assess the effects of dam operations and propose any necessary adjustments, have conducted several experiments over the past 10 years, including a "low steady flow" in the summer of 2000, a "beach habitat building flow" in 2004, the translocation of humpback chub and the removal of non-native fish.

In a recent lawsuit, CBD, Living Rivers, the Glen Canyon Institute and the Sierra Club argued that the program's efforts were not recovering endangered humpback chub and that the program was in violation of the Endangered Species Act.

The new EIS is the result of a settlement between the groups and the Department of Interior.

Reclamation plans to heavily weigh recommendations from the Adaptive Management Program, which includes an inter-agency team of scientists and managers.

The program has proposed four experimental options to include in the document, including one that calls for "seasonally adjusted steady flows" for increasingly longer periods over several years, two others that would allow for wider fluctuating annual flows, which would benefit hydropower, and another calls for a combination of steady flows in late summer and early fall and wider fluctuating flows during the rest of the year.

Bad habits repeated?

Michelle Harrington of the CBD's Phoenix office said that the groups settled the lawsuit with the understanding that the new environmental review would address the immediate recovery needs of the humpback chub and other endangered species and would result in some changes to the adaptive management program. "It appears that Interior had no such intention," she said.

"There's a habit that's being repeated here, which is 10 years of not complying with the Grand Canyon Protection Act," added John Weisheit, conservation director for Living Rivers.

The groups want to see Interior undertake a broad analysis of the effectiveness of the program's efforts to date and make any changes necessary.

"It's time to stop pretending that this program can work," said Weisheit, who has advocated decommissioning or breaching Glen Canyon Dam.

While the dam, built in the 1960s, allows for water storage in Lake Powell and for power generation, it has also altered the river ecosystem downstream, regulating flows that once raged and wimpered, cooling water temperatures and removing sediment that endangered fish once depended on to hide from predators.

A report issued in 2005 by the Grand Canyon Research and Monitoring Center, overseen by the U.S. Geological Survey, concluded that the canyon's resources had not made progress toward recovery under the modified low fluctuating flow regime (MLFF).

"MLFF is what we've been running since 1996 and the 2005 report basically says every resource has declined," said Nikolai Ramsey of Grand Canyon Trust, who serves on the Adaptive Management Work Group and helped craft the steady flow option in the group's recommendations. "It doesn't work."

While Reclamation has been experimenting with varied water release levels to try to help restore downstream resources, the agency has only once undertaken the kind of nature-mimicking experimental flow recommended by the U.S. Fish and Wildlife Service, in the summer of 2000, the groups say. And the results of that experiment still have not been adequately studied, they contend.

Fish population improvement seen According to data released by the U.S. Geological Survey in August, the canyon's adult humpback chub population increased to 5,000 fish between 2001 and 2005, up from about 3,500 in 2002. Scientists also found more juvenile and newly hatched fish in 2005, suggesting that the fish are successfully reproducing, according to the report. But Ramsey said as many as 10,000 fish are needed to reach recovery (Land Letter, Aug. 10, 2006).

Sam Spiller, a FWS biologist who represents the agency on the Glen Canyon Dam Adaptive Management Work Group, said option C, which FWS and the National Park Service helped develop, would help recover the chub while also providing for power needs. That option calls for revisiting dam operations if humpback chub numbers fall below a certain threshold.

Efforts to maintain the endangered humpback chub include a decade of experimenting with water flows on the Colorado River. Photo courtesy of FWS. "We're in a real vulnerable mode right now with chub," Spiller said. While the population has stabilized, reservoir levels in Lake Powell are still low, and it is unclear what long-term effect that will have on the fish, he explained. A shrunken Lake Powell releases warmer water downstream, which Spiller says may be partly responsible for the recent boost in chub numbers, but warmer temperatures may also benefit catfish and other predatory non-natives. "We want warm water, but we know there are questions that come with it," Spiller said.

Spiller added that the option that calls for seasonally adjusted flows, which was proposed by the Grand Canyon Trust, would "definitely" help the fish, but may not meet hydropower needs.

Just how much consideration Reclamation needs to give to hydropower interests remains a major point of contention among stakeholders in the basin. The Grand Canyon Protection Act directs water managers to protect the resources downstream from the dam, but in a way that complies with the Colorado River Compact and other laws governing the "allocation, appropriation, development, and exportation of the waters of the Colorado River Basin."

Environmental groups say Reclamation gives too much weight to hydropower in managing the dam, while the agency contends it is one of several interests it must consider.

"[The agency] says nothing in the act says it should disturb water allocation, but it doesn't say anything about hydropower," Ramsey said.

But Randy Peterson, manager of Reclamation's environmental resources division, said the agency has to consider all of the uses on the river, including hydropower.

"Hydropower is one of the resources that we would evaluate the impacts on from any of the alternatives," he said. "The list is long."

Peterson added that while Reclamation plans to evaluate the work group's four options, it has not yet completed its analysis of all of the scoping comments it has received, and the actual alternatives proposed in the forthcoming draft EIS could be very different.

Peterson emphasized that the purpose of the new plan is not to completely overhaul dam operations. "It is an experiment," he said. "It's not a wholesale revision of previous decisions. It's trying to find answers to important scientific questions." The agency hopes to have the answers to those questions by the end of the experiment, which will likely span seven to 10 years, Peterson said.

Reclamation's scoping report, which will include an analysis of public comments, is due this month, with the draft EIS expected in April 2008. A final document is scheduled for release in October 2008, and Reclamation hopes to begin the experimental flows in 2009, Peterson said.

LR Testimony 04/04/07

Public Meeting on Reclamation Shortage Criteria DEIS, Phoenix, Arizona

Models are only as valuable as the inputs they receive. While the sophistication and effort put into these projections are unprecedented and well appreciated, the model's inputs, however, fail to provide the public with the results necessary from which to make an informed decision as to merits of any of the proposed alternatives.

Garbage in garbage out as they say, but this garbage is so well masked that people of the Colorado River Basin are being asked to put the rubber stamp on a Katrina in the making. Those levees did not hold, and neither will the assumptions painted on what otherwise is probably a valuable model.

Scientists have been in agreement for decades that Colorado River flows of the past century were among the wettest in 1,200 years. Scientists are also in agreement that the Colorado River Basin has warmed upwards of two degrees during this period and the trend is expected to continue, compromising streamflows to upwards of 20 percent in the next 50 years.

We're now in the longest drought in recorded history. Things are changing all over the basin, but not at the Bureau of Reclamation. The results produced by their inflated inputs are based recorded historical streamflow, that while useful, in and of themselves must not alone be used to gauge future runoff.

Failing to account for a more long-term historical view of streamflows coupled with the climate change we are already experiencing is tremendously misleading to the public when developing shortage strategies.

But most importantly, we must begin to accept the reality of climate change. A ten percent reduction on long-term flow estimates show an annual deficit right now of 1.1 maf rising to 2.8 maf by 2060. Anyone will notice how the reservoirs are dropping. Adjust this to 20 percent, as an increasing number of scientists are recommending, and we're looking at a 2.6 maf deficit now and nearly 4 maf in 50 years.

We're at ground zero tonight: Phoenix, Chandler, Tucson, are not going to be protected by token changes in reservoir operations or even its ground water banking. Arizona is first in line for cuts, and there is no plan for how the state will survive if the rosy inputs put into this model evaporate away as Lake's Powell and Mead drop lower and lower.

The public is quite fortunate the National Research Council has completed its recent Colorado River report at this time. It reiterates the warnings that have yet found their way into the assumptions used by this model. We certainly hope this changes and the Final EIS will present a more realistic view of what the future may hold.

And the public would also benefit from a more comprehensive presentation of what the real benefits are to these minimal dam operational changes it is being asked to support. Chart 4.3-26 and 27 illustrate that a significant amount of water savings, at least in terms of increased levels for Lake Mead, occur not because of new operating plans that are the focus of these documents, but the result of anticipated, but as yet mostly undetermined, water conservation activities.

It's already clear in looking at the plotted data presented that at the 50th percentile, the net volume of stored water in Lake's Powell and Mead is greater under the No Action alternative than what the Basin States hope to implement. Reclamation must present a comparable analysis of strictly the reservoir operation component of the Basin States Alternative, not volumes of studies and charts based on undefined activities that may be exaggerating these limited benefits.

There is no question that the objective of this DEIS is critical, or that valuable work has not gone into developing the model, but the public is anxiously awaiting some assurances that the water managers they rely on will develop a real strategy to guide us through what looks to be a very parched future ahead.

Unfortunately, Reclamation is still hoping history repeats itself, and high flows will bail us out as demand continues to grow and temperature continues to rise. But we're already at the end of what the river has historically provided. There's no water left and climate change is taking what's there back. It's time for Reclamation to admit this, and get on with the real task ahead: developing a solution for managing a system headed for failure.

Permanent drought predicted for Southwest

Study says global warming threatens to create a Dust Bowl-like period. Water politics could also get heated.

By Alan Zarembo and Bettina Boxall
LA Times Staff Writers

The driest periods of the last century — the Dust Bowl of the 1930s and the droughts of the 1950s — may become the norm in the Southwest United States within decades because of global warming, according to a study released Thursday.

The research suggests that the transformation may already be underway. Much of the region has been in a severe drought since 2000, which the study's analysis of computer climate models shows as the beginning of a long dry period.

The study, published online in the journal *Science*, predicted a permanent drought by 2050 throughout the Southwest — one of the fastest-growing regions in the nation.

<http://www.riversimulator.org/Resources/ClimateDocs/2007Seager.pdf>

The data tell "a story which is pretty darn scary and very strong," said Jonathan Overpeck, a climate researcher at the University of Arizona who was not involved in the study.

Richard Seager, a research scientist at Lamont-Doherty Earth Observatory at Columbia University and the lead author of the study, said the changes would force an adjustment to the social and economic order from Colorado to California.

"There are going to be some tough decisions on how to allocate water," he said. "Is it going to be the cities, or is it going to be agriculture?"

Seager said the projections, based on 19 computer models, showed a surprising level of agreement. "There is only one model that does not have a drying trend," he said.

Philip Mote, an atmospheric scientist at the University of Washington who was not involved in the study, added, "There is a convergence of the models that is very strong and very worrisome."

The future effect of global warming is the subject of a United Nations report to be released today in Brussels, the second of four installments being unveiled this year.

The first report from the Intergovernmental Panel on Climate Change was released in February. It declared that global warming had become a "runaway train" and that human activities were "very likely" to blame.

The landmark report helped shift the long and rancorous political debate over climate change from whether man-made warming was real to what could be done about it.

The mechanics and patterns of drought in the Southwest have been the focus of increased scrutiny in recent years.

During the last period of significant, prolonged drought — the Medieval Climate Optimum from about the years 900 to 1300 — the region experienced dry periods that lasted as long as 20 years, scientists say.

Drought research has largely focused on the workings of air currents that arise from variations in sea-surface temperature in the Pacific Ocean known as El Niño and La Niña.

The most significant in terms of drought is La Niña. During La Niña years, precipitation belts shift north, parching the Southwest.

The latest study investigated the possibility of a broader, global climatic mechanism that could cause drought. Specifically, they looked at the Hadley cell, one of the planet's most powerful atmospheric circulation patterns, driving weather in the tropics and subtropics.

Within the cell, air rises at the equator, moves toward the poles and descends over the subtropics.

Increasing levels of greenhouse gases, the researchers said, warms the atmosphere, which expands the poleward reach of the Hadley cell. Dry air, which suppresses precipitation, then descends over a wider expanse of the Mediterranean region, the Middle East and North America.

All of those areas would be similarly affected, though the study examined only the effect on North America in a swath reaching from Kansas to California and south into Mexico.

The researchers tested a "middle of the road" scenario of future carbon dioxide emissions to predict rainfall and evaporation. They assumed that emissions would rise until 2050 and then decline. The carbon dioxide concentration in the atmosphere would be 720 parts per million in 2100, compared with about 380 parts per million today.

The computer models, on average, found about a 15% decline in surface moisture — which is calculated by subtracting evaporation from precipitation — from 2021 to 2040, as compared with the average from 1950 to 2000.

A 15% drop led to the conditions that caused the Dust Bowl in the Great Plains and the northern Rockies during the 1930s.

Even without the circulation changes, global warming intensifies existing patterns of vapor transport, causing dry areas to get drier and wet areas to get wetter. When it rains, it is likely to rain harder, but scientists said that was unlikely to make up for losses from a shifting climate.

Kelly Redmond, deputy director of the Western Regional Climate Center in Reno, who was not involved in the study, said he thought the region would still have periodic wet years that were part of the natural climate variation.

But, he added, "In the future we may see fewer such very wet years."

Although the computer models show the drying has already started, they are not accurate enough to know whether the drought is the result of global warming or a natural variation.

"It's really hard to tell," said Connie Woodhouse, a paleoclimatologist at the University of Arizona. "It may well be one of the first events we can attribute to global warming."

The U.S. and southern Europe will be better prepared to deal with frequent drought than most African nations.

For the U.S., the biggest problem would be water shortages. The seven Colorado River Basin states — Colorado, Wyoming, Utah, Nevada, New Mexico, Arizona and California — would battle each other for diminished river flows.

Mexico, which has a share of the Colorado River under a 1944 treaty and has complained of U.S. diversions in the past, would join the struggle.

Inevitably, water would be reallocated from agriculture, which uses most of the West's supply, to urban users, drying up farms. California would come under pressure to build desalination plants on the coast, despite environmental concerns.

"This is a situation that is going to cause water wars," said Kevin Trenberth, a scientist at the National Center for Atmospheric Research in Boulder, Colo.

"If there's not enough water to meet everybody's allocation, how do you divide it up?"

Officials from seven states recently forged an agreement on the current drought, which has left the Colorado River's big reservoirs — Lake Powell and Lake Mead — about half-empty. Without some very wet years, federal water managers say, Lake Mead may never refill.

In the next couple of years, water deliveries may have to be reduced to Arizona and Nevada, whose water rights are second to California.

Press Release from Lamont-Doherty Earth Observatory

New Study Shows Climate Change Likely to Lead to Periods of Extreme Drought in Southwest North America

<http://www.riversimulator.org/Resources/ClimateDocs/2007Seager.pdf>

How anthropogenic climate change will impact the arid regions of Southwestern North America has implications for the allocation of water resources and the course of regional development. The findings of a new study, appearing in Science, show that

there is a broad consensus amongst climate models that this region will dry significantly in the 21st Century and that the transition to a more arid climate may already be underway. If these models are correct, the levels of aridity of the recent multiyear drought, or the Dust Bowl and 1950s droughts, will, within the coming years to decades, become the new climatology of the American Southwest.

The study's findings have implications on policies and decision making that protects the region from such extreme climate conditions. "The arid lands of southwestern North America will imminently become even more arid as a result of human-induced climate change just at the time that population growth is increasing demand for water, most of which is still used by agriculture," said Richard Seager, Senior Research Scientist at the Lamont-Doherty Earth Observatory and one of the lead authors of the study. "The West, and in particular, the United States and Mexico, need to plan for this right now, coming up with new, well-informed and fair deals for allocation of declining water resources."

Projections of anthropogenic, or man-made, climate change conducted by 19 different climate modeling groups around the world, using different climate models, show widespread agreement that Southwestern North America—and the subtropics in general—are heading toward a climate even more arid than now. The models show that human-induced aridification becomes marked early in the current century. In the Southwest the levels of aridity seen in the 1950s multiyear drought, or the 1930s Dust Bowl, become the new climatology by mid-century: a perpetual drought.

According to the study, as the planet warms, the Hadley Cell, which links together rising air near the Equator and descending air in the subtropics, expands poleward. Descending air suppresses precipitation by drying the lower atmosphere so this process expands the subtropical dry zones. At the same time, and related to this, the rain-bearing mid-latitude storm tracks also shift poleward. Both changes in atmospheric circulation, which are not fully understood, cause the poleward flanks of the subtropics to dry.

In contrast to historical droughts, future drying is not linked to any particular pattern of change in sea surface temperature but seems to be the result of an overall surface warming driven by rising greenhouse gases. Evidence for this is that subtropical drying occurs in atmosphere models alone when they are subjected to uniform increases in surface temperature. "Our study emphasizes the fact that global warming not only causes water shortage through early snow melt, which leads to significant water shortage in the summer over the Southwest, but it also aggregates the problem by reducing precipitation," said Mingfang Ting, Doherty Senior Research Scientist also at Lamont-Doherty and one of the study's co-authors.

Drying of arid lands in the southwestern United States and northern Mexico will have important consequences for water resources, regional development and cross border relations and migration. According to the models the drying should already be underway and, over the length of time it takes to plan significant changes in water resource engineering and allocation (years to a few decades), will become well established.

The study also shows that, in addition to the Southwestern North America other land regions to be hit hard by subtropical drying include southern Europe, North Africa and the Middle East as well as parts of South America.

The study was conducted in close collaboration with scientists at the NOAA Geophysical Fluid Dynamics Laboratory. This collaboration emphasizes the close ties between Columbia University and NOAA that has developed since the establishment of the NOAA Cooperative Institute for Climate Applications and Research at Lamont in 2003.

Epic ancient drought grim news for West

Shaun McKinnon The Arizona Republic May. 18, 2007 12:00 AM

A 60-year drought struck the Colorado River during the 12th century, an epic dry period more persistent than any on record and one that suggests a similar megadrought could strike again with devastating consequences.

University of Arizona researchers found evidence of what they call the medieval drought in tree rings used to reconstruct the river's past. Reaching back to A.D. 762, the researchers drew a picture of a river with flows more vulnerable to dry periods than once thought.

What surprised the researchers most was this drought's staying power: For 25 years in the 1100s, the Colorado flowed an average of 15 percent below what is now considered normal. For 13 consecutive years in that period, the river failed to reach that normal level even once.

A recurrence of those conditions would likely drain the reservoirs that store water from the river for Arizona and six other Western states. A streak of just five consecutive below-normal years, from 2000 to 2004, emptied Lake Powell and Lake Mead of more than half of their supply.

"We didn't expect to see that severe a drought," said David Meko, an associate research professor at UA's Laboratory of Tree-Ring Research. "The individual years were not extremely dry by themselves. . . . It was year after year without having a real wet year."

The new study, which provides the longest record of the Colorado's historic flows, could also help other scientists predict the effects of climate change. A study earlier this year

predicted that warmer temperatures could reduce runoff into the Colorado and other rivers significantly.

"This shows that we can have natural events like this regardless of whether there's greenhouse warming," Meko said. "I would expect climate change, if anything, would exacerbate the type of droughts we saw in the past, putting greater and greater stress on the environment."

The UA team collected samples from living and dead trees in both the upper and lower Colorado River basin. Some of the oldest samples actually dated to about 320 B.C., Meko said, but scientists focused on the time periods with the greatest array of samples.

Using cores from living trees, researchers can examine the rings, which tell the story of the surrounding environment. A thin ring means little growth occurred, which suggests drought; a wide ring means the tree collected enough moisture to grow more.

To delve deeper into the past, scientists examined remnant wood, some of which lingered in a forest for centuries after the tree itself died. The remnants still yield a remarkable trove of data.

"This is part of ongoing work to try to understand the climate system that creates these patterns," said Christopher A. Baisan, a UA senior research specialist. "You need the basic data about what happened before you can ask questions such as 'Why were there 60 years of low flow on the Colorado?' ."

Earlier tree-ring studies found serious droughts in the 16th century, both on the Colorado and on the Salt and Verde rivers in Arizona. Other research has suggested that severe droughts swept through the West during the 1100s, forcing entire populations to flee.

This study appears to confirm that the West turned viciously dry in the 12th century and with a persistence few thought possible.

"Seeing those big droughts was a real eye-opener," said Connie Woodhouse, an associate professor at UA and co-author of the study. "Other work in the western U.S. had indicated that period was one of widespread drought. Our question was, 'How did that look in the Colorado River basin?' ."

The length of the medieval dry periods and the lack of intervening wet years would push Western states nearer to crisis than the severity of the conditions. One wet year in the midst of numerous dry years can replace some of the lost reservoir storage. A wet winter in 2005 helped the West avert possible shortages at Lake Powell.

"Having those wet years can really help with recovery," Woodhouse said.

Finding evidence of a six-decade drought in the 12th century doesn't mean a six-decade drought will occur again, Woodhouse said, but the studies help create a record that adds context to actual observations. On the Colorado, those observations, produced by

flow gauges, led state officials in the 1930s to believe the river was more robust than it turned out to be.

"The ironic thing about the gauge record is that the big droughts of the last 100 years are not much compared to the long record," Woodhouse said. "And the wet years of the early 1900s are pretty unusual."

Vile, 'scary' mussel threatening to overrun Lake Powell

By Judy Fahys

The Salt Lake Tribune

Article Last Updated: 08/10/2007

07:39:37 AM MDT

Quagga mussels have arrived in Utah. Think invasion of the boat-

motor-snatchers; think fields gasping for irrigation; think slimy creatures choking drinking-water pipes; think hydropower sputtering to a stop; think of 'Jaws' the size of thumbnails threatening Lake Powell.

The possibilities sound creepier than an environmental horror flick, ever since wildlife officials confirmed this week they've found mussel larvae at Lake Powell.

"These things are incredibly scary," said Larry Dalton, Utah's new Aquatic Nuisance Species Coordinator.

"They may represent the single largest impact to the aquatic environment that I've seen in 36 years."

Thursday, four government agencies - the Glen Canyon National Recreation Area, the Utah Division of Wildlife Resources, the Arizona Fish and Game Department and the U.S. Fish and Wildlife Service - announced they found three microscopic larvae in water samples taken from Wahweap Marina and near the Glen Canyon Dam.

The agencies are not sure how widespread the mussels might be or if there is an established population. They don't know how the mussels might change the Lake Powell ecosystem or spread to other premiere Utah recreation spots, such as Bear Lake and the Jordanelle Reservoir.

In fact, the DNA and microscope tests that were used to identify the mussels do not tell for sure whether the Lake Powell mussels are quaggas or their close cousins, zebra mussels. The state has estimated it will cost \$17 million a year to deal with quaggas if they spread statewide, not including the impacts of fishing. The fear has prompted the creation of Dalton's month-old position, which will eventually oversee an agency with about 40 people, and an emergency expenditure by the state of about \$1 million through next spring.

"If we wait a year," he said, "it will be too late."

Once the mussels are established, they are virtually impossible to eradicate.

Utah officials have kept a wary eye on mussel developments for years, Dalton noted.

One study showed Great Lake facilities spent \$69 million over seven years to deal with mussels. A Canadian report referred to on the Web site 100thmeridian.org described a price tag of more than \$172 million because of mussel infestations at eight hydropower stations, 86 municipal plants and 67 industrial facilities.

"It's just been killing those guys back there," said Dalton, "so we have been worried."

Then, in January, quagga mussels were found downstream on the Colorado River, in Lake Mead.

"That," he said, "put us on high alert."

In late June, quagga mussels were found on a boat at Wahweap Marina that had been in infested waters. It was decontaminated before the boat was allowed to launch.

Water samples were taken from the two Lake Powell locations on July 19 and 30. Three of the five samples showed "extremely small" numbers of larval mussels. A good contrast is Lake Mead, where the infestation is believed to have started two years ago and where similar samples contain hundreds or thousands of mussels.

Baby mussels are about the size of a grain of sand and take about a year to reach full size. Adults are the size of a thumb nail.

All spring, the government agencies with roles at Lake Powell have pushed mussel prevention. Signs posted around the lake urge boaters to inspect their crafts if they have been in other waters in the past 30 days and to use 140-degree pressure washers to clean up the boats, plus a five-day period of drying, before launching into Lake Powell.

State Sen. Curt Bramble, a Provo Republican who owns a houseboat on Lake Powell, said it was "inevitable" that quagga mussels would come to Utah.

He said the findings announced Thursday "could be a serious concern," far more important than its affect on recreation.

Yet, he added: "I'm not sure the research is in and what the ramifications will be."

Kitty Roberts, superintendent of the Glen Canyon National Recreation Area, noted that that the search for better answers is already under way.

"Additional samples have been collected from Lake Powell and are being analyzed for quagga and zebra mussels," she said. "In the coming weeks, more samples will be collected from various location around the lake to determine if mussels are present in other areas."

Dalton said a biologist donning diving gear had inspected 150 boats Thursday. There are another 1,000 to go.

###

Quagga quagmire

A freshwater mollusk indigenous to the Dnieper River in Ukraine has invaded waterways of the United States, altering the food chain and rapidly colonizing on hard surfaces, such as the hulls and outboards of watercraft.

* Range: Found in January in Lake Mead, downriver from Lake Powell. First U.S. sighting was in the Great Lakes in 1989.

* Treatment: Chemical controls pose environmental risks; chlorination has been applied routinely. Biological controls are being researched.

* Prevention: Recreationists are urged to clean their watercraft to curb spread of the mussel.

Navajo Tribe must haul own water

Shaun McKinnon
The Arizona Republic
Aug. 26, 2007 12:00 AM

TONALEA - Ethel Whitehair ran out of water again over the weekend, emptied every bucket and pot, drained the barrels lined up outside her front door. The community well was closed until Monday.

Water from a well at a nearby windmill could supply the sheep, but it was untreated and made Whitehair's skin itch. At another windmill down the road, vandals had torn the cover off the storage tank. Deep inside, a car battery steeped in the soupy dregs, the surface stirred by the bloated bodies of three dead crows.

So Whitehair waited, as she had so often during her 87 years on Arizona's Navajo Reservation. She waited for her children to come and haul water from the good well. She waited for someone to end an unthinkable water crisis.

It is a wait shared by nearly 80,000 others who must haul water to meet basic needs. They live far from a water pipeline, and their communities barely have enough water to sustain what few lines exist.

The Navajos' water crisis has persisted so long, it has wormed its way into the routines of life on the nation's largest Indian reservation. Easing the crisis will require decades of work, billions of dollars and the patience to cut through the politics of Western water.

Tribal leaders have stepped up pressure on federal and state officials to settle claims for water guaranteed by the Supreme Court. Ignore those claims, Navajo President Joe Shirley says, and risk a water war.

"There is so much misunderstanding," said Lena Fowler, vice chairman of the Navajo Nation Water Rights Commission. "We live in a situation where we can't even meet our own basic human needs, which is just a drink of water. When we get up in the morning, after we pray, we have to start thinking about how much water we have. That's the first thought we have every day. Do we have to haul water?"

Link to poverty

Little comes easy for the 200,000 people who live on the Navajo Reservation, which surrounds three of the four corners in Arizona, New Mexico and Utah. Homes and

communities lie scattered across an area the size of West Virginia. The land is harsh, the climate dry, the distances long, the opportunities to earn money few.

Unemployment rates run as high as 26 percent. Per capita income is about \$7,000 a year, compared with about \$21,000 elsewhere in Arizona. With no casinos yet on the reservation, the tribe can't rely on gaming revenue. More than 40 percent of the people live below the poverty line, about the same proportion who lack running water.

Tribal officials say they can't ignore the link between poverty and lack of water. Without reliable water systems, businesses can't survive. New housing must wait. Indian Health Services, the federal agency that installs local water infrastructure on the reservation, faces a construction backlog of \$250 million, or about 700 unbuilt systems.

So people haul water, as many as 80 percent of people in some communities. It is a task that cuts deeply into meager incomes, especially as gasoline prices climb. The Bureau of Reclamation estimated in a 2004 study that the total economic cost to haul water on the reservation is about \$113 per 1,000 gallons, or \$37,000 for an acre-foot. A Phoenix homeowner pays about \$5 a month for as much as 7,480 gallons.

"We're talking about things a lot of people take for granted," said Ray Benally, director of the tribe's water resources department. "It's about our quality of life. The lack of clean, potable water has an effect on people's health."

Water haulers

Water haulers inhabit a subculture of reservation life, easily identifiable by the plastic tanks bulging from pickup truck beds. They learn where the good water is, when the lines form and how to stretch time between trips to the well.

At the Seventh Day Adventist mission in Monument Valley, Utah, a line of trucks forms early each day, snaking past low-lying red rocks buffed smooth by incessant winds. People chat while they wait. Kids bound in and out of truck beds. No one leaves early.

The well is a rarity, a reliable and clean source of water, clean enough that haulers will pass by other wells and make longer trips to fill up. It's a source of pride for Goulding's Lodge, which took it over for the church and offers the water for free.

"We have to take samples and send them to the tribe and the EPA (Environmental Protection Agency)," said Ronnie Biard, Goulding's general manager. "From what we're told, our water is so pure you could actually bottle it right out of the ground. We're very fortunate."

Amy Yazzie and her boyfriend, Jonathan Greyhatt, must haul water from the Tonalea community well and then empty it into a cistern that is buried on a small hill above their house. A pipe from the cistern runs to the house, a wooden hogan with a square addition that encloses a kitchen and a bathroom.

Like many reservation homes, the plumbing fixtures in this one hold more hope than water, installed with promises of a modern water line from Tonalea or Tuba City.

On a recent morning after returning from the well with a second tank full, Greyhatt started the siphon hose from the back of the truck and, as it drained, hiked down to the house. He filled bucket after bucket, more than a dozen in all, a process that made more room in the cistern for a third trip to the well. The buckets sat on tables, chairs, on the floor, like a scene after a long rain beneath a leaky roof.

Greyhatt moved efficiently, spilling little.

"We had a leak last month," he said. "We thought we had enough water to last awhile. But we came back, and it was gone."

Greyhatt and Yazzie drive 8 miles round trip to get water, but it's not uncommon for people to drive 30 miles or more, one way. During the summer, livestock can require daily trips on long stretches of dirt roads.

The reservation sits atop several huge aquifers, but not all wells produce usable water. A shallow well can turn brackish without warning. Many dry up in a drought. Windmill-powered pumps break down, often for weeks at a time. Running water guarantees nothing in communities like Cameron, where what comes out of taps isn't always safe to drink.

Three major rivers flank the reservation - the San Juan on the north, the Colorado on the west and the Little Colorado on the south - but the tribe has never secured rights to divert adequate water nor can it afford to build large-scale delivery systems.

New Mexico has signed a deal that would set aside water for a strip of the reservation along the Arizona border and build a pipeline to it, but money and politics threaten to sink that plan and delay other agreements. Arizona wants broader regional claims settled before Congress signs off on the New Mexico deal and also wants the tribe to drop a lawsuit that accused the federal government of mismanaging the Colorado. Failure to resolve the Navajo Nation's need for water would thrust the issue into court - and threaten water supplies for millions of people.

A way of life

With resources stretched so thin, the Navajos have adapted into some of the most efficient water users anywhere.

In a day, an average Navajo uses as little as 10 to 15 gallons of water in a water-hauling home, closer to 80 gallons in a home with running water. In Phoenix, the average person uses as much as 170 gallons per day.

"We know how to conserve. We know how to get by with less," said Sharon Williams, whose family lives a few miles from the Coyote Canyon chapter house in western New Mexico. "People in Phoenix have it made. They have water for grass. They can step in a shower any time. They never have to wonder if they have water."

She cracked a wry smile. "If they had to come up here and live like us for a day," she said, with only a trace of taunting in her voice, "they wouldn't make it."

Williams' parents still live in the same house on the edge of a canyon the family owns. The house sits at the top of a small rise, overlooking sheep pens and planting fields. A dirt courtyard is kept immaculate. An enclosure offers shade, its slatted roof alive with vines that Williams' mother, Annie Tsosie, fusses over daily.

Mark Tsosie, who is 78, retired from the railroad a few years back and now tends the livestock. He rises with the sun each day to check on the sheep and the crops, and about every other day he waters the cattle and horses that graze in the bottom of the canyon. This is not as easy as it sounds.

The canyon slices through the rolling plateau, its rounded rocks colored with shades of tan and dusty orange and occasional streaks of red. In one crevice, the wind has bored a hole big enough to frame a view straight down, a drop of more than 100 feet.

No water runs through the canyon, except after rainstorms. The old wells on the canyon floor dried up, leaving only a well up top not far the Tsosie house.

So Tsosie built an irrigation system, a rickety but reliable routine that depends on the health of an old GMC pickup, one that sometimes doesn't start and that, on one recent morning, sat disabled with a flat tire until one of Tsosie's sons arrived with a tire pump.

The tire inflated, Tsosie filled the tank and drove the truck along a rocky path to the canyon rim. He backed the truck to the edge and attached a hose from the tank to a plastic pipe that drops down to the floor, where it fills a trough.

"I've been taking care of this for 60 years," he said, more comfortable with English than he lets on sometimes. "I've got to get them water. This is the only way."

Back at the house, Annie had heated a kettle of water on the stove. Her son Matthew poured some of it into a plastic basin and took it outside onto a table. He looked around for his children and their cousins and grabs one.

"Time to wash hair," he said.

Each of five children took a turn at the basin. Shampoo, rinse, no repeat. Same basin of water. If it holds up long enough, it'll be used to wash hands. Later, sponge baths are given with a larger basin, but the water is still shared.

"I had a great shower a few weeks ago when it rained," Matthew said "I hiked down to a ledge on the canyon and stood under water pouring over the side. I got so clean."

Claims to water

Another storm threatened to develop on a recent afternoon. Black clouds piled up on each other above the mesas, building billowy towers that give the desert its own skyline. John Leeper, the director of the tribe's water-management branch, is keeping a close watch on some of the reservation's most vulnerable water systems.

"A monsoon storm can wash out a system," he said. "It's tough to keep it going. We're hoping to build some robust infrastructure that can support a sustainable community, but you can't just build them and forget them. We don't have what we need right now."

Navajo Mountain, a remote community on the Arizona-Utah border, causes a drugstore full of headaches these days.

The springs that supply it drop rapidly during dry weather, forcing the tribe to haul water in tanker trucks. Sometimes that fails when the trucks tear up the dirt road, leaving them nearly impassible.

The tribe is working on regional water projects that would shore up its delivery systems, but most of them are still in the planning stages. The two most critical, pipelines tapping the San Juan and Colorado rivers, will require as much as \$2 billion from the federal government, a check Congress appears unwilling to write.

Opposition from the Bush administration and other Colorado River states has frustrated Navajo officials, who insist they're not asking for a pipeline to nowhere.

"The water needed is not that big an amount," said Benally, the water-resources director. "And there is money. It's just a question of where you put it."

He cited a report by government auditors who found more than \$1 billion wasted in Hurricane Katrina recovery efforts.

"That could have funded our Gallup project all by itself," Benally said. "They put a lot of money into rebuilding after a natural disaster, but out here, we have nothing to start with. This is a basic necessity."

Benally said the tribe is preparing for a drawn-out process to settle claims with Arizona, another fight to secure federal funding for delivery projects and years of studies and construction. He sees it all as entirely unnecessary.

"The question they should be answering," he said, "is how come they didn't include the Indian people to begin with? Why weren't we at the table with everyone else?"

Still waiting

Tribal officials acknowledge they may never provide full running water to every home. The reservation is just too big, the ancestral lands too widely spread.

A more practical goal is ensuring that water haulers can find clean sources within shorter distances.

Back in Tonalea, Amy Yazzie and Jonathan Greyhatt filled their cistern and moved the truck across a dirt clearing to a one-room house, where Yazzie's mother, Ethel Whitehair, waited.

"She stays by herself for long stretches of time . . . I worry," Yazzie said. "She can't go get the water herself anymore."

Whitehair brightened as Greyhatt began to fill the barrels.

She found a pot and started boiling water for noodles.

Navajo music played on a radio above the stove.

A black and white kitten sniffed at a bowl of milk, mixed from powder.

"In the winter, the barrels sometimes freeze," Yazzie said as Greyhatt topped off the last one. "Then we have to move them inside by the stove to thaw out."

Greyhatt pointed toward the main highway.

Surveyors have staked some of the area for water lines, and some neighbors say they expect work to begin soon.

But so far only a few broken stakes remain.

And so they will haul water again in another week or two.

And wait.

"It's hard. . . . It's hard," Yazzie said. "They say we're going to get water out here sometime, but it never happens."

Water rationing said likely

By Fred Ortega, Staff Writer Whittier Daily News Article Launched: 08/31/2007 11:26:13 PM PDT

A federal judge's ruling Friday means Southern California's primary supplier will likely call for water rationing as soon as next year, officials said.

U.S. District Court Judge Oliver Wanger imposed limits on flows caused by pumps sending water from the San Joaquin-Sacramento River delta to users around the state, saying the pumps were drawing in and destroying the endangered delta smelt.

Wanger's ruling — which only lasts for a year — imposes the limits from the end of December, when the smelt are about to spawn, until June, when young fish can move into areas with better habitat and more food.

Metropolitan Water District officials called Wanger's ruling one of the largest court-ordered water curtailments in state history. They said based on initial estimates supplied by the state, MWD stands to lose as much as 30 percent of its supplies from Northern California next year and possibly longer.

That, combined with reduced supplies from the Colorado River and this year's record dry spell, means the MWD has to plan for a shortfall in deliveries to its 26 member cities and agencies, MWD Board President Timothy Brick said earlier this week.

"All of these factors may necessitate Advertisement a curtailment," said Brick, noting that the Southland has gone from having 60 inches of rainfall during the record wet season two years ago to just 3 inches in Pasadena this year. "We don't think (rationing) will happen this year, but maybe next year.

"We are doing everything we can to avoid it, but it is important for people to know this is on the horizon," he said.

MWD General Manager Jeff Kightlinger offered a somber assessment Friday night.

"California simply cannot lose important water supplies without real consequences throughout the state," he said in prepared remarks. "This historic court decision affirms what the water community has realized for some time, but the general public may not fully appreciate — the delta, both as a valuable ecosystem and essential water supply, is broken. This court ruling did not fix it."

The MWD provides water for 18 million residents in parts of Los Angeles, Orange, Riverside, San Bernardino and San Diego counties.

But local agencies like the Upper San Gabriel Valley Municipal Water District have ample reserves in the form of local groundwater supplies, and could probably stave off rationing for up to two years, said district General Manager Timothy Jochem.

"After three years we may have to institute some mandatory reductions," said Jochem, whose agency imports about 35 percent of its water each year from the MWD.

The drought may continue into the next two years and beyond, said JPL climatologist Bill Patztert, meaning San Gabriel Valley agencies will likely end up instituting some type of mandatory cutbacks like those already being implemented in Palmdale and the Coachella Valley.

"Another decade (of drought) is not out of the question," said Patztert, adding that climatologists believe the entire Southwest is undergoing a prolonged dry spell similar to the 20-year-long drought that affected the region in the 1950s and '60s.

"The last eight years have been the driest on record on the Colorado River," said Patztert. "Normal flow on the Colorado is about 15 million acre-feet per year, and there were periods in the 1980s and '90s when we were above 20 million. The average over the last eight years has been about 10 million acre-feet."

An acre-foot of water is equivalent to about 326,000 gallons.

As a result, today the MWD is importing half as much water from the Colorado as it did just five years ago, said Brick.

At the same time increased demand on the State Water Project, which taps the Sacramento River delta, has contributed to an ecological crisis that has threatened native species like the delta smelt.

The tiny fish forced the closure of the pumps that send river water to Southern California for about 10 days in June. The crisis led to a lawsuit against the state by environmental groups led by the National Resources Defense Council.

Wanger on Friday ruled to protect the fish, which experts say might be on the brink of extinction. He said pressure from the pumps helped reverse the natural direction of water within the estuary, damaging habitat and killing delta smelt.

"The evidence is uncontradicted that these project operations move the fish," he said after hearing objections from defendants, who had argued that other factors led to the fish's decline. "It happens, and the law says something has to be done about it."

Jochem said any mandatory reductions imposed by the MWD could include financial incentives for member agencies, like it did the last time water was rationed in the late '80s and early '90s. For example, an agency that consumes below a certain percentage of the water it imported the previous year could get a reduction in rates.

"The agencies can then pass on the savings to consumers or use the money to implement water conservation programs," said Jochem, noting that his agency used extra money from the last round of mandatory cutbacks to begin a low-flow toilet installation program.

As for how agencies would force customers to use less water, one need only look to Palmdale.

That city has already imposed restrictions limiting lawn watering to no more than three alternating days a week, and only during nighttime hours; prohibiting the hosing down of sidewalks; and asking restaurants not to serve water to customers unless they ask for it.

Regular violators can face \$1,000 fines and disconnection of water service.

The MWD's plans are not only necessary and inevitable, said Patztert, but must be part of a sea change in the way Southern Californians consume water.

"In Southern California we overwater our lawns by anywhere from 6 to 8 feet per year, wash our cars twice a week and sprinkle our streets and sidewalks," said Patztert, noting that 70 percent of local domestic water consumption is used to water lawns. "If we got rid of the English gardens and lawns and replaced them with drought-tolerant landscaping, we could conserve enough water to sustain twice the present population."

And coupled with the fact that the area's population is projected to continue growing over the next 30 years, there are little options left to the area's water purveyors.

"The MWD and associated water districts might as well start thinking about this now," Patztert said. "Because more people and less water is what our future looks like."

The Associated Press contributed to this story.

Dam release coalition blocked

By CYNDY COLE Sun Staff Reporter Sunday, September 02, 2007

The Colorado River in the Grand Canyon grows and shrinks tremendously every day.

The volume of water passing through the turbines at Glen Canyon Dam is incrementally doubled or halved in 24 hours to meet momentary power needs in Nevada, Utah, Wyoming, Colorado, New Mexico and Arizona.

But a growing coalition of national park officials, federal biologists, conservationists and river guides contend such dramatic fluctuations are detrimental to the Grand Canyon ecosystem and possibly illegal during low-water years.

They want Interior Secretary Dirk Kempthorne to order that daily flows be evened out and the water releases to more closely mimic seasonal river changes.

But power companies say such a move would cost millions of dollars to replace the cheap power that would be lost if they cannot ramp up releases during hot, summer afternoons.

They outvoted the growing coalition at a showdown meeting in Flagstaff Thursday, but the insurgents, led by the Grand Canyon Trust of Flagstaff, said the issue is far from settled.

The Fish and Wildlife Service recommended a decade ago that such an experiment be conducted to see if it would benefit endangered fish in the Grand Canyon.

"We would love to be able to have a sufficient duration of steady flows to be able to see what the response would be of humpback chub," said Sam Spiller of the U.S. Fish and Wildlife Service.

But other federal agencies and power officials defeated a proposal on Thursday that would have recommended the Interior Department adjust water flows by season, saying they didn't want an experiment that could cost ratepayers tens of millions of dollars in higher utility bills.

A similar experiment conducted for a few months in 2000 cost customers \$31 million in power production, according to one calculation.. The dam supplies power directly to the Navajo Nation, Hopi Tribe and Arizona Strip and sells power to wholesalers that serve an estimated 4.9 million individuals in six states, mostly in rural areas.

The Trust proposed changing water releases from the dam by season only -- not by day -- which would limit the dam's ability to generate more hydroelectricity when electricity demand peaks.

This is an experiment required by law during years when a minimum amount of water is released from the dam, the group said.

Recent drought years have led to such minimal releases, along with reduced power production.

"The Grand Canyon Trust believes the flows currently coming from Glen Canyon are illegal," said Nikolai Ramsey, of the Trust.

Such a change would force utilities to buy power elsewhere during peak hours, said Clayton Palmer, of the Western Area Power Administration, a federal agency.

NO MORE SPRING FLOODS

Before Glen Canyon Dam was built, the Colorado River used to flood wildly.

The dam, completed in 1963, has eliminated seasonal floods that were once powerful enough to toss around house-sized boulders.

Now, even held fully open, the nation's second-tallest dam couldn't produce the large floods that once existed.

So representatives from Colorado River states, utilities, regional tribes, federal entities and environmental and recreational groups meet every few months to hash out management ideas for the river.

They look over technical reports and data, negotiate, and eventually make a recommendation to the secretary of the Interior Department. Interior makes the decisions.

The Grand Canyon has steadily seen beaches erode, river temperatures change and the number of humpback chub decline in recent decades, according to a 2005 report from the Grand Canyon Monitoring and Research Center at USGS in Flagstaff.

"As a result of dam operations and decreased sand supply, the Colorado River now typically transports more sand downstream than tributaries supply on a seasonal to annual basis," U.S. Geological Survey researchers wrote in one report.

The sandbars and beaches in the Grand Canyon have been eroding since 1963, USGS has found, now at an average rate of 15 percent per year.

That spells trouble for the river runners who camp on beaches, as documented in a series of photos taken by Northern Arizona University geologists.

Grand Canyon River Guides support changing dam operations.

"As camping beaches continue to diminish, crowding and congestion will become even more of an issue, especially in areas where beaches are in high demand, or few in number," said Lynn Hamilton, executive director of Grand Canyon River Guides.

"Sediment is the lynchpin for the health of multiple resources in Grand Canyon, including the recreational resource. River runners care deeply about everything that makes Grand Canyon and the Colorado River so unique, and finding better ways to manage and restore the health of those resources is critical."

Watershed year for Colorado River and Glen Canyon Dam

Sunday, September 16, 2007

http://azdailysun.com/articles/2007/09/16/news/opinion/20070916_opinion_50.txt

Serving on the Editorial Advisory Board this week were Publisher Don Rowley, Editor Randy Wilson, and citizens Jacqueline LaFave Perkins, Laurel Shelton, Mary Black and Thomas Gorman.

This is a watershed year for the Colorado River below Glen Canyon Dam, and in more ways than one.

Low snowmelt in the Rockies has again meant lower water levels in Lake Powell, which affects the power production from the dam and how much water can be released into the Grand Canyon below.

Now, with the publication of a new USGS study that shows the increasingly harmful effect of the dam's operations on the native fishes, plants and beach habitats downstream, pressure is mounting to change water releases from the dam.

Raising the stakes even higher is the Grand Canyon Trust, which is calling federal power officials on the carpet for failing to adjust dam releases to account for drought years. Federal rules call for much lower and steadier flows during the hot, summer months and higher flows in the spring to mimic seasonal floods, not the high-volume releases each day in summer to accommodate the power needs of air-conditioned Las Vegas and Phoenix.

As Cyndy Cole reported earlier this month, the Trust, along with officials from Grand Canyon National Park, the Fish and Wildlife Service and river outfitters, confronted the federal group that advises the Interior Secretary on dam releases at a meeting in Flagstaff. They lost by a vote of 14-4 on a motion to implement the drought-year river protections, but that's not the end of the issue. Legal action might come next, along with taking their case to the public. As one of the insurgents noted, "This isn't the Glen Canyon Dam State. It's the Grand Canyon State."

On the surface, the dispute might seem like much ado about nothing. The warmwater, native humpback chub, which is the canary in the coal mine for advocates of river preservation, is not particularly photogenic. Its successors, the coldwater rainbow and brown trout, are much preferred by sport fishermen. As for disappearing beach habitat caused by high summer dam releases, some would say that's an unavoidable cost if urban-dwellers are to survive the searing Southwest desert heat.

If the drought cycle in the Southwest was temporary, we might be inclined to agree that worries over the Colorado River ecosystem's ability to adapt to the massive changes caused by Glen Canyon Dam are overblown. The Grand Canyon has been around for eons and no doubt seen many changes in the river's flow, so why would it not be able to adapt now?

The difference is that those epochal changes occurred gradually, not overnight, as was the case when the dam first closed its gates in 1964. River water temperatures have dropped up to 25 degrees, spring floods no longer occur, and daytime flows in summer now fluctuate wildly, depending on how much hydropower the dam needs to generate on a hot afternoon. It's no wonder that a prehistoric fish like the chub, which took millions of years to adapt to the unique river conditions in the Canyon, is now nearly extinct within four decades, and that other native plants and animals are following suit.

The plan to restore some of the balance being advanced by the Trust, Fish and Wildlife, the national park and others is not an either/or choice. It calls for a modest, three-month experiment that would scale back peak daily releases in the hot summer months and open the floodgates in the spring. The lost power would cost the electric utilities an estimated \$30 million a year to replace it from higher-priced sources, including coal-fired plants.

So the issue is not so much cost -- \$30 million is a drop in the bucket compared to the billions of dollars worth of power sold each year on the Southwest electric grid. Nor is it particularly expensive to customers: There are an estimated 5 million people who use power from Glen Canyon Dam, so the experiment would cost just \$6 apiece. What's more compelling is the concern that, by restoring the Grand Canyon ecosystem, advocates of river preservation would be increasing the carbon "footprint" of power consumption in the Southwest by relying more on coal. Until industrial solar and wind plants go online or nuclear power makes a comeback, this area's cheapest and least-polluting source of power will remain hydroelectric dams.

The major flaw in that argument is related to why the river-flow experiment is needed in the first place: drought. If rain and snowfall continue to be low in the Colorado River basin, setting low summer flows won't be optional, they will be mandated by Mother Nature. That will mean less power can be generated from dams as lake levels decline because there isn't as much water pressure to drive the turbines. At some point in the very near future, all of us in the Southwest might have to come to grips with the demise of hydroelectric power, regardless of how we feel about restoring the Grand Canyon's pre-dam ecosystem.

It's for those reasons that we can't emphasize enough -- as we have in this space before - the importance of ramping up industrial-scale renewable energy plants. If that means a major expansion of the tax credits available to the developers of solar and wind plants, so be it. Climate change is not only exacerbating the problems in the Grand Canyon caused by Glen Canyon Dam. It should force us to rethink what kind of energy infrastructure will support population growth in the Southwest and, indeed, how power consumption might need to be radically modified. As we said above, it's a watershed year not just for the Colorado River in the Grand Canyon but for all of us who depend for power on the dam that controls its destiny.

Regional News 10/04/07

Ariz. fights changes in Colo. River plan

Shaun McKinnon The Arizona Republic Oct. 4, 2007 12:00 AM

Arizona balked Wednesday at proposed changes to a Colorado River drought plan and appealed to the federal government to settle the dispute or delay approval of the plan.

In a letter to U.S. Interior Secretary Dirk Kempthorne and the other six states that take water from the Colorado River, Arizona officials said attempts to rewrite an agreement reached earlier this year put Arizona's share of the river at an unacceptable risk.

"We worked hard to try to put together this agreement, and the only thing Arizona asked is that it did not harm Arizona water users," said Herb Guenther, director of the state Department of Water Resources.

At issue is whether a new system of managing reservoirs on the river would threaten the portion of Arizona's allotment that serves Phoenix and Tucson. Arizona argues that changes sought by states on the upper river could deprive Arizona of water even when storage levels in one reservoir were high.

The request for federal mediation could upset an already-tenuous peace among the seven states, which negotiated for more than two years over how to manage the river in times of drought.

The states' version was undergoing a final review, and Kempthorne was expected to approve it in December.

The federal government wanted the plan in place to avoid protracted legal battles if drought or shifting climate continued to shrink the river's flow.

Growing demand for water among the nearly 30 million people who rely on the Colorado River has also increased tension.

Guenther said a delay could help the states produce a better operating plan and, in turn, ward off future lawsuits.

"We think the whole process is moving too quickly," he said.

"We're not giving enough time to seriously resolve this particular issue. It would be our feeling that it would not hurt to slow the process down a little and give the negotiations a chance to succeed."

Federal officials acknowledged the stalemate between Arizona and the other states but suggested further work within the current framework.

"In light of the fact that in the last eight years the Colorado River has suffered through the worst drought in recorded history, it is extremely critical that we implement new guidelines for managing the Colorado River under low-water conditions this year," said Robert Johnson, commissioner of the U.S. Bureau of Reclamation, the Interior Department's water agency.

Johnson said the bureau had been working with the states for the past two months to resolve the differences and even delayed release of the final environmental-impact statement on the operating plan.

He said he will meet with representatives from the states this week, "however, time is short."

"The basin is still in the grasp of this drought, and it is critically important that we resolve this issue now," Johnson added.

The other states hadn't seen Arizona's letter Wednesday and reacted cautiously.

"Utah's position is we're still talking among the basin states, and we are optimistic that an agreement can be reached that will not harm Arizona and that will be beneficial to all the basin states," said Dennis Strong, director of the Utah Division of Water Resources.

Arizona identified several concerns about the agreement in its letter, but the dispute hangs mostly on proposed changes to the way the states manage water in Lake Powell and Lake Mead, the two largest storage reservoirs on the Colorado River.

Under the proposed drought plan, shortages are triggered by water levels in Lake Mead, which stores water for Arizona, Nevada and California. As the lake level declines, the size of the water shortages grows, which is why the three lower-river states have proposed ideas to increase storage.

Arizona would feel the main brunt of any shortage because it gave up legal seniority to part of its allocation in exchange for the Central Arizona Project Canal, which delivers water to Phoenix and Tucson. The water in that canal is the first to be cut off in a shortage.

The agreement called for a system of balancing the water in Mead and Powell, which store water on behalf of the upper-basin states of Colorado, Utah, Wyoming and New Mexico. Those states fear that if Powell drops too low, they could suffer shortages.

Arizona argues that the upper-basin states tried to rewrite the formula for balancing water in the two reservoirs, producing rules that could create a shortage on Lake Mead even when ample water remained in Lake Powell.

"It's a scenario that may never develop," Guenther said. "But it could happen. And if it did, we don't feel it would be appropriate to short Arizona water users when there was water in Lake Powell."

Reclamation Issues Final EIS for Colorado River Operations under Low Reservoir Conditions

Lower Colorado Region, Boulder City, Nev.

Media Contact:

Kip White

(202) 513-0684

Bob Walsh

(702) 293-8421

Released On: November 02, 2007

Commissioner of Reclamation Robert Johnson today announced that the Bureau of Reclamation (Reclamation) has issued a final Environmental Impact Statement on the proposed adoption of specific Colorado River Lower Basin shortage guidelines and coordinated reservoir management strategies to address operation of Lake Powell and Lake Mead, particularly under low reservoir conditions.

"These proposed operational guidelines will provide Colorado River water users and managers in the U.S. a greater degree of certainty about how the two large reservoirs on the Colorado River will be operated under low water conditions, and when - and by how much - water deliveries will be reduced in the Lower Basin in drought or other low reservoir conditions," Johnson said.

The Final EIS presents six alternatives, including a No Action Alternative and a Preferred Alternative. The Preferred Alternative proposes that:

- * specific water levels in Lake Mead be used to determine when a shortage condition (the availability of less than 7.5 million acre-feet of water) would be declared in the lower Colorado River Basin, and how that shortage would be shared by the three Lower Division States - Arizona, California and Nevada;
- * specific reservoir conditions at Lakes Powell and Mead be used to determine the annual operation of these reservoirs, in a manner that would minimize shortages in the Lower Basin and avoid the risk of water delivery curtailments in the Upper Basin;
- * a mechanism be implemented to encourage and account for augmentation and conservation of water supplies in Lake Mead to minimize the likelihood and severity of

potential future shortages and to provide additional flexibility to meet water use needs, particularly under low reservoir conditions; and

* the Interim Surplus Guidelines established in 2001 be modified and extended through 2026.

"The Preferred Alternative was developed by Reclamation after extensive collaborative efforts with the Colorado River Basin States, environmental organizations and other stakeholders," said Johnson.

"It was designed to allow the river to be managed to meet the demands being placed on it today and into the future. I commend the states and all the other stakeholders who worked so long and hard to develop these guidelines and management strategies - this truly is an historic accomplishment."

Development of the guidelines was spurred by the current drought in the Colorado River Basin, which began in the fall of 1999. In the eight years since then, the Basin has experienced the worst drought conditions in 100 years of recorded history, and storage in Colorado River reservoirs has dropped from nearly full to about 54 percent of capacity.

Because there are currently no specific guidelines for determining shortage conditions in the Lower Basin, or the coordinated operation of Lake Powell and Lake Mead during drought and low reservoir conditions, a public process was initiated in September 2005 to develop them. They are expected to be adopted by the Secretary of the Interior in December, and take effect in January 2008. They would then be used each year through 2026 to develop the Annual Operating Plan for Colorado River reservoirs.

The Final EIS is available for viewing and copying at [Reclamation's project website](#). Alternatively, a compact disc or hard copy is available upon written request to: Regional Director, Lower Colorado Region, Bureau of Reclamation, Attention: BCOO-1005, P.O. Box 61470, Boulder City, Nevada 89006-1470; fax at (702) 293-8156; or [Email: strategies@lc.usbr.gov](mailto:strategies@lc.usbr.gov)

SLC hydrologist says the arrangement means 'everyone shares the pain'

Plan manages Colorado River in drought

By Patty Henetz

The Salt Lake Tribune

Article Last Updated: 11/03/2007 12:25:59 AM MDT

The Law of the River has gotten another adjustment with a federal plan to manage the Colorado River during dry years.

The U.S. Bureau of Reclamation on Friday released a final environmental impact study that could be a way to avoid renegotiating an 85-year-old agreement based on inflated notions of how much water really is in the river.

Or, according to river advocates, the plan that will govern use and allocation through 2026 could be a way to ensure none of the seven Western states that share the river ever has enough water.

The study's conclusions drew from a consensus decision by the seven Western states that depend on the Colorado River on what to do during low-water years, officials said.

"This is an arrangement for operating the river where everyone shares the pain when you're going through a drought time," said Tom Ryan, a Bureau of Reclamation hydrologist in Salt Lake City.

The Bureau of Reclamation began the environmental study in 1999. Since then, the river basin has experienced the worst drought in 100 years of recorded history, and its two largest reservoirs - Lake Powell and Lake Mead - have gone from being nearly full to just over half-full.

The report, expected to be final in December, plans how the upper basin states - Utah, Colorado, Wyoming and New Mexico - will respond to demand from California, Arizona and Nevada, the lower basin states, which have more people and older water rights.

While the Bureau of Reclamation implicitly acknowledges that the 1922 Colorado River Compact is based on estimates from unusually wet years and its report assumes ongoing shortages, it doesn't suggest any changes to the agreement.

"Nobody wants to renegotiate the compact. The feeling is the compact provides an adequate framework for managing the river," Ryan said.

But to John Weisheit, conservation director for the non-profit organization Living Rivers, the bureau's solution entrenches wastefulness and refuses to acknowledge ways to store water more effectively.

"We're extremely disappointed," he said. "Now we're playing this balancing act between two reservoirs that climate change is going to keep empty."

Living Rivers has long campaigned to decommission the Glen Canyon dam and rely on Lake Mead for surface water storage. The organization also believes using aquifers in Arizona and California to store water underground would be a better solution. But the main problem with the bureau's solution is there's not enough water, which speeds destruction of the river ecosystem, Weisheit said.

Reclamation finalizes drought-sharing plan

Eryn Gable, special to Land Letter

The Bureau of Reclamation on Nov. 2 released a final environmental impact statement outlining management of the Colorado River during dry years.

The plan, which will guide the operation of lakes Powell and Mead until 2026, is based on an agreement by seven Western states that depend on the Colorado River. It is expected to be adopted by the Interior Department secretary in December and take effect in January 2008.

"These proposed operational guidelines will provide Colorado River water users and managers in the U.S. a greater degree of certainty about how the two large reservoirs on the Colorado River will be operated under low water conditions, and when -- and by how much -- water deliveries will be reduced in the Lower Basin in drought or other low reservoir conditions," said Reclamation Commissioner Robert Johnson in a statement.

Development of the guidelines was spurred by the current drought in the Colorado River Basin, which began in the fall of 1999. In the eight years since, the basin has experienced the worst drought conditions in 100 years of recorded history, and storage in Colorado River reservoirs has dropped from nearly full to about 54 percent of capacity (Land Letter, April 12).

The final EIS acknowledges that the 1922 Colorado River Compact is based on estimates from unusually wet years, but it doesn't suggest any changes to the agreement, which divvies up water among the seven states.

The document also acknowledges the potential effects of climate change, including decreased mean annual flow, increased variability, more frequent and severe droughts, and decreased runoff. However, Reclamation argues that the science surrounding climate change is not yet precise enough to determine exactly what those effects will be.

Brad Udall, director of the Western Water Assessment, a joint effort by the University of Colorado and the National Oceanic and Atmospheric Administration, said that is a good tack for Reclamation to take. "I actually think that Reclamation did a good job of looking

at the state of the science and acknowledging this is a problem, but the science at the regional level just isn't good enough to provide the answers," he said.

The final EIS presents six alternatives, including a no-action alternative and the agency's preferred alternative. The preferred alternative proposes that:

Specific water levels in Lake Mead be used to determine when a shortage condition (the availability of less than 7.5 million acre-feet of water) would be declared in the lower Colorado River Basin, and how that shortage would be shared by the three lower basin states -- Arizona, California and Nevada.

Specific reservoir conditions at Lakes Powell and Mead be used to determine the annual operation of these reservoirs, in a manner that would minimize shortages in the lower basin and avoid the risk of water delivery curtailments in the upper basin.

A mechanism be implemented to encourage and account for augmentation and conservation of water supplies in Lake Mead to minimize the likelihood and severity of potential future shortages and to provide additional flexibility to meet water use needs, particularly under low reservoir conditions.

The Interim Surplus Guidelines established in 2001 be modified and extended through 2026.

Too optimistic?

John Weisheit, conservation director for the nonprofit organization Living Rivers, said his group doesn't like the agreement at all. "We think the Bureau of Reclamation is hiding behind a model when they really haven't looked at all the parameters we think they should look at," he said.

For example, Weisheit noted Reclamation used the most optimistic estimates of annual yield on the Colorado River based on tree ring records -- 14.7 million acre-feet. Other models show yields as low as 13 million acre-feet, he said.

"There's reason for that," Weisheit said. "The model at 14.7 million acre-feet shows that the world is still rosy, but the model at 13 or 14 million acre-feet shows both reservoirs go empty for a long period. That's not what the Bureau of Reclamation wants the public to know. They're not being honest with the American public."

"There's not going to be water for anything eventually," Weisheit added. "They basically are praying for rain."

Weisheit said his group has not yet discussed whether they will challenge the bureau's plan in court. However, it appears likely that there will be some sort of legal challenge to the plan based on violations of the National Environmental Policy Act.

Gable is an independent energy and environmental writer in Woodland Park, Colo.

LR Press Release 11/15/07

Federal Water Managers Ignore Climate Change on the Colorado River, but You Don't Have to.

FOR IMMEDIATE RELEASE

November 15, 2007

Contacts: Owen Lammers - 435-261-4163; Niklas Christensen - 206-617-2050

Federal Water Managers Ignore Climate Change on the Colorado River, but You Don't Have to.

New simulator puts water shortage forecasting on your desktop.

Two weeks ago the Bureau of Reclamation released its first ever plan for managing the Colorado River under shortage conditions. However, their strategy is based on a narrow set of assumptions that underestimate the potential for future shortfalls, and the risks to the region's \$1.2 trillion economy.

Using the same techniques employed by Reclamation's forecasters, the Colorado River Open Source Simulator (CROSS)* has been developed to allow the public the opportunity to explore a more complete range of scenarios which nature may have in-store for Colorado River water users.

"CROSS's simple interface is designed for anyone to use, whether familiar with the Colorado or not," says Niklas Christensen, who developed the simulator for Living Rivers and is releasing it today at the American Water Resources Association's annual conference in Albuquerque. "Most importantly, using the same inputs, CROSS outputs validate well against Reclamation's far more sophisticated and expensive model, making this a credible and valuable public tool in this era of Colorado River uncertainty."

As a leading scientist on assessing the impact of climate change on the hydrology and water resources of the Colorado river, Christensen is fully aware of the risks that may lie ahead for the watershed. Results from his research, funded by the Department of Energy, predict up to a ten percent reduction in flows by the end of the century. Findings by other scientists, such as Martin Hoerling from the National Oceanic and Atmospheric Administration, predict the change could be much greater and come more quickly, up to a 40 percent reduction in flows by the middle of the century.

"None of us can say with precision what's going to happen, but what the science is telling us is that something very likely will, and it's quite surprising that such an important variable has been omitted from Reclamation's shortage forecasting," adds Christensen.

CROSS shows that a reduction in the middle range of predictions, 20% by the year 2100, would render it highly unlikely that Lake Mead, the nation's largest reservoir, would ever fill again, and a strong likelihood of being empty for good by 2050. By contrast, Reclamation's shortage assumptions have Lake Mead holding steady

throughout their 2008 – 2060 forecast period. Worse still, should flows mimic what the basin has experienced so far this century, CROSS shows how Lake Powell, the Nation's number two reservoir, and Lake Mead would likely become operationally empty within the next five years.

“With the region in its longest recorded drought, reservoirs at below 50% capacity, it's amazing that Reclamation modelers assume the Colorado of the future will likely mimic its high flow periods of the past,” says Owen Lammers, Executive Director of Living Rivers. “With every drop of water already allocated, and just a 2% mistake equivalent to losing Las Vegas's Colorado River water supply, providing the public with comprehensive forecasting is no trivial matter.”

Even if climate change were not an issue, Reclamation's forecasts still errors toward the positive. Current estimates of the long-term annual flow of the Colorado River range from 13.0 to 14.7 million acre-feet (maf). Reclamation's forecasting is largely based on flows of 15.0 maf—the recorded average streamflow from 1900 - 2005. These 20th century flows, however, are now recognized to be among the wettest in 1,200 years. While Reclamation acknowledges this, and has conducted some alternative analysis with flows as low as 14.6 maf, it failed to examine the full range of variability offered by researchers.

CROSS illustrates how at 14.0 maf Reclamation's new shortage policy will be immediately taxed, very likely requiring consultation with the Secretary of Interior to determine who gets what water and when, the precise action these policies were designed to avoid. At 13 maf, the new system collapses altogether with Lake Mead likely operationally empty by 2020, rising for only brief periods through the rest of the century.

“It's not that we feel such scenarios are any more valid than what Reclamation has offered, its just their omission misrepresents the potential for shortages that science suggest we ought to acknowledge,” stresses Lammers. “Fortunately with CROSS, anyone can explore the full range of possibilities, as well as the amount of water conservation we can employ to successfully navigate any uncertainty.”

###

LR Letter 12/02/07

Scoping letter: Castle Rock Cut at Lake Powell

December 2, 2007
Mr. Kevin Schneider
Public Affairs Office
Glen Canyon National Recreation Area
P.O. Box 1507
Page, AZ 86040-1507

Sent via email:
Kevin_Schneider@nps.gov
Sent via fax: 928-608-6259

Re: Environmental Assessment (EA) for the Castle Rock Cut

Dear Mr. Schneider,

Thank you for this opportunity to provide scoping comments for the proposal to excavate a deeper cut at the divide near Castle Rock for the passage of boats during low reservoir conditions. Our comments are written on behalf of the following organizations:

Living Rivers (www.livingrivers2.org)
Colorado Riverkeeper (www.coloradoriverkeeper.org)
Colorado Plateau River Guides (www.riverguides.org)
River Runners For Wilderness (www.rrfw.org)
Southern Utah Wilderness Alliance (www.suwa.org)
Wildlands CPR (www.wildlandscpr.org/utah)

The cut should be left as it is. The previous excavations should be considered as mistakes by administrations of the past.

To many people the managing guidelines for multiple-use criteria at a National Recreation Area (NRA) does not include large-scale, extraordinary alterations to the natural landscape. The basic facilities for the users of the NRA have already been provided. The cut at Castle Rock is an extraordinary development activity that is inappropriate.

The Park Service must surely be aware that this development plan borders on the unethical and is therefore highly controversial within the public perception. It would be wise and prudent for the Park Service to do no harm and, instead, accept the circumstances that Nature presents.

The issues of safety and congestion at The Narrows, near Antelope Point Marina, is a consequence of the Park Service's decision to allow a marina to exist at a poor geographic location. It has essentially been decided by the Park Service that there are

no safety concerns at The Narrows, since the marina at Antelope Point exists at the discretion of the Park Service. Therefore, this issue has already been determined by the Park Service as a non-issue.

If safety is now an issue, then the Park Service needs to also include a remedy to their planning error, and in addition to the whatever decision is made concerning the cut near Castle Rock. Living Rivers addressed this safety issue on the matter of the development plan for Antelope Point Marina in year 2000. We declared that the marina should not be developed for this and many other reasons, and so it is appropriate for us to ask that an alternative to close Antelope Point Marina be appraised.

If the Park Service permits the excavation at Castle Rock, then this also implies that the Park Service will also be responsible for all the other access issues the multiple-users of the NRA may have concerning facilities when the reservoir levels of Lake Powell are low.

For example, does this mean that the Park Service will also excavate a bedrock take-out at Hite Marina and Clay Hills Crossing for river runners? Will the Park Service excavate a trail in the cliffs of Dark Canyon so that river visitors can circumvent the treacherous sediment deposits at this side canyon? Will the Park Service also excavate a trail so that visitors can once again access Clearwater Canyon?

Additionally, what about the impossible and unsafe camping situations due to massive sediment deposits at lower Cataract Canyon, Narrow Canyon, and lower San Juan Canyon? Will the Park Service also be willing to excavate campsites in the bedrock cliffs so visitors can prepare meals and sleep in safety without having to worry about landslides and blocks of dried sediment tumbling into their camps?

On this matter of declining reservoir levels, as it applies to the visitor experience at the NRA, it is apparent that a Environmental Impact Statement (EIS) is clearly in order because a comprehensive assessment of the issues and remedies will be required for the Park Service to make appropriate decisions. We highly suggest that the Park Service implement such a strategy.

For example, considering that the Shortage Criteria EIS prepared by the Bureau of Reclamation has not considered paleoclimate data or atmospheric warming data into their hydrology model, serious management unknowns yet remain about addressing development plans that are presumed necessary to implement in response to lowering reservoir levels at Lake Powell.

We suggest that the Park Service provide the leadership that Reclamation has demonstrated a reluctance to provide; a reluctance that leaves management plans by cooperating agencies, such as the Park Service, hanging in the realms of uncertainty.

We also suggest that the Park Service investigate a recently released open source simulator to determine for itself how persistent drought and climate change would effect Lake Powell. The simulator is called CROSS and is available at the following web site: www.onthecolorado.org/cross.cfm

It is highly probable that the Castle Rock Cut is not a remedy at all in the long-term. For example, if this drought becomes any more persistent than it has already proven to be, is the Park Service contemplating yet another excavation, and yet another, as it chases an ever declining reservoir? If so, then this issue also needs to be addressed more comprehensively as an EIS.

At this time, the most prudent and reasonable alternative for this proposed management action is to leave the cut at Castle Rock the way it is and accept the extraordinary consequences of Nature.

Sincerely yours,

John Weisheit, Conservation Director

States agree on plan to make water last

As reservoirs dwindle, river states agree to a landmark conservation plan

Shaun McKinnon

The Arizona Republic

Dec. 9, 2007 12:00 AM

Water users from the seven Colorado River states are expected to ratify a regional drought plan this week in Las Vegas, ending years of bickering over how to balance uncertain resources with growing demand.

The heart of the plan is the heart of the river system, its two largest reservoirs along Arizona's northern borders. Lake Powell and Lake Mead hold not only the water needed to survive long dry periods but also the key to a landmark deal meant to give the states a chance to find longer-lasting solutions.

Drought has drained the two reservoirs to below half capacity, increasing the threat of water shortages upstream and in Arizona, along with the loss of cheap hydropower and

damage to riparian habitat and recreation sites. With that much at risk, some of the states were prepared to fight costly legal battles. The drought plan can't keep the lakes from shrinking further if dry conditions persist and could trigger the first shortage as early as 2010. But by focusing on the reservoirs and the way they help manage the river's limited supply, the states hope to protect users from the worst effects of drought.

The plan guides management of the river through 2026 using reservoir levels to trigger rationing and a series of experimental conservation programs. Environmental groups say the plan fails to protect the river itself, but the states insist they produced what they could within their limits.

"This won't eliminate the risk of shortage, but it prolongs the period of time before we experience one," said Sid Wilson, general manager of the Central Arizona Project, which delivers Colorado River water to Phoenix and Tucson. "None of us doubt that drought is a more ominous threat than we ever realized."

Finally, a plan

The seven river states - Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming - had never written a drought plan because they never needed one. The region survived a severe dry stretch in the 1950s, before growth pushed up demand. And when a string of wet years followed, the states instead adopted rules to manage surplus water.

Almost before those rules took effect, drought hit again. Faced with potential shortages and threats from the Interior secretary to impose a federal solution, water users started talking about what happens if the river can't supply demands.

What emerged from negotiations was a plan built around the two big reservoirs.

Until now, separate rules governed the way water flowed from Lake Powell - which was built to benefit Colorado, New Mexico, Utah and Wyoming - into Lake Mead, which stores water for Arizona, California and Nevada.

The drought plan, which includes parts of the old surplus guidelines, would impose one set of rules to operate the reservoirs, balancing the needs of users in both the upper and lower basins. Low water levels in Lake Mead will trigger rationing in Arizona and Nevada under the plan; other measures will attempt to delay shortages.

The first trigger would cut Arizona's allocation by 320,000 acre-feet (about 11 percent) until lake levels recovered. Arizona could lose up to 17 percent of its allocation under the plan's most dire scenario. State officials say agricultural users would absorb most, if not all, of the losses.

Lake Mead currently sits about 36 feet above the first shortage trigger. Federal hydrologists say the lake should remain at least 25 feet above the trigger in 2008.

"By managing the two reservoirs together rather than fighting over how much water will be released every year, we'll help mitigate the probability of Arizona taking shortages," said Herb Guenther, director of the Arizona Department of Water Resources.

How it works

Barely 300 miles separate Lake Powell, on the Arizona-Utah border, and Lake Mead, on the Arizona-Nevada border, but what happens at the two reservoirs reverberates up and down the Colorado River.

If water levels at Powell drop too low, upstream users would face cutbacks. Hydropower generation would decline. Recreation venues would close. As Lake Mead shrinks, so would Arizona's CAP supply, cutting off farmers in Maricopa, Pinal and Pima counties until water levels rise again.

How water users along the Colorado manage the water conversely affects the lakes and the people and businesses that surround them.

The construction of Glen Canyon Dam in the 1960s gave birth to Page on the shores of Lake Powell; when drought reduced the reservoir to one-third of its capacity, tourism revenue in the city plummeted.

Mike McNabb has fished Lake Powell for most of the 27 years he has lived in Page and now runs a fishing-guide business. He has seen the city's fortunes rise and fall with the lake levels, and he watches warily as the states plan the future.

"They say it'll never be full again," he said. "But we could have some unbelievable winters and in about three years fill that lake up again. You just never know."

Two years ago, spring runoff inundated parts of the lake that had been dry, covering tamarisk and other plants that had sprouted. With a new food source under water, the fish population exploded.

Anglers get used to events like that, McNabb said. "Right now, the water's going down, and I know a lot of places where it's good when it's down. In the spring, when the lake comes up, I've learned where the good spots are."

Because Lake Powell sits in a narrow river gorge, fluctuating water levels can uncover rocky outcrops and alter boat lanes. The National Park Service, which manages the lake's recreational amenities, is considering a plan to cut a deeper passage through Castle Rock, where exposed rocks have added 12 miles to a trip upstream.

"The problem is now we have to go through the narrows, between the cliffs, and smaller boats have to wait for the big ones to go through so they don't get caught in the wakes," McNabb said. "Sooner or later there's going to be an accident."

Environmental groups have protested the dredging plan, calling it a temporary fix that will degrade the canyon and the lakeshore. They say the boat path, like the broader drought plan, risks the Colorado River's riparian health and ignores the threat of climate change.

Some of those groups proposed their own drought plan, which would have imposed stricter conservation measures. The states' plan, environmentalists say, relies too heavily on the river's past behavior.

"With the region in its longest recorded drought and reservoirs at below 50 percent capacity, it's amazing that the states would assume the Colorado of the future will mimic its high flow periods of the past," said Owen Lammers, executive director of the group Living Rivers.

Brad Udall, an environmental engineer at the Western Water Assessment in Boulder, Colo., helped analyze future climate shifts for the seven states. He said water managers need to consider that the river may behave differently.

"In the Southwest, almost all the models point to drier conditions," he said.

Scientists and decision makers must now figure out which models to believe.

The states say the drought plan before them now will help bridge the gap in scientific study and avoid paralyzing conflicts over water supplies.

"We now have a better understanding of the risks and what the impacts will be associated with those risks," said Wilson, the CAP executive.

The greater immediate risk was failing to reach an agreement and allowing the dispute to spill into a courtroom.

"Failure was not an option," said Pat Mulroy, general manager of the Southern Nevada Water Authority. "Failure is uncertainty for all of us, it's chaos for all of us, it's spending public dollars in absolutely useless ways.

"You'll never get as good an arrangement from a judge," she said. "No matter how well-intentioned or how well-informed a judge is, he's still not responsible at the end of the day to deliver water to people. We are."

Federal pact would allocate Colorado River water to Western states

New York Times

International Herald Tribune

By Randal C. Archibold

Published: December 10, 2007

LOS ANGELES, Dec. 9 — Facing the worst drought in a century and the prospect that climate change could yield long-term changes on the Colorado River, the lifeline for

several Western states, federal officials have reached a new pact with the states on how to allocate water if the river runs short.

State and federal officials praised the agreement as a landmark akin to the Colorado River Compact of 1922, which first outlined how much water the seven states served by the river — California, Nevada, Arizona, Colorado, Utah, New Mexico and Wyoming — would receive annually.

The new accord, outlined by federal officials in a telephone news conference Friday, spells out how three downriver states — California, Arizona and Nevada — will share the impact of water shortages. It puts in place new measures to encourage conservation and manage the two primary reservoirs, Lake Mead and Lake Powell, which have gone from nearly full to just about half-empty since 1999.

The accord is expected to forestall litigation that was likely to have arisen as fast-growing states jockey for the best way to keep the water flowing to their residents and businesses in increasingly dry times. It would be in effect through 2026 and could be revised during that time.

Some environmental groups said the pact did not go far enough to encourage conservation and discourage growth. But federal officials said they took the best of several proposals by the states, environmental organizations and others and emphasized the importance of all seven states agreeing with the result.

“I think for the first time in 85 years we are on the same page,” said Herb Guenther, the director of water resources in Arizona, which had initially balked at some terms of the agreement and was threatening legal action over it.

But with water levels in reservoirs dropping, a record eight-year drought, the prospect that climate change could bring more dry spells and new scientific analyses suggesting the West could be drier than has been traditionally believed, the states were pushed to act.

These factors “forced the issue to the head and we decided to do something unique and different,” Mr. Guenther said.

The agreement, the product of two-and-a-half years of negotiation and study, establishes criteria for the Interior Department to declare a shortage on the river, which would occur when the system is unable to produce the 7.5 million acre-feet of water, enough to supply 15 million homes for a year, that the three downriver states are entitled to.

Water deliveries would be decreased based on how far water levels drop in Lake Mead and Lake Powell. The Bureau of Reclamation, which manages the river system, predicts about a 5 percent chance of such a shortage being declared by 2010, but it all depends on how much the states are able to conserve and, of course, the weather.

The probability projection “does not imply it can’t happen,” said Terry Fulp, a bureau official involved in managing the river.

Water districts, anticipating an eventual cutback of Colorado River water, have been storing large amounts of water and the accord encourages them to continue to do so.

The pact, which Interior Secretary Dirk Kempthorne is expected to sign Thursday, includes a bundle of agreements with the states. One is approval for water managers in the Las Vegas area, which gets 90 percent of its water from the Colorado, to get a greater share of Lake Mead water in exchange for financing a reservoir in California to capture large amounts of river water destined for Mexico but beyond that country's entitlement by treaty.

"It's hugely important for us," said Scott Huntley, a spokesman for the Southern Nevada Water Authority. "This really does provide the bridge for us to get into the next decade."

But John Weisheit, conservation director for Living Rivers, a Utah-based environmental group, said the agreement sends the message to the states that growth trumps sensible water management. Mr. Weisheit said the conservation should have been emphasized and the government's computer modeling was overly optimistic about future water supply.

"There is more water on paper than there actually is on the landscape," he said. "They are looking at this in a way that will allow more development even though the water is not theoretically there."

Scientists want to flush out Grand Canyon again

Past releases from Glen Canyon Dam haven't beefed up sandbars

By Patty Henetz

The Salt Lake Tribune

Article Launched: 12/12/2007 08:39:56 PM MST

LAS VEGAS - Flushing water through the Glen Canyon Dam to try to build up sandbars, beaches and backwaters hasn't worked in the past, but that's not a deterrent to federal scientists who want to try again.

Speaking during a meeting of the Upper Colorado River Commission, U.S. Geological Survey scientist John Hamill said plans are afoot to release 41,500 cubic feet per second of water from behind the dam into the river below for 60 hours.

The release would be a way to incorporate previous results from other experiments to try to find a way to sustain sand flow in a healthy way in the river to discourage exotic invasive vegetation and create safe harbors for species including the endangered humpback chub, said Hamill, chief of the USGS monitoring and research center in Flagstaff, Ariz.

The Upper Colorado River Commission, which manages the Colorado River rights for Utah, Montana [Wyoming], New Mexico and Colorado, met during the annual Colorado

River Water Users Association meeting. The association includes the lower basin states - California, Arizona and Nevada - that have prior rights on the river and hold the balance of power over the entire river system's allocations.

The U.S. Bureau of Reclamation, which already has spent more than \$200 million seeking ways to counter the dam's downstream damage, is actively planning for the release, even though a 2005 USGS report said 13 years of similar efforts had been unsuccessful.

Previous attempts have either blasted away the sand that had accumulated naturally from tributary inflow, or simply didn't deposit any sand. This time, Hamill said, the river below the dam is relatively sandy, and changes in Grand Canyon management have allowed warmer water and more sediments to flow through the dam.

The technique is called "adaptive management," kind of a learn-as-you-go series of experiments designed to run over the long term. The 2008 test would be a synthesis of previous experiments, including a test in summer 2000 where dam releases were kept at a steady 8,000 cubic feet per second from June 1 to Sept. 1.

Hamill said that resulted in water temperatures in backwaters and shallow shoreline habitats reaching about 50 degrees Fahrenheit - the river below the dam is usually about 20 degrees Fahrenheit [colder than the pre-dam river temperature]. The steady release also limited sand drift downstream and kept healthy a population of humpback chub that had been moved near the mouth of the Little Colorado.

Still, there's a limit to building up sandbars; it is only possible if there's already a lot of sand in the river - and there's not.

Scientists acknowledge that the tributaries that feed the Colorado River below the dam, such as the Paria and Little Colorado, don't provide enough sand to keep ecosystems healthy.

And as Lake Powell sediments become increasingly polluted, just sending them down-river isn't a good answer, either, said Living Rivers director John Weisheit. The only solution, he says, is to remove the dam.

Built in 1963, Glen Canyon Dam has provided water and power for the West. The sand-flow issue must be resolved - both because of the need for sandbars in the Grand Canyon, and because the buildup of sediment in Lake Powell will eventually threaten the reservoir and the functions of the already-impaired hydropower plant.

Interior secretary signs historic plan as basin states work on water conservation, augmentation

(Thursday, December 13, 2007)

April Reese, Land Letter Western reporter

After two-and-a-half years of negotiations amid a record drought, an unprecedented agreement aimed at helping the seven states in the Colorado River basin endure future water shortages is final. Interior Secretary Dirk Kempthorne signed the accord today at a ceremony in Las Vegas.

The states and the Bureau of Reclamation claim the new plan will stretch shrinking water supplies in the basin, provide more certainty to the states about what will happen when reservoir levels drop and help avoid lawsuits. Within the framework of the agreement are a series of water management stipulations for the states and a host of conservation and water augmentation measures.

The seven states and the Bureau of Reclamation claim the new plan will stretch shrinking water supplies in the basin and provide more certainty to the states about what will happen when reservoir levels drop. Map courtesy of the Department of Interior.

The agreement, the "Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead," spells out how much the states will be required to reduce their take of the Colorado River during dry times and under what circumstances. In 2005, then-Interior Secretary Gale Norton directed the states to work together to find ways to ease the pain of projected shortages in the basin. The drought, now in its eighth year, along with climate change impacts and increasing growth in many basin states, provided a strong incentive for the states to hammer out their differences during negotiations, federal officials said.

"It really has taken a lot of participation and good will and the commitment among the seven basin states and Reclamation to try to find solutions," said Barry Wirth, spokesman for Reclamation's upper Colorado River Basin office. "They were challenged by the secretary to come up with shortage strategies, and they did."

"It had to be done to stretch the water supply and get through the tough times that are inevitably ahead," said Don Ostler, executive director of the Upper Colorado River Commission. "I think everyone is hopeful this will make a significant difference."

The drought -- the worst the basin has seen in 100 years -- has shrunk water levels in the Colorado River's two main storage reservoirs, Lake Powell and Lake Mead, to about half full. In 1999, before the drought hit, the lakes were near capacity (Land Letter, April 12). Meanwhile, population growth -- and the increased demand it brings -- continues to tax water supplies in the basin, pushing some states to the limit of their Colorado River allocation.

"This is a critical time -- perhaps even an historic time -- in the Colorado Basin," Kempthorne said, during the accord ceremony today.

"We're really trying to take a holistic approach to managing these two reservoirs and come up with a management scheme that really benefits both [upper and lower] basins," said Terry Fulp, area manager for Reclamation's Boulder Canyon operations office and one of the officials involved in writing the plan.

Skeptics of the plan

But river advocates gave the accord mixed reviews. Jennifer Pitt, of Environmental Defense's Boulder, Colo., office, commended BuRec and the states for providing "badly needed flexibility" for managing the river's water. And she lauded a provision that helps clear the way for Mexico to negotiate releases from Lake Mead that could send more water to the beleaguered Colorado River Delta (Land Letter, March 22). But in the end, there may simply not be enough water to go around, she added.

"The bottom line is, if the hydrology stays bad and growth continues, we're still going to be in a water crunch," said Pitt, who submitted a conservation-based proposal during the review process for the plan.

Others criticized the document as a testament to wishful thinking in an increasingly water-strapped -- and overdeveloped -- basin.

"They're not going to conserve a gallon of water," said John Weisheit, conservation director for Living Rivers, an environmental group based in Moab, Utah, that advocates breaching Lake Powell's Glen Canyon Dam. "They're just going to turn around and build another house."

"I'm very skeptical," added Nikolai Lash, senior program director for the Grand Canyon Trust in Flagstaff, Ariz. "It doesn't recognize that we have a very flawed framework of water distribution, that it's based on [estimates from] wet years rather than the realistic climate change years we're in the midst of. We'll be revisiting this agreement 10 years from now."

The 1922 compact that divvies up the river's water among the seven states was negotiated during an unusually wet period in the Colorado River basin, and the allocations to the states may not reflect the hydrological reality in the basin, particularly as climate change takes its toll, he said. In the new plan, Reclamation acknowledged that it may have overestimated average flows in the basin but does not suggest revisiting the compact (Land Letter, Nov. 8).

A balancing act

Reclamation took the best ideas from proposals submitted by the states, environmental groups and other entities, officials said.

Under the 1922 compact and other agreements collectively known as the "law of the river," Lake Powell, on the Utah-Arizona border, stores water for the upper basin, and

Lake Mead, on the Arizona-Nevada border, stores water for Arizona, Nevada and California. The upper basin is required to send 7.5 million acre-feet of water downstream for use in the lower basin each year, and all seven basin states must collectively deliver 1.5 million acre-feet to Mexico.

Under the new agreement, which is intended to direct management of the river until 2026, the two reservoirs will be operated in tandem to ensure that neither drops too low. That will help prevent shortages in the lower basin and the need for curtailments of water usage in the upper basin, Wirth said.

If there is a shortage, which would have to be declared by the secretary of Interior, the states will be required to make specific cuts in their use of Colorado River water, based on three trigger points in Lake Mead.

Under the pecking order laid out in plans, Arizona would be hit first if levels in Mead fell to the first trigger point set in the plan. The state would need to cut 320,000 acre-feet, or 11 percent of the state's Colorado River allocation, until water levels in Lake Mead rose again. If reservoir levels continued to fall, Nevada would then have to reduce its use. Further drops would prompt cuts by California, although some officials question whether reservoir levels would drop that low, even in a severe drought.

In most cases, agriculture would be hardest hit.

Levels in Lake Mead are now about 35 feet above the first trigger point. Fulp of Reclamation said there is a 5 percent chance that shortages will occur in the basin by 2010.

Conservation and augmentation

In an effort to cushion the blow of a potential shortage, the lower basin states also agreed to undertake a host of measures and projects to improve efficiency in the system, increase conservation, and tap alternative supplies to lessen their dependence on the Colorado River and leave more water in Lake Mead to avoid reaching shortage triggers.

Population growth taxes water supplies in the basin, pushing some states to the limit of their allocation. Photo courtesy of NOAA.

For instance, the Southern Nevada Water Authority, which relies on the Colorado River for 90 percent of the water that quenches the fast-growing Las Vegas area, will be able to draw more water from Lake Mead in exchange for helping to build a new reservoir in California, called "Drop Two." The reservoir, which will be built near the Mexican border, will capture additional water not needed by Mexico. Currently, if rainfall adds more water to the lower reaches of the basin, it simply ends up as a bonus to Mexico because there is currently no way to store it, said Bob Walsh, a spokesman for Reclamation's lower Colorado River office.

The lower basin states also have come up with ways to make it easier for managers to transfer water from agricultural lands to cities.

Creating new water supplies through desalinization, which involves treating ocean water to turn it into potable water, is also under discussion.

Essentially, those conservation and augmentation measures would allow states to leave more water in Lake Mead that they could later withdraw for future use. "If you provide that water instead of Colorado River water, therefore saving water in Lake Mead, it could be conserved and used by a state," said Ostler of the Upper Colorado River Commission. Currently, a state that banks water in the reservoir loses it if it is not used within one year.

Under the agreement, only the state that adds water to Lake Mead can remove it later. But about 5 percent of a water contribution is banked for use in the entire lower basin, and some of that water can be used for environmental purposes -- a provision for which environmental groups fought.

The new guidelines, which will go into effect in January, can be revisited if the states or Reclamation feel they are not working or if new information about climate change impacts required a retooling of the plan, Wirth said.

Experimental flow plan for Glen Canyon Dam aims to recover endangered fish

Thursday, January 24, 2008 April Reese, Land Letter Western reporter

The Department of Interior last week announced plans to release an experimental high flow from behind Glen Canyon Dam to help recover endangered fish and other resources downstream in Grand Canyon National Park.

Federal officials hope the surge, which will mimic historic, pre-dam flows on the Colorado River, will deliver sediment downstream and rebuild eroded beaches. Beaches and sandbars provide crucial habitat for wildlife and create backwaters for native fish, including the endangered humpback chub. The accumulation of sand also helps protect archaeological sites.

The Bureau of Reclamation, which manages the dam, conducted a similar experiment in 2004 (Land Letter, Dec. 2, 2004). The new experiment, announced Jan. 17, will build on the information gleaned from the 2004 experiment and another in 1996, said John Hamill, head of the U.S. Geological Survey's Grand Canyon Monitoring and Research Center. This time, there is an influx of sand in the Colorado River system, which will be carried by the high flows released from the dam.

"Given the current amount of sand in the system, we have a tremendous opportunity to learn more about whether high flows can be used to improve important natural, cultural, and recreational resources in Glen and Grand canyons," Hamill said.

If the secretary of the Interior Department approves the plan, Reclamation will send 41,000 cubic feet per second of water surging down the Colorado River through the Grand Canyon for about two-and-a-half days. That is more than twice the amount of water typically released from the dam; since 1996, releases have ranged between 8,000 and 20,000 cubic feet per second.

The effects of the high flows, tentatively scheduled to begin March 4, will be studied by a cadre of federal scientists. The experiment will "provide the valuable information needed to protect the resources within Grand Canyon National Park," said Steve Martin, superintendent of Grand Canyon National Park.

Under the Grand Canyon Protection Act, Reclamation must make sure operations are conducted in a way that protects Grand Canyon resources.

Larry Walkoviak of Reclamation said the experiment will not increase the overall amount of water released over the course of the 2008 water year. Monthly releases later in the year will be lower to make up for the higher flows in March, he said.

Criticisms

But critics say the experiment is not enough to help the park's resources, which have suffered because of the dam.

"This is a half measure," said John Weisheit, conservation director for Living Rivers. "Unless they do it every year, it's not going to work."

And the amount of sediment flowing in from the Paria River and other tributaries is insufficient to make up for the dam's restriction of sediment in the Colorado River itself, he added. Dam managers estimate that 92 percent of the sediment that would be carried downstream by an undammed river is blocked by Glen Canyon Dam.

"They seriously need to start looking at other alternatives, which are sediment augmentation and decommissioning," Weisheit said.

Augmentation would involve trucking or piping sediment around the dam, an option that has been discussed but never tried, partly due to its exorbitant expense.

Decommissioning would involve breaching or removing the dam, a controversial option Living Rivers has advocated for years but Reclamation and power interests oppose.

In December, environmental groups filed suit against Reclamation over the agency's normal operation of the dam (Land Letter, Dec. 13). The groups argue that a 1994 biological opinion from the U.S Fish and Wildlife Service requires the agency to release high flows in the spring and low flows in the summer and fall to benefit the chub. Currently, Reclamation releases low, fluctuating flows throughout the year.

A final decision on the experimental flow proposal is expected in late February.

April Reese writes from Santa Fe, N.M.

Reclamation Releases Environmental Assessment for Public Comment on Proposed High-Flow and Steady Flow Experiment on the Colorado River

Salt Lake City, UT - The Department of the Interior's Bureau of Reclamation today released for public comment an Environmental Assessment that describes a proposed early-March 2008 high-flow test and fall steady flow experiment from Glen Canyon Dam

downstream through the Grand Canyon. Comments will be due by close of business February 22, 2008.

"Reclamation continues to support the application of science and adaptive management to the operation of Glen Canyon Dam and the management of natural resources in Glen and Grand Canyon," Reclamation Commissioner Robert W. Johnson said in announcing the availability of the Environmental Assessment. "Experiments such as the proposed high-flow and fall steady flow continue to advance our understanding of the ecosystem while providing tangible benefits to the fishery, river environment, and recreational users in Grand Canyon National Park."

The environmental assessment evaluates the impact of the proposed test on a wide range of environmental and socioeconomic resources. A decision by the Department of the Interior is anticipated in late February 2008, with plans to conduct the high flow in early March 2008, if the decision is to move forward with the experiment.

The high-flow experiment and associated research activities, should they occur, will be undertaken cooperatively by scientists and resource managers from Interior's U.S. Geological Survey (USGS), Reclamation, National Park Service, U.S. Fish and Wildlife Service, and Bureau of Indian Affairs.

The 2008 test would be similar to the previous high-flow tests conducted in 1996 and 2004, but the amount of sediment available is considerably larger. In particular, scientists have concluded that more sand is needed to rebuild sandbars throughout the 277-mile reach of Grand Canyon National Park than was available in 1996 or 2004. Currently, sand supplies in the river are at a 10-year high with a volume about three times greater than in 2004 due to tributary inflows below the dam over the past 16 months.

The Environmental Assessment is available for public review on the Internet by following the link at [Click Here](#) or by contacting Dennis Kubly, Bureau of Reclamation, Upper Colorado Regional Office, 125 S. State Street, Salt Lake City, Utah 84138, and by telephone at (801) 524-3715.

Comments: West-wide Energy Corridor DEIS

West-wide Energy Corridor DEIS
Argonne National Laboratory
9700 S. Cass Avenue
Building 900, Mail Stop 4
Argonne, IL 60439
Sent via fax: 866-542-5904

Dear Ms. Julia Souder,

Thank you for this opportunity to submit comments on West-wide Energy Corridor Programmatic Environmental Impact Statement (PEIS). Living Rivers is a non-profit organization based in Moab, Utah, which is situated along the Colorado River and two national parks, Canyonlands and Arches. Our mission is to preserve, protect and restore watershed ecosystems and resources in the Colorado River basin.

The Colorado River is the lifeblood of the seven western states and Mexico. The river supplies water for federal reserve lands, agriculture and 30 million people. The geophysical province, the Colorado Plateau, is the major drainage area by volume in the Colorado River basin.

The Colorado Plateau and the Colorado River will be adversely affected by the development of energy transmission corridors considered in this PEIS. This development will encourage industries that are inappropriate for a watershed of this importance, because it will jeopardize our drinking water and watershed habitats that are necessary to recover federal endangered species.

This development sets the stage for extractive industries, and power-generation facilities, of both fossil and nuclear fuels, to enter the Colorado Plateau. The Colorado Plateau is the largest intact wilderness and refuge by area in the contiguous United States.

These industries require incredible amounts of water to operate. Water the Colorado River can no longer reliably provide, because the legal documents of the system have created a situation of over-allocation. Additionally, over-consumption and excessive evaporation from rising temperatures in the atmosphere, will continue the trend of dwindling supplies. Reservoirs are currently lowering and in-stream flows are diminishing throughout the basin.

The energy program proposed in this document, and its connection to large-scale energy fuel development projects, will cause unnecessary harm to the various communities dependent on the Colorado River. They are also financially burdensome and will not reduce our dependency of finite energy resources.

The paradigm of status quo energy development must be changed. Research and development funds must be appropriated to begin a new paradigm of renewable resources and conservation. These programs will reduce the ever-increasing amount of pollution entering the atmosphere and the landscape.

Furthermore, transmission lines spanning the open spaces of the Colorado Plateau, which has the highest concentration of national parks in the United States, can be avoided completely by keeping energy-producing facilities as close to the market place as possible. Eliminating extensive transmission lines altogether will help to increase the yield of electricity through efficiency, and protect what cherished landscapes yet remain in our wild lands of the Colorado Plateau.

If we can be of further assistance to you, please do not hesitate to contact us.

Sincerely yours,

John Weisheit
Conservation Director

Lake Mead Could Be Dry by 2021

From: Scripps Institution of Oceanography/UC San Diego

[Scripps's Press Release](#)

[Scripps's science paper](#)

[Reaction by the water managers to the Scripps's press release](#)

Tuesday, February 12, 2008

Lake Mead Could Be Dry by 2021

Analysis of current and scheduled use and human-induced climate change sparks urgent warning from researchers at Scripps Institution of Oceanography, UC San Diego.

There is a 50 percent chance Lake Mead, a key source of water for millions of people in the southwestern United States, will be dry by 2021 if climate changes as expected and future water usage is not curtailed, according to a pair of researchers at Scripps Institution of Oceanography, UC San Diego.

Without Lake Mead and neighboring Lake Powell, the Colorado River system has no buffer to sustain the population of the Southwest through an unusually dry year, or worse, a sustained drought. In such an event, water deliveries would become highly unstable and variable, said research marine physicist Tim Barnett and climate scientist David Pierce.

Lake Mead at Hoover Dam, October, 2007. According to Scripps researchers, the lake could dry up by 2021 if preventative measures are not taken. Photo courtesy of Dr. Ken Dewey, Applied Climate Sciences Group, University of Nebraska, Lincoln.

Lake Mead at Hoover Dam, October, 2007. According to Scripps researchers, Lake Mead could be dry by 2021 if climate changes as expected and future water usage is not curtailed. Photo courtesy of Dr. Ken Dewey, Applied Climate Sciences Group, University of Nebraska, Lincoln. Barnett and Pierce concluded that human demand, natural forces like evaporation, and human-induced climate change are creating a net deficit of nearly 1 million acre-feet of water per year from the Colorado River system that includes Lake Mead and Lake Powell. This amount of water can supply roughly 8 million people. Their analysis of Federal Bureau of Reclamation records of past water demand and calculations of scheduled water allocations and climate conditions indicate that the system could run dry even if mitigation measures now being proposed are implemented.

The paper, "When will Lake Mead go dry?," has been accepted for publication in the peer-reviewed journal *Water Resources Research*, published by the American Geophysical Union, and is accessible via the AGU's website (see instructions below).

"We were stunned at the magnitude of the problem and how fast it was coming at us," said Barnett. "Make no mistake, this water problem is not a scientific abstraction, but rather one that will impact each and every one of us that live in the Southwest."

"It's likely to mean real changes to how we live and do business in this region," Pierce added.

Research marine physicist Tim Barnett (right) and programmer/analyst David Pierce of the Climate, Atmospheric Science and Physical Oceanography (CASPO) division at Scripps Institution of Oceanography, UC San Diego.

Research marine physicist Tim Barnett (right) and programmer/analyst David Pierce of the Climate, Atmospheric Science and Physical Oceanography (CASPO) division at Scripps Institution of Oceanography, UC San Diego.

The Lake Mead/Lake Powell system includes the stretch of the Colorado River in northern Arizona. Aqueducts carry the water to Las Vegas, Los Angeles, San Diego, and other communities in the Southwest. Currently the system is only at half capacity because of a recent string of dry years, and the team estimates that the system has already entered an era of deficit.

"When expected changes due to global warming are included as well, currently scheduled depletions are simply not sustainable," wrote Barnett and Pierce in the paper.

Barnett and Pierce note that a number of other studies in recent years have estimated that climate change will lead to reductions in runoff to the Colorado River system. Those analyses consistently forecast reductions of between 10 and 30 percent over the next 30 to 50 years, which could affect the water supply of between 12 and 36 million people.

The researchers estimated that there is a 10 percent chance that Lake Mead could be dry by 2014. They further predict that there is a 50 percent chance that reservoir levels will drop too low to allow hydroelectric power generation by 2017.

The researchers add that even if water agencies follow their current drought contingency plans, it might not be enough to counter natural forces, especially if the region enters a period of sustained drought and/or human-induced climate changes occur as currently predicted.

Barnett said that the researchers chose to go with conservative estimates of the situation in their analysis, though the water shortage is likely to be more dire in reality. The team based its findings on the premise that climate change effects only started in 2007, though most researchers consider human-caused changes in climate to have likely started decades earlier. They also based their river flow on averages over the past 100 years, even though it has dropped in recent decades. Over the past 500 years the average annual flow is even less.

"Today, we are at or beyond the sustainable limit of the Colorado system. The alternative to reasoned solutions to this coming water crisis is a major societal and economic disruption in the desert southwest; something that will affect each of us living in the region" the report concluded.

The research was supported under a joint program between UC San Diego and the Lawrence Livermore National Laboratory and by the California Energy Commission. The views expressed here do not necessarily represent the views of the California Energy Commission, its employees, or the state of California.

[U.S. Faces Era Of Water Scarcity: Profligate Use Hurts In Unexpected Places; Quest For New Supplies Nationwide](#)

Regional News 02/13/08

Lake Mead Not Going Dry, say Dozier and Fulp

"We were contacted by some newspaper reporters to respond to a report to be released by Scripps Institute that says Lake Mead could be dry by 2021," said Larry Dozier, Deputy General Manager of Central Arizona Project.

"That is absurd," he added.

The seven states that draw water from the Colorado River, in conjunction with the U.S. Bureau of Reclamation (BOR), recently reached an agreement on management of the Colorado River. That agreement was reached after extensive studies about the drought conditions and how severe shortages could be avoided. "The studies evaluated a broad range of potential hydrologic conditions and several alternative operating criteria," Dozier said. "Lake Mead did not "go dry" at any time during the various scenarios. Shortages were manageable."

In addition, CAP produced its own separate drought impact analysis in 2007 by creating a "worst case" scenario based on the University of Arizona's tree ring study and it showed that Lake Mead did not go "dry," Dozier said.

Terry Fulp, an area manager of Boulder Canyon Operations for BOR, which oversees water deliveries and hydropower output at Hoover Dam put the chances of Lake Mead running dry at almost zero, according to a story in the Las Vegas Review-Journal.

Ultimately, Fulp said, there is nothing new about the findings in the Scripps study. Such "doom and gloom" predictions have been circulating for years now.

"In my lifetime, I don't expect to ever see it," he said. CAP is a 336-mile-long system that brings about 1.5 million acre-feet of Colorado River water to its customers -- cities, businesses, agriculture and Indian communities -- in Pima, Pinal and Maricopa counties.

An acre-foot of water is about 326,000 gallons.

LR comments on EA for operations at Glen Canyon Dam 2008-2012

February 22, 2008

Mr. Dennis Kubly
Bureau of Reclamation, Upper Colorado Regional Office
125 S. State Street, Salt Lake City, Utah 84138
Fax: (801) 524-3858
GCexpReleases@uc.usbr.gov

Re: Environmental Assessment of Experimental Releases from Glen Canyon Dam, Arizona 2008 through 2012.

Dear Mr. Kubly,

On behalf of Living Rivers and the Center for Biological Diversity, we submit the following comments on the February 08, 2008 *Environmental Assessment of Experimental Releases from Glen Canyon Dam, Arizona 2008 through 2012*. While we appreciate Reclamation's intentions to potentially aid in the redistribution of sediment, such that it might improve habitat conditions for endangered native fish, we find this action insufficient on its own to offer any lasting benefits toward fulfilling this objective.

1. Sediment Augmentation

Past experience has already illustrated the limited benefits such experimentation can achieve. The 1996 and 2004 high flow experiments have revealed that there is not enough sediment entering the river ecosystem below Glen Canyon Dam to make up for the 44 million tons that would otherwise be entering the system on an annual basis were the dam not in place. In 2005, during the Science Symposium by Grand Canyon Monitoring and Research Center (GCMRC), and again in 2006 during meetings of the Technical Working Group, scientists discussed or recommended that the Adaptive Management Program should consider bringing additional sediment into the system through a mechanical augmentation plan. The public also recommended augmentation during the scoping period for the Long-Term Experimental Plan Environmental Impact Statement. Absent such augmentation, this proposed action will offer no lasting benefits, either to endangered fish or recreational beaches. As noted in the 2005 Score Report by the United States Geological Survey, Grand Canyon is running a sediment deficit, and

no amount of experimental flows can fix this problem. Reclamation must explore sediment augmentation as a viable alternative to meeting the objectives of this action.

2. Seasonally Adjusted Steady Flows

As has been stated repeatedly, Reclamation is in violation of the terms set forth in the 1994 Biological Opinion requiring that Seasonally Adjusted Steady Flows be implemented from Glen Canyon Dam for reasons of insufficient progress to remove jeopardy to threatened and endangered species, and during minimal releases of 8.23 million acre feet (maf). Only when such flows are integrated with sediment augmentation, as noted above, will there be any real opportunity for species recovery.

We find it particularly unfortunate that the 2007 Biological Assessment also chose to ignore Seasonally Adjusted Steady Flows (SASF). It's unfortunate that such operating criteria may offer the best opportunity for meeting the objectives of the Grand Canyon Protection Act, but continues to be shunned by the hydropower interests.

3. Declining Reservoir Levels

This action is wholly contingent on there being sufficient water in Lake Powell, such that flood flows greater than 41,500 to 45,000 cfs (cubic feet per second) can be created. However, should the reservoir elevation drop below 3,490 feet msl (mean sea level), this will be impossible. The maximum flow that could be achieved would be less than 15,000 cfs through the bypass tubes alone. While current snow pack indicates that for at least the next two years, there should be sufficient water in Lake Powell to undertake such experiments, there is no guarantee that this will be the case through the completion of the proposed action period in 2012. Lake Powell's present elevation is 3,595 feet, meaning reduced inflows during the experiment period to 2012 of a net -6.8 maf will be sufficient to force the shut down the penstocks, and this proposed action. As you are well aware, in the three years after 2000, Lake Powell's level dropped 11 maf, thus history illustrates that such reductions have occurred, yet the EA assumes, without any justification, that they will not.

While section 3.1.1.1 discusses climate change, it relies on the same limited analysis undertaken by Reclamation for Shortage Criteria—analysis which Reclamation states does not take into account climate change. More importantly, isolating the ISM single trace (index sequential hydrologic modeling) that begin with water years 1950 or 2000, would clearly show the potential for Lake Powell dropping to levels near or below the 3,490 msl threshold. While Reclamation may wish to argue the likelihood of such an occurrence, it cannot ignore the prospect altogether.

4. Water Quality

The continued avoidance by Reclamation to address the likelihood of reservoir levels dropping significantly below their current levels, represents a potentially ticking time bomb for Grand Canyon. The implications are far greater than whether or not GCMRC scientists find more grains of sand near the Little Colorado River six months following a

high-flow experiment. The quality of water entering Grand Canyon could become so poor as to pose a serious threat to Grand Canyon's entire river ecosystem.

As the EA points out in section 3.1.3.1, dissolved oxygen levels at the upper portion of the reservoir are far greater than that of the water that is typically released from the penstocks. Even now, the levels flowing into Grand Canyon are higher than prior to the experimentation of 1996. This situation only worsens the lower the surface of the reservoir becomes and with the decreased volume of water generally. This issue has never been addressed by Reclamation, nor a number of other potential water quality impacts to Grand Canyon including: extreme water temperature, increased nutrient concentrations, higher salinity, high hydrogen sulfide, heavy metals such as mercury and selenium, and the pass through of exotic reservoir animals. This EA must therefore evaluate the potential water quality impacts the Grand Canyon ecosystem might face from decreasing reservoir levels during the period of the proposed action. More importantly, Reclamation must immediately undertake a comprehensive assessment of the potential water quality impacts on Grand Canyon should the reservoir drop to dead pool.

5. Archeology

As noted in section 3.2, this action is likely to cause harm to a number of archeology sites, as well as to cultural vegetation. Such a problem would not occur were Reclamation to implement SASF as noted above in combination with sediment augmentation. Reclamation continues to make archeology a low priority, preferring to dig and relocate sites and artifacts than preserve them in situ as is their mandate.

Lastly, we remain frustrated by Reclamation's ongoing policy of unnecessarily limiting public comment periods. This action has been contemplated by Reclamation since December of 2007, yet the Environmental Assessment is offered for public comment less than one month prior to the scheduled date of the proposed action. Additionally, a federal action of this magnitude deserves a proper *Federal Register* notice, which Reclamation has failed to do.

Whether it's poor management on behalf of the AMP and the GCMRC, an intentional disregard for public participation, or both, Reclamation must correct this problem, beginning with extending the deadline for comments on this EA an additional 15 days.

As evidenced by the ramping up of publicity for the first experimental flow contemplated with this action on March 4, it appears Reclamation is more interested in mobilizing media interest in support of Reclamation's own interpretation of this action, than it is on assuring the public has an opportunity to evaluate it for themselves and draw their own conclusions.

In conclusion, we view this EA as merely one more volume in the unfortunate history the Bureau of Reclamation and the Adaptive Management Program has visited on Grand Canyon. Until such time as Reclamation and the AMP makes a commitment to restoring the natural process that nurtured the evolution of Grand Canyon's river ecosystem, no

possibility exists for the ecosystem itself to be restored consistent with intent of the 1992 Grand Canyon Protection Act.

Sincerely,

John Weisheit, Conservation Director, Living Rivers
Michelle Harrington, Rivers Conservation Manager, Center for Biological Diversity

Moab activists call builder a threat to area's water supply

By Christopher Smart
The Salt Lake Tribune
Article Last Updated: 03/17/2008
06:42:03 AM MDT

[Download "A Look at Johnson's Up-On-Top"](#)

Developers call it fear-mongering. But a group of residents against a proposed upscale housing project on a redrock mesa overlooking Moab say it could put the town's drinking water in jeopardy.

In a slick, 10-page brochure distributed inside Moab's The Times- Independent newspaper, the Grand County Citizens for Clean Water claim that neither the developer nor Grand County can ensure that the Cloudrock project will not harm the aquifer that feeds the municipal water system.

It's the latest round in an eight-year battle.

The joint proposal by Leucadia National Corp. and the Utah School and Institutional Trust Lands Administration (SITLA) already has been approved by the Grand County Planning Commission and the County Council. The plans include a 225-room lodge, 150 condominiums and 110 home sites on 1,935 acres of state trust lands on the mesa called Johnsons Up On Top.

But the group that distributed the flyer has put the developers on notice that any groundwater pollution and a subsequent cleanup would be cost prohibitive.

"Should damage occur to the aquifer, it is reasonable for the affected parties to insist that SITLA be responsible for the full cost of mitigation," the brochure states.

The group earlier filed suit in 7th District Court alleging that Grand County's adoption of the Cloudrock development was "arbitrary and capricious."

A SITLA official said Friday the agency is confident that Leucadia's plans have gone "above and beyond" engineering requirements - set by Grand County and Grand Water and Sewer Service Agency - to prevent pollution of the aquifer.

"Based on what we've seen, we don't see any risk in the world of reality," said Associate Director John Andrews.

A Salt Lake City-based attorney representing Leucadia said the four-color brochure was just the latest installment of an ongoing "misinformation campaign" aimed at scuttling an approved development.

"It's NIMBYism - not in my backyard," said Michael Zimmerman. "It is our view that the opponents are fundamentally against any development and have been since the origin of the project" in 2000.

Nonetheless, County Councilwoman Joette Langianese, who is not affiliated with the group of residents, said because of the complexities of the sandstone formations surrounding the aquifer, she continues to have doubts about the safety of the water source.

"There isn't enough information for me to be comfortable with a big development like that on top of our aquifer," she said. "Hopefully, nothing will go wrong."

What's next? 7th District Judge Lyle Anderson will hear arguments April 15 at 9 a.m. on whether the group of residents can appeal the Cloudrock proposal to the Grand County Board of Adjustment. Anderson also could rule that the project can go forward.

###

Lionsback not first controversial project

The Daily Sentinel
Saturday, July 19, 2008

The proposed Lionsback Resort is not the first luxury development to stir up controversy in Moab.

The Cloudrock Resort Development office in downtown Moab has been fully furnished but not staffed since 2001, and Lionsback may be forced to travel a path similar to that development, which has been tied up in lawsuits since 2003.

The Cloudrock resort would sit on State Institutional and Trust Lands Administration land about seven miles south of Moab as per an almost mirror-image agreement of what the Lionsback developers had with the trust lands organization.

Only in Cloudrock's case, the developers sought approval and annexation into Grand County, not the city of Moab.

The approved preliminary plat for the Cloudrock Desert Lodge consists of a 225-room "Wilderness Lodge," 150 residential condominiums, and 110 homes in small clusters.

The development would be across four phases, with the first phase centering on the construction of the lodge.

"These are well-developed units. World-class units, but the developers don't want all their money tied up in construction," said Gene Ciarus, Grand County Council member. "The hotel was first to give people a reason to go out there."

A coalition of Moab residents, the Moab Citizens Alliance, protested the proposed annexation of the property, but the county approved it in 2001.

The complaints also included concerns over water protection and road width within the development, Ciarus said.

"These protesters are grasping at straws," Ciarus said. "This development will bring in big money and tax revenue without taxing our resources. It has exceeded every requirement, and that has been tested in court."

The first of several back-and-forth court filings between the county, SITLA and the MCA began in 2003, leaving the Cloudrock development in limbo.

Ciarus said the "continuing saga" is about to end, however, as the court has two more issues to settle.

He said he didn't want to speak before the judge's ruling, but Ciarus said every prior decision had been in favor of the developers.

"I'm sure with every decision regarding Cloudrock, they will file an appeal until they realize the developers aren't violating any law or asking for anything out of the ordinary," Ciarus said.

Though protesters of the Lionsback development say they don't want litigation, City Councilman Rob Sweeten said he foresees a legal battle in the future.

"They've already tried," Sweeten said.

“You look at what happened at Cloudrock, and it’s happening at Lionsback.”

Additional News

Group appeals council approval of Cloudrock phase 1
by Craig Bigler

Once again the group of citizens has filed an appeal of a Grand County Council decision on the Cloudrock development proposed for Johnson’s Up On Top mesa. Because the action taken by the council to approve the final plat for the first phase (phast 1A) of the development was administrative, according to group member John Weisheit, the appeal should be heard by the Grand County Board of Adjustment.

Last month the council approved the first phase, for development of 12 lots, even though an appeal by the same group is pending in the Utah Court of Appeals. The earlier appeal, if granted, would stop the entire project, except for the approved first phase, Cloudrock Land Company representative Mark Oligschlaeger said at the time.

This latest appeal is designed to stop any development, the appellants have said. It asserts the application for the first phase was incomplete and did not comply with requirements of the amended development agreement approved by the county council last December. The appeal claims that requirements for detailed sewer line construction plans were not submitted or approved.

“Our intent,” appellant Barb Morra said, “is to preserve and protect our drinking water recharge area, which is primarily on Johnsons Up On Top, where Cloudrock is being developed.”

The appeal claims that cost estimates for improvements required by the agreement are incomplete. It also asserts that the \$1.5 million financial guarantee proposed by Cloudrock covers only the estimated costs of roads and drainage required for the first phase, and “violates the requirements of the code and the amended development agreement that the financial guarantee be sufficient to cover the costs of all required improvements.”

During the county council’s deliberation on the issue last month, Grand County Planner Kristine Killoy said the bond was “adequate.”

“They didn’t follow the law,” Morra said, adding that the development’s financial guarantee should cover all required improvements, not just the access road. If the development goes bankrupt or loses in the court of appeals, it may not proceed beyond phase 1A and the county would be stuck with the cost of remediation, she said.

Weisheit said that Cloudrock must pay interest on the bond, and it is not large enough to cover all improvements. “They’re just ensuring their right to develop while waiting for the court to act,” he said.

Oligschlaeger declined to comment on the appeal. But when the county approved the first phase last month, Oligschlaeger said that if the 12 lots contained in that phase are

sold, that cannot be reversed, even if the court rules for the appellants. But, he said, such a ruling would stop the rest of the project. He also said that the Cloudrock Land Company would make full disclosure to potential customers about the possibility.

"Once again, they are putting the cart before the horse," Weisheit said. "It is wrong to move ahead until we've had our day in court."

###

New appeals contest PC approval of Cloudrock special exceptions
by Craig Bigler

Once again, attorneys representing a group of Grand County residents have filed appeals of decisions made by the Grand County Council and the Grand County Planning and Zoning Commission that give the go-ahead to development of the proposed Cloudrock Lodge.

Salt Lake City-based Smith Hartvigsen, PLLC, has filed two new appeals with the Grand County Board of Adjustment. The group is appealing the county council's Nov. 20 approval of Cloudrock's use-on-review application, and the planning commission's Dec. 12 approval of Cloudrock's two special exception applications.

Smith Hartvigsen also recently filed a cross-motion to a motion for summary judgement filed by Cloudrock in a separate appeal that was filed last year in 7th District Court in Moab. "It is nothing new, just the next step in resolving the lawsuit," said Smith Hartvigsen attorney Nancy Delacenserie.

The cross-motion asks Judge Lyle Anderson to remand the appeal to the board of adjustment and direct the BOA to hear the plaintiffs' appeal. Delacenserie said the appeal should go first to the board of adjustment because the decision last May by the county council to approve the amended Cloudrock development agreement was an administrative decision.

Smith Hartvigsen argues that the court has first jurisdiction only if the decision is legislative. "The court can decide on the facts if all parties agree on the facts," Delacenserie said. "We don't agree on the facts."

Noting that additional briefs will be filed before the court sets a hearing date to hear the issues, Mark Oligschlaeger of Leucadia Corp., which has partnered with Cloudrock Land Company, for the proposed Johnson's Up On Top project, agreed that nothing new has happened. "This process is playing out in the court system," he said.

Grand County Attorney Happy Morgan disagreed with Smith Hartvigsen assertions that the board of adjustment has jurisdiction over county council decisions and that the Grand County residents who filed the appeal represent the general public.

In an Aug. 29 memo, Morgan refers to the appellants as "a small contingent of persons opposed to the Cloudrock PUD."

Morgan's memo concludes, "The BOA has no authority to overturn an ordinance enacted by the Grand County Council. The elected Grand County Attorney represents both the BOA and the Council, and it is the opinion of the Grand County Attorney that the BOA has no jurisdiction over the appeal filed by Contingent [the appellants]; the proper venue is the District Court."

Regarding special exceptions, the appeal before the board of adjustment stems from the board's refusal to consider nearly identical appeals at a hearing on Dec. 10. The board decided to vacate the planning commission's approval of the exceptions on grounds that the public hearing held by the commission was invalid because proper 15-day notice was not given to the public.

Two days later, the planning commission held another set of public hearings and immediately re-approved the two special exceptions. One exception allows larger lodge unit size, the other allows streets as narrow as 20 feet. These re-approvals are now under appeal.

The use-on-review appeal is in regard to the county council's approval of changes that allow Cloudrock to alter the configuration of the lodge and "village" from the preliminary plat that was approved in May, 2007.

The use-on-review appeal argues that the change in configuration is so dramatic that the preliminary plat approval process should start over. Both the council and the commission indicated that they based their 2007 approval on the original preliminary plat approved in 2002, and the land use code that was in effect at the time.

###

Cloudrock LLC to withdraw phase one plat by Craig Bigler contributing writer 12 hrs ago | 83 views | 0 | 0 | | The Cloudrock development is on hold once again. In a Nov. 26 letter to the Grand County Council, Cloudrock Land Company LLC told elected officials the company has elected to withdraw its pending final plat application for the first phase of development, called phase 1A. The letter also states that the project will resume once the current national financial crisis turns around.

The letter from Cloudrock principal Mark Oligschlaeger notes that the pending final plat has not officially received final approval because it has not been signed by the applicant or by the county, and, it has not been submitted to the Grand County Recorder for official recordation.

The development agreement between Cloudrock and the county does not set a deadline for when final plats must be submitted. Council chairman Gene Ciarus said Cloudrock LLC's withdrawal of the plat means that the process for final approval of the first phase will have to start over again when the company determines it is ready to begin development.

"The primary purpose for this withdrawal is related to deteriorating market conditions, and not to pending legal challenges concerning the project," Oligschlaeger wrote, "Cloudrock will continue to aggressively defend and litigate these specious claims, and

anticipates that it will be successful in each case, as it has in the cases which have already been decided.”

Barb Morra, a spokesperson for the group of residents that has filed those appeals with 7th District Court in Moab and the Utah Court of Appeals, said she thinks the delay was caused because bonding for all infrastructure must be in place before the first phase development can begin. The bonding required amounts to \$8-10 million because it must include not just the access road along with sewer and water pipes, but also electricity and other utilities, Morra said she has been told “on good authority.”

The council approved phase 1A on Oct. 7 with a requirement that Cloudrock secure bonding of \$1.5 million for the access road and drainage. In a statement to the council last week Grand County Engineer Mark Wright acknowledged that an additional bond of \$2.5 million for sewer and water facilities is also required by the development agreement. A letter from Daniel Velazquez, project manager for Cloudrock, apologized for the “oversight” and stated Cloudrock’s intention to activate a letter of credit for the additional amount.

Morra said she believes that all infrastructure means more than just a road, sewer, and water.

“Who is going to move there without DSL?” she asked. Morra said that bonding for infrastructure for the entire proposed Cloudrock development planned for Johnson’s Up On Top mesa southeast of Moab (a total of 309 units) is far too great to be justified by the preparation and sale of only 12 units in the first phase.

Oligschlaeger closed his letter to the council by saying the company will move forward with the development.

“Cloudrock intends to submit applications for final platting when the timing is appropriate, consistent with the terms of the Development Agreement,” Oligschlaeger wrote.

Ciarus said the current economic climate and the pending appeals make it more difficult to proceed with the first phase at this time.

“I think [withdrawing the plat is] the rational thing to do,” Ciarus said. “Why spend a lot of money until these things [the appeals] get settled in court?”

“They’re just trying to keep the development agreement alive any way they can,” Morra said.

Oligschlaeger has requested that the county council hear the request to withdraw the plat at its upcoming meeting on Dec. 16.

Moab City Council approves development agreement for proposed Lionsback Resort

Moab Times-Independent by Jeannine Wait contributing writer

In a 3-2 vote Tuesday night, the Moab City Council approved a development and phasing agreement for Lionsback Resort. Council members Kyle Bailey and Sarah Bauman voted against the measure.

The council's decision moves the development, planned for property east of Moab owned by the state School and Institutional Trust Lands Administration, another step closer to becoming a reality.

The controversial Lionsback proposal has been in the works for several years, as the project wound its way through the city planning process that included a series of public hearings and efforts to annex the property into city limits .

From the submission of the proposed resort's design concept to the planning commission in 2007 to Tuesday night's decision on the development and phasing agreement, the Lionsback process has included contentious public hearings before the planning commission and the city council, approval of the preliminary plan, annexation of the 175.12 acre parcel of SITLA land into the Moab city limits and the creation of a new sensitive area resort zone that city officials have said was specifically designed for large, environmentally sensitive developments such as Lionsback. Future approval of a final plan will be the last step in the development process for the proposed resort.

The Lionsback resort development is planned for a 46.8-acre portion of the property located on Sand Flats Road that was formerly the Lions Back Campground. The development will be constructed in five phases, according to the development plans. Phase one calls for the construction of a large hotel center, 50 hotel guest condominiums and the platting of 34 single-family lots.

According to the development and phasing agreement approved Tuesday, a variety of infrastructure requirements will have to be met in phase one. Internal subdivision roads and 105 parking spaces near the hotel are included in the construction design. A storm drain will be required for storm water management, and connections to the city sewer system and the city water system will be included, along with the installation of a large water storage tank that will distribute water to all proposed development facilities located within the resort.

Electric, natural gas, cable television and telephone lines will be extended and installed along Sand Flats Road to serve the resort. Sand Flats Road will be improved to allow for greater public safety with an expected increase of traffic the presence of the resort will bring on the road.

Unlike a standard subdivision agreement, the development agreement approved by the city council requires separate agreements for each proposed phase in order to establish the responsibilities for construction of particular onsite and offsite improvements, city officials said.

A Drinking Water Source Protection Plan will also be required, according to city officials. But that plan is not an element of development agreements and will be presented within the next two council meetings for approval.

At a public hearing held at city council Aug. 26, 2008, Moab citizens spoke for an hour about their concerns regarding the proposed development. Many who spoke raised concerns about the possible effect the development might have as a potential source of contamination of the sole-source aquifer located on a portion of the property.

Lionsback Resort development partner Mike Lawler, and Tom Kennedy, attorney for the developers, were present at Tuesday's council meeting. After the council approved the development and phasing agreement Lawler and Kennedy were asked when construction could possibly begin. Kennedy explained that the partners are still in court defending a decision by the city council to approve the preliminary master plan for the development.

Several area residents and groups, including Living Rivers and Julianne Fitzgerald, who have been fighting the city's decision to grant approval, filed an appeal of the council's decision last year. The matter was heard by the city Board of Adjustment in August 2008. The BOA ruled that the city of Moab acted in accordance with city code. The BOA decision was then appealed to 7th District Court in Moab. Judge Lyle Anderson has yet to issue a decision in the matter, and a final ruling could take several more months.

"We feel that the earlier approval decisions will be validated in the court," Kennedy said Tuesday.

Lawler expressed confidence in the Lionsback plan. "This is a good project and we're still committed to it," he said.

LR Letter 03/20/08

Comments: Oil Shale and Tar Sands Draft Programmatic Environmental Impact Statement

Sherri Thompson
Bureau of Land Management
Colorado State Office
2850 Youngfield Street
Lakewood, CO 80215
Sent Via Fax: 303-239-3808

Re: Oil Shale and Tar Sands Draft Programmatic Environmental Impact Statement

Dear Ms. Thompson,

Thank you for this opportunity to provide comments for the Programmatic Environmental Impact Statement on development of oil shale and tar sands in Utah, Colorado and Wyoming. We understand that this NEPA process will be ongoing for several years and we desire to be added to the contact list for all future correspondence about public participation in this process.

Living Rivers/Colorado Riverkeeper is a non-profit organization based in Moab, Utah. Our mission is to mobilize the public toward restoring the ecological integrity of the Colorado River and its tributaries, especially as it relates to federal reserve lands.

We understand this federal action now under review will have serious negative impacts on the scarce water resources of the Colorado River basin. This federal program should be terminated because it will harm the water supply of 30 million people and to critical habitat for threatened and endangered species.

We support a new direction for the federal government to provide leadership toward energy independence through conservation, improving efficiency standards, and investing in renewable alternatives that do not further impair water resources and the atmosphere.

Quality fossil fuel products derived from deposits of oil shale and tar sands are wholly dependent on the availability of water resources. The demand for water in the Colorado River basin remains over-allocated and federal and state leadership to balance demand with supply has yet to occur. The annual supply from the Colorado River at the Compact Point, Lees Ferry, Arizona, has declined by 2 million acre feet since 1922, when the Colorado River Compact was first negotiated. Contrarily, the over-allocated demand continues to increase, of which this federal action will contribute to. Consequently, this federal leasing program will cause unnecessary harm to existing downstream users and ecosystems in the acquisition new water rights.

Furthermore, the transfer of senior water rights from agriculture to shale and tar extraction will adversely affect water quality in the form of diminished return flows, which will bring harm to wildlife habitat and increase the load of total dissolved solids in the water supply.

Many hydrology and climate studies funded by the federal government continue to provide more evidence that the downward trend in the water supply will continue into the 21st century and beyond. Indeed, it is highly probable that senior water rights are at risk as well. This federal action is poised to further aggravate an already serious water quantity/quality problem for the basin.

The Bureau of Reclamation recently completed an EIS (2007) called Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lakes Powell and Mead (Shortage Criteria). This document permits further depletions in the upper basin of the Colorado River. Contrarily, hydrologists and climate scientists have recently provided evidence, since the signing of the Record of Decision, that Lakes Mead and Powell have a 50/50 chance of going empty as soon as 2021. Regardless of

the odds or the dates, these reservoirs will empty for reasons of over-consumption and increased evaporation due to atmospheric warming.

We strongly recommend that the Bureau of Land Management do what the Bureau of Reclamation for Shortage Criteria did not: model the water supply of the Colorado River using paleoclimate and climate change data to make a sound determination of the hydrologic condition of the Colorado River basin for the 21st century.

Again, we thank you for this opportunity to comment and if we can be of any assistance to you please do not hesitate to call us.

Sincerely yours,

John Weisheit
Conservation Director
Colorado Riverkeeper

Comments: EA Castle Rock Cut

Mr. Kevin Schneider
Public Affairs Office
Glen Canyon National Recreation Area
P.O. Box 1507
Page, AZ 86040-1507
Sent Via Fax: 928-608-6259

Re: Environmental Assessment (EA) for the Castle Rock Cut

Dear Mr. Schneider,

Thank you for this opportunity to provide comments concerning the excavation of bedrock near Castle Rock at Glen Canyon National Recreation Area (GCNRA) for the purpose of creating a short-cut on Lake Powell when reservoir levels are below 3620

feet (mean sea level). Our comments are written on behalf of the following organizations:

Living Rivers, www.livingrivers2.org
Colorado Riverkeeper, www.coloradriverkeeper.org
Colorado Plateau River Guides, www.riverguides.org
Red Rock Forests, www.redrockforests.org
River Runners For Wilderness, www.rrfw.org
Southern Utah Wilderness Alliance, www.suwa.org
Water Advocacy Center, www.wateradvocacy.org
Wildlands CPR, www.wildlandscpr.org

In the Environmental Assessment the National Park Service made no comment in regard to our scoping request for an Environmental Impact Statement to consider not only this federal action, but all impacts associated with declining reservoir levels at GCNRA. To piece-meal a single impact on the reservoir is not internally consistent.

Since submitting our scoping comments in December, scientists from the Scripps Institute provided further evidence that Lakes Mead and Powell will naturally drain due to the effects of over-consumption and increased overall evaporation due to atmospheric warming. Their report has forecasted that the reservoirs have a 50/50 chance of going empty by 2021.

See: Barnett, T. P., and D. W. Pierce (2008), When will Lake Mead go dry? Water Resources Research, doi:10.1029/2007WR006704, in press.

<http://www.onthecolorado.org/Resources/ClimateDocs/2008BarnettPierce.pdf>

This science journal cites the comment letter by Living Rivers for the Draft EIS for Shortage Criteria (now called 2007 Interim Guidelines): [Living Rivers letter Shortage Criteria DEIS](#)

Regardless of the odds and the dates of this forecast (including all the previous scientific reports that reach the same conclusion), reservoirs levels will likely be in a situation of decline for the 21st century. This scientific forecast compels the Park Service to complete, instead, an Environmental Impact Statement to manage all the facilities in the GCNRA and for all benefit of all the different kinds of users in the NRA.

Though some may argue that this science justifies deepening the cut near Castle Rock in the short-term, but it does not justify this federal action for the long-term. Does the Park Service intend to continue deepening Castle Rock Cut until the reservoir reaches the level the penstocks at Glen Canyon Dam (3490 feet), or the level of the bypass tubes (3375 feet)? Rather than create an ever-deepening eyesore to this federal reserve land, it makes more sense to just leave Castle Rock Cut the way it is and educate and encourage the public to accept and work with this situation.

Our organizations want the federal government to provide effective leadership toward conserving and managing our finite natural resources wisely in a new century of uncertainty. This includes preserving all the natural features and resources in our

federal reserve lands. This also includes the conservation of diminishing fuel resources, improving the degraded condition of the atmosphere, and to protect our diminishing water resources for people and endangered species.

The majority of comments provided so far on this issue have come from a specific recreation group that is dependent on motorized boat activities at Lake Powell. This user group claims they need this excavation to save time, fuel and ensure their safety.

It is important to our members and partners that we educate the public about the impacts of popular motorized recreation at Lake Powell. This form of recreation is consumptive no matter what the reservoir level is. A boat owner/renter will spend anywhere from \$500 to a \$1000 in fuel alone for a typical motorized vacation at Lake Powell. This includes the fuel to get to and from Lake Powell by highway. Our question to the federal government is who or what is the real impact here to our diminishing and altered natural resources? Is it the consumer or the half-full reservoir?

This proposal is not about saving fuel. This proposal is about providing convenience. The federal government should encourage consumers of fuel to provide alternatives that will reduce their personal consumption at Lake Powell, rather than consumers of fuel asking the federal government and taxpayers to provide expensive alternatives for the sake of convenience with a trade-off that incurs permanent destruction to a natural landscape on federal reserve lands.

Safety is always an issue at Lake Powell. There are narrow channels throughout the reservoir. Boat accidents occur when the reservoir is full and when it is low. The Park Service claims the cut will reduce the dangers of congestion inherent at The Narrows near Antelope Point Marina. Yet the Park Service is responsible for creating this liability in the first place, because it approved the development of the marina. Again, the Park Service is not internally consistent in its management of GCNRA because the environmental studies are not comprehensive and instead done in a piece-meal fashion.

The Castle Rock Cut will be tight and narrow too. Indeed, it is possible the cut will increase the danger of boating at Lake Powell. It is possible that the risk to non-motorized boaters will actually be higher at the cut than The Narrows. Our organizations are compelled to suggest that the problems of boat safety have not been properly addressed at all in this Environmental Assessment.

Thank you for this opportunity to comment. We again ask that the Park Service perform a comprehensive Environmental Impact Statement to address the impacts of declining reservoir levels at GCNRA before engaging in any action at Castle Rock Cut. Please do not hesitate to contact us should you have any questions.

LR letter to Western Area Power Administration: Rate Increase Review

Living Rivers comment letter on Rate Order No. WAPA-137 for Colorado River Storage Project Transmission and Ancillary Services Rates for new rate schedule (SLIP-F8) that expires September 30, 2010, and that the current rate is insufficient to meet within the allowable period the revenue requirements for the Salt Lake City Area/Integrated Projects.

The requirements include operation, maintenance, interest expenses, and the required repayment of investment, commonly called the Basin Fund.

This proposal will extend the service rates for five years to 2015. The long-term contracts (20-year) will expire on September 30, 2024.

Scientist: Warming bodes ill for water

By Phoebe Sweet for The Las Vegas Sun

Federal scientists and Western water managers will call Congress' attention Friday to the potentially devastating effects of climate change on the Colorado River, warning that an expected warming trend would reduce the amount of water in the river.

All told, the Colorado is a water source for more than 25 million people in seven states and Mexico. The volume of the river is particularly critical for Southern Nevada because the Colorado feeds Lake Mead, which supplies 90 percent of the Las Vegas Valley's water.

At Friday's congressional briefing, research scientist Gregory J. McCabe will present a study that shows even a 1.5-degree increase in the overall temperature of the Southwest will decrease the river's flow and increase the likelihood that it will fall short of the amount needed to meet the annual allocations upon which Nevada and the other members of the Colorado River Compact rely.

"I live in the West. I worry about water supply," McCabe said. "We have lived in an anomalously wet century. A shift to a much drier climate coupled with additional warming spells trouble for the future."

"Because the water usage is so large in the (Great) Basin, it is very sensitive to even small warmings," McCabe said.

McCabe's study estimated the effects of 0.86-degree Celsius warming, which is 1.548 degrees Fahrenheit — the same amount as the climate has changed in the past century — and the 2-degree Celsius, or 3.6-degree Fahrenheit, warming of the climate that scientists say is possible in the next century. He analyzed these changes against the backdrop of tree ring records used to estimate river flows going back more than 500 years, as well as more than 100 years of data from the river.

Friday's hearing comes on the heels of the release last week of a report detailing effects of warming on fish, forests, rangelands and arid lands. The U.S. Agriculture Department report predicts dwindling rivers, an increase in extreme weather — droughts and floods — and the death of plant life.

None of these conclusions should come as a surprise, said Eric Kuhn, general manager of the Colorado River Water Conservation District. Kuhn said he hopes Friday's briefing will impress upon congressional staffers — including two from the office of Nevada Rep. Jon Porter, a sponsor of the briefing — that continued funding for scientific studies and river flow monitoring is crucial.

But Tim Barnett, author of a controversial study published in February that predicted a 50 percent chance that Lake Mead would go dry by 2021, said Wednesday that no

matter how much new science is done, the future is clear. The professor with the Scripps Institution of Oceanography said every credible Southwest water study has concluded that serious water shortages will hit in the 2020s.

If global climate models are anywhere close to correct, Barnett said Wednesday, “we’ve got a real problem coming.” The time line is so short that preventing global climate change before the predicted water shortages become reality is impossible, so it’s time to plan, instead, for how we’ll deal with the inevitable deficits when they arrive, he said.

And shortage guidelines agreed upon in December by state and federal water management agencies, designed to cut water deliveries to Western states if river flows and reservoir storage dip below certain levels, won’t cut it, he said.

We are heading toward a future in which water will probably be rationed, Barnett warned.

CAP official's vision for 2048: Mexican-gulf desalination

Salt water foreseen as vital to Southwest

By Tony Davis for the ARIZONA DAILY STAR
Tucson, Arizona | Published: 06.25.2008

PHOENIX — It's 2048 in the Sonoran Desert. Do you know where your water will come from? Thomas McCann, a top official with the agency that runs the Central Arizona Project, laid out a vision in response to that question Tuesday at a conference on the future of the Colorado River:

- Three desalination plants are on line by that year to increase the supply of CAP water flowing to Phoenix and Tucson. One is removing salt from seawater along the Gulf of California in the Mexican state of Sonora, and its booty is shared by Arizona, California, Nevada and Mexico.
- Two others are treating salt-laden groundwater in the areas of Buckeye and Gila Bend.
- A huge nuclear power plant is humming along the Gulf of California in Sonora, producing 600 megawatts of power to provide the juice for the adjoining seawater desalination plant.
- Construction is under way to expand the size of the concrete CAP canal running from the Colorado River to Tucson to deliver up to 2.2 million acre-feet of water a year. An

acre-foot — 325,851 gallons — will supply enough water for two to three families for a year. Currently, the aqueduct can deliver 1.8 million acre-feet.

- The Colorado River, over-allocated by 1.5 million acre-feet a year to the seven river-basin states and Mexico, has been boosted in supply by about one-third that much through cloud seeding and other forms of weather modification.

McCann, resource-planning manager for the three-county Central Arizona Water Conservation District, which oversees the CAP, was looking at how the state could furnish water to support a 2048 population of 11.5 million in Pima, Pinal and Maricopa counties, compared with less than 6 million today.

It was a controversial vision, with many conservationists, led by Sierra Club members and others in the crowd of more than 300, attacking it as a fantasy. They questioned whether the money would be available for such a large number of projects and whether the increased energy use for desalination would make it economically and environmentally unfeasible.

The critics also said leaders should concentrate on conserving water rather than simply searching for more water to serve population growth.

And they questioned whether solutions would ever be found to handle the waste produced by the nuclear plant. Bob Cook, a planner and economist active in Sustainable Tucson, an environmental group, said the presentation ignored the rising costs of energy that already are causing crises in the airline and trucking industries.

"People will migrate to where the water is," Cook said. "There's no real analysis here of the factors behind our population growth — cheap water, cheap land and cheap energy — and how they are changing."

It's good that CAP officials are looking that far ahead, but "I didn't get a sense of the problems to be overcome, so we can do all the things to get us where we need to be," said University of Arizona professor Karl Flessa, head of the geosciences department.

But the CAP's top official predicted that at least some of the ideas in McCann's vision will come to pass, although the agency has no formal blueprint for turning them into reality.

"Every element of what Tom talked about will be addressed by 2048, although I'm not sure how large of a scale," CAP General Manager Sid Wilson said to the crowd immediately after McCann's talk. "I'm absolutely sure he hit the right buttons."

The ideas also had many supporters in the audience. One was Sahuarita-area pecan farmer Richard Walden, whose father, Keith Walden, pushed for congressional approval of the CAP 40 years ago.

Walden said it's realistic to start looking at desalination now, given that water projects are something that needs planning 40 years in advance.

"We built CAP and started getting water from it (nearly) 25 years ago, and for a while we had more water than we needed," said Walden, of Farmers Investment Co. "Years later, we have to start looking for more."

The CAP has four Pima County representatives on its board and runs the day-to-day operations of the country's largest water project.

Educators, activists, economists, planners, consultants and researchers came to the Colorado River conference from at least 45 cities and towns around the state, including a substantial contingent from Tucson. The conference, held at the Arizona Biltmore, was sponsored by the University of Arizona Water Resources Research Center and a host of other parties.

The prospect of desalination has in recent years gained more currency among water leaders in Arizona and the West as they try to deal with the twin pressures of population growth and drought that have kept flows in the river below normal for seven of the past 10 years. State and Mexican officials have started preliminary talks on possibly building a plant along the Gulf of California.

The CAP agency has hired a consultant to explore the feasibility of desalinating salt-laden groundwater inside Arizona.

After his speech, McCann said his ideas were based on population projections for Pima, Maricopa and Pinal counties for the late 2040s. His vision also assumed that people would reduce their water use by about 5 percent per person by then, that local governments increase the amount of sewage water captured from homes by 5 percent, and that they increase the re-use of wastewater by the same amount.

He also assumed that the river would have minor shortages of water in 2018-19 and in 2025, but nothing affecting urban users until a major five-year shortage hits in the 2030s. He acknowledged, however, that those projections were based on simple speculation.

Arizona mulls new water source: Ocean Mexican city considers desalination plant; U.S. partnership a possibility

By Shaun McKinnon - Aug. 31, 2008 12:00 AM
The Arizona Republic

The water for Arizona's future needs may lie off the coast of a popular Mexican resort, in the Gulf of California.

State officials are studying the idea of importing filtered ocean water from an as yet unbuilt desalination plant in Puerto Peñasco, 60 miles south of the U.S. border. The water - potentially billions of gallons a year - would help sustain urban supplies in

Arizona and could someday bring relief to rural residents, who have long sought a water source to replace rapidly depleting aquifers.

A Scottsdale company already is looking at possible designs for the plant in Puerto Peñasco, where overworked groundwater wells are on the verge of running dry. Arizona water managers see an opening for the state to team up with the seaside resort on a larger plant to serve both countries.

Such a project would raise a host of political, economic and environmental issues, and it's not clear who would pay the construction costs, which could top \$250 billion.

But if backers can clear those hurdles, Arizona and neighboring states could tap a plentiful supply of water largely immune to the effects of drought and climate change.

"Desalinated ocean water is the future sustainable source," said Herb Guenther, director of the Arizona Department of Water Resources. "It's only logical that eventually we'll migrate toward it. We don't need interim supplies now. We need a permanent supply."

Oceans, which hold 97 percent of the Earth's water, were long considered a source of last resort, mostly because of the high cost of removing enough salt to produce drinking water.

Big desalination plants operate widely in arid Middle Eastern nations, where water is pricey and energy is cheap, but only recently has the ocean emerged as a viable resource in the United States. At least two dozen plants are now on drawing boards in California, a state beset with water woes.

"People explored and utilized the most cost-effective sources of water as long as they could," said Randy Truby, past president and a current director of the International Desalination Association, an industry group. "In California, they had the state water project, the Colorado River, sewage-water reclaim, conservation . . . but once you exhaust all of those things, seawater desalting is about the only place you can go."

That's where Puerto Peñasco finds itself. The city's groundwater resources have dwindled after years of steady use. The wells produce poor-quality water, and many are nearly exhausted. With growing interest from American developers, the city decided to turn to the most obvious alternative: the ocean.

"The water needs are severe," said Walt Bouchard, whose Scottsdale-based environmental consulting company was hired to study desalination options for Puerto Peñasco. "There are concerns that water may not be available for future development."

A need for water

The city, also known as Rocky Point, has long drawn Arizonans looking for a quick trip to the coast, but in recent years it also has attracted American investors eager to build hotels and time-share condominiums. About 81 projects sit in the planning stages, Bouchard said, and "they are going to need water."

Bouchard's company was asked by city officials to determine the feasibility of a seawater desalination plant, settle on a technology, produce a blueprint and prepare a bid package for a company that would design, build and operate the plant.

The study is based on a desalter that would produce 11.4 million gallons a day at the start and up to 45.6 million gallons a day by 2020, when the final stage is completed. That is enough water to serve at least 250,000 people a year.

Construction costs will depend on the technology, the location, the workforce and other factors. Poseidon Resources, a private company, is working on a plant near Huntington Beach, Calif., that could produce up to 50 million gallons of drinking water a day. The company estimates it will cost \$250 million to build.

Mayor Heriberto Rentería put the Puerto Peñasco project on a fast track, with a goal of firing up the first desalination module by 2010 or 2011. Bouchard said his team expects to deliver its findings by the end of the year.

So far, the plan calls for a plant that would produce water for the local and tourist demand, but Bouchard said the city is aware of Arizona's interest and could consider a joint project once Puerto Peñasco's needs are met.

"Could they supply water to Arizona? The answer to that is very likely yes," Bouchard said. "We believe it is feasible. The question becomes what about the cost of conveyance? Could it work for Arizona? As part of the state's overall water portfolio, it might have a place."

A Mexican partnership

Arizona isn't desperate for water yet, but the prospect of finding a Mexican partner in Puerto Peñasco persuaded state officials to start planning now. In June, the Arizona-Mexico Commission, a non-profit trade and business group that works with government officials, endorsed a plan to study the feasibility of a jointly operated U.S.-Mexico desalination plant on the Gulf of California.

That study will look at a range of issues, including cost, funding sources, energy needs and environmental effects on the gulf. Its findings could point toward a joint project with Mexico or to some other alternative. The major players so far are Puerto Peñasco; the states of Arizona and Sonora; and Arizona's two largest water providers: Central Arizona Project and Salt River Project.

"CAP does not need the water today or for a good long while, not for 20 years, maybe 30," said Tom McCann, CAP's resource planning manager. "But the opportunity presented itself, and if we don't do it now, it could slip away for another 40 years. Just because we don't need it, others could."

McCann said neighboring California and Nevada, which are desperate for water, could participate in the project and use their share of water early, before Arizona needs it. Other Arizona cities also could help build infrastructure that could allow water exchanges as far away as Flagstaff or Prescott.

Although water from a plant would probably be used mostly in southwestern Arizona to start, it would give the entire state added security. Water normally drawn down the lower Colorado could remain in Lake Mead, offsetting the risk of shortages. Water made available to rural areas could help protect rivers and riparian habitat.

"Water is limited in Arizona, and it's a lot easier to help people find supplies than to fight over supplies," said John Hetrick, water-rights analyst for SRP. "One of our tactics has been to augment Arizona's water supplies. If we can help solve a community's problems, we can avoid a conflict in the future."

The price of water

Potential roadblocks exist. One of the biggest unanswered questions for this project and any new desalination plant is how it will be powered. Desalting ocean water requires significant amounts of energy, which is why many of the early plants were built alongside power plants.

The proposed Puerto Peñasco plant would likely be built in stages. The first stage could operate using power from the existing electrical grid, but at full operation it would need additional sources. Bouchard, the consultant on the project, said his team is exploring clean technologies, such as a solar-energy array that uses molten salt, a technology that allows a power plant to store electricity after the sun sets.

A higher-capacity U.S.-Mexico plant would require even more electricity, which is another issue under study by the Arizona consultants.

The environmental effects of a desalination plant also raise red flags. Seaside plants can disturb or damage ocean habitat and risk contaminating the water with chemicals used in the process. The waste product - a concentrated brine - threatens sea life and water quality.

A National Research Council study released earlier this year warned that significant uncertainties remain about the environmental effects of seaside desalination. The council said researchers need to more thoroughly explore what happens on both ends of the process.

Protecting the ocean will make the water more expensive, but "part of the real cost of desalination means spending the money to properly address the environmental impacts," said Peter Gleick, president of the Pacific Institute, a non-profit research center in Stanford, Calif., that monitors water and the environment.

"It's a classic economic issue, making sure the full costs are addressed. We can't ignore environmental costs."

The institute studied California's plans to expand desalination and concluded that cities in that state could find water more quickly and cheaply through conservation and better management of existing resources.

For an inland state like Arizona, desalinating mineral- laden groundwater might be cheaper and require less energy, Gleick said. Filtering seawater and moving it even a short distance could push prices so high that no one will buy it.

An acre-foot of desalinated seawater costs from \$750 to more than \$1,200, depending on the location and the technology used. CAP and SRP sell water to cities and agricultural customers for \$30 to \$110 per acre-foot, and farmers along the Colorado River rarely pay more than \$50 an acre-foot. An acre-foot is 325,851 gallons, enough to serve one or two typical households for one year.

California's higher water costs have made desalinated supplies more attractive. Municipal customers pay about \$600 per acre-foot to the Metropolitan Water District of Southern California, the region's largest water provider.

The break-even point could take longer to reach in Arizona, especially if rising energy prices push the cost of desalination higher. The gap could close faster if the same high energy prices raise the cost of traditional water sources, such as the CAP Canal, which moves supplies 336 mostly uphill miles.

"We are spoiled by cheap water," said Guenther, the state water chief. "Right now we're fighting over the few remaining scraps of an inexpensive water supply. We'll have to get used to the fact that these alternative or sustainable supplies are going to be considerably more expensive than we're used to. We're going to have to bite the bullet."

Projections have doubled Inflation driving up cost estimate of planned Lake Powell pipeline Plan now tabbed at \$1.1 billion, but that's before debt service

By Patty Henetz for The Salt Lake Tribune
Article Last Updated: 07/18/2008 09:43:55 PM MDT

The estimated cost of building the Lake Powell pipeline has nearly doubled in three years and could continue to grow.

State officials on Friday say they expect construction of the 174-mile pipeline that would bring water to Washington, Kane and Iron counties would cost at least \$1.1 billion. In 2005, the cost estimate was \$585 million.

"We're still working through the economic analysis," said Eric Millis, spokesman for the Utah Division of Water Resources. "This is a good snapshot of where the project is now."

But the estimate doesn't include debt service on bonds, which pipeline critics say could push the ultimate cost much higher, perhaps beyond residents' ability to pay.

Paul Van Dam, a former Utah attorney general and director of Citizens for Dixie's Future, said debt repayment would at least triple the pipeline cost to \$3 billion, and could reach \$6 billion by the time the project is finished.

"It's pretty striking that this cost estimate can double in three years. What's going to happen in the next three years?" Van Dam said. "I wonder how in the world anyone thinks these counties can pick up these costs?"

The engineers who put together the construction estimate included building small hydroelectric stations on the pipeline.

A line-item breakdown of the estimate shows the hydroelectric components account for \$95.5 million of base construction costs for Washington County.

Necessary electrical transmission lines would cost about \$73.3 million. Together, they come to about one-quarter of Washington County's total cost. A 15 percent contingency would be added to the base.

Power transmission would account for \$14.8 million of the Cedar City spur, which would incur a base construction cost of about \$100 million. Kane County's base cost estimate is \$5.3 million.

The pipeline would provide about 100,000 acre-feet of water per year, with 70 percent going to Washington County, 20 percent to Iron County and 10 percent to Kane County. An acre-foot is enough for one or two households a year.

While the hydroelectricity generated by falling water in the 69-inch diameter pipes could offset the cost of the power needed to pump the water uphill, there still would be a net energy loss, Millis said.

But he couldn't say whether it might be less expensive to build the pipeline and pump the water uphill without the added hydroelectric construction costs.

"We know that we have to pay for the pumping regardless," Millis said. "We know first and foremost that it's a water development project."

Strong has said the state chose the Federal Energy Regulatory Commission as the lead agency on the water-delivery project because licensing the hydro and then doing required environmental studies of the massive project would be quicker and less expensive than with the U.S. Bureau of Land Management at the helm as originally planned.

FERC says it could produce 300 megawatts of power, equivalent to the needs of at least 225,000 households. But even FERC acknowledges it will take far more power to pump the water uphill than the little electric projects could yield. The hope is that selling the electricity at peak-hour prices will raise extra cash.

The money would go to a state-run enterprise fund set up to pay for operations, maintenance and other costs associated with the project, Millis said.

Pipeline costs: Lake Powell project looks less like smart idea

Tribune Editorial

Article Last Updated: 07/21/2008 06:57:53 PM MDT

More scientists are making more dire predictions about how much the Colorado River water levels could shrink in coming years due to climate change and less snowpack in the Rockies.

At the same time, the estimated price tag on a pipeline to carry 100,000 acre feet of that dwindling water from Lake Powell 139 miles to three Utah counties grows ever bigger. In fact, it has nearly doubled in the three years the pipeline project has been on the Utah Division of Water Resources' drawing board, from its original \$585 million to \$1.1 billion at least.

The uncertainty about future water flow and the eventual cost of the pipeline makes the project too risky. Taking that risk would be foolhardy, when conservation of existing water sources could make the pipeline unnecessary.

Opponents of the project, many of whom live in the St. George area, where the additional water would encourage more growth (read: sprawl), say the project could end up costing \$6 billion.

That is speculation, of course. So is the DWR estimate, which does not include debt service on bonds needed to finance the project. The three counties that would benefit from the additional water - Washington, Iron and Kane - will pay off the debt. At least, that's the current plan. But if the cost continues to escalate as steeply as it has so far, it's doubtful the counties would be able to raise connection fees and water rates enough to make the payments. Who would be on the hook then? All Utah taxpayers.

But the most speculative - and most important - of these unknowns is whether the pipeline will be worthless by the time it is built because the 100,000 acre feet of water it is designed to transport no longer flows into Lake Powell.

Climate scientists believe the American West will feel the effects of climate change more intensely than other areas. Some predict the annual mountain snowpack that feeds not only the Colorado but all the other streams Westerners rely on for drinking water and irrigation will shrink drastically or even disappear. That would leave all Utahns holding the bag - an empty bag attached to hefty debt payments.

The more we learn about the potential effects of this project, both intended and unintended, the less appealing it is. Moving ahead with it could be disastrous.

Is growth over?

California's continuing water crisis may mean the end of the state as we have known it.

By Cary Lowe for Los Angeles Times
July 20, 2008

Gov. Arnold Schwarzenegger's recent executive order certifying that California is in a drought and directing state agencies to start thinking about what to do about it is only the latest sign that a way of life built on cheap and readily available water is coming to a close. For much of the state, June was the driest month on record, according to the National Climatic Data Center. The continuing water crisis raises the question of whether we are approaching the limits of growth in California.

For the last century, it seemed there was no limit. More than any other state, California's economy and population exploded, a growth spurt fueled in large part by abundant water supplies. Now we may be at a turning point, especially in Southern California.

Growing Western cities at crossroads, report says

The most obvious indicators certainly point in that direction. Snowmelt in the Sierras, which historically has filled the state's major reservoirs and aqueducts, has been shrinking steadily. California's rights to Colorado River water have been gradually scaled back by regional agreements and mounting claims by other states. Court orders in response to environmental lawsuits aimed at protecting endangered fish species have slashed water deliveries from the San Joaquin-Sacramento River Delta. And reduced rainfall throughout the region has made it increasingly difficult to replenish groundwater basins.

Initially, the public agencies responsible for ensuring water supplies were cautious in their response to the signs of a growing water crisis, perhaps fearing a political backlash from Californians who expect to be able to open a tap and let it flow, without limits, any

time, anywhere, for any purpose. Adding a reservoir, drilling a few more wells or cutting deals with farmers to transfer some of their water to nearby cities helped soften, if not avoid, the effects of the state's growing water shortage. Now, however, the situation is becoming sufficiently dire that the water agencies are beginning to give the public a taste of what lies ahead.

Earlier this year, the Metropolitan Water District of Southern California, the largest water agency in the region and the principal supplier to the cities of Los Angeles, San Diego and numerous others in between, announced a 30% reduction in deliveries to agricultural customers, which means that farmers will have less water for their crops and to give to cities. And things could get worse. The agency also adopted a contingency plan that could result in similar cutbacks to urban consumers and rate hikes of up to 20%. Local water agencies, including the Los Angeles Department of Water and Power, followed suit, beginning with voluntary conservation programs but warning of mandatory ones to come.

Such steps alone will probably not make enough of a difference to avert a water-supply crisis. There is a finite amount of water available in Southern California, and it has not increased since 1990. The MWD annually imports 2.1 million gallons of water to the region. Without a plan of action by state and local governments, coupled with across-the-board changes in how we consume, major sectors of the state's economy such as agriculture and real estate development will soon face previously unimagined restrictions.

Meanwhile, environmental groups such as the California Water Impact Network are contending that many of our water-use practices violate the state's constitutional mandate that water be put to beneficial use to the maximum possible extent and that waste or unreasonable use be prevented. They particularly object to pumping water from the San Joaquin-Sacramento River Delta to irrigate thirsty crops like cotton and alfalfa, as well as lawns. These environmentalists plan to petition the state Department of Water Resources to permanently reduce Delta pumping. If state officials or the courts agree, it would affect virtually every aspect of water use.

Real estate development already is feeling the pinch. State laws that took effect six years ago require water agencies to document sufficient long-term water supplies to support large developments. If they can't, they must block the developments, and these agencies are increasingly doing just that. The Eastern Municipal Water District, the largest water agency in Riverside County, recently delayed approval of a huge industrial development because it couldn't guarantee water supplies to the facility. The agency also indicated that it may withhold certifications of water availability for other projects if conditions do not improve.

Courts are increasingly weighing in on the issue. Last year, the state Supreme Court overturned approval of a major new planned community in the Sacramento area because the project's environmental impact report did not adequately address long-term water supplies. Earlier this year, a court in Riverside County reversed the go-ahead for a large residential project in Banning, in part on similar grounds. All told, dozens of

planned developments throughout Southern California already have been delayed or abandoned because of uncertainty about long-term water supplies. And that number will soar once the recession in real estate eases.

Scaled-down developments that clear the water-supply hurdle must still meet tough new water-use standards. For instance, don't expect new homes to be built along the fairways of a new golf course or the shores of a man-made lake. The appliances in the new homes will be low-flow, and the pavement outside permeable to help replenish groundwater. State legislation that would have required developers to utilize all feasible water-efficiency measures in new construction and carry out other conservation measures in the surrounding community didn't pass earlier this year, but it undoubtedly will be back. Meanwhile, the Legislature is considering a requirement that all urban water agencies reduce their consumption by 20% within 12 years.

Agriculture, which consumes two-thirds of the delivered water in the state and remains a huge component of the California economy, is also feeling the sting of dwindling water supplies. Beginning with the MWD's reduction in water supplies, agencies throughout the state are pressing farmers to cut their water consumption by not growing water-intensive crops, investing in more efficient irrigation systems and even taking land out of agricultural use altogether. Pending state legislation would establish agricultural water conservation requirements.

The entire state economy ultimately will be affected by the water crisis. Yet it is unrealistic to expect that California's population and economy will stop growing. Accommodating that growth will require major commitments to reducing water consumption and increasing supply.

Unlike previous droughts, the current shortage of water is largely the product of long-term climate change because of global warming. This means that the shortage will not abate without major changes in how we consume water. The cheapest and easiest way to increase water supplies is conservation. Even small increases in the efficiency of agriculture's use of water can produce huge savings. Cutting back landscape irrigation, which accounts for more than half of urban and suburban consumption, is another option, as is treating and recycling water. Finally, rain and snowmelt can be collected and stored for future use.

As things stand now, California is rapidly approaching the limits of growth. Those areas of the state with limited local water supplies already are off-limits for development, and those sectors of the economy that are big users of water, such as agriculture, are cutting back. We can extend the period of growth and prosperity by pursuing the measures mentioned above. What remains to be seen is whether that will just postpone the day of reckoning -- when we have done all we can do to cut consumption but demand still exceeds supply. At the point, California will have reached the limit of its growth.

McCain stirs uproar with call for renegotiating Colorado River Compact

By Patty Henetz for The Salt Lake Tribune

Article Last Updated: 08/21/2008 09:32:13 AM MDT

The bonfire has been stacked for some time, but Arizona Sen. John McCain tossed in a match last week when he said the 86-year-old law that governs use of the Colorado River 'obviously' should be renegotiated.

The presumptive Republican presidential nominee clarified his statement Wednesday, saying it may have been "mistakenly construed as a call to rescind the Colorado Compact" when all he wanted was a more measured approach - which nevertheless could mean less water for Utah.

But Wednesday morning, after speaking during a water-conservation symposium in the tiny mountain town of Alta, Republican Gov. Jon Huntsman Jr. said he, too, would be open to at least looking at changes to Colorado River law--as long as regional governors lead the way.

By Kristen Wyatt for THE ASSOCIATED PRESS

2:38 p.m. August 20, 2008

DENVER – Sen. John McCain has backed off his comment that a key Western water agreement should be renegotiated, but Democrats signaled they plan to pummel him for his remarks, which even Republicans in swing-state Colorado denounced.

The GOP presidential candidate told the Pueblo (Colo.) Chieftain last week that the 1922 Colorado River Compact ought to be “renegotiated over time.” But in a letter Wednesday to Sen. Wayne Allard, R-Colo., McCain wrote that his comments were misconstrued.

“Let me clear that I do not advocate renegotiation of the compact,” the letter said. McCain aides said the letter was e-mailed across the West after even fellow Republicans derided McCain for suggesting the water agreement may need to be retooled.

The Colorado River is one of the most important water sources in the West, and the 1922 compact allocates the river among the lower basin states – Arizona, California and Nevada – and the upper basin states – Colorado, New Mexico, Utah and Wyoming.

A second agreement signed last year a 2007 was designed to ease tension among the compact states caused by a long-term drought.

Despite McCain's letter, Democrats heated up their criticism of McCain's comments, apparently seeing political traction in their criticisms.

Several Mountain West states once considered solid GOP country are now seen by Democrats as within reach of their candidate, Barack Obama. Democrats pounced on McCain's water remark last week and renewed their criticism Wednesday.

Sen. Ken Salazar, D-Colo., a former head of the state's Department of Natural Resources, said McCain's comment was "dangerously naive."

"It reflects, in my view, a fundamental misunderstanding" of the importance water politics has in the arid West, Salazar said. He cited the old Colorado political adage that "whiskey's for drinking, water's for fighting."

Wyoming Gov. Dave Freudenthal, also a Democrat, said McCain's water comment could provide an opening for Democrats.

"I was absolutely astonished that anybody running for president would suggest it," Freudenthal said Wednesday at a news conference in Casper, Wyo.

Democrats argued that McCain's misstep shows that, if elected, he may give Southwest population centers such as Los Angeles or Phoenix priority over the less-populous states along the Colorado River.

"I don't think his suggestion was premised on the idea that he'd like to have the upper Colorado basin states keep their water. Quite the contrary," Freudenthal said.

Arizona Democratic Gov. Janet Napolitano said she hoped McCain misspoke in his original comments "because he obviously doesn't know that we actually went in and revised that compact and signed that agreement" in 2007.

"I think he needs to be briefed on what's actually happening with the Colorado River," she said.

In his letter, McCain said he is a Westerner who understands water is scarce. He said he advocates cooperation and dialogue among the seven states – but "in a way that is fully consistent with the compact."

An Allard aide did not immediately return a call for comment on the letter. Last week, Allard denounced McCain's comment.

Democratic Colorado Gov. Bill Ritter brushed aside McCain's letter and said his comment shows the Republican has "a bias for the lower basin states" such as Arizona.

"The word 'renegotiate' does not have double meaning," Ritter said.

A political scientist at Colorado College in Colorado Springs, Bob Loevy, said Democrats would love to establish an image of McCain as someone more concerned with California and Arizona than the Mountain West. But Loevy said McCain's water comment likely won't remain on voters' minds until November.

“Above all, he didn't say, 'We're going to reduce Colorado's allotment,’” Loevy said.

A new set of negotiations need for The Colorado River Compact

Robert W. Adler

Article Last Updated: 08/30/2008 12:19:59 AM MDT

In its Aug. 24 editorial, "Law of the river: Don't dis the Colorado River Compact," The Salt Lake Tribune suggested that Sen. John McCain's proposal that the 1922 Colorado River Compact be revisited might generate costly and divisive conflict among the Colorado River Basin states.

Strategic amendments to the compact, however, could prevent rather than generate conflict, correct mistakes made when the compact was originally negotiated, and address issues that were beyond consideration in 1922.

The Tribune suggests that the compact is like the Constitution, and equally resistant to change. But we have amended the U.S. Constitution 17 times (not including the 10 in the Bill of Rights). The Colorado River Compact has never been amended in 85 years.

The Southwest is a very different place than it was in 1922. The region's population has grown dramatically, and shifted from rural to urban. Recreational and other instream water uses compete with traditional offstream uses such as farming and ranching. We know more about the river's hydrology. We better understand the environmental impacts of dams and water diversions, and the public places a higher value on environmental protection.

As The Tribune noted, compact negotiators relied on a 20-year hydrological record and assumed they could safely dole out at least 16.5 million acre-feet of water per year. Unfortunately, the rest of the 20th century was much drier. The average flow from 1896 to 2004 was less than 15 million acre-feet, but even that may understate the long-term picture. Based on tree-ring records, scientists have identified periods of longer and much more severe droughts in the basin than anything in the 20th century.

But other factors also support renegotiation of some aspects of the compact. First, recent scientific models show that global warming is likely to exacerbate water shortages in the basin. We may face as much as 25 percent declines in streamflow by 2030, 45 percent by 2060, and flows too low to meet even current water demands in as little as 20 years.

Second, neither Mexico nor Native American tribes had a seat at the compact negotiating table. Although the United States negotiated a treaty with Mexico two decades later, questions remain about the fairness of that allocation, especially during

dry periods. Some tribal water rights have been quantified, but water rights for other tribes remain unsettled.

Third, environmental impacts of water development were not considered in 1922. The Colorado River once hosted the largest percentage of endemic fish - species found nowhere else on the planet - of any river system in the world. Some are now extinct, and many more species of fish, birds, amphibians, reptiles and mammals are threatened or endangered. The American public has supported new environmental laws that profoundly affect how and where Colorado River water can be used.

Fourth, growth patterns in the basin have shifted dramatically. In 1922 it was obvious that rapid growth would continue in Southern California, but no one anticipated the urban booms in Nevada, Arizona and along Utah's Wasatch Front.

Fifth, while the upper basin states (including Utah) have not used all of the water they are entitled to under the compact, that water may not be available when they are ready to do so. So what happens when we try to use those allocations, honor tribal rights and our treaty obligations to Mexico, try to restore the river's endangered ecosystems, and satisfy demand in growing urban areas, all with less water to go around?

All negotiations require parties to guess about the future and then live by their predictions. A deal is a deal. However, it is one thing to apply that principle to commercial transactions, but quite another to apply it to decisions made by one generation on behalf of another across an entire region.

Interstate agreements with profound implications for growth and development, ecological health and societal welfare across seven states should not be revisited lightly. But neither should reconsideration be off-limits.

A new set of negotiations will implicate a broader, more complex set of tradeoffs between offstream and instream uses, international and domestic factors, economic versus environmental needs, and private versus public uses and values.

If the federal government, the basin states, tribes, environmental groups, Mexico and other players wait for water conflicts to become more acute, the likely response will be litigation and/or political warfare. A fairer and more reasoned agreement would be more likely if we addressed the future of the Colorado River sooner rather than later.

ROBERT W. ADLER is associate dean for academic affairs, James I. Farr chair and professor of law at the University of Utah's S.J. Quinney College of Law. He also is the author of "Restoring Colorado River Ecosystems: A Troubled Sense of Immensity" (Island Press, 2007).

Poll says half of Nevadans willing to live with tighter restrictions on water use

By HENRY BREAN for Stephens Media

Half of Nevada residents would support restrictions on their water use to help stretch the region's shrinking supply in the face of climate change, according to a Las Vegas Review-Journal opinion poll.

Fewer than one third of Nevadans polled said they would oppose new restrictions on water use, while 19 percent of respondents were undecided.

Among the likely voters interviewed in six Western states, those in Nevada and Utah were most willing to accept new limits on their water use.

Activist Bob Fulkerson was pleasantly surprised by the results in Nevada.

"It shows that people are willing to do a lot more with water conservation, and that's encouraging," said Fulkerson, who is executive director of the Progressive Leadership Alliance of Nevada.

Several recent scientific studies warn that climate change could reduce rainfall and snow accumulation in the Rocky Mountains, leading to longer and more severe droughts on the Colorado River. The Las Vegas Valley gets 90 percent of its water from the river.

Though Nevadans remain split over whether climate change is real or unproven, 57 percent of those polled said the benefits of reacting to the phenomenon will be worth the economic costs.

Fifty-six percent of respondents said they thought efforts to address climate change would create new jobs in agriculture and alternative energy research and production.

The questions on climate change came as part of a wide-ranging survey commissioned jointly by the Las Vegas Review-Journal, the Denver Post and the Salt Lake Tribune.

The poll was conducted in mid-August by Mason-Dixon Polling & Research of Washington, D.C., which interviewed 400 likely voters each in Nevada, Arizona, Colorado, New Mexico, Utah and Wyoming.

The margin of error for the regional results is plus or minus 2 percentage points.

The margin of error for state-specific results is plus or minus 5 percentage points.

The level of support for water restrictions among Nevada residents comes as no surprise to J.C. Davis, spokesman for the Southern Nevada Water Authority.

In a desert state that ranks as the nation's driest, the importance of water is never far from people's minds, he said. "It hits home. It's not some invisible factor to us."

There are limits to which conservation measures people are willing to support.

If pollsters asked about harsher punishments for water wasters, the response would be overwhelmingly positive. If they asked about making it illegal to wash a car in your driveway, "they'd get what we got when we tried that in 2003: torches and pitchforks," Davis said.

Of the seven Western states that share water from the Colorado River, all but one was included in the Review-Journal poll. Davis said he was "surprised" by the omission of California, whose share of the river is 14 times the size of Nevada's and the largest among the seven states.

Fewer than half of the Westerners polled, and 48 percent in Nevada, consider climate change to be "scientifically established reality." Arizona residents were the most confident and Wyoming residents the most skeptical about climate change.

Slightly more than half of those polled in the six states said climate change is no more of a threat in the West than it is throughout the country.

A similar percentage said taking action to deal with climate change would be worth the economic costs, though neither the action to be taken nor the costs were spelled out in the poll question.

Some 54 percent of those polled in the region believe addressing climate change in the West would create jobs "through the development of new energy and agricultural technologies."

A breakdown of the responses in the six states polled also reveals:

- More women than men, 53 percent to 45 percent, consider climate change to be scientific reality;
- More women than men, 51 percent to 45 percent, favor conservation measures to curb water use;
- And Western Democrats and independents, at 59 percent and 54 percent respectively, support conservation measures more than do Republicans, at 36 percent.

And, finally, there is this striking result from the poll, a disparity for which Al Gore might bear some responsibility:

While 74 percent of Democrats in the West see climate change as a reality, 70 percent of Republicans consider it "unproven and subject to debate."

Crucial Grand Canyon sandbars have rapidly eroded

By AMANDA LEE MYERS for The Associated Press

PHOENIX (AP) — Newly built-up sandbars crucial to wildlife in the Grand Canyon have rapidly eroded in the last four months, some shrinking back to the size they were before a costly manmade flood.

Torrents of water were released from the Glen Canyon Dam on the Arizona-Utah line in March to mimic natural flooding and rebuild sandbars along the 277-mile river in the Grand Canyon, where the ecosystem was forever changed by the dam's construction more than four decades ago.

Officials had expected erosion following the three-day flood, but they hadn't expected so much so fast.

"Circumstances conspired against our being able to protect the beaches as long as we had hoped," Grand Canyon National Park Superintendent Steve Martin said Tuesday. "Substantial erosion has occurred."

The accelerated erosion is the result of a requirement to release extra water from Lake Powell above the dam into the Colorado River, said John Hammill, chief of the Grand Canyon Monitoring and Research Center.

The requirement says that when Lake Powell has extra water, some of it needs to be released and go to Lake Mead on the Arizona-Nevada line. The requirement is designed to ensure that Colorado River states all get an equal share of water, a precious and limited resource in the West.

Lake Powell rarely has extra water because of extended drought, but a wet winter led to the highest water level in the reservoir in six years. That triggered the requirement in April, a month after the three-day flood in the Grand Canyon.

Between April and Sept. 1, officials increased flows from the Glen Canyon Dam by 20 percent. Time-lapse videos taken by the U.S. Geological Survey of two sections of the Grand Canyon show that the three-day flood created sandbars as large as football fields. But the sandbars began shrinking in April and by August, appear to be much smaller and about the same size they were before the flood.

Four to five times the normal amount of water was released from the dam during the flood, picking up sediment and depositing it in sandbars.

The 20 percent higher flows this summer then washed away much of it. Compounding the erosion is the practice of sending more water through the dam in the daytime to maximize power generation, then trimming output at night.

Martin said some benefits remain from the three-day flood, and despite the erosion, more floods should be released into the canyon whenever there's enough sediment to be deposited along the shoreline — about every one to two years.

Since 1963, the Glen Canyon Dam has blocked sediment from the Colorado from flowing downstream, turning the once muddy and warm river into a cool, clear environment that helped speed the extinction of four fish species and push two others near the edge.

The sediment provides a habitat for plants and animals, builds beaches for campers and river runners and helps protect archaeological sites from the elements.

Watch time-lapse videos of erosion in the Grand Canyon:

Grand Canyon flood results erode. Some of the sandbars and beaches built up in the March high-flow release are back to pre-flood levels.

By CYNDY COLE for Sun Staff Reporter
Wednesday, September 10, 2008

A half-year after a manmade flood built bigger sandbars and beaches in the Grand Canyon that are boon to native fish and plants, U.S. Geological Survey researchers say beaches are again eroding.

The data at this point is incomplete, researchers say, but some of the photos to date point to eroding sand bars as water releases from Glen Canyon Dam vary to meet peak power demands and interstate water-sharing agreements. A group of federal agents, tribes, environmentalists and power agencies that advises the Interior Department on how the Colorado River in Grand Canyon should be managed is meeting in Flagstaff Tuesday and today to discuss the latest research and propose next steps.

A budget up for discussion by the group today could determine whether there are any more experimental floods in the next five years. The next one called for in an earlier report by the Bureau of Reclamation is not until 2012.

About \$3.3 million is projected to be spent on USGS research related to the flood this year and next.

The amount of sand in the Colorado River is of interest because it is believed to be linked to the creation of backwaters that could help promote the survival of some fish species, and because boaters use beaches for camping.

All of the sand that once flowed into the lower Colorado River upstream of Lake Powell is now trapped by the dam, leaving it to the remaining tributaries to supply sand to the main channel during periods of high water.

The advisory group did some battle publicly this spring, when Grand Canyon Superintendent Steve Martin proposed more regular floods to improve the canyon's ecosystem, to the disagreement of power producers and his bosses.

The floods are conducted as part of an experimental program to manage the Grand Canyon ecosystem to allow for power generation at the dam, while offsetting the dam where possible.

USGS researchers say it is possible to maintain some sandbars and beaches along the Colorado River with the dam in place.

But for that to happen, according to researchers' findings, power production would often suffer.

Environmental groups, including the Grand Canyon Trust, have litigated over dam operations, saying what's beneficial for peak power production puts some of the canyon's few remaining endangered fish species in jeopardy.

Trust employee Nikolai Lash, who works on this issue, said it's hopeful that the coming presidential election could change the Colorado River.

"The orientation has been completely backwards," he said. "This dam has been operated not for the benefit of Grand Canyon, but for the benefit of hydropower interests."

The third experimental flood since 1996, the March experiment was timed to move around three times more sand than was available in the tributaries to the Colorado River in 2004.

LR Letter 09/11/08

Proposed pump station, reservoirs and hydroelectric power plant in Grand County, Utah.

FERC Project Nos. 13227 and 13146. Comments on the application for a preliminary permit known as Bull Canyon Pumped Storage Water Power Project and Long Canyon Pumped Storage Water Power Project by Utah Independent Power, the applicants. Pursuant to Federal Register Notice of July 16, 2008, Vol. 73, No. 137.

Proposed hydro-electric reservoirs raise concerns about environmental impact

By Ron Georg for The Times-Independent

Representatives of Utah Independent Power, including company president Frank Mazzone, will make a presentation at the Grand County Council's Aug. 19 evening session detailing their plans to create two reservoirs – that would comprise a pumped water energy storage facility – in the Bull Canyon area.

The plan appears simple. The company would build two reservoirs, one higher than the other. They'd allow the higher reservoir to drain into the lower one, through a set of turbines to create electricity. Then they'd pump it up and start over.

Mazzone said that because there is much less demand on the electrical grid during low-peak hours and electricity is cheaper, Utah Independent Power would purchase the inexpensive, surplus electricity to pump the water. Then they would turn the stored water back into electricity during peak times, when power is at a premium.

"What we do is we displace the use of high cost fossil fuel with low cost energy that's available when people aren't using it," Mazzone said.

The plan has a potential ecological benefit, he said. The nation's electrical power grid is dominated by coal-fired plants, as well as some nuclear facilities, which can't vary their output easily. So they operate at a level slightly below peak need, and they are supplemented by plants which can be ramped up quickly, mostly natural gas facilities.

The need to supplement the grid with natural gas plants can be offset by storage, according to Mazzone. Since there is no battery technology that can handle this task, pumped water energy storage is one of the few available options. Because wind power is more effective during off-peak hours, the technology can be used to store green energy. According to Mazzone, there are more than 100 such plants operating worldwide, mostly owned by major utilities in this country.

Utah Independent Power has applied for a permit with the Federal Energy Regulatory Commission, which will be a 30-month, \$5 million process, according to papers filed with FERC. That process will include input from the Bureau of Land Management, though Moab Field Office Manager Shelley Smith said she is uncertain how much input the agency will have. "I'm not sure how that FERC process works," she said.

Further complicating matters for the BLM is the transition between resource management plans, which set the context for all BLM decisions. "We're kind of between plans, so we have to operate under our 1985 plan until our new plan is final," Smith said. "We're identifying what the resource conflicts would be under both plans."

Those conflicts could include some that preclude disturbance of natural areas. "I think there's bighorn sheep habitat, but I'm waiting for our specialists to see what sort of conflicts exist," Smith said. She emphasized that the agency doesn't make judgments. "We identify the conflicts within our resource plan; we don't opine one way or the other. We would have to issue the right of way, and we would conduct that environmental assessment."

The Southern Utah Wilderness Alliance won't be quite so objective in their response, according to field advocate Scott Braden. "We're opposed, and we're going to be participating," he said. "While we're sympathetic to people's need for energy, we feel this is unsuitable. It would be tragic to lose more wild areas."

Braden said the proposal would affect an area known for its wilderness qualities. "It would not be appropriate in an area the BLM has identified as having wilderness characteristics, especially in a place like Moab, where the economy is based on the scenery," he said.

Mazzone said he hopes other aspects of his plan will outweigh those concerns. "We have nothing to hide. The facility produces no air emissions, no water emissions, no noise, and we are looking to build the facility so the only thing you see will be the surface of the lakes," he said. "All we can do is be honest with what we have, and trust that people will be logical about decisions they make. We look upon this as a public good."

Moab mayor plans to protest BLM's planned lease sale

By Patty Henetz for The Salt Lake Tribune

Article Launched: 11/14/2008 02:25:44 AM MST

Moab's sole source of drinking water could be in jeopardy unless federal officials back off a plan to sell an already-disputed oil and gas lease next month during a regular quarterly sale.

Mayor Dave Sakrison said Thursday that he has met with U.S. Bureau of Land Management officials about a 600-acre parcel in the aquifer the city and Grand County tap for all of their municipal uses. Sakrison said he would ask the Moab City Council on Nov. 25 to submit an official protest against the sale of the lease parcel, which also underlies several neighborhoods.

"Obviously we've got some major concern. It's our sole-source aquifer protection area," Sakrison said. And despite federal assurance that any actual drilling would have to occur outside the neighborhoods, "that's still problematic as far as we're concerned," he said.

"Part of our golf course sits in this lease parcel and a whole lot of private property. We're taking this very seriously," Sakrison said.

Moab residents were shocked earlier this week to discover that a BLM oil and gas lease sale scheduled for Dec. 19 includes a parcel in unincorporated Grand County just beyond the Moab city line. Several residential neighborhoods in Spanish Valley, parts of the municipal golf course and popular hiking trails are on the parcel.

That was bad enough. But the prospect of petrochemical pollution in the 10,000-acre aquifer is even more unacceptable, said John Weisheit, conservation director of the nonprofit group Living Rivers in Moab.

"If we have accidents in our aquifer, the toxic material would move very quickly into our water [taps]," Weisheit said. A cleanup would have to be done in a matter of hours, which is impossible, he said.

Shelley Smith, the BLM's Moab field office director, said the long-range management plan for the region prohibits "surface occupancy" - that is, no drill pads would be allowed on the 600-acre lease parcel. However, drillers could reach the oil from an angle, which means pipes and other industrial apparatus would be intruding on the aquifer that lies just under the ground's surface.

The Moab resource management plan has stricter protections on the watershed that feeds the aquifer; absolutely no oil or gas drilling is allowed around the springs and wells on the sandstone rims above the valley. Once the water is in the aquifer, however, restrictions are no stricter than those in place for the Moab airport and landfill.

The Environmental Protection Agency has certified the aquifer as pristine. The certification means that as the sole source of potable water, special guidelines and policies are in place to ensure the aquifer is not put at risk.

Smith said the BLM knows the parcel doesn't have high potential for oil yield; in fact, there is very little oil and gas development in the area - just a few pumps operate around Dead Horse Point State Park and the BLM's Island in the Sky.

So who nominated the parcel? And why? Smith said she doesn't know the answer to either question. Even if she had the name of the person who made the nomination, there likely would be no direct link to a developer.

"Maybe whoever nominated it won't be interested now that it would have development costs it wouldn't have had before," she said. "We're giving it a real close look."

The BLM already is battling the National Park Service over oil and gas lease parcels near Arches and Canyonlands national parks and Dinosaur National Monument also on the list. The Park Service wants to delay the Dec. 19 lease sales. The BLM has refused to do so. Senior officials with the two agencies, both administered under the Interior Department, are in negotiations that Mike Snyder, the Denver-based Park Service regional director, says he expects to conclude by Nov. 24.

Moab's concerns

- * At issue: BLM oil and gas lease plans include local pristine water source.
- * Complaint: Locals believe the plan poses a danger of contamination.
- * Response: BLM maintains proper planning process and protections are in place.
- * Ahead: Moab's mayor is asking City Council to make a formal protest.

Drought deepens strain on a dwindling Colorado Flows falling

California first in line as Utah, other states fight for water.

By Patty Henetz for The Salt Lake Tribune

Updated: 11/29/2008 08:49:15 AM MST

Utah's water forecast: Thirsty times are a-brewin' The drought gripping Utah, Southern California and the rest of the Southwest this century shows no sign of ending. Scientists see it as a permanent condition that, despite year-to-year weather variations, will deepen as temperatures rise, snows dwindle, soils bake and fires burn.

That's grim news for all of us in the West, perhaps most especially for the 10 million residents along the northern stretch of the Colorado River -- Utah, New Mexico, Wyoming and Colorado -- whose water rights are newer, and therefore junior, to those in Southern California, Nevada and Arizona.

Making matters worse, the Colorado -- the 1,450-mile-long lifeline that sustains more than 30 million souls and 3.5 million acres of farmland in seven states, 34 tribal nations and Mexico -- is in decline, scientists warn.

Even so, demand for the Colorado's water echoes from city leaders, industry giants, oil drillers, farmers, fishers, ranchers, boaters, bikers and hikers -- along with silent pleas from wildlife and the ecosystem. Trend analyses by federal scientists, probably conservative, predict the population dependent on the river will reach at least 38 million during the coming decade.

Right now, California, with the most senior rights and the largest share of the Colorado under a 1922 law, is struggling with a statewide water shortage. Not enough rain has fallen in the southland, as weathercasters like to call it, home to 18 million people, roughly half the state's population.

California already uses all of its Colorado River allocation. As the drought has worsened, Southern California water bosses have labored to keep the taps running through a host of conservation schemes.

Meanwhile, water managers in Utah and the Upper Basin are working to get all of their water rights in use, even as their cities and counties register some of the highest per-capita consumption in the nation.

Demand is up. Flows are down. Something has to give. And when it does, Utah could be in trouble if it doesn't change its wasteful ways -- just as 19th-century explorer Maj. John Wesley Powell predicted.

The West lacks water, he wrote in his 1879 Report on the Lands of the Arid Region of the United States, With a More Detailed Account of the Lands of Utah. "Disastrous droughts will be frequent."

Law of the River

The 1922 Colorado River Compact may have given California water rights senior to the other six states, but the Metropolitan Water District (Met), which supplies up to 60 percent of the water for 19 million people spread across six Los Angeles-area counties, made its claims after the state's allocation already had been divvied up. That means the most populous part of California is last in line among its peers when water runs low.

"If California ever did take a shortage," said Assistant General Manager Roger Patterson, "Met would take the hit."

That's already happened.

In 2003, California had to curtail its Colorado River use to its 1922 allocation of 4.4 million acre-feet per year, enough water for about 8 million households. Previously, under water-sharing deals with Arizona, the Golden State had been funneling about 5.2 million acre-feet. Because of its junior standing, Met had to eat about half the total shortage. No one else in the state had to cut supplies, Patterson said.

In February, Met agreed to a rationing plan for most of Southern California, including Los Angeles and San Diego. It expects to add 5 million residents during the next five years. Since the Pacific Ocean blocks growth to the west, the district is pushing eastward, where it's hotter.

A federal judge has ordered California water managers to leave 30 percent more water in the Sacramento-San Joaquin Delta in Northern California to stave off fish kills and keep the massive estuary healthy. More for the environment means less for Los Angeles.

Other populous regions of California also have taken steps to ensure a good water supply.

-- Developers in Riverside, Kern, Santa Barbara and San Luis Obispo counties must guarantee a 20-year water supply before they build.

-- The state has brought back a water bank, last used 17 years ago, in which Southern California cities can buy water from willing Sacramento Valley farmers. However, given the high prices farmers can get for their crops, especially rice, willing sellers might be hard to find.

-- Orange County residents are drinking recycled sewer water.

-- In San Diego County, the Coastal Commission greenlighted a \$300 million desalination plant adjacent to a state beach. The operation still has to meet lots of conditions -- which probably will make the plant more costly to build and run -- but even if completed would supply no more than 9 percent of San Diego's current needs.

Met residents have cut back to about 185 gallons of water per person per day. Residents of Long Beach are down to 115 gallons.

"If Long Beach can do this," said Kevin Wattier, the city water department's general manager, "so can every other city in Southern California."

Splish, splash

Upstream, Utahns on average use 291 gallons of water per person per day, a rate second only to Nevada. In Salt Lake County, it's 255 gallons; Washington County, 350 gallons; Kane County, a bloated 430 gallons. Sixty percent of Utah's water goes for outdoor use, including landscaping and agriculture. In California, agriculture consumers about 85 percent. California, however, is the fifth-largest farm economy in the world.

By comparison, Utah's agriculture profile is nearly nonexistent, contributing less than 1 percent to the state's economy.

The system might seem out of balance. Yet no state, not even Nevada, which has the measliest Colorado allocation, wants to reopen the 1922 Colorado River Compact that divided the water. Each fears getting an even worse deal. Nor does anyone know what soon-to-be-settled Navajo claims on the river will mean to both basins.

There is, however, a growing sense that the Colorado Basin states are all in this together.

"Everybody ought to share in the reality of the river," said former Utah Attorney General Paul Van Dam, now director of Washington County-based Citizens for Dixie's Future. "And there ought to be great flexibility in how we use it without losing it."

Dozens of scientific studies issued since 2004 have documented the Colorado's decline.

The river's annual flow has averaged 11.7 million acre-feet this decade, according to federal records. In 2002, the U.S. Bureau of Reclamation measured only 6.2 million acre-feet passing Lee's Ferry below Glen Canyon Dam, the lowest flow of the decade. Even after this year's above-average precipitation, Lake Powell and Lake Mead combined are at 57 percent capacity.

A 2007 U.S. Geological Survey report found that, by 2050, rising temperatures in the Southwest could rival those of the nation's fabled droughts, including the Dust Bowl of the 1930s. Hotter weather is expected to reduce Colorado River runoff by at least 30 percent during the 21st century.

If the USGS is correct, and if this century's trend persists, average annual flow in the Colorado could fall to 8.2 million acre-feet per year.

Imagine that. The Law of the River requires 9 million acre-feet to pass Lee's Ferry on the way to the Lower Basin and Mexico. Under a strict interpretation of the law, the Upper Basin could be left with nothing.

A far more likely scenario would have the states banding together to rework the river allocations. But when Arizona Sen. John McCain suggested just that during his failed presidential campaign, the shrieks emanating from Colorado's halls of power were enough to prompt the Republican nominee to back down.

Pipeline dream

Dennis Strong, director of the Utah Division of Water Resources, in October told the state Water Development Commission that the state is using about 1 million acre-feet of its yearly 1.4 million acre-foot allotment from the Colorado.

Tribal water settlements yet to be signed would take up about 186,000 acre-feet, he said. New agricultural uses, mostly dedicated to controlling the salinity of the water that flows back to the Colorado, would take 35,000 acre-feet. Municipal and industrial uses along the river corridor would account for 5,000 acre-feet, and the proposed Lake Powell Pipeline would need 100,000 acre-feet, leaving about 74,000 acre-feet unused, theoretically.

Utah water managers are pushing the \$1 billion-plus pipeline, which would lavish more water on a Dixie desert region likely to feel the full brunt of global climate disruption and permanent drought within the next 40 years.

The state hasn't actually secured rights to the 100,000 acre-feet for the pipeline. Strong said that would have to be nailed down by 2010, when the Federal Energy Regulatory Commission is expected to issue the license necessary to start building it. He's confident the water will come.

By 2040, the pipeline's water would be entirely committed to a regional population of about 400,000, Strong said.

Given current scientific warnings about the shrinking Colorado, that prospect looks shaky.

But Strong isn't worried. He's skeptical about global warming, though he "sees evidence" of it. "Water managers," he said, "have been dealing with drought forever."

Climate change, drought to strain Colorado River

By MIKE STARK – December 5, 2008

SALT LAKE CITY (AP) — Seven Western states will face more water shortages in the years ahead as climate change exacerbates the strains drought and a growing population have put on the Colorado River, scientists say.

"Clearly we're on a collision course between supply and demand," said Brad Udall, director of the Western Water Assessment at the University of Colorado.

Although there is some disagreement about when the most dire conditions will materialize, scientists at a conference in Salt Lake City said Thursday they expect less water to be available in the coming decades. Without fundamental shifts in water management, the result will be shortages and difficult decisions about who in the seven states the river serves will get water and who will go without, said Dave Wegner, science director for the Glen Canyon Institute, which organized the one-day conference at the University of Utah.

"To me, it's not going to be a pretty debate," Wegner said.

The changes are already being seen in reduced water flows, higher air temperatures and an unrelenting demand on the Colorado, which snakes across more than 1,400 miles and provides water for farms, businesses, cities and homes. The river serves Arizona, California, Colorado, Nevada, New Mexico, Wyoming and Utah, an area where 30 million people live.

Last year, officials from the seven states and Interior Secretary Dirk Kempthorne signed a far-reaching agreement aimed at conserving and sharing scarce Colorado River water. The 20-year plan formalized rules for cooperating during the ongoing drought.

A study released in February by the Scripps Institution of Oceanography in San Diego said there's a 50 percent chance that Lake Mead, which straddles the Arizona-Nevada state line, could run dry by 2021.

Several models by different scientists have made predictions about the future flow of the Colorado, all of which forecast less water, said Tim Barnett, one of the Scripps study's authors. The prospect of warming temperatures only increases the strain on an already strained system, he said.

"The current usage is simply not sustainable," Barnett said.

Udall quibbled with Barnett's prediction about 2021 but not the overall speculation that water in the Colorado River basin will become more scarce. "It's a question of when," he said.

Even if the West's climate doesn't get as warm as predicted, the river system will likely be faced with shortages, said Gregory McCabe, a project chief at the U.S. Geological Survey's water resources division in Denver.

Building more reservoirs to store water probably won't be enough to mitigate the effects of changes to the system — especially warming temperatures, he said. One of the best approaches will be to drive down demand by finding better and more ways to conserve water, McCabe said.

The Colorado has long been the source of controversy as thirsty states fight for their share to quench growing economies.

The 20th century was one of the wettest going back several centuries. But it shouldn't be assumed that water levels will remain as plentiful in the future, researchers said.

Connie Woodhouse, a University of Arizona scientist, said tree rings in the basin indicate that the amount of moisture has fluctuated widely over hundreds of years, but has tended to be drier than was seen in the last 100 years.

It's time to consider a "new normal" for shrinking water supplies in the Colorado River basin, Wegner said. That will require a sweeping re-evaluation of allocations, use, conservation, dams and legal obligations, he said.

Water agency needs an overhaul, congressman says

Conservation award » George Miller was honored for leadership on natural resource policies.

By Judy Fahys for The Salt Lake Tribune
Updated: 12/05/2008 09:16:21 AM MST

The federal government's water-management agency can no longer operate as though Colorado River water is abundant, said one of Congress' leaders on natural resources Thursday night.

"The Bureau of Reclamation has to reinvent itself," said U.S. Rep. George Miller, D-Calif. and longtime leader on natural resource policy. "It has to address the future in an innovative way and not be tied so strongly to the past."

Miller made the remarks as he accepted the David R. Brower Award for Conservation by the Salt Lake City-based Glen Canyon Institute, an organization that made its name by calling for the draining of Lake Powell.

The institute now focuses on scientific issues surrounding the vitality of the Colorado River, and much of Thursday's program was devoted to updates about how climate change might affect the 27 million people and 3.5 million acres of farmland that rely on the 1,450-mile river.

Miller was a driving force behind legislation in the early 1990s to complete the Central Utah Project -- the water program behind construction of the Jordanelle Dam in Wasatch County -- along with the creation of a mitigation fund to address the environmental damage caused by decades of dam-building in Utah.

He also pushed for moderating flows through the Glen Canyon Dam to lessen the harm high-energy water releases were causing to Grand Canyon National Park. The northern California lawmaker served from 1991 to 1994 as the chairman of the House committee that oversees the nation's mining programs, water, national parks and other natural resources.

Miller attacked the departing Bush administration for what he described as a culture of corruption in the Interior Department. Science, he added, was "tampered with" and "pushed aside." "You don't get to change the conclusions for political reasons," he said.

Instead, with a change in administration in Washington, science should be harnessed to help make smarter decisions about preserving already-taxed water supplies.

Scientists who spoke at the conference talked about Western water resources that are dwindling in the face of growing populations and are threatened by global warming.

Tim Barnett, a researcher at the Scripps Institution of Oceanography in San Diego, told the conference that no models of Colorado River water -- even without climate change factored in -- predict an increased flow.

"You have a river that's on the brink of failure," he said.

Abrupt Climate Change: Will It Happen this Century?

Contact Information:
U.S. Department of the Interior
U.S. Geological Survey
119 National Center
Reston, VA 20192

John McGeehin
Phone: 703-648-5349

Jessica Robertson
Phone: 202-821-2698, 703-648-6624

The United States faces the potential for abrupt climate change in the 21st century that could pose clear risks to society in terms of our ability to adapt.

"Abrupt" changes can occur over decades or less, persist for decades more, and cause substantial disruptions to human and natural systems.

A new report, based on an assessment of published science literature, makes the following conclusions about the potential for abrupt climate changes from global warming during this century.

Climate model simulations and observations suggest that rapid and sustained September arctic sea ice loss is likely in the 21st century.

The southwestern United States may be beginning an abrupt period of increased drought.

It is very likely that the northward flow of warm water in the upper layers of the Atlantic Ocean, which has an important impact on the global climate system, will decrease by

approximately 25-30 percent. However, it is very unlikely that this circulation will collapse or that the weakening will occur abruptly during the 21st century and beyond.

An abrupt change in sea level is possible, but predictions are highly uncertain due to shortcomings in existing climate models.

There is unlikely to be an abrupt release of methane, a powerful greenhouse gas, to the atmosphere from deposits in the earth. However, it is very likely that the pace of methane emissions will increase.

The U.S. Geological Survey led the new assessment, which was authored by a team of climate scientists from the federal government and academia. The report was commissioned by the U.S. Climate Change Science Program with contributions from the National Oceanic and Atmospheric Administration and the National Science Foundation.

"This report was truly a collaborative effort between world renowned scientists who provided objective, unbiased information that is necessary to develop effective adaptation and mitigation strategies that protect our livelihood," said USGS Director Mark Myers.

"It summarizes the scientific community's growing understanding regarding the potential for abrupt climate changes and identifies areas for additional research to further improve climate models."

Further research is needed to improve our understanding of the potential for abrupt changes in climate. For example, the report's scientists found that processes such as interaction of warm ocean waters with the periphery of ice sheets and ice shelves have a greater impact than previously known on the destabilization of ice sheets that might accelerate sea-level rise.

How the West's Energy Boom Could Threaten Drinking Water for 1 in 12

by Abrahm Lustgarten for ProPublica
David Hasemyer for The San Diego Union-Tribune
December 21, 2008 11:23 am EDT
Dec. 22: This post has been corrected [1].

This story was co-published with the [2]San Diego Union-Tribune [2] and also appears in that newspaper's Dec. 21, 2008 issue.

[Click here for ProRepublica site with document archive](#)

The Colorado River, the life vein of the Southwestern United States, is in trouble.

The river's water is hoarded the moment it trickles out of the mountains of Wyoming and Colorado and begins its 1,450-mile journey to Mexico's border. It runs south through seven states and the Grand Canyon, delivering water to Phoenix, Los Angeles and San Diego. Along the way, it powers homes for 3 million people, nourishes 15 percent of the nation's crops and provides drinking water to one in 12 Americans.

Now a rush to develop domestic oil, gas and uranium deposits along the river and its tributaries threatens its future.

The region could contain more oil than Alaska's National Arctic Wildlife Refuge. It has the richest natural gas fields in the country. And nuclear energy, viewed as a key solution to the nation's dependence on foreign energy, could use the uranium deposits held there.

But getting those resources would suck up vast quantities of the river's water and could pollute what is left. That's why those most concerned are water managers in places like Los Angeles and San Diego. They have the most to lose.

The river is already so beleaguered by drought and climate change that one environmental study called it the nation's "most endangered" waterway. Researchers from the Scripps Institution of Oceanography warn the river's reservoirs could dry up in 13 years.

The industrial push has already begun.

In the eight years George W. Bush has been in office, the Colorado River watershed has seen more oil and gas drilling than at any time in the past 25 years. Uranium claims have reached a 10-year high. Last week the departing administration auctioned off an additional 148,598 acres of federal land for gas drilling projects outside Moab, Utah.

As still more land is leased for drilling and a last-minute change in federal rules has paved the way for water-intensive oil shale mining, politicians and water managers are now being forced to ask which is more valuable: energy or water.

"The decisions we are making today will be dictating how we will be living the rest of our lives," said Jim Pokrandt, a spokesman with the Colorado River Conservation District, a state-run policy agency. "We may have reached mutually exclusive demands on our water supply."

Some experts and officials say the economic and ecological importance of the Colorado is just as vital to American security as the natural resources that can be extracted from around it.

"Without (the Colorado), there is no Western United States," said Jim Baca, who directed the Bureau of Land Management, or BLM, in the Clinton administration and says the agency's current policy is narrow-sighted. "If it becomes unusable, you move the entire Western United States out of any sort of economic position for growth."

Balancing that risk with the need for energy is complicated, because scientific understanding of the Colorado is limited and no single agency manages the river as a national resource.

The Interior Department, which includes the BLM, oversees where the water goes, but not how it is kept clean. The EPA is charged with maintaining water quality, but it can't control who uses it and doesn't conduct its own research.

Furthermore, the EPA delegates much of its authority to the states that the river runs through, and the federal, state and local authorities in charge of separate aspects of the river don't always coordinate or cooperate. "I don't know that there is, quite honestly, anyone that looks at an entire overview impact statement of the Colorado River," said Robert Walsh, a spokesman for the Bureau of Reclamation, which governs the allocation and flow of the southern part of the waterway.

Oil and natural gas drilling in Colorado already require so much water that if its annual demand were satisfied all at once, it would be the equivalent of shutting off most of Southern California's water for five days. If Colorado's oil shale is mined, it would turn off the spigot for 79 days.

Although company executives insist they adhere to environmental laws, natural gas drilling has led to numerous toxic spills across the West. According to the Environmental Protection Agency, mining has contaminated four out of 10 streams and rivers in the West. Similarly, mining has topped the government's list of the most polluting industries for the past decade, and new mine problems continue to arise today.

Industry representatives and the Bush administration say breaking America's dependence on foreign oil makes using all available energy resources here at home a priority.

"I believe this country needs to offer domestic resources to be energy independent," said Tim Spisak, a senior official who heads the BLM's oil and gas development group. "The way to do that is to responsibly develop public resources on our lands."

Critics of Bush's energy policies said they favor business interests at a time when climate change demands a fundamental shift in the way the nation values water. They also complain that the administration doesn't grasp the West's looming water problem.

"When Lake Mead goes dry, you cut off supply to the fifth largest economy in the world," said Patricia Mulroy, general manager of the Southern Nevada Water Authority, referring to the reservoir that sits behind the Hoover Dam and controls water flow to the Southwest's cities. She points out that while some dispute the timing of Lake Mead's demise, no one says it won't happen. "We've ignored the need to adapt," Mulroy said. "We've never looked at what the secondary impact of, say, an energy decision is."

Both the U.S. House and Senate are considering bills that would require better management of the nation's water quality and water assets. But the bills focus more on the threat of climate change than the threat of industrial development. A growing number of water professionals say even a congressional act isn't enough to clarify the government's responsibility. They want the president to appoint a new national water authority -- or even a cabinet-level water czar.

"If you are really going to deal with water, the nation needs to deal with it in a far more comprehensive manner," said Brad Udall, director of the National Oceanic and Atmospheric Administration's water assessment program at the University of Colorado. "We can't afford to play around with potentially damaging activities."

The Southern Nevada Water Authority, the state of Arizona and the Metropolitan Water District, which governs the water supply to Los Angeles and San Diego, have implored Bush's Interior to proceed with caution as it races in these last days to develop mining, gas and oil near the river.

"We have other sources of power," said Jeffrey Kightlinger, MWD's General Manager. "We don't have other sources of water."

Hot Water

One of those alternative sources of energy is uranium, which is essential to the production of nuclear energy. In the last six years, new uranium mining claims within five miles of the river have nearly tripled, from 395 to 1,195, according to a review of BLM records by the Environmental Working Group, a Washington-based policy organization.

Although few of those claims will actually be mined, mining has a track record of contamination that alarms water officials dependant on the river. The Metropolitan Water District points to a 16 million ton pile of radioactive waste near Moab as a warning of what can happen when mining isn't carefully controlled.

The pile sits on the banks of the Colorado at the site of a mill that once processed uranium for nuclear warheads.

The plant closed in 1984, but the Grand Canyon Trust estimates 110,000 gallons of radioactive groundwater still seep into the river there each day. The U.S. Department of Energy decided in 2000 to move the pile away from the river. But the planning was so complicated and the cost so high -- estimates top \$1 billion -- that the first loads of waste won't be hauled off until next year.

The industry says the Moab case is an outdated blight from the distant past.

"What gets my ire up is when we get compared to stuff that happened in the 60s. There is no argument from us now about being careful... with an eye to preserving the environment," said Peter Farmer, CEO of Denison Mines, a Canadian company that operates seven U.S. mines as well as the nation's only operating uranium mill in Blanding, Utah.

Denison recently spent more than \$5 million to triple-line a waste pit and outfit it with leak detection sensors. It's cheaper to pay up front, Farmer says, than to clean up later.

Roger Haskins, a specialist in mining law at the BLM, agrees that concerns over mining are overblown. He says landmark environmental regulations in the 1970s prepared the industry for the 21st century. While it's still easy to stake a mining claim, projects must now undergo extensive environmental review before they can be turned into mines.

"Whatever happens out there is thoroughly manageable in today's regulatory environment," Haskins said. Scientists say some degree of pollution is inevitable, because mining sometimes uses toxic chemicals like cyanide. It also exposes naturally toxic metals that would otherwise remain deep underground.

Drilling for uranium creates pathways where raw, radioactive material can migrate into underground aquifers that drain into the river. Surface water can seep into the drill holes and mine shafts, picking up traces of uranium and then percolating into underground water sources. The milling process itself creates six pounds of radioactive and toxic waste -- including ammonia, arsenic, lead and mercury -- for every ounce of uranium produced.

"There has to be some impact to downstream water. Whether or not we can measure -- that is the question," said David Naftz, a hydrologist at the U.S. Geological Survey in Salt Lake City who studies uranium mining. Naftz has documented dangerous levels of uranium near waste dumps at more than 50 separate test sites in Utah.

While much of the mining happens in high, dry places where contaminants don't easily seep into surface water, he says periodic storms can still wash them into the river.

"What we've done is kind of upset the geochemical equilibriums in these basins by taking these ores and exposing them to conditions on the surface," he said. "The question is, how long is it going to take to transport them down to water systems?"

Pollution problems with gold, copper and other mines also challenge the assertion that technology and better regulation have eliminated the environmental risks.

One study compared the EPA's environmental impact statements for 25 sites to what really happened after mining took place. Water at three quarters of the mines was found to be contaminated, even though the mines used technology and techniques that the EPA had said would keep the environment clean, according to the research done for the Earthworks by Jim Kuipers, an environmental engineer in Butte, Mont. and Ann Maest in Boulder, Colo.

At least four large mines that operated as recently as the 1990s -- long after new regulatory standards were put in place -- have caused so much contamination that the EPA designated them as priority Superfund cleanup sites. One rendered a 20-mile stretch of a Colorado River tributary completely dead.

"Promises are made and promises are broken," said Roger Clark, who is director of the Grand Canyon Trust's air and energy program and has been monitoring the rise in

mining claims near the Grand Canyon. "This is not something we can sit back and take industry's word for."

Clark, who explored the Colorado River as a Boy Scout and later as a river guide, already has seen signs of the park's decline. On a recent hike along the Grand Canyon's rim, he passed a stream whose water he drank freely as a boy.

Now it's marked with a sign saying, "Drinking and bathing in these waters is not advisable." The Park Service posted the same warning along five other canyon streams that feed into the Colorado, because high concentrations of uranium have leached into the water, likely from old mines.

In June, the House Natural Resources Committee invoked a rarely-used authority to force the Bush administration to make one million acres of public land adjacent to the park ineligible for exploration. Two months later, though, Interior Secretary Dirk Kempthorne allowed some 20 new claims in the area by deciding that the committee's move violated executive authority.

Secret Chemicals

In the last decade, a pattern of contamination has also emerged in places where natural gas drilling has intensified. If drilling increases substantially across Colorado, Wyoming and Utah, it could also imperil the river.

Most wells rely on a process called hydraulic fracturing [3], which requires as much as two million gallons of water plus small amounts of often-toxic chemicals for a single well. The waste water then sits in open pits until it is treated, recycled or disposed of.

In February a waste pit high on a mesa overlooking the town of Parachute, Colo. sprang a leak, allowing some 1.6 million gallons of fluid to soak into the arid earth. According to state records, the spill migrated underground until it seeped from a cliff side and froze into a gray pillar of ice more than 200 feet tall. When it melted, the fluids dripped into the torrid currents of Parachute Creek and finally dumped into the Colorado River.

Although the number of gas drilling accidents in the upper Colorado River watershed is small relative to the amount of drilling, they have begun adding up. Colorado state records show that of some 1,500 spills in drilling areas since 2003, more than 300 have seeped into water. In one case last summer a truck carrying drilling fluids crashed into the Colorado, where it remained partially submerged for more than three weeks.

In neighboring Wyoming, the BLM found a 28-mile-long plume of benzene contamination in an aquifer beneath a gigantic gas field. The aquifer is near a tributary to the Green River, which in turn flows into the Colorado.

Doug Hock, a spokesman for the Canadian gas company Encana, which drills in Colorado and Wyoming, says that while there will always be spills, the fears of pollution are exaggerated. Encana uses steel and concrete casing around its drill pipes, lines its waste pits and, increasingly, cleans its waste water and re-uses it inside its wells.

"We have put in place safeguards to protect the water," Hock said. "There is always a balance -- this country has a great demand for energy."

But because the energy industry has been exempted from so many federal environmental regulations during the Bush administration, it's difficult to assess the industry's true impact on the river.

The mix of chemicals used in hydraulic fracturing is held as proprietary competitive information by the industry and kept secret from even the EPA. Scientists say that without knowing the specific ingredients in the mix, they don't know what compounds to test for after a spill and can't check to see if they've reached the river.

The 2005 Energy Policy Act exempted hydraulic fracturing from the Safe Drinking Water Act. Also exempted from federal control and water protection laws are the drilling industry's construction activities, including the sediments and dust produced from thousands of miles of road building, site grading and the drilling itself, even though that debris often ends up in waterways.

"We have seen an explosion in drilling, and at the same time we have seen a weakening of the federal standards under which drilling occurs," said Dusty Horwitt, an analyst with the Environmental Working Group.

Given the relaxation in regulatory authority, the development may be out-pacing scientists' ability to measure the implications.

In August drilling companies bid on 55,000 acres of federal parcels atop the Roan Plateau, a cherished wilderness area in central Colorado that drains into the Colorado River. A September report from the University of Colorado Denver predicted that in 15 years Garfield County, a western drilling area bisected by the river, will have 23,000 wells, six times what it has now, based on permit applications already filed with the state.

The push to drill continued last week, when the BLM opened 148,598 more acres of federal land near Moab to drilling.

Quarterly lease sales in that area during the last two years were typically about 75,000 acres.

"It seems reckless," said Bill Hedden, director of the Grand Canyon Trust. Near his home outside Moab, natural gas drilling rigs may soon be visible through Delicate Arch, the wind-hewn bridge of rock at Arches National Park that graces Utah's license plate.

"We Americans have tried to export a lot of our problems off to the boondocks -- but in this case the boondocks is the watershed and the problem is coming right back to us," Hedden said.

According to Spisak, the BLM official in charge of drilling, the Moab sale is the result of "pent up build-up" in the queue of requests the agency is handling. Companies that want to drill on federal land ask the BLM to consider listing that land for a future lease sale.

Over the past few years, Spisak said, environmental organizations have challenged some of the listings the BLM approved, delaying their sale. Now the agency is catching up. "We are required to push them forward," Spisak said. "It's due to pressures of prices and industry, and we are responding to the market demand."

An Unprecedented Demand

No project poses a greater threat to the Colorado River -- or better represents the choice between water and energy -- than mining for oil shale.

In mid November the BLM quietly approved a rule change that paved the way for extracting oil from rock deposits in Colorado and Utah, smack in the heart of the river's watershed. If the vast deposits are mined to their potential -- and it could be a decade before any of the projects go forward -- the reserves could help the United States make a significant leap towards energy independence.

Getting oil from the shale, if researchers can find a reliable way to do it on a large scale, would be astronomically expensive. It might also require more water than the Colorado River can provide.

A recent study for the state of Colorado estimates that if the oil shale industry takes off in northwest Colorado, the region's energy industry will need at least 15 times as much water as it uses now. In 30 years, the report predicts, the energy industry in the upper Colorado River basin would stop the river's entire flow for nearly six weeks if it used the water all at once.

"It would take every bit of water rights that we currently have plus more," said Scott Ruppe, general manager of Uintah Water Conservancy District in northeastern Utah.

Counties across the Western states are apportioned a limited quota of water rights that can be used for industry, farming, or municipal use, he explained. Using Colorado River water for oil shale means less water for urban growth, agriculture and personal use. It means trading fresh fruit and vegetables -- not to mention green lawns -- for energy.

"It just comes down to how needy the nation is for energy," he said. "If energy is short then some of the other concerns might get pushed aside."

These stark choices have driven Congress to begin examining the water problem in the absence of leadership from the White House. One of the bills that has been written would, if passed, direct the Interior Department to undertake the kind of comprehensive inventory of the nation's water quality and supply that critics say is missing.

It will be up to the Obama administration, though, to ultimately decide the nation's priorities. The appointment of Colorado Sen. Ken Salazar to head the Interior Department will inject a unique understanding of western water issues into Washington politics. Salazar is a long-time rancher and a former water attorney.

The new administration could temper some of Bush's decisions by limiting mining claims in sensitive areas, refusing to finalize leases sales that haven't been signed, and

rigorously enforcing existing environmental regulations. It also could try to reverse some of the rules the Bush administration has issued to speed development, although that will be difficult.

Obama's greatest opportunity to address the conflict between water and energy may lie not in undoing policies from the past, but in looking to the future.

"The administration has an opportunity to start thinking about water as a national resource," said Nevada's Mulroy. "We have no rear view mirrors anymore."

Correction: This post originally stated that the Bureau of Land Management had auctioned off 359,000 acres of land for natural gas drilling near Moab Utah. In fact, as a result of protests over that lease sale, the BLM made a last minute change to the total amount and auctioned 148,598 acres of land on Dec. 19, 2008. This story also refers to a study comparing real pollution at 25 mines to that anticipated by the EPA. That study was commissioned by Earthworks, not the Environmental Working Group, and was authored by James Kuipers and Ann Maest.

Advocacy groups greening Utah

Study shows groups are increasing at nearly double the rate of other nonprofits.

By Judy Fahys for The Salt Lake Tribune

Updated: 01/04/2009 09:20:04 AM MST

The grass roots sprouting up around Utah are mostly green.

New environmental groups are sprouting up all over -- contrary to a declaration five years ago that the green movement had grown monolithic, fossilized and died. Some of Utah's new groups focus on neighborhoods, such as the San Juan County community concerned about uranium mining planned for their area.

Others organize constituencies, like the Utah Physicians for a Healthy Environment and the Utah Moms for Clean Air.

And still more focus on a particular environmental problem, like Uranium Watch, concentrating on pollution from nuclear energy, or Urgency Utah, campaigning to bring climate-change solutions to the forefront.

Brigham Young University political science professor Kelly Patterson says the sprouting of new green groups makes sense on an issue as diverse as the environment. While Utahns might snub a Washington-based organization focused broadly on national environmental policy, they readily welcome neighbors addressing a problem down the block.

"It's what you do about uranium tailings," said Patterson, who studies interest groups. "It's what you do about particulate matter [air pollution], it's what you do about preserving open spaces."

The trend isn't unique to Utah. A new study by the Urban Institute shows that green groups are increasing at nearly double the rate of other kinds of nonprofits.

Meanwhile, author Paul Hawken describes the phenomenon as part of a global movement in his book *Blessed Unrest*.

For Cherise Udell, president and founder of Utah Moms for Clean Air, none of this is surprising.

Exasperated with the apparent apathy about high-pollution periods in the Salt Lake Valley, she recognized "a need and a niche to be filled" when she launched Moms nearly two years ago.

"Caring about the environment has become mainstream," says Udell. "It's no longer a fringe issue." The group now has an e-mail list of around 1,200 and a track record of accomplishments that include reducing motor vehicle idling at schools and a school-bus retrofitting program intended to lessen children's exposure to polluted exhaust. Members, many with a professional background, have been known to petition lawmakers with a baby balanced on their hips, a loaf of banana bread in one hand and legal documents in the other.

"We really brought the air issue to the kitchen table," says Udell.

Air-quality problems also prompted Salt Lake City anesthesiologist Brian Moench to create the doctors' group. With about 80 members now, the doctors emphasize health impacts of pollution to nearby communities.

"The public's knowledge of these issues is probably our biggest ally," he says. "The best progress that will be made is through public pressure."

Jim Westwater, founder of the Utah Valley Sierra Forum, says he rallied inactive Sierra Club members and others interested in environmental issues after he relocated to Utah a couple of years ago. Now over 400 people are part of the network, participating in hikes, cleanups and the group's monthly discussion forums.

The debate has included lively sessions on such issues as the benefits of nuclear power, consumerism and faith and the environment. It's a delicate balance to strike in a community where environmentalism is often shunned.

Says Westwater: "We're trying to appeal to people's higher nature."

Sarah Fields, of Moab-based Uranium Watch, agrees that public education is key. For many years the go-to person for information on all things nuclear in southeastern Utah, Fields now shares the government documents she digs up on the group's Web page.

A better-informed community years ago might have gone a long way toward preventing the Atlas uranium-processing mill from becoming a \$1 billion hazardous waste cleanup, she says.

"It's when you are in the local community -- that's when you know what's going on."

In the end, the proliferation of environmental groups is a trend that's likely to continue, says University of Utah political science professor Dan McCool. It's also bound to be good for democracy, he says.

"Small, local groups, can target in a way that national groups cannot."

The West is hurtling toward a water crisis

Opinion

The Salt Lake Tribune

Updated: 01/09/2009 03:21:23 PM MST

The Utah Legislature will soon begin its 2009 session, and we may expect bills promoting two favorite pieces of home-grown pork, the Lake Powell pipeline and Transition Power's nuclear nightmare on the Green River.

But before legislators cast more of our recession-stretched cash before these two swine, they should read the latest study of Colorado River issues, James Powell's [Dead Pool](#), from which the following is taken.

For eight years under George W. Bush, the Bureau of Reclamation has refused to acknowledge the effects that global warming is having and will yet have on the Colorado, in spite of record temperatures and the recent 500-year drought that nearly brought Lake Powell to its knees. Instead, the bureau continues to use only data from the last century, the first half of which was one of the wettest periods in the known history of the Colorado.

According to Bush's BOR, in 2050 Lake Powell, which reflects the health of the river as a whole, will stand at 3,660 feet, just 40 feet below full pool.

Studies done by climate scientists suggest an entirely different future. Recent tree-ring studies have shown that the true multicentury average flow of the river is well below that used by the BOR. They also show periods when river flow, even without the effects of global warming, was lower than that experienced in our 500-year drought.

When one adds to this natural variability and drought-prone history even a conservative estimate of projected global warming effects, the results are devastating. Current estimates of how much the flow of the Colorado might be reduced range between 6 and 30 percent.

Using just a 10-percent figure, and accepting the bureau's own estimates of increased demand and new draws such as the Lake Powell pipeline, Powell gives a harrowing scenario in which Lake Powell drops to "dead pool" by 2022, rendering projects such as the pipeline useless almost as soon as they become operational.

But far scarier is the possibility that in this time frame the effects of the devastation of the Colorado due to overuse and reduced flow could well render life in today's desert megacities such as Phoenix and Las Vegas impossible. What Powell's book shows is that global warming is without any stretch of imagination capable of rendering life in western America unrecognizable not in our grandchildren's lifetime but in ours.

While I doubt that the 2009 Legislature will take this scenario seriously, there are others in this state who might. No one has more at stake in this crisis-in-the-making than the LDS Church. Let me therefore pose a "morality" question to church leaders.

Given the possibility that the Colorado will not be available for future development in the Mormon heartland, what stance is the church willing to take on growth and conservation in southern Utah? Given the possibility that St. George will have no additional sources of water for future use, and that all sources will be put under climate strain, what is a provident church to do today to prevent future catastrophe?

With such possibilities to consider, the proposition that we will take Colorado River water to run nuclear power plants or to promote continued unsustainable growth in the nation's second-driest state is not only an absurdity. It is cultural genocide.

What the federal government failed to accomplish in its persecution of the Mormons a century ago, Mormon legislators, county councils, mayors, and developers are visiting on themselves.

In the words of Bernard DeVoto, "The future of the West hinges on whether it can defend itself against itself."

Mulroy issues harsh predictions on global warming

Jan. 12, 2009

Copyright © Las Vegas Review-Journal

By STEVE TETREAULT

STEPHENS WASHINGTON BUREAU

WASHINGTON — Southern Nevada's top water official warned federal policymakers today that they underestimate climate change at their own risk as they consider ways to bolster the nation's infrastructure.

"We need to understand where the floods are going to occur and where the drought conditions are going to be protracted before we start making long-term investments," said Pat Mulroy, general manager of the Southern Nevada Water Authority.

In the short term, fixing long-neglected bridges, roads and water and sewer systems is fine, Mulroy said. But beyond that, she said, "We need to look at (infrastructure) through a 21st century lens in a very different climate and not take a 19th century climate and assume that is going to be the norm."

“We have not spent any time in this country investing in the science of climate change in any kind of concerted action,” she said. “We have not spent time talking about how we are going to adapt.”

Mulroy, who directs the agency that supplies most of the water in Clark County, sounded the alarm as part of a panel assembled by the Brookings Institution to discuss infrastructure and recommendations for President-elect Barack Obama to pursue in his economic stimulus strategy and beyond.

Investments in infrastructure create jobs as well as shore up the physical foundations of the nation, but panelists said the ways such projects are weighed and funded are grossly inefficient.

The audience of several hundred at the think tank grew silent at Mulroy’s striking predictions. She said Southern California “is very much facing the real possibility of having a major water crisis in 2010,” and that three more years of drought along the Colorado River will cost Southern Nevada 40 percent of its water supply.

“Two more years after that, we lose 90 percent of our water supply,” if the drought persists over the longer period, she said, referring Lake Mead levels dropping beneath the intake pipes that draw water for municipal use.

Professional water managers recognize climate change “could destroy the very underpinnings of every economy of the United States, whether it is dikes that are going to break from rising ocean levels to whether it is wastewater or water treatment plants that are situated on the banks of rivers that can be flooded out, to if it is in the West from the most dire and desperate drought that we have ever experienced.”

Mulroy said she was hopeful at the appointment of former EPA administrator Carol Browner to become the global warming coordinator in the Obama White House. While federal science agencies now compete for climate change funding, there might be some coordination in the new administration.

“Once that science gets going and we get a better understanding of the true impacts of climate change, then we can look at the most at-risk situations, whether it is the dikes in California, whether it is the potential of losing a significant part of Florida, whether it is the protracted droughts that are going to wipe out whole economies, and what are the possible solutions,” she said.

Policymakers will need to become creative, even “outrageous,” Mulroy said. For instance, she suggested that floodwaters from the Mississippi River might be diverted west for drought prevention.

“Why can’t floodwaters in one part of the country, through a series of exchanges, be a water supply in another part of the country?” she said. “I could show you a series of exchanges between the Mississippi and California and you could start fixing some problems.

“When it comes to watersheds and water supplies, we are all interconnected,” she said.

Navajo President Shirley won't sign Glen Canyon measure

Copyright © 2009
Gallup Independent
By Kathy Helms
Diné Bureau

WINDOW ROCK — Legislation passed by the Navajo Nation Council to dissolve a memorandum of agreement related to the use and development of Glen Canyon National Recreation Area has been returned to the Office of the Speaker without the signature of President Joe Shirley Jr.

In a Jan. 5 memorandum to Speaker Lawrence T. Morgan, Shirley said he was returning the legislation, sponsored by Morgan, due to a transmittal error, but also said he felt compelled to express his concern about Council's action and "hope that we can work diligently to negotiate a new agreement for the benefit of the Navajo Nation."

Shirley said the terminated agreement was the foundation of existing economic development at Antelope Point and formed the basis for several other subsequent agreements between the federal government and the Navajo Nation. In the 1970 agreement, the federal government committed to seeking congressional action to transfer the annual franchise fee collected at Rainbow Bridge to the Navajo Nation, however, Congress never passed the legislation approving the transfer.

Shirley said the legislation approved by Council relies on this failure as justification for terminating the agreement, and that while it is true that the Nation has never received the annual fee, it does receive revenue from the existing development at Antelope Point, including revenue from economic activities occurring off the Navajo Nation on National Park Service lands in the Glen Canyon area.

Various agreements and business arrangements have been entered into as a result of the 1970 agreement, Shirley said, and terminating that agreement likely will have an adverse impact on Antelope Point development, including providing the Park Service with potentially sufficient justification to terminate agreements reached in 1994 and 2003, thus making joint administration at Antelope Point extremely difficult, if not impossible.

Without a mechanism for joint administration of development at Antelope Point, the Nation's ability to play a role in Antelope Point Holdings LLC's operations is severely

limited, Shirley said. Future development calls for expanding marina operations, building a hotel and developing a visitor center — all of which would result in increased tourism and tax revenue to the Nation.

Should the Park Service terminate the company's concessions contract, the Nation's business site lease with the company also would terminate and it would not be able to continue operations on Navajo lands at Antelope Point. Shirley said the company has invested more than \$20 million, and in the event its business site lease is canceled, the company could take legal action.

Agreements entered by the company in 2004 to obtain financing from National Bank of Arizona also would be affected and the company could be considered in default, in which case the bank could call the loan, he said.

"Termination of the 1970 MOA provides National Bank of Arizona with a basis for arguing that a default has occurred," Shirley said.

This would have a potentially crippling impact on the company's operations at Antelope Point, thus opening the door to potential legal action, he said.

"The intent of the legislation to pursue economic development in the Antelope Point area of the Navajo Nation is to be commended. Unfortunately, the termination of the 1970 MOA will have significant harmful consequences on the existing economic development," he said, adding that the potential benefits associated with possible new economic opportunities may not outweigh the adverse economic impacts.

In addition to Shirley's refusal to sign the legislation, Morgan also has taken a hit from the LeChee Chapter, which has unanimously approved a resolution denouncing a potential development by Texas billionaire B.J. "Red" McCombs of 50,000 acres along Navajo Canyon in LeChee, Kaibeto and Inscription House for private home sites, hotels, casinos, and possibly other business ventures. "We, the people of the LeChee Chapter, adopt this resolution to put the central government on notice that we will resist any move to take our land. The chapter calls upon the central government of the Navajo Nation, specifically Speaker Lawrence Morgan and Delegate Ervin Keeswood to disclose any discussions on such a venture before proceeding further."

The chapter also is requesting Kaibeto, Gap/Bodaway, Navajo Mountain, Oljato, Cameron and Tsah Bi Kiin (Inscription House) chapters join in the resolution.

Ivan Gamble of LeChee said the chapter has cultivated a relationship with Antelope Point Holdings and Jerry Moyes and has worked tirelessly for more than 30 years to make the marina a reality.

"Over 300 jobs are at risk for our regional economy because of Mr. Morgan's legislation to unilaterally withdraw from this agreement. Now, because of his actions, we are on rocky ground with our marina and our neighbors, the U.S. Park Service. Our water source of Lake Powell, which we share with our neighbors in Page, is at risk; our Diné way of life is threatened because of Mr. Morgan.

"LeChee will not allow this to happen and will fight this at every step. We are unanimous in our dissent of this and have retained legal representation," Gamble said.

There was no response from the Speaker's Office Wednesday.

Interior Ignored Science When Limiting Water to Grand Canyon

By Juliet Eilperin

Washington Post Staff Writer

Wednesday, January 28, 2009

<http://www.washingtonpost.com/wp-dyn/content/article/2009/01/27/AR2009012703283.html>

Interior Department officials ignored key scientific findings when they limited water flows in the Grand Canyon to optimize generation of electric power there, risking damage to the ecology of the spectacular national landmark, according to documents obtained by The Washington Post.

A [Jan. 15 memo](#) written by Grand Canyon National Park Superintendent Steve Martin suggests that the department produced a flawed environmental assessment to defend its actions against environmentalists in court. The Grand Canyon Trust, an advocacy group, has sued Interior for reducing the flow of water from Glen Canyon Dam at night, when consumer demand for electricity is low, on the grounds that the policy hurts imperiled fish species such as the endangered humpback chub and erodes the canyon's beaches.

"The government's brief as presented continues to misinterpret key scientific findings related to the humpback chub, status of downstream resources in Grand Canyon, and the need for the Secretary to acknowledge [National Park Service] authorities and responsibilities to protect resources under [National Park Service] administration," Martin wrote in a memo that The Post obtained from the group Public Employees for Environmental Responsibility. Martin added that his agency continues to fear that the current policy "will significantly impair Grand Canyon resources."

The behind-the-scenes skirmish, which took place just days before President George W. Bush left the White House, highlights the sort of challenges Interior Secretary Ken Salazar will face in his new position. While Salazar declined to comment specifically on the Grand Canyon case because it is the subject of an ongoing legal battle, he said in

an interview yesterday that he would emphasize "the need to have sound science in all decision making in the Department of Interior."

"Science should not be shoved under the table in order to deal with special interests that are knocking at the door," said Salazar, adding that he will be looking at several last-minute decisions made by Bush before he left office. "My point of view is, nothing is sacrosanct in terms of being reexamined."

The federal government has spent about \$100 million studying water flows on the Colorado River, and the studies indicate that the ecosystem would benefit from occasional short bursts of massive amounts of water along with more regular flows during the day and night. This pattern would mimic the river's natural fluctuations and deposit sediment on canyon beaches while also sustaining fish populations.

Last February, however, Interior approved a five-year "experiment" in which it would allow only one river surge, in March 2008, and afterward would control the water and prohibit any high flows through 2012. Martha Hahn, chief of science and resource management for Grand Canyon National Park, said the power and water industry representatives belonging to Interior's advisory committee on the plan "didn't want to see a high flow" on the Colorado River.

Leslie James, executive director of the Colorado River Energy Distributors Association, said the utilities that use the power generated by the dam do not see why federal authorities would change the water flows, because the number of humpback chub in the river has increased recently.

"Hey, it's a good thing, so let's not make any radical changes," James said, adding that timing the water flows to meet public demand saves money for the 4 million customers using electricity generated from the river.

Hahn, however, said the canyon's humpback chub population is still struggling. The fish's numbers had dipped from 15,000 in the mid-1980s to 2,000 before rising to 5,000 recently, she said: "That's hardly a recovery."

Bureau of Reclamation spokesman Kip White said he could not discuss the controversy in detail because it was "under litigation," but he noted that a federal judge had already ruled that Interior had not violated any laws in drafting its operating plan for the Colorado River.

Mike Snyder, the Park Service's intermountain regional director, received Martin's memo this month. He said yesterday that he concurred with the superintendent's analysis and had tried to petition the Interior Department's top officials to reexamine the Colorado water experiment.

"I think we have some really good science. My concern is we're not using that science to make our decisions," Snyder said. "This is an issue of protecting the resources and values of the Colorado River and Grand Canyon National Park."

When asked whether he had been cautioned by political appointees to mute his criticism of the water plan, Snyder responded, "I was counseled on the importance of having a single Department of Interior family response [to environmentalists' criticism], particularly as it relates to lawsuits."

Jeff Ruch, executive director of Public Employees for Environmental Responsibility, challenged Salazar to change the policy and allow for a more natural water flow. "If Secretary Salazar really means to clean house at Interior, he needs to start right here," Ruch said.

In the interview, Salazar said he had made it clear to his department's 64,000 employees that "the ethical lapses of the past will be no more" and that he will push for greater accountability at Interior. On Thursday, he plans to travel to Lakewood, Colo., to address Minerals Management Service employees. In September, the Interior Department inspector general accused more than a dozen MMS employees of engaging in unethical and criminal behavior.

'Clean coal' plant proposed for Emery County

by Ron George and Rick Shaw
special to The Times
01.29.09 - 10:28 am

[Click here to visit The Times-Independent](#)

Southern California Edison is proposing a new power plant for an area south of Woodside and west of U.S. 6 in Emery County.

The project, revealed in a Jan. 14 public meeting in Price, would include a power station with the capability of producing 500 megawatts while sequestering liquid CO₂ in an underground saline aquifer.

"There are many things that need to be done and many hurdles to go over before anything like this can happen," said Jenifer Hedrick, an engineer and the project manager.

The initial hurdle, she said, is to secure money through an application process with the United States Department of Energy for a feasibility study for such a "clean coal technology" plant. The application deadline for that money was Jan. 15 and the DOE will make grant decisions in July. Depending on the outcome of funding and further studies, the plant could be up and running in 2017 or 2018, Hedrick said.

The plant would use existing technology, but would be the first of its kind to employ all the technologies for a clean coal plant together in one place, according to Hedrick.

Hedrick said the goals for the plant would be converting coal to hydrogen to run the plant, capping the CO₂ emissions so they meet California standards now coming on line concerning clean electricity generation, and generating power that could be used across the West.

The plant would use integrated combined cycle turbines (IGCC), like those currently used in natural gas plants, to generate the power.

The gasification of coal into hydrogen is also in use in smaller scale in some places and Hedrick said that would be a key to the plant's operation. The process of converting the coal and sequestering the CO₂ would make the power that came out of the plant 20-40 percent more expensive than conventional plants, she said.

"But this would be an on-line plant that could supply power at anytime," said Hedrick.

Hedrick said conservative estimates show that the aquifer into which the company wants to inject the compressed liquid CO₂ would hold 500 million tons of the material. The plant would generate about four million tons of CO₂ every year.

"We wouldn't be able to fill that aquifer up in 50 years," Hedrick said. "In fact, if this project goes on line and works we would expect other plants might be built in the same area to utilize the same technology and that storage space."

Gasification of coal, as the process is now known, takes a great deal of water and there were questions from the assembled group about where California Edison would acquire the water for the project.

"We are still very preliminary on this study, but we think we could piece together enough water rights to run the plant or we wouldn't be looking at that site," Hedrick said.

John Weisheit, conservation director for Moab-based Living Rivers, has concerns about how that will be pieced together. "Our number one concern was, 'where are you going to get the water,' and they explained that they're going to get it from farmers, on the Price River," Weisheit said.

"I am very concerned about the endangered fish, of course," he said. "During the summer the flows on the Green River are going to become so small, the water's going to heat up. I've been a river guide for 30 years, and I've been watching dead catfish in the middle of the summer. When it gets warm, and the dissolved oxygen is depleted, these critters succumb to suffocation, which tells me it's already bad. They're going to make it worse."

Hedrick said that the company estimated that the plant would use one million tons of coal a year and would employ about 100 people at the plant, but could create about 1,000 jobs during construction.

The plant would be located on Bureau of Land Management property, and the sequestering site is on state School and Institutional Trust Lands Administration property.

California Edison has partnered with the University of Utah in the sequestering study process, she said.

“We have no detailed engineering yet and there is no permitting done,” said Hedrick. “We have a long way to go... But we wanted the community to know what we are doing.”

While non-toxic slag and sulfur were discussed in Hedrick’s presentation, it didn’t address potential mercury contamination. There is already a fish consumption warning for channel catfish from the Green River in Desolation Canyon due to mercury contamination.

Edison spokesman Steve Conroy said further research will be done regarding mercury. “Those issues, like the by-products, the sequestration, the unburned products and how it will be used or captured are all part of that process. That is part of the entire scope of work we have to do to determine the viability of the entire process,” he said.

Weisheit said he is skeptical that a coal plant can be built that addresses all the environmental concerns, but he acknowledges the need to develop new energy sources. “By the way, I’ll be happy to give my roof for solar panels,” he said. “I realize we’re in an energy crisis, but this isn’t the answer – we need a brighter portfolio for the area.” © moabtimes.com 2009

Regional News 02/26/09

Las Vegas Running Out of Water Means Dimming Los Angeles Lights

By John Lippert and Jim Efstathiou Jr.

Feb. 26 (Bloomberg) -- On a cloudless December day in the Nevada desert, workers in white hard hats descend into a 30- foot-wide shaft next to Lake Mead.

As they’ve been doing since June, they’ll blast and dig straight down into the limestone surrounding the reservoir that supplies 90 percent of Las Vegas’s water. In September, when they hit 600 feet, they’ll turn and burrow for 3 miles, laying a new pipe as they go.

The crew is in a hurry. They’re battling the worst 10-year drought in recorded history along the Colorado River, which feeds the 110-mile-long reservoir. Since 1999, Lake Mead has dropped about 1 percent a year. By 2012, the lake’s surface could fall below the existing pipe that delivers 40 percent of the city’s water.

As Las Vegas’s economy worsens, the workers are also racing against a recession that threatens the ability to sell \$500 million in bonds so they can complete the job.

Patricia Mulroy, manager of the Southern Nevada Water Authority, is the general in this region's war to stem a water emergency that's playing out worldwide. It's the biggest battle of her 31-year career.

'We've Tried Everything'

"We've tried everything," says Mulroy, 56, who made no secret of her desire to become secretary of the U.S. Interior Department before President Barack Obama picked U.S. Senator Ken Salazar of Colorado in December.

"The way you look at water has to fundamentally change," adds Mulroy, who, after 20 years of running the authority, said in January she's ready to start thinking about looking for a new job, declining to say where.

Across the planet, people like Mulroy are struggling to solve the next global crisis.

From 2500 B.C., when King Urramma of Lagash diverted water in the Tigris and Euphrates Valley in a border dispute with nearby Umma, to 1924, when Owens Valley, California, farmers blew up part of the aqueduct that served a parched Los Angeles, societies have bargained, fought and rearranged geographies to get the water they need.

Mulroy started her push with conservation. She's paying homeowners \$1.50 a square foot (0.09 square meter) to replace lawns with gravel and asking golf courses to dig up turf. That helped cut Las Vegas's water use by 19.4 percent in the seven years ended in 2008, even as the metropolitan area added 482,000 people, bringing the total to 2 million. It wasn't enough.

Paul Bunyan

So she's planning a \$3.5 billion, 327-mile (525-kilometer) underground pipeline to tap aquifers beneath cattle-raising valleys northeast of the city. She's even suggested refashioning the plumbing of the entire continent, Paul Bunyan style, by diverting floodwaters from the Mississippi River west toward the Rocky Mountains.

If Mulroy's ideas are extreme, one reason is that the planet's most essential resource doesn't work like other commodities.

There's no global marketplace for water. Deals for property, wells and water rights, such as the ones Mulroy must negotiate to build the pipeline, are done piecemeal. As the world grows needier, neither governments nor companies nor investors have figured out an effective and sustainable response.

"We have 19th-century ways of utilizing water and 21st-century needs," says Brad Udall, director of Western Water Assessment at the University of Colorado at Boulder.

Unyielding Pressure

Water upheavals are intensifying because the population is growing fastest in places where fresh water is either scarce or polluted. Dry areas are becoming drier and wet

areas wetter as the oceans and atmosphere warm. Economic roadblocks, such as the global credit crunch and its effects on Mulroy's attempts to sell bonds, multiply during a recession.

Yet local governments that control water face unyielding pressure from constituents to keep the price low, regardless of cost. Agricultural interests, commercial developers and the housing industry clash over dwindling supplies. Companies, burdened by slowing profits, will be forced to move from dry areas such as the American Southwest, Udall says.

"Water is going to be more important than oil in the next 20 years," says Dipak Jain, dean of the Kellogg School of Management at Northwestern University in Evanston, Illinois, who studies why corporations locate where they do.

No Cheap Water

Even before the now decade-long drought began punishing Las Vegas, people used more than 75 percent of the water in northern Africa and western Asia that they could get their hands on in 2000, according to the United Nations.

In 2002, 8 percent of the world suffered chronic shortages. By 2050, 40 percent of the projected world population, or about 4 billion people, will lack adequate water as entire regions turn dry, the UN predicts.

"We can no longer assume that cheap water is available," says Peter Gleick, editor of *The World's Water 2008-2009* (Island Press, 2009). "We have to start living within our means."

Over the Sierra Mountains from Las Vegas, Shasta Lake, California's biggest reservoir, is less than a third full because melting snow that fed it for six decades is dwindling. A winter as dry as the previous two may mean rationing for 18 million people in Southern California this year, says Jeffrey Kightlinger, general manager of the Metropolitan Water District.

Across the Pacific Ocean, wildfires fueled by a 10-year drought and fanned by 60-mile-per-hour winds around Melbourne killed more than 200 people in February.

Developing Giants

In Asia, developing giants are battling pollution as their populations grow. China, home to 21 percent of the world's people last year, has just 7 percent of the water. Nine in 10 Chinese-city groundwater systems are fouled by industrial toxins, pesticides and human waste, says Maude Barlow, the first senior adviser on water to the UN and author of *"Blue Covenant"* (New Press, 2007).

In India, with 1.2 billion people, three-quarters of the surface water is contaminated, that country's government said in September.

In the Mideast, where the Dead Sea is dropping 3 feet (1 meter) a year, Israel, Jordan and Syria are diverting water upstream from the Jordan River. That's adding another source of discord to an already volatile region.

'Gambling, Gluttony and Girls'

"There's a growing risk of conflict over water shared by nations, ethnic groups or economic interests," Gleick says.

Las Vegas, an adult-entertainment haven carved into the Mojave Desert, may not draw much sympathy as a poster child for water emergencies.

For decades, new residents imported their cravings for lawns, sprinklers, pools and golf courses to a region that receives 4 inches (10 centimeters) of rain a year, about 1/10 of what Chicago enjoys. Casinos and hotels with water slides and river rides sucked up limited groundwater.

Until the real estate meltdown, Nevada was the fastest-growing U.S. market, with a 33 percent surge in new homes from 2000 to '07.

Now the city is getting a dose of reality, says Cecil Garland, a rancher in neighboring Utah who opposes Mulroy's groundwater pipeline.

"Las Vegas is a place of gambling, gluttony and girls," Garland, 83, says.

He says there's no extra water along the proposed route, which travels through valleys green with 3-foot-tall shrubs called greasewood. If pumping kills the greasewood, dust storms that plague his town of Callao would soar 5,000 feet into the sky, he says.

'Driest Areas'

"We live in one of the driest areas of the driest part of the U.S.," Garland says. "How in the world can anybody with reason or common sense think they can pump water in the amount they're talking about and leave the integrity of the valley in place?"

Mulroy says Nevada's resorts use 3 percent of the state's water compared with 90 percent going for farms and ranches.

For the past two decades, Mulroy, a lifelong government employee whose business attire tends toward pantsuits with the collar of her blouses pointed up behind her neck, has wrestled with the competing truths that dog all water managers: There's only so much to go around, somebody has already claimed most of it, and citizens and companies keep demanding more.

"People view water as a human right and expect it to be virtually free," says Michael LoCascio at Boston-based Lux Research Inc., which analyzes water issues. "Governments respond to that, and you end up with inefficiency."

Without price-setting markets, water that cost 33 cents a cubic meter for the first 15 cubic meters delivered to homes in Memphis, Tennessee, in June 2007 was \$3.01 in Atlanta and 57 cents in Las Vegas.

That's cheap compared with Copenhagen, where the same amount that month was \$7.71 per cubic meter, Gleick says.

Human Survival

Robert Glennon, a University of Arizona law professor, says governments must provide enough water for human survival. Beyond that, only freely functioning markets can allot it to people who need it most, he says.

Fast-growing cities should buy from farmers who use water on marginal land, says Glennon, author of "Unquenchable" (Island Press, 2009). That would cut inefficiency caused by irrigating deserts, such as those around Las Vegas, to raise alfalfa or beef, he says.

Worldwide, about 60 percent of fresh water goes to irrigate crops through flooding, losing 70 percent of the moisture to evaporation, Lux Research says.

Rudimentary Markets

The rudiments of water markets are cropping up across the American West.

In 2005, after 19 years of negotiations, Los Angeles's Metropolitan Water District signed a 35-year "dry year option" with the Palo Verde Irrigation District south of Las Vegas in California. Los Angeles pays 7,000 farmers to leave land fallow during droughts and ship their water to city residents. The city gives a one-time payment of \$3,170 an acre (0.4 hectare) to farmers who sign up and then \$630 per year for every acre not farmed.

Companies and investors that see moneymaking opportunities in strategies to quench the world's thirst may draw lessons from corporations that have tried.

In October, General Electric Co. named the third head of its water unit in three years. GE had paid \$3.8 billion to buy several treatment and filtration companies, including Watertown, Massachusetts-based Ionics Inc., which makes reverse-osmosis membranes for purifying salt water.

Big Deals

Last year, GE opened a \$250 million desalination plant, Africa's largest, with state-owned Algerian Energy Co. GE had hoped to profit from its newly acquired water technologies with the backing of its General Electric Capital Corp. financing arm, says Jeffrey Fulgham, chief marketing officer for the Trevose, Pennsylvania-based unit. Instead, GE wound up footing a lot of the building work for the plant, he says.

"At the end of these big hardware deals, there isn't much profit," says Fulgham, who adds that GE now focuses on water technology and avoids construction.

Pure Cycle Corp., which buys and transports water for housing developments near Denver, seemed to have scored a windfall. Starting in 1976, it paid \$110 million for water rights valued at \$4 billion last year, Chief Executive Officer Mark Harding says. Yet shares in the Thornton, Colorado, company tumbled by 47 percent during the six months ended on Feb. 25. to trade at \$3.25 apiece.

The real estate slowdown convinced investors that profits from water rights may be years away, Harding says.

Just financing water for municipal use is getting harder in the global recession.

\$8.3 Billion

The southern Nevada authority is about halfway through a 30-year, \$8.3 billion construction campaign. Last year, 57 percent of the money for it came from a \$6,310 fee to hook up new homes. The Las Vegas real estate slump is so severe that total hookup collections dropped to \$61.5 million last year from \$188.4 million in 2006. Mulroy says the authority actually lost money on hookups in January because of refunds to developers who abandoned construction projects.

As a result, reserves in the construction fund dropped 6 percent in the first six weeks of 2009, to \$480 million. Without those reserves, Mulroy says, she couldn't assure investors the authority would be able to repay the \$500 million in bonds she plans to start selling by early fall to complete the Lake Mead project. The authority had \$3.9 billion in liabilities on June 30.

'Rub Two Sticks Together'

The authority also gets money from water deliveries, property taxes and fees from federal land sales. If she has to protect the reserves, Mulroy says, she'll raise water rates, which total about \$21 a month for a single-family home.

She's asked fellow Nevadan Harry Reid, the U.S. Senate majority leader, for a federal guarantee on the bonds. Reid is exploring how to help big municipal water systems, including Mulroy's, get easier access to credit, spokesman Jon Summers says.

In February, Mulroy presented such a dire description of the authority's finances to the Nevada legislature that Jerry Claborn, chairman of the Natural Resources Committee, told her, "You'll have to do like you did years ago: rub two sticks together."

Mulroy said afterward she wanted to quash any notion that cash-strapped legislators could appropriate her reserves for some other purpose.

To Richard Bunker, who hired her as an administrative assistant when he managed Clark County, Nevada, in 1978, Mulroy's hardball tactics are a delight.

"She walks into a room with guys who've been on the river 50 and 60 years and they just cringe," he says with a smile.

'Pay Me Enough'

One thing Mulroy has ruled out, even in the economic meltdown, is using water as an excuse to limit Las Vegas's growth.

"During the next 50 years, this country's population is expected to explode by another 140 million," she says, citing U.S. Census projections. "I always ask, 'Where do you want the people to go?'"

Mulroy also opposes the idea of privatizing water, or giving investors power to set prices.

"You'd be telling people, 'Pay me enough or I withhold it,'" she says, her voice rising, in the cafeteria of Clark County's terra cotta-colored municipal headquarters. "It's like you're telling me I can live."

Mulroy's unflagging commitment to keeping Las Vegas green and growing gets the blessing of casino owner Stephen Wynn.

"Pat is the best public servant I've met in my 40 years on the Strip," says Wynn, who credits her with teaching him to save money by using treated groundwater for the lagoons surrounding the artificial volcano at the Mirage hotel, now owned by MGM Mirage.

Lake Mead

Finding the water for casinos is one reason crews are working around the clock at Lake Mead.

In 2002 alone, lack of rainfall lowered the deep-blue waters by 24.6 feet, leaving white bathtub-ring-like marks on the brown cliffs and stranding docks half a mile from shore.

Today, the lake is 1,112 feet above sea level. Should it fall to 1,075 feet, the federal government would cut the water to seven states that depend on the Colorado River, according to an agreement they all signed in 2007. If that happens, the states would likely renegotiate a 1922 pact that divided up the river's water rights in the first place, Mulroy says. Mexico's allocation under a 1944 treaty could also change.

If the drought persists and more water is diverted from the Colorado, the lake could drop to 1,050 feet. That would prevent water from flowing into the intake pipe and cut 40 percent of Las Vegas's supply -- the disaster Mulroy is trying to head off. Hoover Dam, completed in 1935 to regulate the river and form Lake Mead, wouldn't be able to produce electricity for the 750,000 people it supplies in Los Angeles.

No More Water

At 1,000 feet, the remaining intakes and the rest of the Lake Mead water would go. Because of climate change and population growth, chances of this are as great as 50 percent by 2026, the University of Colorado's Udall says.

When Mulroy, a daughter of a civilian employee of the U.S. Air Force, arrived in Las Vegas in 1974, the city had yet to be consumed by a water quest. Until the 1940s, parts of downtown had freely flowing springs.

Mulroy, a native of Germany, studied German literature; got her master's degree from the University of Nevada, Las Vegas; and went to work for Bunker at Clark County. A Mormon bishop, he later ran the state's Gaming Control Board and the Nevada Resort Association.

Shoeboxes

Bunker supported her promotion to administrator for the county justice court, which was storing records in shoeboxes when she took over. In 1989, he backed her as general manager of the Las Vegas Valley Water District, which the state legislature had formed four decades earlier. Mulroy helped create the seven-community Southern Nevada Water Authority two years later.

"Absent her being here, I don't know where we'd be," Bunker says.

Around the time Mulroy became water czar, Wynn unleashed the era of Wall Street-financed megaresorts with his 30-story Mirage. He tinted the hotel's windows with real gold.

Mulroy raced to boost water deliveries throughout the city by as much as 20 percent a year. With Bunker's help, she started planning the pipeline to tap melting snow under Wheeler Peak, Nevada's second-highest mountain.

The pipeline's planned path runs northeast out of Las Vegas, enters Lincoln County and passes through the Pahrangat National Wildlife Refuge, where, in December, gold leaves of cottonwoods shimmer and migratory birds swoop onto lakes fed by artesian springs. Farther north, hilltops are dotted with abandoned mining towns and bands of wild horses.

'Already Spoken For'

As Mulroy marched north to secure land and permits, she ran headfirst into what Gleick says is a fundamental truth about water across the U.S. and other parts of the world.

"Nearly every drop is already spoken for, often more than once," he says.

Determined to get what she required, Mulroy went into horse-trading mode.

"You need a large amount of money and some very powerful people to make water projects happen," says Greg James, a California water rights attorney and a consultant for pipeline opponents.

She struck a deal with Harvey Whittemore, then Nevada's top gambling lobbyist. Members of Whittemore's law firm include Rory Reid, Harry Reid's son. The younger Reid later served as the water authority's vice chairman, from 2003 to '08.

120,000 New Homes

Whittemore, 56, is also a developer who's planning a new suburb called Coyote Springs, 55 miles north of the Las Vegas Strip. Even with the real estate crash, Coyote Springs will have 120,000 homes and a dozen golf courses when it's finished in four or five decades, he says.

Whittemore's land included one of the most productive wells ever drilled in southern Nevada. He sold 9,000 acre-feet of groundwater that he wasn't using to Mulroy for \$30.1 million. (One acre-foot equals about 326,000 gallons, or 1,240 kiloliters, enough for two average U.S. homes for a year.) That led to what Mulroy describes as a partnership in which Whittemore will help pay for the pipeline and use it to ship water to Coyote Springs.

In 2003, Mulroy bargained with reluctant officials in neighboring Lincoln County, persuading them to drop opposition to the project by ceding back to them some of the water rights that she held.

In 2006, farther up the route, she learned how tough the water business can be. She paid \$22 million for a ranch that had cost \$4.5 million six years earlier. The seller, Carson City, Nevada-based Vidler Water Co., a unit of PICO Holdings Inc., based the price on similar purchases Whittemore had made, Vidler President Dorothy Timian-Palmer says.

Fight Over Greasewood

Last year, Mulroy got into a fight over greasewood with Tim Durbin, a hydrologist who'd once been a consultant for her. Durbin disputed Mulroy's assessment that the pipeline would avoid major damage to the shrub. In his rebuttal, Durbin described a scene that still touches an open wound in the psyche of the American West.

In 1913, William Mulholland built a 223-mile aqueduct from Owens Valley in California's Sierras to Los Angeles, where he was water superintendent. The aqueduct drained a 40-foot-deep lake, exposing the valley floor and unleashing dust storms that plagued Los Angeles throughout the 20th century. The aqueduct also inspired the 1974 movie "Chinatown." In 1970, Los Angeles built a second aqueduct.

'A Model'

Today, the valley's 75-mile-long expanse looks like it did a millennium ago. The water diverted to Los Angeles makes economic development in the valley impossible.

"Because of groundwater pumping, vegetation was disappearing in the Owens Valley," says Durbin, who was chief hydrologist for the U.S. Geological Survey in California and Nevada before becoming a private consultant in 1984. "It's a model for what one would expect in eastern Nevada."

Because of such memories, Mulroy hasn't won many friends among eastern Nevada's old-timers.

Rancher Dean Baker fears Mulroy's pipeline would drain the water that's let him survive in Snake Valley, in the shadow of Wheeler Peak, for more than half a century.

Baker, 69, remembers when people staked uranium claims only to realize their Geiger counters were clicking because of residue from atomic tests outside Las Vegas. He recalls flying solo in a Piper J-3 Cub before he could drive.

Most of all, Baker remembers water. He rose at dawn to deliver it to cattle 50 miles away. He culled his herd and watched greasewood wither during droughts. It took 20 years for him to afford a backhoe with a jackhammer that could break rocks that covered a spring on his ranch.

Legacy of Dust

"Water is the limiting factor in everything we do," Baker says. "The legacy of this pipeline will be dust."

Baker says people who want to move to Las Vegas should look instead to Mississippi and Louisiana. "People should go where there's water," he says.

Mulroy says her job is to bring water to the people. Last year, she said she thought the proposed pipeline could begin transporting water in 2015. Now, because of the recession, she doesn't know when she'll have the money to build it.

She says she'll wait for the economy to recover to decide -- unless Lake Mead drops even more and forces her to act.

Mulroy's struggle to get water to a growing desert population wouldn't have surprised John Wesley Powell, the first known explorer to pass through the entire Grand Canyon 130 miles east of Las Vegas.

"You are piling up a heritage of conflict and litigation over the water rights," he told the International Irrigation Congress in Los Angeles in 1893. "There is no sufficient water to supply the land."

'Little Bubbles'

Four generations later, Mulroy is a veteran of these age-old conflicts. She says the region's water emergency is becoming more dangerous because of climate change and population growth. The crisis is too big to be solved one river or one continent at a time, she says.

"We've managed water in such small, incremental units," she says. "We won't be able to survive in our little bubbles."

Even people who agree with Mulroy's warning won't have an easy time acting on it. As she has, they'll discover the effort it will take to quench the world's thirst and realize that the time and money to do so -- like water itself -- are running short.

Fast-growing Western U.S. cities face water crisis

Rueters

Wed Mar 11, 2009 4:56am EDT

By Tim Gaynor and Steve Gorman

LAS VEGAS/LOS ANGELES - Desert golf course superintendent Bill Rohret is doing something that 20 years ago would have seemed unthinkable -- ripping up bright, green turf by the acre and replacing it with rocks.

Back then "they came in with bulldozers and dynamite, and they took the desert and turned it into a green oasis," Rohret said, surveying a rock-lined fairway within sight of the Las Vegas strip. "Now ... it's just the reverse."

The Angel Park Golf Club has torn out 65 acres of off-course grass in the last five years, and 15 more will be removed by 2011, to help conserve local supplies of one of the most precious commodities in the parched American West -- fresh water.

But Rohret's efforts have their limits. His and many other golf courses still pride themselves on their pristine greens and fairways and sparkling fountains, requiring huge daily expenditures of water.

Aiming to cut per capita use by about a third in the face of withering drought expected to worsen with global warming, water authorities in the United States' driest major city are paying customers \$1.50 per square foot to replace grass lawns with desert landscaping.

Built in the Mojave Desert, Las Vegas leads Western U.S. cities scrambling to slash water consumption, increase recycling and squeeze more from underground aquifers as long-reliable surface water sources dry up.

From handing out fines for leaky sprinklers to charging homeowners high rates for high use, water officials in the U.S. West are chasing down squandered water one gallon at a time.

Nowhere is the sense of crisis more visible than on the outskirts of Las Vegas at Lake Mead, the nation's largest manmade reservoir, fed by the once-mighty Colorado River. A principal source of water for Nevada and Southern California, the lake has dipped to below half its capacity, leaving an ominous, white "bathtub ring" that grows thicker each year.

"We are in the eye of the storm," said Pat Mulroy, general manager of the Southern Nevada Water Authority. "As the realities of climate change began to manifest themselves at the beginning of this century, we had to get serious about it."

For now, policymakers have emphasized the need to curb water use rather than urban growth, though the U.S. recession has put the brakes on commercial and housing development that otherwise would be at odds with the West's water scarcity.

GETTING TOUGH

Warm, dry weather has long made the American West attractive to visitors, but piped-in water has created artificial oases, luring millions to settle in the region. Las Vegas has ranked as one of the fastest-growing major cities.

But scientists say climate change is shriveling the snow pack in California's Sierra Nevada, the state's main source of fresh surface water, and in the Rocky Mountains that feed the Colorado River, whose waters sustain seven states.

Further pressure from farming and urban sprawl is straining underground aquifers, placing a question mark over the future growth of cities from Los Angeles to Tucson, Arizona.

"There is going to have to be a big adjustment in the American Southwest and in California as we come to grips with limits in this century -- not just limited water, but also limited water supply," said James Powell, author of the book "Dead Pool," exploring challenges facing planners in the West.

Reactions among local water authorities differ.

In Phoenix, the United States' fifth-largest city, authorities say sustainable groundwater and ample surface water allocations from the Colorado and Salt rivers meet the city's needs, even factoring in growth through a moderate drought. The city is also recycling waste water and plans to pump some back into the aquifer as a cushion.

Tucson will require new businesses to start collecting rainwater for irrigation in 2010.

California requires developers of large housing projects to prove they have sufficient water.

In Las Vegas, where rain is so infrequent that some residents can remember the days it fell in a given year, front-yard turf has been banned for new homes.

The Southern Nevada Water Authority also has hired "water cops" to fan out into the suburbs to identify violations of mandatory lawn irrigation schedules and wasteful run-off. Repeat offenders get \$80 fines.

Major hotel-casinos such as the MGM Mirage and Harrah's Entertainment have adopted "green" building codes, including modifications designed to slash water use by 40 percent.

Those measures are starting to pay off, with daily water use down 15 percent per person in the greater Las Vegas area.

BUYING TIME

In a wake-up call to California, water officials there recently announced that prolonged drought was forcing them to cut Sierra-fed supplies pumped to cities and irrigation districts by 85 percent.

That has led many California cities, topped by Los Angeles, the nation's second-largest, to plan for rationing, including price-enforced household conservation and tough new lawn watering restrictions.

"The level of severity of this drought is something we haven't seen since the early 1970s," Los Angeles Mayor Antonio Villaraigosa said in unveiling his city's drought plan, which also would put more water cops on the beat.

California Gov. Arnold Schwarzenegger last month called on the state's urban users to cut water consumption 20 percent or face mandatory conservation measures.

The California drought, now in its third year, is the state's costliest ever. Complicating matters are sharp restrictions on how much water can be pumped from the Sacramento-San Joaquin Delta in northern California, which furnishes much of the state's irrigation and drinking supplies, to protect endangered fish species.

Moreover, the severe dry spell is leaving the state more vulnerable to wildfires, which last year consumed some several Los Angeles suburbs. The previous year, fires forced a record 500,000 Southern Californians to flee their homes.

PLANNING FOR THE WORST

Conservation will buy time, experts say. But bolder steps are needed in anticipation of longer droughts and renewed urban expansion once the recession ends.

Cities like Los Angeles and San Diego are revisiting an idea once abandoned in the face of staunch political opposition -- recycling purified sewer water for drinking supplies.

Disparaged by critics as "toilet-to-tap," such recycling plans have gained new currency from the success of the year-old Groundwater Replenishing System in Orange County near Los Angeles.

That system distills wastewater through advanced treatment and pumps it into the ground to recharge the area's aquifer, providing drinking supplies for 500,000 people, including residents of Anaheim, home of Disneyland.

Water specialists also see a need to capture more rainfall runoff that otherwise flows out to sea and to change the operation of dams originally built for flood control to maximize their storage capacity.

The situation in Las Vegas has grown so dire that water authorities plan to build a \$3 billion pipeline to tap aquifers lying beneath a remote part of Nevada, a project critics call the greatest urban water grab in decades.

Southern Nevada water czar Mulroy says a broader national conversation about water is needed -- but not happening.

"We are talking about investing in public infrastructure, we are looking at building projects, but I get frustrated because we are doing it in complete denial of the climate change conditions that we are facing," she said.

"We are not looking at where the oceans are rising, where the floods are going to occur, where things are going to go from that normal state to something extraordinary."

Climate change accelerates water hunt in U.S. West

Wed Mar 11, 2009 4:54am EDT By Peter Henderson

SAN FRANCISCO (Reuters) - It's hard to visualize a water crisis while driving the lush boulevards of Los Angeles, golfing Arizona's green fairways or watching dancing Las Vegas fountains leap more than 20 stories high.

So look Down Under. A decade into its worst drought in a hundred years Australia is a lesson of what the American West could become.

Bush fires are killing people and obliterating towns. Rice exports collapsed last year and the wheat crop was halved two years running. Water rationing is part of daily life.

"Think of that as California's future," said Heather Cooley of California water think tank the Pacific Institute.

Water raised leafy green Los Angeles from the desert and filled arid valleys with the nation's largest fruit and vegetable crop. Each time more water was needed, another megaproject was built, from dams of the major rivers to a canal stretching much of the length of the state.

But those methods are near their end. There is very little water left untapped and global warming, the gradual increase of temperature as carbon dioxide and other gases retain more of the sun's heat, has created new uncertainties.

Global warming pushes extremes. It prolongs drought while sometimes bringing deluges the parched earth cannot absorb. California Department of Water Resources Director Lester Snow says two things keep him up at night: drought and flood.

"It isn't that drought is the new norm," said Snow. "Climate change is bringing us higher highs and lower lows in terms of water supplies."

Take Los Angeles, which had its driest year in 2006-2007, with 3 inches (7.6 cms) of rain. Only two years earlier, more than 37 inches (94 cms) fell, barely missing the record.

California Governor Arnold Schwarzenegger declared a drought emergency last month, and Los Angeles plans to ration water for the first time in 15 years. Courts are limiting the amount of water taken from into rivers to save decimated fish populations, which is cutting back even more to farms.

California farmers lost more than \$300 million in 2008 and economic losses may accelerate to 10 times that this year as 95,000 people lose their jobs. Farmers will get zero water from the main federal supplier.

Nick Tatarakis sank his life savings into the fertile San Joaquin Valley but now thinks his business will die of thirst.

"Every year it seems like this water thing is getting rougher and rougher," he said. "I took everything I had saved over the last three or four years, put it into farming almonds, developed this orchard. Now it is coming into its fifth year and probably won't make it through this year."

SWINGING TEMPERATURES, PRICES

In the global economy, a little trouble goes a long way when supplies are tight, said University of Arkansas Ecological Engineering professor Marty Matlock.

The essence of climate change is greater swings in precipitation -- and thus food production. At times of peak demand, prices can skyrocket, he said, as happened to food prices last year.

"There's no slack any more. The rope is tight, and if you give it a tug, it yanks on something," he said.

While farmers suffer, cities continue to grow. The sunny, warm American West remains a magnet.

"Add water and you have the instant good life," said James Powell, author of "Dead Pool," a book about global warming and water in the U.S. West.

"For the last few years, the driest states, Arizona, Utah, and Nevada, have been the fastest growing. And you know that can't be sustained," he said.

California, the world's eighth-largest economy, already uses a staggering amount of water -- roughly enough to cover the nearby state of Washington with a foot (30 cms) of it.

Some 80 percent is used by farms, growing organic lettuce on the temperate coast; rice and citrus inland. Almost anything will grow in the ideal climate -- if there is water.

California water planners in a draft report see three different scenarios for the state by 2050. In the most unfettered, suburbs sprawl ever-farther, replacing productive farms with water-soaking lawns and the population doubles -- as does urban water use. In the best case scenario for water use, the population increases about 20 percent, but denser housing and conservation help keep urban water use roughly steady.

All of the scenarios show agricultural output dropping -- it is just a question of how much.

Businesses, too, have much to fear. Semiconductor manufacturers and beverage companies are high on a list of at-risk sectors in a report on corporate water by Pacific Institute and investor group Ceres.

SLOW CHANGE

Change is happening too slowly, nearly all water planners say, but they disagree about what to do and which options are financially viable, especially the expensive dam projects favored by agricultural interests.

Climate change's challenge to traditional water supplies starts in the mountains. The snow-capped Sierras in eastern California and the Rockies farther east fuel rivers that provide a steady supply of water through much of the year.

The Sierras will have 25 percent to 40 percent less snow by 2050 as rising global concentrations of greenhouse gases raise the temperature, California's water department forecasts.

The U.S. Climate Change Science Program sees the entire West on average getting less precipitation, but there is plenty of debate about that. There is a consensus, however, that most of today's snow will turn in coming decades to rain, often in the form of blinding thunderstorms early in the year, when it is needed least.

California wants to raise or build new dams to catch the increased flow as part of a broad set of solutions.

"There is no one silver bullet," the water department's Snow said.

But the Natural Resources Defense Council and a Los Angeles business coalition see dams as a costly solution that mostly favors farmers.

"The dams are an expensive detour that I don't think will ever be built," said Lee Harrington, executive director of the Southern California Leadership Council, a group of urban public utilities and other businesses.

A study by his group put the price of new dams at up to \$1,400 per acre foot. Current supplies cost about \$700 for one acre foot -- a year's supply for two houses. Urban water conservation costs \$210, local stormwater \$350 and desalination of ocean water or contaminated groundwater about \$750 to \$1,200 an acre foot.

The NRDC estimates that California could get 7 million acre feet per year from conservation, groundwater cleanup and stormwater harvesting.

Even energy-intensive desalination is cheaper than dams, the group argues. "People always used to think that desal was the lunatic fringe of water supply. (Now) desal is the mainstream, and dams are exiting the mainstream," said policy analyst Barry Nelson.

But so far water is the cheapest utility in most homes and businesses, and it's treated that way.

"As long as you are undervaluing a resource, you are going to be perpetually short," said Robert Wilkinson, director of the Water Policy Program at the University of California, Santa Barbara.

Many see water's pricing future following that of electricity. Despite the energy crisis of the early 2000s, California leads the nation in controlling electricity use. One key strategy was letting utilities charge more when consumers use less, making power producers advocates for conservation.

But the simple conclusion is that the West must secure a water supply, even at a high price, says business advocate Harrington.

"While these options are expensive, the options of not having the water makes them all viable at the end of the day," he said.

Aquifer recharge projects catching on in water-strapped cities

April 2, 2009

By APRIL REESE, Greenwire

ALBUQUERQUE, N.M. -- For about a mile, a steady stream of water flows down Bear Canyon before finally petering out in the sand near a golf course. The arroyo is not supposed to be wet this time of year; the spring snowmelt does not usually occur until later in the season. But under a new demonstration program, local water managers are diverting water from the Rio Grande and sending it down the arroyo, where it seeps through the riverbed into the aquifer 500 feet below.

If all goes according to plan, the water percolating underground will provide a sort of water savings account for the city of Albuquerque to draw upon during times of drought.

"You put a little in each year, and then one year, when there isn't enough water in the river, you can take it out of the aquifer," said Stephanie Moore, manager of the Bear Canyon Recharge Demonstration Project, this week while standing along the banks of the arroyo.

The new \$400 million project to tap the water will eventually supply up to 90 percent of the Albuquerque metropolitan area's drinking water needs.

"It could be very important for us," added John Stomp, manager of the water resources program for the Albuquerque-Bernalillo County Water Utility Authority.

The move toward artificial aquifer recharge signifies a shift in thinking about water supplies in the West. Just a few decades ago, "people thought they were sitting on a huge lake, and that we'd never run out of water," Moore said. Then, after hydrologists found that overpumping was depleting aquifers, water managers began to look to surface waters like the Rio Grande to supplement dwindling resources.

The Bear Canyon water comes from the San Juan-Chama Project, which pipes water from the Colorado River Basin across the Continental Divide to the Rio Grande Basin. Moore, a hydrologist with the consulting firm Daniel B. Stephens & Associates, which is overseeing the project for the water utility authority, said flows from the San Juan-Chama project currently provide more water than is needed for immediate use, so the extra water is routed to the aquifer.

"We have more water to divert than we have demand for," she said.

While the Bear Canyon project is a first for New Mexico, the artificial aquifer recharge concept is gaining momentum across the country. Utilities and water managers from Florida to California are increasingly relying on recharged aquifers to help maintain water supplies during periods of drought.

"The trend has picked up," said Moore, who worked as a hydrologist for the U.S. Geological Survey before joining Daniel B. Stephens & Associates.

In some places, such as Florida, aquifers are routinely recharged in the winter, then tapped in the summer when water demand exceeds supply. But in other areas, geologic constraints and the need for long-term storage have led water managers to view aquifer recharges and withdrawals as a last resort.

In Nevada, for instance, there are restraints on how much water one can draw from an aquifer in a given year without causing subsidence of the ground above, said J.C. Davis, a spokesman for the Southern Nevada Water Authority, which serves the Las Vegas metropolitan area. The authority has stored an estimated 350,000 acre-feet in the aquifer underlying the city.

"It's a good long-term resource. We view it as a savings account -- we'll use it as we encounter specific needs," Davis said.

Nevada is augmenting its in-state aquifer storage with a water "bank" in neighboring Arizona, as well. Under a deal signed in 2004, Nevada pays Arizona \$330 million to store up to 1.25 million acre-feet of water from the Colorado River for its northern neighbor (See below: Land Letter, Dec. 9, 2004). Nevada can take up to 40,000 acre-feet of the water each year as long as the Lower Colorado River Basin is not facing a shortage.

In Albuquerque, water officials hope the Bear Canyon pilot project, which is funded by a grant from the state of New Mexico, will demonstrate that infiltrated water from the Rio Grande can recharge the overpumped Middle Rio Grande Basin aquifer and effectively store water for use in times of drought.

According to the monitoring data, the project sank about 750 acre-feet of Rio Grande water into the aquifer during its second run, from Dec. 11, 2008, to this week. The project's first run funneled about 400 acre-feet into the aquifer.

Cities typically store water in reservoirs, but in arid states like New Mexico, 10 to 15 percent of that water is lost to evaporation, Moore noted. Storing some of the water underground reduces that loss to about 3 percent, and shields it from the vagaries of the elements.

"Surface water is renewable [because of snowmelt], but it's highly variable and affected by drought and climate change," unlike water stored underground, Moore said.

But whether the water can be withdrawn in places like New Mexico has yet to be determined. A withdrawal permit is still under review by the New Mexico State Engineer John D'Antonio, who regulates water use in the state. He will likely make his determination after reviewing a report summarizing the data culled from the Bear Canyon project's monitoring wells over the past two seasons.

Moore acknowledged that the project's outcomes remain uncertain. "They're risking their water," she said of the Albuquerque-Bernalillo County Water Utility Authority. "There's a chance they won't be able to take it back out."

But Stomp, the utility manager, remains optimistic.

"Bear Canyon has been a tremendous success," he said. "I can't imagine that he wouldn't allow it. I think it makes really good sense for New Mexico to do this."

Stomp is also thinking about future potential aquifer recharge sites in other areas of the city, including a former gravel pit that could potentially store up to 30,000 acre-feet of river water. There, however, water would be injected into the aquifer via wells instead of being filtrated through a streambed.

"We're going to have to continue to come up with innovative ideas if we're doing to address these huge water challenges the West has," Stomp said.

WATER: Arizona, Nevada strike storage deal
(Land Letter, 12/09/2004)
April Reese, Land Letter Southwest reporter

SANTA FE, N.M. -- In the ongoing effort to meet water needs in the drought-stressed West, one state has found a way to buffer against future shortages -- by storing water in a neighboring state.

Under a deal approved by the Central Arizona Project board last week, Arizona will store up to 1.25 million acre-feet of water for Nevada's future use. In return, Nevada will pay \$330 million to Arizona and will boost CAP's efforts to upgrade its junior rights status among Colorado River users.

Nevada can take up to 40,000 acre-feet each year out of its water "bank" in Arizona during years when there is not a shortage. If drought forces Arizona cities to reduce their water use, Nevada will voluntarily cut its use as well.

The deal amends a tentative storage agreement between the two states, making it the first to guarantee the delivery of stored water from one state to another. Federal regulations that prohibited interstate water transfers were revised two years ago to allow for water banking.

"I believe this amendment is in the best interests of the state and the people of Arizona," Herb Guenther, director of the Arizona Department of Water Resources, told the CAP Board last week.

CAP officials said the agreement will help Arizona take its full 2.8 million acre-foot allocation of Colorado River water while also adding momentum to the push to change CAP's water rights status. And the money that Arizona receives from the deal could be used to help protect some of the state's riparian areas, Guenther added.

In moving closer to taking its full Colorado River apportionment, Arizona hopes to buffer itself against any future claims on unused water -- most likely by California, said CAP spokesman Bob Barrett.

"Our concern is that if we don't take off our full allocation, some judge might say, 'Wait, they've come to depend on it so much, they can take it, since Arizona is not using it,'" he said. "It's a fear of 'use it or lose it.'"

As for Nevada, the water will help prevent shortages as the state develops new in-state supplies, which is expected to take several years.

"It's very important," said Pat Mulroy, general manager of the Southern Nevada Water Authority. "It provides some protection from shortages, and it gives us back the bridge we've lost because of the drought."

Under an agreement with the Interior Department, Nevada initially planned to use Colorado River water not needed by other states to meet its needs over the next 15 years. But because of the drought, there is no excess water flowing down the Colorado for Nevada to use.

The state has two water development projects in the pipeline: one that involves tapping groundwater in Lincoln, northern Clark and White Pine counties; and another that calls for diverting water from the Muddy and Virgin rivers. But both involve studies and other obligations that could take about 10 years, said Southern Nevada Water Authority spokesman J.C. Davis.

If Nevada takes the maximum amount of water allowed each year under the Arizona deal, the storage agreement will expire in 35 years. But if the drought recedes, the deal will give Nevada a water buffer until 2060. "That's the beauty -- if the river comes back up, we don't have to use it," Mulroy said.

The Arizona Water Banking Authority must still decide whether to approve the interstate banking agreement, but it is expected to do so at a meeting scheduled for today.

Both Arizona and Nevada water officials said changing CAP's status in the Colorado River water allocation hierarchy is necessary to ensure that neither state finds itself at the end of the line if the drought continues.

Under the Colorado River Compact, which divvies up the river's water among seven Western states, California receives 4.4 million acre-feet (maf), Arizona gets 2.8 maf and Nevada is allocated 300,000 acre-feet. Currently, if a shortage is declared on the Colorado River, California could take its full apportionment, potentially forcing junior users upstream to cut their use. Arizona and Nevada are advocating for equal

reductions among all three lower Colorado River Basin states -- California, Arizona and Nevada -- in the event of a shortage.

"The only two states that are assigned shortages are Nevada and Arizona," said Mulroy. "It becomes very, very difficult when only two states bear the brunt."

When Congress authorized the construction of CAP, it was assigned junior rights to assuage concerns from California lawmakers. But the water hierarchy among the three states is unfair in light of growing water needs in the lower basin, Arizona and Nevada water officials say.

"If there's a half-million acre-foot shortage on the river, if everybody took a 2 percent cut, then that would be relatively easy, as opposed to taking it all out of our hide," Barrett said.

But all three lower basin states would have to agree to change the CAP's water rights status, and some California water officials have expressed reservations about the plan.

Mulroy said she is confident that Nevada and Arizona can work out their differences with California. But Nevada and Arizona are prepared to take the matter to court if the parties cannot agree, she added.

"I know that Arizona doesn't want this to be confrontational with California, and we don't want this to be, but given the reality, it's almost impossible for the two states to not go to court if necessary," she said. "With the drought, I'm not sure we have a choice."

Water Wars in the West / Nevada's thirst a threat to Utah

By Charles Trentelman
Standard-Examiner staff
ctrentelman@standard.net

LOGAN -- Utah can oppose Nevada's plan to pump water from an aquifer that reaches under Millard County, but Nevada will get its water one way or another, says the director of the Southern Nevada Water Authority.

If it can't pump the aquifer, which is under both states, Nevada will demand, and get, more water from the Colorado River, even if that means less for Utah, said Patricia Mulroy.

To avoid that, she said, Utah needs to start talking to other Western states about changing how water is managed in the West.

Utah needs to enter into shared shortage agreements with Nevada.

"It's culture in the West to fight over every single drop," she said, and that has to stop.

Mulroy was a keynote speaker at Friday's session of Utah State University's annual spring runoff conference. The two-day conference features speakers on the science and management of water in the West.

Mulroy manages the water supplies that feed Las Vegas, one of the nation's fastest-growing cities in one of the nation's driest areas.

In the past two years, her agency has been criticized in Utah for plans to pump water out of an aquifer in Spring Valley in central Nevada. The area is just west of Snake Valley, in Millard County, Utah.

Ranchers in Millard County say the pumping will harm their underground water supplies.

In 2007, the Utah Legislature ordered the Utah Geological Survey to dig wells in Snake Valley to monitor the effect of the Nevada work.

Mulroy was just one of several speakers talking about climate change and its impact on water in the West. Her position is unique, she said, because Nevada is facing the crisis now, not sometime in the future.

"We're the canary in the mine shaft," she said.

Several other speakers made it clear that the Colorado River Basin is on a steadily declining supply curve because of climate change.

David Pierce, of the Scripps Institution of Oceanography in San Diego, said new studies have narrowed down the possible effects on the Colorado River Basin over the next 50 years.

Climate records, he said, and tree-ring data all show that the 20th century was the wettest of the last 1,200 years. With carbon emissions worldwide exceeding even the most pessimistic predictions, he said, the West will continue to get warmer and drier.

If runoff in the Colorado River Basin drops only 10 percent, he said, flows in the Colorado River will drop to 13.7 million acre-feet per year and delivery quotas to customers in all states will be missed 58 percent of the time by 2050.

If runoff drops 20 percent, he said, flows in the basin will plunge to 12.5 million acre-feet per year. Deliveries will be missed 88 percent of the time, and levels in Lake Mead and Lake Powell will continue to drop.

Mulroy said Las Vegas gets 90 percent of its water from Lake Mead. The city already recycles all of its wastewater and has spent more than \$100 million to pay people to rip out lawns at \$1 a square foot.

As a result, she said, in 18 months, per-capita use dropped from 360 gallons per day to 248, and the city wants to hit 199.

Even so, she said, the drought that began 10 years ago is still lowering the level of Lake Mead.

The lake is currently at 1,100 feet above sea level, she said, 104 feet below full. With the declines in the river that people like Pierce are predicting, she said, Southern Nevada has to find more water somewhere else.

Either that, she said, or demand it from the Colorado River under the terms of the 1922 Colorado River Compact, which divided the Colorado River into an upper basin of Utah, Wyoming, New Mexico, Arizona and Colorado and a lower basin of Nevada and California.

The compact guarantees the lower-basin states specified amounts of water, even if that means less for the upper-basin states.

In 2007, she said, Nevada and the other states in the compact signed an agreement that said Nevada would not make a call on states in the upper basin for water if there was a shortage.

"Imbedded in that is the in-state project" to pump water in Spring Valley, she said.

If Utah stops that project, she said, the agreement to not make a call is dead.

"The prospect of losing southern Nevada water supplies is a daunting proposition because it is where the results of climate change come home to roost," she said.

If no other source of water can be found, "we have no choice but to make a call on the upper basin."

Nevada would do it, she said, because "you cannot say to a community, 'You have to come to an end,' and that is what will happen if Lake Mead drops below 1,000 (feet above sea level)."

Lake Mead water level set to drop below 1965 mark

The Associated Press

LAS VEGAS—Drought-stricken Lake Mead is expected to drop this summer to its lowest level since May 1965, and water managers say it is approaching the trigger point for restrictions on water use by Nevada and Arizona. A U.S. Bureau of Reclamation report projects that by July, the vast Colorado River reservoir behind Hoover Dam will stabilize about 13 feet below its current level of 1,105 feet above sea level.

The lower level of 1,092 feet would be below 1,100 feet for the first time in 44 years, and just 17 feet above the 1,075-foot elevation that would trigger the first shortage declaration under a sweeping interstate pact signed in December 2007.

That 20-year agreement involving California, Arizona, Nevada, Wyoming, Utah, Colorado and New Mexico provided new rules for jointly operating the Lake Mead and Lake Powell reservoirs during extended dry spells such as the one that has gripped the Southwest since 2001.

Colorado River water flow to Mexico is not affected by the 2007 pact, said Bob Walsh, a Bureau of Reclamation spokesman in Boulder City.

The bureau manages two large Colorado River reservoirs—lakes Powell and Mead—in tandem to capture snowmelt from the Rocky Mountains and deliver water to seven downstream states under water rights agreements dating to 1922.

A declaration of shortage would cut Lake Mead water deliveries to Nevada by 13,000 acre-feet, and Arizona deliveries by 320,000 acre-feet. Excluding surplus water available in wet years, Arizona is entitled to 2.8 million acre-feet of water from the Colorado River annually. Officials say an acre-foot of water is about enough to serve two southern Nevada families per year. Nevada receives some 300,000 acre feet of water per year from Lake Mead, including about 90 percent of Las Vegas-area drinking water.

Lake Powell was 52 percent full Monday, with some 12.7 million acre-feet of water, Walsh said. Lake Mead, on the Nevada-Arizona border east of Las Vegas, was 46 percent full, with 12 million acre feet of water. Since 2000, the Lake Mead water level has dropped more than 100 feet. But the lake remains enormous, with some 500 miles of shoreline and water as deep as 300 feet in some places.

Walsh said the projections in the bureau's April 6 water level report may be revised after new data is collected in May. But he said the surface of Lake Mead was projected to be 1,092 feet at the end of September.

That has marina operators planning to extend gangplanks to reach moored boats, and Las Vegas' main area water provider scrambling to finish a new Lake Mead drinking water intake in case two existing intakes become ineffective. The \$817 million construction project is slated for completion in 2013.

"We're going to continue to race against Mother Nature to get that third intake done," said J.C. Davis, spokesman for the Southern Nevada Water Authority in Las Vegas.

Jim Holland, park planner for the Lake Mead National Recreation Area, said several boat ramps, access roads and utility lines might need to be extended this summer to reach the receding water line.

"It's going to cost a lot of money to accommodate a 10-foot drop in such a short amount of time," he said. Andrew Munoz, a recreation area spokesman, estimated that each 20-foot drop in the lake level costs the park service and its contract marina operators about

\$6 million.

Lake Mead braces for lowest level since 1965

Marinas, docks are moved as water level drops below last year's lowest point

By Jean Reid Norman

Fri, Apr 24, 2009 (2:01 a.m.)

On the concrete launch ramp of Boulder Harbor, where a marina once docked boats at Lake Mead, National Park Service spokesman Andrew Munoz points to a thin strip of land that protrudes almost a foot out of the water. "See that?" he asks. "A week ago, if you were to stand on that finger of land, you would be knee deep in water." Lake Mead's elevation has dropped to 1,103 feet above sea level, and by July, the Bureau of Reclamation forecasts that it will be at 1,092, its lowest level since 1965, when Colorado River water was being retained upstream to fill Lake Powell in Arizona.

Rough asphalt installed in the 1960s to help boats reach the lake at the previous low-water mark at Boulder Harbor is visible at the end of the concrete launch ramps. Munoz points in the distance to a wooden structure hanging over a small bluff. It used to be a fishing pier, he says.

After nine years of drought, the Lake Mead National Recreational Area is preparing for another year of moving ramps, marinas and other facilities, chasing the shoreline as it recedes.

Echo Bay Marina in the northern part of Lake Mead began preparations Thursday to tow the docks to deeper water, Munoz said. The marina will close from April 26 through May 5, but boat owners who use the slips will be shuttled from shore to their vessels, Munoz and marina employees said. Boat rentals will still be available by reservation, Munoz said.

Temple Bar Marina on the Arizona side will also close soon to move it to deeper water, Munoz said. At Boulder Harbor, pipe matting made of corrugated steel will be laid over the dirt where the concrete launch ramp ends, to prevent vehicles and vessels from creating potholes at the water's edge, he said. That will be a temporary fix while a contract is sought to extend the launch ramp yet another time.

In addition, park rangers continually move buoys and other navigational aids to help boaters avoid an unpleasant run-in with a rock or other obstruction that used to be well

below the water's surface. The work is expected to cost the park service \$10 million, and the marinas are expected to put another \$1 million into the move, he said.

These changes are part of the larger story of the drought that has gripped the Southwest. Fourteen months ago, Lake Mead Marina, which used to occupy Boulder Harbor and was known as a place where tourists and children could feed popcorn to carp, pulled up its anchors and was floated down the shore to Hemenway Harbor.

The Southern Nevada Water Authority, which draws 90 percent of Southern Nevada's water supply from two intake pipes in Lake Mead, is racing the falling water levels to complete a third intake that will preserve its ability to fill Las Vegas' water needs, spokesman J.C. Davis said.

One of the intake pipes will lose its ability to draw water when the lake reaches 1,050 feet elevation, a level that the Bureau of Reclamation is not predicting in its two-year forecast, Davis said.

The Water Authority has drawn a line in the sand at 1,000 feet, he said. That's the lowest level the second intake and the new intake will be able to accommodate, he said. Before the lake reaches that point, the states that depend on Colorado River water have agreed to renegotiate the way water is divided, Davis said. The current low-water level can be traced upstream, Davis said. The snow pack in the Rocky Mountains was 82 percent of normal, which is better than the average of 67 percent over the past several years, he said. If there had been more, he said, the water level of Lake Powell might have reached a high enough level that more water would have been released to Lake Mead.

In addition, he said, the growing season in California and Arizona is beginning, and orders are coming in for agriculture, which uses 80 percent of the water taken out of Lake Mead. Because of that cycle, summer is when the lake always reaches its annual low-water mark, Davis said.

Still, it's discouraging to boaters like Jesse Keenan, who was pulling his boat in from an outing at Boulder Harbor Thursday morning.

"There's nothing you can do about it," he said. "It's like a martini glass. You take one sip at the top and it's no big deal. When you get to the bottom, each sip is a big deal. "We didn't used to have a problem. Now, are you kidding me?"

CORRECTION: This story was updated to correct the area of Lake Mead referenced as Boulder Harbor.

Regional News 04/20/09

Study: Shortages 60% to 90% likely on Colorado River by 2050

By MIKE STARK, Associated Press Writer

Monday, April 20, 2009

(04-20) 15:03 PDT Salt Lake City, UT (AP)

If the West continues to heat up and dry out, odds increase that the mighty Colorado River won't be able to deliver all the water that's been promised to millions who rely on it for their homes, farms and businesses, according to a new study.

Less runoff — the snow and rain that fortify the 1,400-mile river — caused by human-induced climate change could mean that by 2050 the Colorado won't be able to provide all of its allocated water 60 percent to 90 percent of the time, according to two climate researchers at the Scripps Institution of Oceanography at the University of California at San Diego.

The more parched the landscape, the more difficult the choices will be for those with dibs on the Colorado's water and those in charge of divvying it up, said Tim Barnett, lead author of the study.

"The dry year scenarios in the future are going to be absolutely brutal," he said.

Barnett and fellow Scripps scientist David Pierce made waves last year with a study saying there's a 50 percent chance that Lake Mead, the reservoir created by the Hoover Dam, could run dry by 2021.

They teamed up on the latest study to predict when the river — under different climate scenarios predicting 10 percent to 30 percent reductions in runoff — will be unable to fully meet all of the demands put on it.

The results were published Monday in the journal Proceedings of the National Academy of Sciences.

"Without numbers like this, it's pretty hard for resource managers to know what to do," Barnett said.

The Colorado is a lifeline of the southwest, flowing through seven states and into Mexico and quenching the thirsts of some 27 million people who use it to irrigate crops, water lawns, produce drinking water and operate businesses.

Drought has already stressed the river. The problem is being compounded by growing populations demanding more water and the expected effects of climate change, said Brad Udall, director of the University of Colorado's Western Water Assessment.

"We're on a collision course between supply and demand," Udall said.

The Bureau of Reclamation, the federal agency that plays a key role in how the river system is managed, has used a different set of calculations than the Scripps researchers to reach a similar — though less dire — prediction, according to Terry Fulp, the agency's Nevada-based deputy regional director for the Lower Colorado.

His agency's calculations predict the Colorado could run short of water 58 percent to 73 percent of the time by 2050.

There's room to quibble over percentages, Fulp said, but the overriding point remains.

"We've got some serious issues to grapple with," he said.

Under conservative climate change scenarios in the West, Barnett and Pierce found decreases in runoff could short the Colorado River by about 400,000 acre feet of water 40 percent of the time by 2025. That's equivalent to the amount of water needed to supply 400,000 to 800,000 households.

Those figures double later in the century, according to the Scripps researchers.

The signs point toward tough decisions about who will get less water. Agricultural operations use about 80 percent of the water taken out of the Colorado, Barnett said. He knows the arguments, though: Shorting farms could drive up food prices. Curbing development in cities and suburbs will make developers unhappy. Whatever the case, he said, some decisions need to be made soon.

"The actions that need to be taken aren't going to be fun," Barnett said. "It's not going to be life as usual."

But, Barnett and Pierce said, it isn't too late to buffet some of the harshest effects.

Measures such as conservation and water exchanges, which can require upfront investments and flexibility, could play a key role in avoiding some of the biggest shortfalls, they said.

In 2007, officials from the seven states that get water from the river — Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming — and then-Interior Secretary Dirk Kempthorne signed a far-reaching agreement aimed at conserving and sharing the scarce resource. The 19-year plan formalized rules for cooperating during the ongoing drought.

Meanwhile, researchers will continue gathering information on climate change and looking for ways to keep the Colorado functioning — albeit with a new set of climate-driven rules.

"It really depends on how innovative people get," Fulp said.

Dust Storms Escalate, Prompting Environmental Fears

By Juliet Eilperin
Washington Post Staff Writer
Thursday, April 23, 2009

Nestled in the San Juan Mountains at 9,300 feet, and surrounded by 13,000-foot peaks, Silverton, Colo., seems an unlikely place for a dust storm, especially with two feet of snow on the ground. So Chris Landry was alarmed on the afternoon of April 3 when he spotted a brown haze on the horizon; an hour later, a howling wind had engulfed the town in a full-fledged dust storm, turning everything from the sky to the snow a rusty red.

"It was almost surreal," recalled Landry, executive director of the Center for Snow and Avalanche Studies. The landscape looked like Mars after the storm passed, he said: "You could feel the dust, you could taste the dust."

The scene Landry witnessed that day was the most severe example of a phenomenon that has overtaken parts of the West this year, one that could exacerbate a slew of environmental problems there in the years to come. The Colorado Rockies, including the headwaters of the Colorado River and the Rio Grande, have experienced 11 serious dust storms this year, a record for the six years researchers have been tracking them.

More important, an increasing amount of airborne dust is blanketing the region, affecting how fast the snowpack melts, when local plants bloom and what quality of air residents are breathing.

The dust storms are a harbinger of a broader phenomenon, researchers say, as global warming translates into less precipitation and a population boom intensifies the activities that are disturbing the dust in the first place. Jayne Belnap, a research ecologist at the U.S. Geological Survey who has studied the issue, predicts that by midcentury, the fragility of the region's soil "will be equal to that of the Dust Bowl days."

"We're headed for this massive soil movement, these massive dust storms on a frequency we're not used to, and it's going to have enormous ecosystem impacts," Belnap said. "No one has an appreciation for the scope of the calamitous impacts."

Dust storms are not new in the West, but the fact that so much dust is on the move reflects that across vast areas, soil is being loosened by off-road vehicles, livestock grazing, and road development for oil and gas production, much of it on public land. A Washington Post analysis of federal data from areas managed by the Bureau of Land Management found that between 2004 and 2008, off-road vehicle use rose 19 percent,

the number of oil and gas wells increased 24 percent and grazing acreage climbed 7 percent.

The trends have sparked an intense debate between interests being blamed for loosening the soil and those calling for controls on those activities.

Advocates for off-road vehicle users, for example, charge that environmentalists have seized upon the dust issue as a political club in their efforts to curb the increasingly popular recreational sport.

"A lot of the public land in the West is a very dusty place. What human uses make it more dusty, and to what extent, is unknown," said Brian Hawthorne, public lands policy director for the BlueRibbon Coalition, which represents off-road enthusiasts. "There's just no studies on it."

Scientists are trying to get better measurements of how much soil is getting stirred up -- and the consequences.

People tend to think of arid regions as inherently dusty, but research by the U.S. Geological Survey and others has shown that even dry soil, if undisturbed, stabilizes plant life and can provide a critical, albeit fragile, crust.

Once disturbed by off-road vehicles, grazing, plowing or other forces, however, the dust can travel long distances on the wind.

According to several studies, a vehicle traveling at 27.5 miles per hour over a dirt road composed of 20 percent silt can kick up five to 30 pounds of dust with every mile it drives.

By studying sediment cores from high-elevation lakes in the San Juan Mountains, Jason Neff, a geological sciences professor at the University of Colorado at Boulder, has estimated that the amount of dust falling back to Earth now is up to five times as much as the amount before Europeans arrived. Dust deposition was even greater around the turn of the last century, before the government put restrictions on grazing.

"Nobody could deny all this activity is causing more dust," Neff said, adding that the phenomenon is depositing more nutrients at higher elevations, changing what plants grow there and disrupting ecosystems.

The groups most frequently cited for stirring up Western soils -- cattle growers, oil and gas companies, and off-road vehicle users -- all challenge the charge that their activities are to blame.

Tom Field, director of production education for the National Cattlemen's Beef Association, said his members have improved their land-management practices, and he argued that "without the ranching industry in the Western U.S., much of the accessible private and public land would be converted to housing developments and recreational sites, which would diminish open space and create ecosystem disturbance."

Tim Sampson, manager for exploration and production at the American Petroleum Institute, questioned whether oil and gas exploration has worsened the dust problem: "We have high winds, and we have dust storms. They've been there since before Texas was a state."

One of the biggest problems, scientists say, is that each storm deposits a layer of dark material on the mountain snowpack; that layer absorbs the sun's heat and causes the snow to melt earlier. Thomas H. Painter, a University of Utah cryospheric science professor, has calculated that dust deposition significantly reduces snow's reflectivity.

"It's effectively like turning up the sun 50 percent and putting that energy into the snow," he said.

The earlier snowmelt changes the blooming and growing times of vegetation, triggering ripple effects that hurt Colorado farmers. Steve Vandiver, general manager of the Rio Grande Water Conservation District, said farms in the valley are getting the snowmelt runoff two to four weeks earlier each year, making it difficult to keep grain and potato crops irrigated.

"A lot of the water's gone by the time the crops need it," he said.

Snowpack melt is not the only effect: Many Southwestern communities are struggling with poor air quality, and dust is making it worse. Arizona's Maricopa County, which includes Phoenix and Scottsdale, has failed to meet federal air quality standards and is cracking down on off-road vehicles and unpaved roads to limit dust.

Lawrence Odle, director of the Maricopa County Air Quality Department, said officials have little choice.

"We have vehicles that just tear across the desert," he said, adding that the county stands to lose \$7 billion in federal transportation funds if it does not improve its air quality. "Do you allow for recreational activity, or do you try to get into compliance with federal health standards?"

Researchers say a shift in policy could help avert some of the worst impacts in the coming years.

"We can do something about it," USGS's Belnap said. "We just have to decide it's important."

But the Bureau of Land Management says it sees no reason to change its rules for issuing permits for dust-generating activities on the land it controls.

"It's something we look at," said Scott Archer, a senior air resource specialist at the bureau. "In the big scheme of things, no, it's not that big a deal."

Database editor Sarah Cohen contributed to this report.

Colorado River adaptive management program needs overhaul, critics say

By APRIL REESE, Greenwire After 13 years of experimentation, a collaborative program aimed at reversing some of the ecological damage wrought by Glen Canyon Dam in the Grand Canyon's stretch of the Colorado River has failed to live up to its congressional mandate, critics within the program say.

And even as the science on the river's health points in the direction of flow changes that would mimic natural conditions, members of the 25-member Adaptive Management Work Group remain entrenched along old battle lines that pit power producers and Colorado River Basin states against environmental groups and wildlife agencies concerned about the river's ecological decline.

The result is a policy stalemate that has effectively kept Glen Canyon Dam operating under the same conditions as in 1992, when Congress passed the Grand Canyon Protection Act, calling on the Interior Department and stakeholders to figure out ways to "protect, mitigate adverse impacts to, and improve" conditions within Grand Canyon National Park's river corridor.

The construction in the 1960s of Glen Canyon Dam and its reservoir, Lake Powell, has drastically altered historic downstream flows on the Colorado River. Among other things, the dam captures sediment that once gave the river its signature murky reddish color, and water releases from the bottom of the reservoir have substantially cooled river temperatures, creating adverse conditions for federally endangered humpback chub, a native fish, and other species.

Yet despite the continued impacts on the Grand Canyon ecosystem, the Glen Canyon Dam Adaptive Management Work Group, or AMWG, has never reached sufficient consensus to execute its primary charge -- recommending a new dam operations policy to the Department of Interior.

"My frustration with this process is that it's not an adaptive management program," Rick Johnson, who represents the Grand Canyon Trust on the work group, said during a break of a meeting of the work group last week in Phoenix. "We've never changed policy."

Battle over flows

Since the mid-1990s, the Bureau of Reclamation, which operates the dam, has conducted three high-flow experiments aimed at mimicking spring surges of snowmelt that historically inundated the Grand Canyon, scouring sediment from the Colorado River's channel and depositing it downstream in sandbars and beaches.

In studying those three controlled floods, scientists have found that a large surge, carried out after spring thunderstorms have stirred up sediment, followed by low summer flows to reduce erosion of new sandbars and beaches, appears to benefit the humpback chub, which needs backwater habitat created by the sandbars, and improves conditions for recreational rafters, who use the beaches as campsites.

Last month, the U.S. Geological Survey issued a report that found the humpback chub population in the Grand Canyon had increased by 50 percent between 2001 and 2008, partly due to such flow experiments.

While some questions about the effects of the experimental flows remain unanswered, federal biologists and some advocacy groups say there is sufficient evidence from the 13-year, \$80 million research program to suggest a flow regime change.

"I think that there's enough data that we could propose that," said Sam Spiller, a biologist and Lower Colorado River coordinator for the U.S. Fish and Wildlife Service and an AMWG member. "There seems to be a consensus among scientists that that's what the resources in the Grand Canyon need."

The National Park Service also would like to see more high flows. Last year, Grand Canyon National Park Superintendent Steve Martin said in an interview that "the science is clear" and justifies regular surges from Glen Canyon Dam (Land Letter, April 10, 2008).

But while the work group has voted for three high-flow experiments in recent years, all seven of the Colorado River Basin states -- Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming -- along with power utilities that sell hydropower to some of those states, have resisted recommending permanent changes to the dam's operating regime, citing concerns about lost power and reduced revenues.

Currently, the dam is operated under a "modified low fluctuating flow" regime, under which releases vary throughout the day. While that prescription is ideal for power generation, it has proved problematic for the humpback chub and other Grand Canyon resources.

Two reports, a biological opinion from FWS in 1994 and a USGS analysis (pdf) of the effect of 10 years of dam operations issued in 2005, concluded that modified low fluctuating flows have not restored sediment transport or helped native fish recovery in the Grand Canyon.

"There's going to be a huge debate if there's a management action to alter flows on a regular basis," John Shields, interstate streams engineer for the state of Wyoming who represents Wyoming on the AMWG, said in an interview after the meeting.

'Who pays?'

Part of the problem, said Shane Capron of the Western Area Power Association, who heads the adaptive management program's technical working group, is that it is unclear

who would shoulder the economic burden of tweaking flows to more closely mimic historic conditions.

"We don't know right now how to transition from science to management," he said at the meeting. "There are big implications of moving these things into management: Who pays? Who implements?"

The inherent difficulties of balancing resource protection and power and water needs were on display at last week's meeting, when Andre Potochnik, who represents Grand Canyon river guides on the work group, floated a motion calling for consideration of a new high-flow test within the next couple of years.

That motion was rejected on a 10-8 vote, with three abstentions. The seven Colorado River Basin states voted no, while three American Indian tribes, along with the Bureau of Indian Affairs, the National Park Service, two environmental groups and Potochnik, voted yes.

Leslie James of the Colorado River Energy Distributors Association, which distributes power from Glen Canyon Dam to customers in the Colorado River Basin, said the association supports high-flow tests. But James emphasized conditions have to be right to conduct them, and that the science is not yet solid enough to determine what those conditions are.

"So I think it's premature" to recommend a new high-flow test, James said.

Shields, the Wyoming representative, noted that under a 2008 Bureau of Reclamation plan, the working group cannot recommend a new high-flow test until scientists complete their evaluation of the 2008 test, which is not due until next year.

Furthermore, the Bureau of Reclamation's plan calls for an annual "steady flow" experiment each fall through 2012. And before a new high-flow experiment can go forward, Reclamation would have to undertake an environmental review of its effects under NEPA, a process that could take one to two years.

"We've committed to five years of those fall steady flows," said Larry Walkoviak, Reclamation's regional director for the Upper Colorado region, who is serving as the Interior secretary's acting designee to the work group. "I think it's probably too early to tell" how the flow regime should be changed, he added.

Voting blocs

But environmental advocates said there are other considerations driving the panel's reluctance to call for another high-flow experiment.

"It's all about money," said John Weisheit of the nonprofit group Living Rivers, which has advocated breaching the dam. "They're doing the minimal things to be compliant."

Since power distributors have to purchase replacement power from more expensive sources during flow experiments, they incur a loss with every test flow. The 2008 high-flow experiment, for example, cost power contractors \$4 million in lost revenues.

"The optimal flow for sediment -- keeping it in the channel -- is a constant steady flow [after a high flow in the spring], but we realize that's not really an option because of power needs," Ted Melis of USGS's Grand Canyon Monitoring and Research Center said during a presentation at last week's work group meeting.

Johnson of the Grand Canyon Trust said that according to his group's estimates, power customers would have to pay only an additional 10 cents a month under an altered flow regime.

He suggested that the very makeup of the adaptive management work group favors electric power interests over ecological ones, since group members tend to vote in blocs, with power contractors and the states voting together against environmental groups, natural resource agencies and tribes.

"The secretary should say, 'This group isn't doing what I need,'" Johnson said.

The Grand Canyon Trust has carried that frustration into the courtroom, where a pending lawsuit against the Interior Department charges that the government has failed to protect the Grand Canyon's resources downstream from the dam.

Privately, some federal officials speculated that the program -- and perhaps the controversial flow regime -- might change under the Obama administration.

Interior Secretary Ken Salazar nominated Deanna Archuleta to be deputy assistant secretary for water and science last month. If confirmed, Archuleta would become Salazar's designee at the AMWG meetings.

Archuleta, the board chairwoman of the Bernalillo County Water Utility, which serves the Albuquerque, N.M., region, formerly served as the Southwest regional director for the Wilderness Society. She is considered an expert in developing water policy and has extensive experience in dealing with Western water issues, including drought, climate change and population growth.

But Weisheit of Living Rivers said a change in senior leadership will make little difference in the direction of the program. "The administration might change, but the voting bloc never changes," he said. "It's designed to make sure that hydropower has precedence over Grand Canyon restoration."

Letter to Utah Division of Water Rights regarding proposed nuclear power plant at Green River, Utah

[Click here](#) to download letter with attachments

[Press Release](#)

OFFICE OF THE STATE ENGINEER
DIVISION OF WATER RIGHTS
STATE OF UTAH

PROTEST and HEARING REQUEST

In the Matter of Change Application No. A35402
(Water Right Nos. 89-74, 89-1285, and 89-1315)

May 26, 2009

Living Rivers, Uranium Watch, and the Glen Canyon Group of the Sierra Club hereby submit a timely PROTEST and request for a HEARING, pursuant to Utah Code Ann. §73-3-7, regarding Application for Permanent Change of Water No. A35402 (Application) filed by the Kane County Water Conservancy District (KCWCD or Applicant), received by the Salt Lake Office of the Division of Water Rights on March 30, 2009.

Living Rivers is a public interest, non-profit organization dedicated to the restoration of Colorado River ecosystems that are presently damaged by excessive diversions and pollution.

Uranium Watch is a public interest, non-profit organization that works to educate and advocate for protection of public health and the environment from impacts of uranium mining and milling and other nuclear fuel cycle operations in Utah.

The Glen Canyon Group of the Sierra Club works to restore and protect the environment of Southeastern Utah, in the heart of Red Rock Country.

Uranium Watch and Living Rivers are located in Moab, Grand County; the Glen Canyon Group has members in Carbon, Emery, Grand, San Juan, and Wayne Counties.

The change application relates to the provision of water for a nuclear power generating station a few miles west of the Green River in Emery County. Grand County, just east of Green River, and Carbon County, north of Green River, will be in the nuclear power station's plume exposure pathway Emergency Planning Zone (EPZ). Moab and other communities will be in the ingestion pathway EPZ, as designated by the U.S. Nuclear Regulatory Commission (NRC).

The Application proposes to change the point(s) of diversion, place of use, and nature of use for water rights 89-74 (A35818), 89-1285 (A35818a), and 89-1315 (A35818B). The Application proposes to change the point(s) of diversion from Lake Powell on the Colorado River to the Green River; the place of use from Lake Powell to land about 3 miles west of the City of Green River and the Green River; and the use from a coal-fired power plant to a nuclear power plant to generate electricity, named the Blue Castle Project. The water would be used by Transition Power Development LLC (Transition Power) pursuant to a Water Rights Lease Agreement, dated September 20, 2007.

See Attachment A.

The proposed site for the proposed reactor is land that Emery County leased from the Utah School and Trust Lands Administration for an industrial development park on November 17, 2008 (Development Lease No. 813). The site is just north of Interstate 70 and the Union Pacific passenger and freight railway, and just east of Hwy. 6.

See Attachment B.

Water for the proposed nuclear power generation station must provide an adequate supply of cooling water for normal operation, anticipated operational occurrences, safe shutdown, and cool down (first 30 days) and long-term cooling (periods in excess of 30 days) during natural and emergency conditions.

This protest is based on the following grounds:

1. Standing.

Living Rivers and Uranium Watch are “persons interested” for the purposes of Utah Code Ann. §73-3-7.

2. Utah Code Ann. §73-3-8.

The KCWCD Application fails to address any of the criteria that the State Engineer must consider when approving a water right appropriation or change application.

Utah Code Ann. §73-3-8 lays out the criteria for the approval of a water right appropriation or change application. Section 73-3-8 states, in pertinent part: (1) (a) It shall be the duty of the state engineer to approve an application if:

- (i) there is unappropriated water in the proposed source;
- (ii) the proposed use will not impair existing rights or interfere with the more beneficial use of the water;
- (iii) the proposed plan is physically and economically feasible, unless the application is filed by the United States Bureau of Reclamation, and would not prove detrimental to the public welfare;
- (iv) the applicant has the financial ability to complete the proposed works; and

(v) the application was filed in good faith and not for purposes of speculation or monopoly.

(b) (i) If the state engineer, because of information in the state engineer's possession obtained either by the state engineer's own investigation or otherwise, has reason to believe that an application to appropriate water will interfere with its more beneficial use for irrigation, domestic or culinary, stock watering, power or mining development, or manufacturing, or will unreasonably affect public recreation or the natural stream environment, or will prove detrimental to the public welfare, it is the state engineer's duty to withhold approval or rejection of the application until the state engineer has investigated the matter.

(ii) If an application does not meet the requirements of this section, it shall be rejected.

There is nothing in the Application to demonstrate that there is unappropriated water in the proposed source; the proposed use will not impair existing rights nor interfere with more beneficial use of the water; the proposed plan is physically and economically feasible; the applicant (or, in this instance, Transition Power, the entity that would carry out the proposed project) has the financial ability to complete the proposed works; the application was filed in good faith and not for the purposes of speculation or monopoly; the Application will not interfere with more beneficial uses; the Application will not unreasonably affect public recreation or the natural stream environment; and the Application will not prove detrimental to the public welfare.

Normally, when a government regulatory agency has criteria that must be addressed for the approval of an application for agency action, the applicant must submit information responsive to those criteria. If the information is incomplete, the agency does not accept the application until it is, and the agency does not notice the application for public comment, challenges, or hearing requests until an acceptable application has been submitted. However, this has not been the case with water right applications in the State of Utah.

For some inexplicable reason, the Division of Water Rights did not require an applicant to provide any information that addresses the criteria in Section 73-3-8(1)(a) or is pertinent to the withdrawal and use of the water for such a large, expensive, and technologically complex project. So, an interested person does not know if the information that the State Engineer might rely on is complete, relevant, and accurate.

In this instance, the State Engineer lacks the required information on which to base any findings responsive to the requirements of Utah Code Ann. §73-3-8.

Therefore the Application must be rejected.

3. Unappropriated water in the proposed source.

Section 73-3-8(1)(a)(i) requires sufficient unappropriated water for the proposed appropriation or change.

3.1. The State Engineer must evaluate the availability of unappropriated water in the proposed source over the long term. The State Engineer must identify and assess the factors that could impact the availability of an adequate water supply for the proposed use — over the full life of the project. Such factors would include drought, impacts from climate change, icing on the river, use limitations imposed by federal and state agencies authorizing the use of Colorado River Basin water, agreements and compacts affecting the use of Green River water, potential blockage, effect of existing and proposed water-control structures, and site and regional hydrological conditions.

3.2. The Application does not contain information regarding how long the water is needed for the purpose of use. A nuclear power plant usually has an operating life from 20 to 40 years. It can take up to 20 years to go through the licensing and construction phase, and Transition Power can obtain an NRC Early Site Permit that is good for 20 years, but can be extended for another 20 years before initiating construction.

See Attachment C.

Also, see <http://www.nrc.gov/reactors/new-reactors/esp.html>.

Transition Power submitted a January 30, 2008, Letter of Intent to the NRC, stating that they intended to submit an Early Site Permit Application and/or a Combined License Application by April 2010.

See Attachment D.

After the operating life of the reactor there is the period of reactor shut down and decommissioning, with the possibility of on-site storage of spent fuel for many years. This easily adds up to over 100 years for the life of the proposed project.

Therefore, the State Engineer must consider the amount of water that will be available, with the numerous demands on water from the Green River and Colorado River systems and factors impacting the availability of water, over the next 120 years — at the very minimum. This is because, if the Application is approved, the water sought could be tied up, with or without use, for that length of time.

3.3. Since the Colorado River Compact was negotiated in 1922, the annual yield of the Colorado River has been reduced naturally by over 2 million acre-feet (maf). Since 1948, when the Upper Colorado River Basin Compact was negotiated, the annual yield of the Colorado River has only averaged 14.1 maf. This declining trend is expected to continue beyond the next century as a result of human activities that cumulatively load the atmosphere with greenhouses gases.

It is reasonable to assume that a full 10% reduction in the annual streamflow of the Colorado River will occur by the time this proposed project begins construction, and a 20% reduction will likely occur before the current century ends.

The Colorado River system cannot function properly with a 10% reduced annual yield of 13.5 maf, and a 20% reduction to 12 maf will render an impossible situation that will assuredly lead to complex legal struggles that will include the State of Utah.

Considering this cumulative impact, it would be appropriate for the State Engineer to fully consider a worst-case scenario occurring within the next 100 to 120 years. Specifically, the State Engineer must evaluate how this proposed water withdrawal in a time period of severe water shortages would likely contribute harm toward preexisting water users in the State of Utah.

For example, the State Engineer should consult with the National Oceanic and Atmospheric Administration (NOAA) in Boulder, Colorado, as a cooperating agency in this regard. These scientists will soon complete the task of reconciling the various results of general circulation models that were developed to help water managers prepare for the long-term effects of global warming on the water supply of the Colorado River.

3.4. Transition Power may apply for and receive an Early Site Permit, which is good for a period of 20 years and may be extended for an additional 20 years. Construction of the project might not commence during that time. Already the subject water rights have not been put to beneficial use since they were first appropriated in 1964 — 45 years ago. So, it could be another 20 to 50 years before the water is put to use, and there is no guarantee that the reactor will eventually be constructed and the water put to use. This is an unreasonable amount of time for an entity to hold onto water for a specific project and not put it to beneficial use.

The State Engineer must obtain and consider all relevant data and information related to all aspects of the planned life of the project and the amount of time before the water will actually be put to use. This is also necessary if the Application is approved, because any approval decision must state "the time within which the construction work must be completed and the water applied to beneficial use." See Utah Code Ann. § 73-3-10(5). These dates must be realistic. 4. Impairment of existing rights or interference with the more beneficial use of the water.

Section 73-3-8(1)(a)(ii) requires that the proposed use will not impair existing rights or interfere with the more beneficial use of the water.

4.1. As discussed above at 3.3, the proposed withdrawal has the potential to impair all of the existing water uses and water rights in the event of a severe drought.

4.2. The appropriation of water could adversely impact existing uses and rights because, once operating, a nuclear power plant requires water, even during shut down. Water for the plant cannot just be turned off in times of low water availability in order to provide water to senior water rights holders, for recreation, to maintain a healthy stream environment, or to satisfy commitments to Colorado River Compact members. The safe operation of the reactor systems would take precedence. This could impair existing rights and interfere with other uses of the water.

The Applicant must submit information regarding the projected use of the water — under varying water availability conditions — for various operational, shutdown, emergency, and long-term scenarios.

4.3. The proposed use will interfere with the beneficial uses of the Green River water for recreation due to the intake structures in the Green River, withdrawal of water, and the threat of planned and emergency releases of radioactivity from the site. The proposed project would interfere with other recreational, agricultural, and municipal uses of the water. It would adversely impact the native fish and other wildlife habitats, including the habitat of endangered fish species that are unique to the Colorado River Basin: Colorado pikeminnow, razorback sucker, bonytail chub, and humpback chub. Intake structures kill fish and aquatic organisms. The withdrawal of the water lowers the water level, which could impact spawning areas and fish habitat, particularly during low flow conditions.

4.4. The proposed withdrawal use has the potential to impact the Upper Colorado River Endangered Fish Recovery Program. The State Engineer must consult with the participants in the Upper Colorado River Endangered Fish Recovery Program and state and federal agencies that have responsibilities for the health and well being of the Colorado River Basin and the wildlife that depends on it.

4.5. The State Engineer must thoroughly identify and evaluate all of the potential adverse impacts to the current and proposed beneficial uses of the Green River water.

The State Engineer must fully investigate the amount and kinds of radiological and non-radiological effluents that will be released into the air from the site, the meteorological conditions that will influence the dispersion of those effluents, and the impacts of those effluents on the agricultural lands and agricultural activities in the vicinity of Green River, including melon growing, grazing, stock raising, gardens, and growing of alfalfa and other feed crops.

The State Engineer must fully investigate the potential impacts to the agricultural lands and agricultural community from a radiological emergency. According to the NRC, the primary source of radioactivity beyond a few miles from the site is the ingestion of contaminated water and food, including agricultural products.

See <http://www.nrc.gov/about-nrc/emerg-preparedness.html>.

Also, see Attachments E and F. 5. Physical feasibility.

Section 73-3-8(1)(a)(iii) requires that "the proposed plan is physically . . . feasible."

A nuclear reactor makes many demands on the physical environment. Neither the Applicant nor Transition Power has made any information available to the public regarding the feasibility of the proposed project. There are a number of issues that should be considered.

5.1. It is not known whether the amount of water that Transition Power has leased (29,600 acre-feet from the KCWCD and 24,000 from the San Juan Water Conservancy District) will provide the water necessary for a 2-unit reactor. There is no information about the specific design of the proposed reactor. There is no information about the amount of water that would be required to cool the reactor core, operate the plant, and as a heat sink to dissipate of heat after reactor shutdown and in the event of an accident

— based on a specific reactor design at the proposed site and under the specific site conditions.

The Application states the water would be diverted for storage in a reservoir that would inundate 100 acres and have a 2,000 acre-foot storage capacity. It is not known if the site is suitable for a storage reservoir or if the capacity of the reservoir is sufficient for the multiple water demands of the reactor.

This technical information must be provided to the State Engineer and the public.

5.2. Transition Power has not purchased the proposed site, and little is known about the numerous site aspects relevant to placement of a reactor; for example, hydrology, geology and seismic conditions, local meteorology, emergency planning, ecological systems and biota, water availability, and the exclusion zone requirements. So it is not known if the site is suitable for a nuclear power facility and meets the siting and safety assessment requirements of the NRC.

5.3. The Application does not contain information about the required depth of the Green River to accommodate the water intake structures and assure the required flow into those structures. There is no information about the past and expected future variations in the depth of the Green River during various flow conditions. Therefore the feasibility of the use of the Green River, based on depth requirements, is an important factor affecting the feasibility of the proposed project. The Applicant should submit this information for the review of the State Engineer and the public.

5.4. There is no information in the Application or available to the public elsewhere that demonstrates that Transition Power has exercised due diligence in pursuing plans for a nuclear generating station.

5.5. The State Engineer should not approve the Application until he has obtained, evaluated, and made public relevant information about the feasibility of the proposed nuclear reactor project.

6. Economic feasibility.

Section 73-3-8(1)(a)(iii) requires that "the proposed plan is . . . economically feasible."

6.1. A nuclear reactor is a multi-billion dollar project. There is no information in the Application or that is available to the public elsewhere that demonstrates that constructing and operating the proposed nuclear power reactor is an economically feasible plan. The State Engineer should have substantial data, information, and analysis to support a claim that the proposed project is economically feasible and there are no unacceptable economic risks. One of the economic risks that should be evaluated is that associated with a lack of water availability during the life of the reactor.

6.2. The State Engineer must also identify and evaluate the economic impacts associated with emergency response planning and other community responsibilities associated with the construction and operation of a nuclear facility near Green River.

According to the NRC, "Before a plant is licensed to operate, the NRC must have 'reasonable assurance that adequate protective measures can and will be taken in the event of a radiological emergency.'"

See <http://www.nrc.gov/reading-rm/doc-collections/fact-sheets/emerg-plan-prep-nuc-power-bg.html>.

Also, see <http://www.nrc.gov/about-nrc/emerg-preparedness.html>.

This emergency planning for the protection of the public from exposure to, and the inhalation of, airborne radioactive contamination and/or the ingestion of food and liquid that is contaminated by radioactivity will involve local, state (Utah and Colorado), and federal entities. Who will pay for this emergency planning and implementation of the plans?

There will be other economic impacts on the community of Green River and in the surrounding area, such as an increase in the school population and demands for community resources on a long-term and day-to-day basis. The State Engineer must obtain, review, and consider information about all of the economic demands of the proposed reactor on the surrounding communities and consider whether the proposal is economically feasible for those communities.

7. Detriment to public welfare.

Section 73-3-8(1)(a)(iii) also requires that the Application "would not prove detrimental to the public welfare."

KCWCD has submitted no information regarding the impacts of the proposed uranium mill on the welfare of the City of Green River and surrounding communities, the Green and Colorado Rivers, and their environments. A nuclear reactor releases radiological and non-radiological particulates on a routine basis. It will require thousands of gallons of water a day to operate and be prepared for an emergency in an area that has historically been used for grazing, agriculture, and recreation. It will bring in hundreds of workers, which may adversely impact the resources of the community: schools, housing, emergency services, health providers, law enforcement, and social services. There are potential adverse and costly impacts to air quality, ground and surface water, and the health and safety of the workers and the community.

A nuclear reactor is potentially a very hazardous enterprise. A radiological emergency or grave accident could devastate the economy of the area and the land, the resources that the human community relies upon, and the mental and physical health of the who live there — for years to come. Any appropriation of water and proposed use of water that has a clear potential to be detrimental to the public welfare should not be approved without thoroughly identifying all of the potential adverse impacts to the economy, services, environment, and human health and welfare over the complete life of the project.

Until that information has been made available and thoroughly reviewed by the State Engineer, the Application should not be approved.

8. Financial ability to complete proposed works.

8.1. Section 73-3-8(1)(a)(iv) requires a finding that "the applicant has the financial ability to complete the proposed work." There is no information in the Application or that is available to the public elsewhere that demonstrates that Transition Power is financially able to permit, engineer, construct, operate, and decommission the proposed nuclear power generating station, including funds for the required financial assurances.

8.2. Utah Code Ann. § 73-3-11 addresses the question of the financial ability of the applicants. In this instance, it is the financial ability of Transition Power, not KCWCD, that is crucial. Section 73-2-11 states: 73-3-11. Statement of financial ability of applicants.

Before either approving or rejecting an application the state engineer may require such additional information as will enable him properly to guard the public interests, and may require a statement of the following facts: In case of an incorporated company, he may require the submission of the articles of incorporation, the names and places of residence of its directors and officers, and the amount of its authorized and its paid-up capital. If the applicant is not a corporation, he may require a showing as to the names of the persons proposing to make the appropriation and a showing of facts necessary to enable him to determine whether or not they are qualified appropriators and have the financial ability to carry out the proposed work, and whether or not the application has been made in good faith.

Completion of the proposed works should include the construction and operation of the nuclear reactor, not just receipt of an Early Site Permit. It will take millions of dollars just to develop an application to the NRC and the applications to other appropriate local, state, and federal agencies. It will take billions to complete the project. Transition Power is not public utility, is not a publicly traded company, and has no experience in the nuclear power industry, so the State Engineer should require additional information that would enable him to determine whether or not Transition Power has the financial ability to carry out and complete the proposed work and to fulfill its responsibilities to the surrounding communities for emergency planning and the mitigation of adverse impacts on community resources.

8.3. NRC regulations set out general requirements for a combined license application in 10 C.F.R. § 50.33. The requirements include the financial assurance requirements in § 50.33(f): (f) Except for an electric utility applicant for a license to operate a utilization facility of the type described in Sec. 50.21(b) or Sec. 50.22, information sufficient to demonstrate to the Commission the financial qualification of the applicant to carry out, in accordance with regulations in this chapter, the activities for which the permit or license is sought. As applicable, the following should be provided:

(1) If the application is for a construction permit, the applicant shall submit information that demonstrates that the applicant possesses or has reasonable assurance of obtaining the funds necessary to cover estimated construction costs and related fuel cycle costs. The applicant shall submit estimates of the total construction costs of the

facility and related fuel cycle costs, and shall indicate the source(s) of funds to cover these costs.

(2) If the application is for an operating license, the applicant shall submit information that demonstrates the applicant possesses or has reasonable assurance of obtaining the funds necessary to cover estimated operation costs for the period of the license. The applicant shall submit estimates for total annual operating costs for each of the first five years of operation of the facility. The applicant shall also indicate the source(s) of funds to cover these costs. An applicant seeking to renew or extend the term of an operating license for a power reactor need not submit the financial information that is required in an application for an initial license. Applicants to renew or extend the term of an operating license for a nonpower reactor shall include the financial information that is required in an application for an initial license.

(3) If the application is for a combined license under subpart C of part 52 of this chapter, the applicant shall submit the information described in paragraphs (f)(1) and (f)(2) of this section.

(4) Each application for a construction permit, operating license, or combined license submitted by a newly-formed entity organized for the primary purpose of constructing and/or operating a facility must also include information showing:

(i) The legal and financial relationships it has or proposes to have with its stockholders or owners;

(ii) The stockholders' or owners' financial ability to meet any contractual obligation to the entity which they have incurred or proposed to incur; and

(iii) Any other information considered necessary by the Commission to enable it to determine the applicant's financial qualification.

(5) The Commission may request an established entity or newly-formed entity to submit additional or more detailed information respecting its financial arrangements and status of funds if the Commission considers this information appropriate. This may include information regarding a licensee's ability to continue the conduct of the activities authorized by the license and to decommission the facility.

Transition Power is a newly formed entity; Transition Power is not an electric utility. Transition Power has stated that it intends to submit an Early Site Permit and/or a Combined License Application. Therefore, the State Engineer should require the submittal of the same information that the NRC would require of a newly-formed entity that is applying for a Combined License, in accordance with 10 C.F.R. § 50.33(f), (1) through (5), in order to demonstrate the financial qualification to carry out the proposed works.

8.4. Information about Transition Power's financial ability to complete the proposed works must also be made available to any protestors.

9. Speculation.

Section 73-3-8(1)(a)(v) requires a finding that "the application was filed in good faith and not for purposes of speculation."

At this time there is no information that demonstrates that Transition Power has not leased the KCWCD water for purposes of speculation. Transition Power is not an established nuclear industry or utility company, and there is no information to show that Transition Power has retained personnel and contractors who have the expertise to fully carry out the proposed project. Sometimes companies obtain land, leases, rights, permits, and similar resources necessary for a project, and then attempt to sell those resources or join with other, better funded, companies to carry out the proposal. This type of activity is speculative, because the original company cannot carry out the proposed project on its own. Even if Transition Power intends to carry out the project, it will use the water rights to encourage speculative investment in the project. Since Transition Power is not public utility, obtaining the water for a nuclear power plant would be an important stepping-stone in convincing others to invest in this speculative venture or purchase the project's assets from Transition Power.

Section 73-3-11 also addresses the question of good faith and should be considered.

The State Engineer should request the necessary data and information to enable him to determine whether or not the Transition Power is operating in good faith and in not appropriating the water (through a lease agreement with KCWCD) for purposes of speculation.

10. Effect on public recreation.

The Green River and the Colorado River are used extensively for commercial and non-commercial recreation. Recreation on land and water is an important part of the economies of Emery and Grand Counties (Utah) and Mesa County (Colorado)—the counties that would be most impacted by a nuclear reactor in Green River. A reactor would adversely impact public recreation, for example, by:

- Discouraging visitation to the area,
- Need for commercial companies to have emergency response plans so that they can care for clients during an emergency,
- Lowering water levels in the river,
- Water intake structures in the Green River creating a boating hazard,
- Competition with public accommodations, or
- Having a radiological emergency that requires sequestration or evacuation and impacts transportation.

Since there is no information in the Application about the effects on public recreation, the State Engineer must seek and consider information about the potential impacts a nuclear reactor would have on public recreation both in Green River area and on the Colorado River downstream. The inquiry should include obtaining information about

intake structures that Transition Power intends to place in the Green River to bring the water from the river to the shore and evaluating how the intake structures would impact the recreational boating on the river.

11. Effect on natural stream environment.

The State Engineer must identify and evaluate the impacts of the withdrawal of water over the lifetime of the reactor. As discussed above at 3.2, that would be for at least the next 120 years. The State Engineer must consider the impacts of the intake structures and the withdrawal of water during a drought situation. The State Engineer must consider the impacts to the biota in the river, birds and other wildlife, the deposition of sand and sediments, and other aspects of the natural stream environment.

This evaluation must also address the impacts during normal operation of the nuclear power reactor, as the result of a minor to serious accidents, and as the result of a catastrophic accident. 12. Time of use.

12.1. Section 73-3-8(2)(a) requires that the period of time for the use of the requested water cannot be "for a period of time less than that ordinarily needed to satisfy the essential and primary purpose of the application." In this instance, KCWCD has not indicated the amount of time the appropriated water would be used from the Green River for the proposed project. There is no information regarding the expected life of proposed nuclear power plant, through complete decommissioning and removal of all radioactive waste — when water will not longer be needed. A nuclear reactor requires a continual supply of cooling water for safety-related structures, systems, and components. Water is needed to maintain the reactor is a safe operating, emergency, and decommissioning environment, so any reduction in the amount of available water would have serious health and safety implications. If the available water for the power plant decreases, for any reason whatever, the plant cannot just be shut down to stop water usage. It is not like a ranch, where the rancher can choose not to plant that year because there is not enough water. Once a nuclear power plant starts operating, water for safety related operational, shutdown, and decommissioning components will be required. The water will have to come from somewhere. Unfortunately, there is no information on the amount of water required during various permitting, design and construction, operational, and shutdown scenarios and various time frames.

The State Engineer must ascertain how long the Applicant has requested the water and how long the water will be needed by Transition Power over all phases of the nuclear power generating station, using the most conservative estimate. Without such information, the State Engineer should not approve the change. The State Engineer should deny the Application if the time for the use of the requested water is less than that needed to satisfy the purposes of the appropriation.

12.2. The Water Rights Lease Agreement (Attachment A) between KCWCD and Transition Power is 40 years from the "EPC" Approval Date. According to the Lease, the EPC (engineering, procurement, and construction) is when "the performance warranty from the construction company has been accepted, in writing, by the owning and

operating entities, and the power site facilities have been scheduled for commercial operation.

If the power plant operates for 40 years, there will still be the need for water during shutdown and decommissioning. Therefore, the Water Rights Lease Agreement does not cover the full life of the facility.

Information is needed regarding all of the water needs for the power plant over time in order to justify the Lease Agreement term. If the Lease term does not allow for all the water uses for the full life of the facility, then the Application must be denied.

12.3. As discussed above at 3.4, the State Engineer must also determine the length of time the water would be appropriated, but not used, for the proposed project. The State Engineer should take into consideration the amount of time that the water will not be put to use once appropriated, due to the lengthy permitting processes; because Transition Power applies for and receives an Early Site Permit; time for contracting, engineering, procurement, and construction; or other reasons. The State Engineer needs to know when Transition Power expects the construction work to be completed and when they would apply the water to beneficial use, in order to provide those dates in any approval order, as required by Utah Code Ann. 73-3-10(5).

13. Application to the NRC, Safety Evaluation Report, and Environmental Impact Statement.

The State Engineer should not approve the Application until information that would be provided in an Early Site Permit of Combined License Application, the Safety Evaluation Report (SER), and the Environmental Impact Statement (EIS) are available.

It would be premature for the State Engineer to approve the Application until the relevant technical and environmental information has been made available and the NRC develops an SER and EIS that will thoroughly evaluate all of the relevant technical issues and environmental impacts related to an Early Site Permit or a Combined License. There are a number of impacted individuals, groups, organizations, and local, state, tribal, and federal entities that will have a chance to participate in the EIS process and explore all of the relevant impacts to public recreation, the natural stream environment, and the public welfare that no protestor or the State Engineer alone would be able to do.

14. Extension of time to show proof of beneficial use proceeding.

On September 25, 2008, KCWCD applied for an extension of time to show proof of beneficial use of the water rights that are the subject of the change application, at issue herein. Living Rivers and Uranium Watch were parties to a timely submittal of a protest and request for hearing regarding that extension request, submitted to the State Engineer on November 4, 2008.

The State Engineer should clarify the relationship between the hearing on the extension of time and any hearing on the change application. 15. Supplement to protest.

Protestors reserve the right to supplement this protest in writing or at the hearing as additional information becomes available.

16. CONCLUSION

16.1. The State Engineer must obtain all of the necessary information that would enable him to fully address all of approval criteria set forth in Utah Code Ann. §§ 73-3-8(1), 73-3-8(2), and 73-3-11.

16.2. The State Engineer must make that information available to protestors in a timely manner so that protestors will have an opportunity to review and respond to the new information that is submitted.

16.3. Based on the information that is currently available in the Application, the State Engineer must reject the Application, because the Application does not meet the requirements of Utah Code Ann. 73-3-8.

Respectfully submitted, this 26th day of May 2009,

John Weisheit

Congressional Testimony 05/28/09

Problems with Colo. River water could trickle down to Tucsonans

By Tony Davis
ARIZONA DAILY STAR
Tucson, Arizona | Published: 05.28.2009
<http://www.azstarnet.com/allheadlines/294755>

[Congressional hearing documents](#)

For many years, many local officials and others with water expertise have seen the Colorado River as a regional plumbing system, providing water to thirsty cities, farms and Indian tribes.

But at a congressional subcommittee hearing Wednesday in Tucson, speakers from a host of government agencies agreed that it's time to give equal weight to water-quality issues plaguing or threatening the Colorado River, such as sewage discharges, pharmaceuticals, invasive mussels, uranium, salinity and a rocket-based jet fuel known as perchlorate.

The bottom line is that if more attention isn't paid to these problems soon, they could filter from the Colorado River down to Tucson, which lies at the end of the 330-mile Central Arizona Project canal-pipeline system, said the subcommittee chairman and the head of one of the agencies.

The speakers said more federal attention is needed for these problems. The solution is not just more money, but a big-picture approach that looks at the problems as a whole rather than separately, they said. The Lower Colorado needs a massive, regional approach like those now being applied to cleaning up or restoring other major ecosystems such as Puget Sound, the Everglades and the San Francisco Bay, speakers said.

After the hearing, Rep. Raúl Grijalva, a Tucson Democrat and a subcommittee member, said he plans to introduce some kind of comprehensive legislation to try to address these problems after two more congressional field hearings are held on them.

"Water quantity and water quality are totally linked," said one of the speakers, CAP chief David Modeer, immediately after the hearing of the House Subcommittee on Water and Power held at the Pima County Board of Supervisors hearing room Downtown.

Solving these water-quality problems is directly linked to the future economy, tourism and quality of life for the Southwest, said Rep. Grace Napolitano, a Southern California Democrat who chairs the subcommittee. "If they don't do anything about these problems, their children may be forced into some serious, hard choices in the future," Napolitano said.

These quality problems will be aggravated by climate change and megadroughts and, paradoxically, more intense rainfall and flooding, a prominent University of Arizona climate scientist told the subcommittee. In part, that's because there will be less water to dilute the pollution. And because the more intense storms and floods will wash more sediment and other polluting or potentially polluting materials from mines and other sources into the river, testified Prof. Jonathan Overpeck, co-director of UA's Institute of the Environment.

Today, threats from pollution put at risk a \$400 million farming economy of the four Colorado River Indian tribes who irrigate 100,000 acres of crops from the Lower Colorado River, testified Eldred Enas, a tribal chairman.

Overall, the river serves an estimated 24 million people in seven Western states with water and makes up 40 percent of Arizona's water supply, testified Herb Guenther, Arizona's water resources director.

Contact reporter Tony Davis at 806-7746 or verdin@azstarnet.com

DETAILS OF SOME OF THE PROBLEMS DISCUSSED AT THE HEARING

SEPTIC DISCHARGES Nitrate-laden wastes from septic plants in communities along the river such as Lake Havasu and Bullhead cities are slowly seeping underground toward the river. The communities have gone heavily into debt to build sewage plants to properly treat the wastes, but they can't afford the \$2.1 billion tab alone, Lake Havasu City Mayor Mark Nexsen told the subcommittee.

QUAGGA MUSSELS The invasive mussels, which can clog water-pipeline intake valves and disrupt a lake's delicate ecology, were discovered in Lake Havasu in early 2007. A

year later, their numbers had grown to more than 40,000 per square yard. The mussels have already reached Lake Pleasant, a CAP storage reservoir northwest of Phoenix.

URANIUM Uranium-mining claims have increased significantly across the West, including areas near Grand Canyon National Park. Grijalva and other congressmen have tried to block uranium leasing and exploration in and around the park but have been unsuccessful. In testimony, Roger Patterson, a top Metropolitan Water District of Southern California official, said that while the district doesn't want uranium mining totally stopped, "it needs to be done safely for the river's sake. If it can't be done safely, don't expand it."

PHARMACEUTICALS Concentrations of various kinds of what's known as "emerging contaminants," including antibiotics, anti-epileptics, anti-coagulants, insecticides, insect repellents and other compounds, have been found in levels in the parts-per-trillion range in Lakes Havasu and Mead. The health effects of the compounds at those levels are unknown but being researched.

PERCHLORATE Cleanup efforts at a rocket fuel plant in Henderson, Nev., that started in 1999 have dramatically reduced levels of the toxic compound entering the Colorado to the point where the concentrations entering local water systems have dropped below drinking water standards. But in January, the company now running the facility — Tronox — filed for Chapter 11 bankruptcy protection, calling into question the cleanup's future.

###

Degraded Lower Colorado River Needs Federal Help to Recover

TUCSON, Arizona, June 4, 2009 (ENS)

<http://www.ens-newswire.com/ens/jun2009/2009-06-03-095.asp>

Protection of Lower Colorado River water quality needs comprehensive legislation and adequate funding for a major effort like programs underway in the Chesapeake Bay and the Great Lakes, local officials told a hearing held by the House Natural Resources Subcommittee on Water and Power in Tucson on May 27.

The Colorado River is the major water resource in the arid southwestern United States. It is the source of drinking water for 25 million people throughout southern California, southern Nevada, Arizona, and Mexico. The river provides irrigation water for almost two million acres, fish and wildlife habitat and water-based recreation for millions of people.

Calling for a comprehensive approach to surface water protection, Lake Havasu City Mayor Mark Nexsen testified on behalf of the 56,000 Havasu residents and the 42,000 people living in Bullhead City. He also spoke as chairman of the regional Colorado River Regional Sewer Coalition, which serves area tribes, cities and towns, including Tucson.

Nexsen called for comprehensive legislation and adequate funding to address all the threats to the Colorado River with a coordinated council of relevant agencies, "similar to clean up efforts in the Chesapeake Bay and the Great Lakes Region."

"Tens of millions of dollars of federal, state, regional and local government money are being spent to protect endangered species through the Lower Colorado Multi-Species Conservation Program, yet virtually no federal money has been expended to help mitigate water quality issues," Nexsen said.

The largest water quality federal program, the Clean Water State Revolving Fund, provides low cost loans to fund water quality protection projects for wastewater treatment, nonpoint source pollution control, and watershed and estuary management in place to assist communities with infrastructure.

But, Nexsen told the subcommittee, "it has been well documented that the funding for this program over the years has not been sufficient to meet our nation's clean water needs."

Threats to water quality on the Lower Colorado include a Pacific Gas & Electric compressor station site on the California side of the river at Topock that emits a plume of hexavalent chromium that is now only 60 feet from the river.

The threat of Uranium tailings from mines near Moab, Utah is of great concern, said Nexsen. The tailings pile is built in the center of an alluvial fan, which is vulnerable to possible failure during a large flood.

Pharmaceuticals in the Colorado River are a growing concern, the mayor said. Tests performed by Lake Havasu City have discovered detectable levels of pharmaceuticals in the river and in the local ground water.

The most recent threat to the Colorado River is the alien invasive quagga mussel, discovered there in early 2007. These mussels have become established in the Colorado River from Lake Mead downstream. Over 40,000 quagga mussels per square meter have been reported in Lake Havasu and Lake Mohave one year after their discovery.

Water agencies are now spending tens of millions of dollars annually to remove quagga mussels from intake pipes and other water distribution equipment, said Nexsen.

"The quagga mussel not only threatens the water supply for millions of Americans but also, along with the other aforementioned threats to the River, imperils the economic existence of cities such as Lake Havasu City and Bullhead City that depend on tourism from boaters that enjoy the River," he said.

Research indicates a relationship between the mussels' feeding habits and nutrient loading such as nitrates and phosphates from septic tanks.

Soaring sewer costs led Mayor Nexsen to tell the subcommittee, "The citizens of Lake Havasu City in a valiant effort to deal with nitrates are now, quite frankly, in an emergency situation."

With a large proportion of the population retired or on a fixed income and the average wage at \$12 per hour, the mayor said, Placing the financial burden to protect the River alone by Lake Havasu City and Bullhead City residents is unacceptable."

The river cannot be protected by local governments alone, he said, citing a March 2007 wastewater improvements report from the federal Bureau of Reclamation that documented the cost of remediation at roughly \$2.1 billion through the year 2025.

Lorri Lee, regional director for the Bureau of Reclamation Lower Colorado Region, confirmed to the subcommittee that septic systems appear to be adversely impacting groundwater quality along the Colorado River.

To meet federal and state water discharge standards, she said, communities along the river are being required to construct costly municipal wastewater systems.

The total population of the 24 communities along the Colorado River is projected to increase from 290,000 to 480,000 by 2025 according to State of Arizona projections, said Lee.

"A total of over 1,400 miles of wastewater pipelines and 26 million gallons per day of wastewater treatment capacity may be needed," she said.

Alexis Strauss, Water Division director with the U.S. EPA Region 9, told the subcommittee that under Clean Water Act Section 319, the nonpoint source program, states receive EPA funding to develop watershed-based plans and support local projects to address nonpoint source pollution.

"A Watershed Plan for the Lower Colorado River is under development by the state of Arizona Department of Environmental Quality," Strauss said. "This plan, which we expect to be drafted within the next year, will identify the causes and sources of pollution to the lower Colorado, management measures to address pollution sources and the pollutant load reductions expected as a result."

Strauss said the 2010 President's Budget requests \$2.4 billion for the Clean Water State Revolving Fund, an increase of over \$1.5 billion from 2009 levels. If passed by Congress, the 2010 budget will increase Arizona's share of Clean Water SRF monies, making more low-cost financing available to municipalities' most critical wastewater needs.

An additional \$26.4 million has come to Arizona under the American Reinvestment and Recovery Act for State Revolving Fund programs, plus another \$55.3 for the drinking water SRF program, Strauss said.

Lake Havasu City applied for \$5 million for its Wastewater Sewer Expansion project, she said, "and we expect them to receive this funding later this year, partly as a grant and partly as a low interest loan."

Judge: Dam power releases invalid

By CYNDY COLE Sun Staff Reporter Thursday, May 28, 2009

A federal judge has delivered a notable legal victory to the Flagstaff-based Grand Canyon Trust and Earthjustice in a yearslong dispute over how best to manage the Colorado River below Glen Canyon Dam.

If upheld, the ruling could lead to conditions on the Colorado that more closely follow seasonal snowmelt and summer dryness -- and reduce electricity generation in seasons when it is currently most demanded. At present, releases from the dam increase and decrease, within some limits, based on how much electricity is needed by customers in the Southwest.

The agency charged with telling the Interior Department how to operate Glen Canyon Dam to promote the recovery of endangered fish species in the Colorado last year reversed its longstanding recommendations with little explanation, the judge found.

Now the U.S. Fish and Wildlife Service must explain by October how it concluded in 2008 that more than a decade of research establishing dam operations were eroding beaches and harming habitat was wrong.

Just one year earlier, the same agency had concluded that the science showed current dam operations were harmful to beaches and ecosystems downstream. It had said since the mid-1990s that operating the dam to mimic natural seasons was best for endangered fish.

Federal lawyers were unable to prove otherwise in oral arguments, the judge wrote.

"...an agency cannot entirely fail to consider an important aspect of a problem, nor can it offer an explanation for its decision that runs counter to the evidence before it," U.S. District Judge in Arizona David Campbell wrote in a ruling issued Tuesday.

The Grand Canyon Trust has argued that the politics of keeping one's job under the Bush Administration forced Fish and Wildlife personnel to reconsider their long-held scientific advice on the Colorado River last year.

Ultimately, it is up to the Interior Secretary to set operations at Glen Canyon Dam.

The Trust is calling recent management decisions a waste of more than \$100 million in taxpayer-funded research over more than a decade on the Colorado River through Grand Canyon.

"The Bureau of Reclamation has done a very good job in misleading the public about what they're doing at Glen Canyon Dam," said Nikolai Lash, of the Grand Canyon Trust. "... They have been aware of science over and over saying things need to change at Glen Canyon Dam, and they have ignored that science."

Glen Canyon Dam generated enough power in 2008 to supply more than 300,000 homes.

The changes the Trust is proposing would cost one-third of the ratepayers about a nickel per month, and two-thirds of them nothing, Lash said.

PROTECTION FOR HUMPBACK CHUB

The Grand Canyon Trust filed the lawsuit against the Bureau of Reclamation in 2007, arguing that federal agencies weren't doing all they were legally obligated to do to restore a federally-listed endangered fish, the humpback chub.

The chub is a fish originating in the Colorado River 3 million to 5 million years ago. It lives in six spots on the Colorado River, with one downstream of Glen Canyon Dam near the Little Colorado River.

The fish's population has fluctuated from an estimated 2,400 to 4,400 fish in 2001 to an estimated 7,650 last year, with multiple factors possibly contributing to the rise, including a trout removal project and warmer river temperatures.

Its populations were estimated at 10,000 to 11,000 in 1989, according to the ruling and U.S. Geological Survey science.

Disputes over how best to manage Glen Canyon Dam began with construction of the dam.

From 1963 to 1991, the dam was operated for maximum power generation, with daily fluctuations that resulted in river levels that sometimes rose and fell 13 feet in a day.

In 1996, Interior Secretary Bruce Babbitt set limits on how much releases from the dam could fluctuate in a day, and those limits are in place most of the time today.

In 1994, the U.S. Fish and Wildlife Service recommended releases from the dam change with the seasons. That would lead to a spring flood and smaller flows in summer.

While the Bureau of Reclamation did implement many other recommendations intended to improve life for the humpback chub, it did not change dam operations as prescribed.

One question, wrote Judge Campbell, is whether changing dam operations to make the river calmer in summer and wilder in winter could also make it more hospitable to non-native fish that prey on the chub.

Another is whether any solution will work, given that 84 percent of the sediment that once flowed into the Grand Canyon is now trapped behind the dam.

A Fish and Wildlife spokeswoman said the agency was reviewing the case and would respond to the judge's questions.

Cyndy Cole can be reached at 913-8607 or at ccole@azdailysun.com.

LR Press Release 05/28/09

Groups Protest Use of Water from Green River for Nuclear Power

FOR IMMEDIATE RELEASE

May 28, 2009

Contacts: Sarah Fields - 435-210-0166; sarah@uraniumwatch.org
John Weisheit - Cell: 435-260-2590; john@livingrivers.org

Moab, Utah — Living Rivers, Uranium Watch, and the Glen Canyon Group of the Sierra Club filed a joint protest and request for a hearing on the application by the Kane County Water Conservancy District (KCWCD) to provide water for a proposed nuclear power plant near Green River, Utah. The protest was submitted to the State Engineer, Division of Water Rights, on May 26. KCWCD requested a change the point of withdrawal of 29,600 acre feet (over 2.5 million gallons per day) from the Colorado River to the Green River so that Transition Power Development LLC (Transition Power) would have some of the water they need for the 2-unit nuclear reactor, called the Blue Castle Generation Project.

Transition Power proposes to site the reactor on land about three (3) miles west of the City of Green River in Emery County. The site is part of an industrial development park on land that Emery County has leased from the Utah School and Institutional Trust Lands Administration. The KCWCD leased the water to in 2007. In addition to the water from the KCWCD, Transition Power has leased 24,000 acre-feet of water from San Juan County Water Conservancy District. There is no information about the reactor design, costs, or where the electricity will be sent.

The joint protestors are concerned that the application does not provide any information responsive to the criteria that the State Engineer must consider. These include the feasibility of the project, availability of water, ability of Transition Power to finance the project, and environmental impacts of the withdrawal of the water and the nuclear facility.

"The Conservancy District and Transition Power can no longer withhold information about the proposed reactor and the viability of such a hazardous project so close to a major tributary of the Colorado River, major transportation corridors, and the center of a recreational and agricultural economy," said Sarah Fields of Uranium Watch.

"The State Engineer must evaluate how this proposed water withdrawal in a time period of severe water shortages would likely contribute harm toward preexisting water users in the State of Utah," according to John Weisheit, Living Rivers' Conservation Director.

Critics say N-plant would harm ecosystem

By Amy Joi O'Donoghue

Deseret News

Published: Wednesday, May 27, 2009 10:38 p.m. MDT

Critics of a proposal to divert nearly 30,000 acre feet of water from the Green River for use at Utah's first nuclear-power plant say it would threaten already endangered fish and rare plants.

The protest by the Center for Biological Diversity, filed with the Utah State Engineer's Office, raises concerns over the Kane County Water Conservancy District's application to change the nature of the water's use and its diversion point.

Specifically, the center questions "how the water diversion will be consistent with the need to protect river flows and habitat conditions critical for the survival of imperiled plants and animals in the vicinity of the power plant's footprint, including endangered fish," according to a news release from the group.

The Las-Vegas based organization joins other conservation and environmental groups like Living Rivers, Moab Local Green Party, Red Rock Watch and Uranium Watch, in addition to Healthy Environment Alliance (HEAL) of Utah, in protesting the water's diversion.

A total of 239 protests were filed, said state engineer Kent Jones. Of those, 195 came as part of a combined protest from HEAL Utah.

Headed by Rep. Mike Noel, R-Kanab, the district made an application to divert 29,600 acre feet of water to lease to Transition Power Development, which wants to build a two-unit nuclear-power reactor, named the Blue Castle Generation Project.

Transition's chief executive officer is former Utah Rep. Aaron Tilton. Earlier this year, Transition contacted the federal Nuclear Regulatory Commission to convey the company's intent to submit an application for an early site permit of two nuclear units by April 2010.

Transition is proposing to site the reactor three miles west of Green River city in Emery County.

Protests over the water diversion — which were due Tuesday — raise a variety of issues in general.

"There are major health and safety and environmental issues associated with the construction and operation of a nuclear-power station next to a major Union Pacific passenger and freight line, an interstate highway (I-70), the town of Green River and the Green River (a major tributary of the Colorado River)," according to Uranium Watch.

The site is part of an industrial-development park on land that Emery County has leased from the Utah School and Institutional Trust Lands Administration.

Earlier this year, an escrow agreement was inked to put in motion the development of a uranium mill at the site. There will likely be a formal hearing this fall, in which parties on both sides of the issue can speak publicly.

Proposed water transfer for Green River nuclear plan draws protests

by Craig Bigler
contributing writer
06.11.09 - 01:04 pm

A number of state, federal and local agencies and environmental organizations and individuals will have a seat at the table when the State Engineer conducts meetings on Kane County's application to transfer 29,600 acre feet of water for use by a nuclear power plant near Green River. But the Grand County Council will not, because council members chose last month not to submit a protest letter.

The Center for Biological Diversity, the Uintah County Water District, U.S. Fish and Wildlife Service, the Bureau of Reclamation, several farmers and outfitters, Living Rivers, the Green Party, Ruby Ranch, and several dozens of others, including many individuals have formally submitted letters protesting the water transfer.

Directed by state representative Mike Noel, the Kane County Water District has applied to transfer water rights originally slated for the (now defunct) Kaiparowits power plant in the 1960s. According to Grand County Council member Pat Holyoak, that water right must be transferred to a use, or it will be lost.

Heal Utah submitted 76 pages of postcards the group solicited, along with a detailed analysis of the application's shortcomings.

"I think if we're going to act as a board for the environmental group, this council is strongly in the wrong position," Grand County Council member Gene Ciarus said when the council considered the matter. Ciarus opposed submitting the protest letter because, he said, it is not appropriate for the council to get involved with the economic interests of another county. He also said water shareowners have the right to sell their shares.

"By protesting we get a place at the table," Scott Ruppe, director of the Uintah County Water District said. "It looks to me like Kane County is selling [the water right] for profit. Our biggest concern is we want to know how this will affect our water rights." Ruppe said his agency is also worried about reduced stream flows and negative effects on fish.

The Fish and Wildlife Service's protest raises the issue of three sensitive fish species – roundtail chub, bluehead sucker, and flannelmouth sucker – currently being protected under a joint plan including several federal and state agencies.

The depletion of the Green River would degrade river habitat and could result in the three species being listed under the Endangered Species Act, agency argued. Such a listing could restrict future development, including agriculture, along the river, according to Jana Mohrman of FWS's Mountain-Prairie Region office.

"We felt we were doing a public service by pointing out the possible impacts in the future should the three species be listed," Mohrman said.

The Bureau of Reclamation, in its protest, noted that Central Utah Project water rights are junior to the rights in question. But current water users "who depend on and have committed billions of dollars to develop" the CUP could lose out if they lose their water to the nuclear plant. "We ask that the next extension of time [for the application] reduce the priority of this water right to make it junior to the CUP water rights," Bureau Area Director Bruce Barrett wrote in his protest.

The nuclear power plant proposed by former state representative Aaron Tilton, may or may not actually happen in Green River's industrial park. Or the water could be used for something else.

Living Rivers objects to such speculation because it violates the state engineer's regulations against speculative transfers of water rights.

Nearly all protesters raised health and safety issues for nearby communities and major recreation areas.

Attempts to assess attitudes about a potential nuclear plant from the Moab Area Chamber of Commerce were unsuccessful. President Phil Mueller discussed it with members and the board and found such a diversity of opinion that "the board hesitates to take a position," he said.

Calls to Noel, Green River Mayor Pat Brady, and Kane County Commissioner Mark Habbeshaw were not returned.

The state engineer's office has confirmed that a public hearing will be held, possibly in August or September.

The protests, or at least the first pages of them, can be viewed at the state engineer website at waterrights.utah.gov. Click on "water rights", then "queries." Type in water right number 89-74, then under "select related information" click on "scanned documents."

Lake Mead level trigger for Las Vegas pipeline project

By HENRY BREAN
LAS VEGAS REVIEW-JOURNAL

Opponents of a proposed pipeline to tap groundwater across eastern Nevada now have one more way to fight the project: Pray for the drought to end on the Colorado River.

For the first time, the Southern Nevada Water Authority has established a direct link between its multibillion-dollar pipeline project and the shrinking water level at Lake Mead.

Actually it's more than a link; it's a trigger.

If Lake Mead's elevation falls another 23 feet, the water authority board will be asked to give the official go-ahead to construct the pipeline.

The lake trigger is the newest addition to the authority's Water Resource Plan, which plots how the valley's wholesale water supplier expects to keep local taps running amid unprecedented drought on the Colorado.

Board members have already approved the pipeline concept and signed off on ongoing efforts to secure water rights and environmental permits, but they have never actually voted to build the project.

That decision will come if, or perhaps when, the surface of Lake Mead sinks to elevation 1,075, a low-water mark not seen since 1937 when the reservoir was being filled for the first time.

Water authority General Manager Pat Mulroy doesn't know when the trigger point might be reached.

Current projections by the U.S. Bureau of Reclamation call for Lake Mead to remain above 1,075 for the next two years at least. The closest it is expected to come is in July, when the reservoir is projected to slip below elevation 1,092 for the first time since March 1965.

The problem, Mulroy said, is that bureau projections are based on average flow, and the Colorado has been anything but average over the past 10 years.

Between 1999 and 2008, the river has seen about 66 percent of its normal inflow, most of which comes from melting snow in the Rocky Mountains. Over that same period, lakes Mead and Powell, the two largest man-made reservoirs in the United States, lost about half their total volume.

Elevation 1,075 could arrive quickly if the drought deepens, Mulroy warned. "It could be next year."

The trigger point was set at 1,075 to give the agency enough time to reach its closest groundwater holdings in rural Nevada, Mulroy said.

If the lake level falls to 1,050 feet above sea level, the authority will be forced to shut down one of the two intakes it uses to draw about 90 percent of the valley's drinking water from the reservoir.

The surface of Lake Mead now stands about 1,098 feet above sea level. The last time it was that low was April 1965, when much of the Colorado River's flow was being withheld upstream to fill Lake Powell for the first time.

Mulroy said it will take about three years to build a pipeline from Las Vegas to Delamar and Dry Lake valleys, the first two Lincoln County basins from which groundwater will be drawn.

From there, the pipeline is expected to push into Cave Valley in Lincoln County and Spring Valley in White Pine County.

The authority also has applied for permits in Snake Valley that would allow it to pump more than 16 billion gallons of groundwater a year, enough to serve about 100,000 average Las Vegas homes. A state hearing on those applications is tentatively set for September 2011.

The groundwater project is expected to take 10 to 15 years to build, Mulroy said.

When it is done, the network of pipes, pumps and reservoirs is expected to stretch about 300 miles north and cost between \$2 billion and \$3.5 billion, according to authority cost estimates now several years old.

Opponents of the project expect the scheme to cost billions of dollars more and deliver less water than the authority expects. Some fear that large-scale groundwater pumping in the arid valleys of eastern Nevada would threaten wildlife and the livelihoods of ranchers and farmers.

The authority's 2009 Water Resource Plan, which the board adopted on May 21, calls for Las Vegas to eventually tap 134,000 acre-feet of groundwater a year from eastern Nevada.

The plan calls for that water -- enough for almost 270,000 homes -- to be put to use by 2020, though it "may be needed sooner if drought conditions persist or intensify," the document states.

Critics argue that the drought is used as a smokescreen for the pipeline's real purpose: to fuel unfettered development in Southern Nevada.

Bob Fulkerson is executive director of the Progressive Leadership Alliance of Nevada, an advocacy group that has come out against the groundwater development project. He said the new trigger point seems "arbitrary" and a little suspicious to him.

"It could be just a Trojan Horse to allow more unrestrained growth in Las Vegas," Fulkerson said.

"If there's going to be a trigger, why not a trigger for curbing irresponsible water waste and growth?"

Of course, authority board members could always vote not to build the pipeline when the time comes.

Mulroy said the board's decision will come down to a question of risk, as in can the community risk losing access to some of its Lake Mead supply before the pipeline goes on line.

Elevation 1,075 is significant for another reason. It is the legal threshold for a shortage on the Colorado River, a federal designation that would force Nevada and Arizona to reduce the amount of water they pull from the river.

Nevada's share of such a shortage would be 13,000 acre-feet a year, roughly the amount used by 26,000 average households. Arizona would be shorted more than 10 times that amount.

Water authority officials long have said the pipeline is not about sustaining growth, but protecting the community from extended drought on the Colorado River.

In that respect, the new trigger point seems like good news for even the pipeline's staunchest opponents. It means the project might never be built so long as the river rebounds and Lake Mead remains above 1,075.

Mulroy isn't optimistic about that. As chief of the agency charged with keeping water flowing to Las Vegas, she gets paid to plan with pessimism.

"If we can avoid building it, we won't build it," Mulroy said of the pipeline. "But we haven't had a lot of luck on the Colorado River lately."

UNLV prof to Congress: Mining contaminates Colorado River

Las Vegas Sun

By Mary Manning

Tuesday, July 21, 2009 | 4:13 p.m.

<http://www.lasvegassun.com/news/2009/jul/21/unlv-professor-congress-uranium-mining-contaminate/>

Restarting uranium mining near the Grand Canyon poses a contamination risk to the Colorado River, serving more than 25 million people in western states, a UNLV hydrology professor told a congressional committee today.

David Kreamer, a UNLV professor, said that assuming renewed uranium mining would have little or no effect on the river and surrounding springs is "unreasonable" and cannot be supported by past investigations and research.

Kreamer and his students have been conducting studies on springs in the Grand Canyon for 25 years and he told the House Natural Resources Committee's parks subcommittee that past mining activities have polluted a spring that feeds the Colorado River and that pollution is expected to continue if more mining occurs.

The committee is hearing a bill by Rep. Raul Grijalva, D-Ariz., that would permanently bar new claims filed on 1.1 million acres of federal lands north and south of the canyon. Renewed interest in building nuclear power plants as alternative energy sources has spurred a surge in uranium mining claims in the area, Grijalva said.

As many as 10,000 mining claims exist on neighboring federal lands for all hard-rock exploration and some 1,100 uranium mining claims exist within five miles of the canyon.

Neither the proposed bill nor Interior Secretary Ken Salazar's announcement Monday that he is barring new claims on public lands for two years while a study is conducted would stop mining on existing claims.

Kreamer said his research found uranium levels three times above the Environmental Protection Agency's recommended limit on water supplies in Horn Creek, a canyon creek that runs into the Colorado. He said that the uranium polluted the creek's water from mining that stopped more than 10 years ago.

The potential for uranium reaching the Colorado River poses a risk for water consumers in California, Nevada and Arizona, said Kay Brothers, deputy general manager of the Southern Nevada Water Authority. Las Vegas draws 90 percent of its water from the Colorado River, she said.

Two scientists said modern mining has improved environmental protection and new mining development shouldn't stop because of old practices.

Most of the uranium claims have been staked in the Arizona Strip, an area just north of the Grand Canyon National Park notable for its superior uranium ore.

Uranium mining stopped 20 years ago as the price of uranium for nuclear energy, weapons and medicine went into freefall. The nuclear industry believes mining should be restarted as the price of uranium has climbed to about \$55 a pound.

The Associated Press contributed to this report.

Western Reservoirs Could Be Dry By 2050 (one-in-two chance)

Note (as of April, 2026): hydropower at Glen Canyon Dam will cease in December of 2026.

By LiveScience Staff

<http://www.livescience.com/environment/090720-colorado-river-dryup.html>

There's a one-in-two chance that the water reservoirs of the Colorado River will dry up by 2050 if water management practices remain unchanged in our warming world, a new study finds.

Roughly 30 million people — including many in Arizona and Southern California — depend on the Colorado River for drinking and irrigation water.

The Colorado River system is enduring its 10th year of drought, with the reservoir system currently at 59 percent of capacity, about the same as this time last year.

Previous studies have warned of the potential for water shortages with the drier conditions in the West brought about by climate change. The region's growing population has also put pressure on the water supplies of the desert West.

The researchers, including Balaji Rajagopalan of the University of Colorado in Boulder, examined the effects of a range of reductions to the water flowing through the Colorado River and held in local reservoirs, as well as how different water management strategies might affect those water levels.

Rajagopalan and his colleagues found that even under the harshest drying caused by climate change, the large storage capacity of reservoirs on the Colorado might help sustain water supply for a few decades, but only if new management practices are enacted.

"This study, along with others that predict future flow reductions in the Colorado River Basin, suggests that water managers should begin to re-think current water management practices during the next few years, before the more serious effects of climate change appear," Rajagopalan said.

Specifically, the researchers found that through 2026, the risk of fully depleting reservoir storage in any given year remains below 10 percent under any scenario of climate fluctuation or management alternative. During this period, the reservoir storage could even recover from its current low level, according to the researchers.

Part of this is due to the enormous capacity of the reservoirs: The river hosts more than a dozen dams along its 1,450-mile journey from Colorado's Rocky Mountains to the Gulf of California. Total storage capacity of reservoirs on the Colorado exceeds 60 million acre feet, almost four times the average annual flow on the river; and the two largest reservoirs — Lake Mead and Lake Powell — can store up to 50 million acre feet of water.

But if climate change results in a 10 percent reduction in the Colorado River's average stream flow as some recent studies predict, the chances of fully depleting reservoir storage will exceed 25 percent by 2057, the study found. If climate change results in a 20 percent flow reduction, the chances of fully depleting reservoir storage will exceed one in two by 2057, Rajagopalan said.

"On average, drying caused by climate change would increase the risk of fully depleting reservoir storage by nearly ten times more than the risk we expect from population pressures alone," Rajagopalan said. "By mid-century this risk translates into a 50 percent chance in any given year of empty reservoirs, an enormous risk and huge water management challenge."

Implementing more aggressive management practices — in which downstream releases are reduced during periods of reservoir shortages — could reduce the risk of depleting all reservoir storage during this period, the study suggests.

The magnitude of the risk will ultimately depend on the extent of climate drying and on the types of water management and conservation strategies established.

"Water conservation and relatively small pre-planned delivery shortages tied to declining reservoir levels can play a big part in reducing our risk," said study co-author Ken Nowak, a graduate student at CU-Boulder.

"The important thing is not to get lulled into a sense of safety or security with the near-term resiliency of the Colorado River basin water supply. If we do, we're in for a rude awakening," he added.

The study, which will be detailed in an upcoming issue of the journal Water Resources Research, was conducted with support from the Western Water Assessment, a joint venture of CU-Boulder and the National Oceanic and Atmospheric Administration (NOAA), as well as CADSWES and the Bureau of Reclamation.

Appeals Court Rejects Suit Against Motorized Rafts in Grand Canyon

By NOELLE STRAUB of Greenwire

<http://www.nytimes.com/gwire/2009/07/22/22greenwire-appeals-court-rejects-suit-against-motorized-r-20848.html>

A federal appeals court yesterday upheld a decision rejecting attempts by environmental groups to stop rafters from using motors and helicopters in Grand Canyon National Park.

Four conservation groups had argued that the use of motorized rafts on the Colorado River and helicopters to make passenger exchanges impairs the wilderness character of the park and that the National Park Service violated its management policies and federal law by allowing their continued use.

In 2007, Judge David Campbell of the U.S. District Court for the District of Arizona concluded that the Park Service can allow motorized rafts under its own rules and followed the law when revising its Colorado River Management Plan in 2006 (Greenwire, Nov. 29, 2007).

The groups appealed, and the 9th U.S. Circuit Court of Appeals yesterday agreed with the decision that the Park Service met its requirements under various laws when developing the plan. Both courts rejected all the claims of River Runners for Wilderness, Rock the Earth, Wilderness Watch and Living Rivers.

The groups had sued the Park Service; a group of commercial operators, the Grand Canyon River Outfitters Association; and a coalition of private rafters and kayakers, the Grand Canyon Private Boaters Association.

Grand Canyon Superintendent Steve Martin welcomed the news, saying the plan is the result of many years of work "and required making many difficult decisions after

considering extensive analysis of impacts and widely divergent points of view on many issues." He added, "We look forward to working with persons of all interests, including wilderness advocates, as we continue to implement the plan."

Jo Johnson, co-director of River Runners for Wilderness, said her group is "extremely disappointed" with the decision. It will continue its efforts in other ways, she said, such as pursuing a congressional wilderness designation for the park or a broader grass-roots effort the next time the plan is revised.

"We certainly hoped for better because the place deserved it," Johnson said. "It's not a negation of what we were trying to accomplish in the end, but it was a rejection of that particular channel for doing so."

Earlier this month, the Park Service proposed to extend the rules for boating on the Colorado River through portions of the Grand Canyon to cover the river's entire length in the park (Greenwire, July 10).

Environmental groups have long been critical of the management plan for the river, claiming that the park's continued authorization of motorized watercraft damages wilderness characteristics of the waterway. The park recommended the river for wilderness designation in 1980, but the proposal has never been carried out by Congress.

LR Letter 07/27/09

Scoping for Million Conservation Resource Group's Regional Watershed Supply Project

July 27, 2009
Ms. Rena Brand
U.S. Army Corps of Engineers
Denver Regulatory Office
9307 S. Wadsworth Blvd.
Littleton, CO 80128-6901
(303) 979-4120
mcrgeis@usace.army.mil

Dear Ms. Brand:

Thank you for this opportunity to provide scoping comments to the Army Corps of Engineers (Corps) for developing an Environmental Impact Statement (EIS) for the

effects of the proposed Regional Watershed Supply Project (RWSP) sponsored by the Million Conservation Resource Group. Living Rivers is a non-profit organization based in Moab, Utah and dedicated to restoring the Colorado River ecosystem.

The Big Picture

For the past few years Colorado River water users have come to the realization that current consumption levels may not be sustainable. Colorado River flows over the past decade have been about 25% below normal, forcing the establishment of the first “Shortage Criteria” for the operations of Lake Powell and Lake Mead reservoirs. This new environment of scarcity was predicted as far back as the debates surrounding the authorization of the Colorado River Storage Project Act, and arguments presented in *Arizona v. California*.

Moreover, scientists continue to stress that drying reservoirs are likely to be a persistent problem in the coming decades due to climate change. Proposed depletions, such as the RSWP, will surely aggravate this condition. The EIS team should consult with the National Oceanic and Atmospheric Administration, Colorado University at Boulder, in developing an up-to-date analysis of the Upper Basin’s ability to utilize the proposed project under a full range of climate change scenarios.

At present, it is reasonable to assume that a 10% reduction in the Colorado River’s annual streamflow has already occurred, and that forecasting should be based on a mean annual flow of 13.5 maf. It’s quite possible that runoff could fall to 12.0 maf or less by mid-century. Such a reduction would certainly complicate deliveries for holders of new water rights in the Upper Basin.

Such hydrologic modeling should then be applied to complete a programmatic, basin-wide EIS to establish water budget for the Colorado River, perfect the water rights of federal reserve lands, and to develop and initiate programs to improve the ecological health of the Colorado River system as a whole. Neither the RSWP nor any other water supply project should be examined until some of the larger issues affecting the management of the Colorado River system have been resolved first.

Water Quality and Quantity

One of the provisions in the Colorado Compact of 1922 is that the water delivered to the lower basin not be impaired, which indicates that the commissioners considered water quality is just as important as water quantity. Development of water diversions in the upper basin is partly why Congress authorized the Salinity Control Act of 1974. Other authorizations by Congress of concern include the Clean Water Act of 1972 and the Endangered Species Act of 1973.

Extracting these flows from the basin will increase salinity for the lower basin, and deplete instream flows for the Green River above Lake Powell, and the delta ecosystem in Mexico. The Corps must determine how this depletion will affect critical habitat of endangered species, and assess the potential for salinity damage to downstream agriculture and urban water infrastructure.

Such an analysis must include increases in heavy metals, industrial toxins and waste from agricultural fields, oil and gas drilling, and mining (with particular emphasis in the renewed uranium mining in the upper basin). The Corps should therefore consult with the US Fish and Wildlife Service, the Salinity Control Forum, the Bureau of Land Management, and the Environmental Protection Agency.

Water quality impacts to Lakes Powell and Mead will also likely result. The dramatic remobilization of stored sediment in these reservoirs has already been observed in the present decade. These perched sediment deposits include toxins, heavy metals, salt, hydrogen sulfide and create a situation of lower dissolved oxygen in the water column. It would be appropriate to investigate these impacts and consult with the US Geological Survey and with the Technical Service Center of the Bureau of Reclamation at Denver.

Contributions to Global Warming
