Erosion of terraces in Glen Canyon that support cultural resources (GCFEI)[a]	No change from current conditions which may contribute to slumping of terraces in Glen Canyon (GFEI = 22.7).	Compared to Alternative A, increase in the potential for slumping of terraces in Glen Canyon (1.5% increase in GFEI); experimental hydropower improvement flows would increase the potential for slumping (1.6% increase in GFEI).	Compared to Alternative A, decrease in the potential for slumping of terraces in Glen Canyon (4.4% decrease in GFEI)	Compared to Alternative A, increase in the potential for slumping of terraces in Glen Canyon (3.1% increase in GFEI).	Compared to Alternative A, decrease in the potential for slumping of terraces in Glen Canyon (6.4% decrease in GFEI; lowest impact alternative).	Compared to Alternative A, increase in the potential for slumping of terraces in Glen Canyon due to sustained high flows in the spring (62% increase in GFEI; highest impact alternative).	Compared to Alternative A, increase in the potential for slumping of terraces in Glen Canyon (8.7% increase in GFEI).
Spencer Steamboat	No change from current conditions. The cumulative effects of multiple HFEs on the Spencer Steamboat are not known, but potentially increase the risk of degradation.	No change from current conditions. The cumulative effects of multiple HFEs on the Spencer Steamboat are not known, but potentially increase the risk of degradation.	No change from current conditions. The cumulative effects of multiple HFEs on the Spencer Steamboat are not known, but potentially increase the risk of degradation.	Similar to Alternative A. The cumulative effects of multiple HFEs and extended-duration HFEs on the Spencer Steamboat are not known, but potentially increase the risk of degradation.	No change from current conditions. The cumulative effects of multiple HFEs on the Spencer Steamboat are not known, but potentially increase the risk of degradation.	Similar to Alternative A. The cumulative effects of multiple HFEs and extended high flows on the Spencer Steamboat are not known, but potentially increase the risk of degradation.	Similar to Alternative A. The cumulative effects of multiple HFEs and extended-duration HFEs on the Spencer Steamboat are not known, but potentially increase the risk of degradation.

TABLE 4.8-1 (Cont.)

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Impacts on Cultural Resources in the Grand Canyon							
Wind transport of sediment to high-elevation cultural resources (WTSI)[b]	Negligible influence on windblown sediment (WTSI = 0.16 out of 1); some benefit from HFEs until 2020 when HFEs are discontinued; potential adverse impact due to reduction in sediment availability after 2020 (highest impact alternative).	Compared to Alternative A, increase in the availability of sand for wind transport to protect stability of archaeological sites in the Grand Canyon (7.5% increase in WTSI); some benefit from HFEs over entire LTEMP period.	Compared to Alternative A, increase in the availability of sand for wind transport to protect stability of archaeological sites in the Grand Canyon (137% increase in WTSI) resulting from increase in frequency of HFEs over entire LTEMP period.	Compared to Alternative A, increase in the availability of sand for wind transport to protect stability of archaeological sites in the Grand Canyon (139% increase in WTSI) resulting from increase in frequency of HFEs over entire LTEMP period.	Compared to Alternative A, increase in the availability of sand for wind transport to protect stability of archaeological sites in the Grand Canyon (96% increase in WTSI) resulting from increase in frequency of HFEs over entire LTEMP period.	Compared to Alternative A, increase in the availability of sand for wind transport to protect stability of archaeological sites in the Grand Canyon (88% increase in WTSI) resulting from increase in frequency of HFEs over entire LTEMP period.	Compared to Alternative A, increase in the availability of sand for wind transport to protect stability of archaeological sites in the Grand Canyon (193% increase in WTSI) resulting from increase in frequency of HFEs over entire LTEMP period (lowest impact alternative).
Visitor effects on cultural resources (TORI)[c]	Negligible effect on visitor time off river (TORI = 0.82 out of 1).	Compared to Alternative A, no change in visitor time off river.	Compared to Alternative A, negligible change in visitor time off river (<1% change in TORI).	Compared to Alternative A, decrease in visitor time off river (1.6% increase in TORI).	Compared to Alternative A, decrease in visitor time off river (1.9% increase in TORI).	Compared to Alternative A, increase in visitor time off river (8.9% decrease in TORI) mostly resulting from high flows in spring (highest impact alternative).	Compared to Alternative A, decrease in visitor time off river (2.1% increase in TORI; lowest impact alternative).

Footnotes on next page.

TABLE 4.8-1 (Cont.)

[a] The Glen Canyon flow effects index (GFEI) represents the average number of days flows would be higher than 23,200 cfs during the 20-year LTEMP period. Higher values indicate a higher likelihood of slumping of terraces in Glen Canyon and greater impact on cultural resources that occur on those terraces. See Appendices B and H for a description of the index.

[b] The wind transport of sediment index (WTSI) is a 0 to 1 index that represents the potential for operations over the 20-year LTEMP period to provide conditions that are favorable for windblown transport of sediment to high-elevation terraces in the Grand Canyon that support archaeological sites. Any sand blown to these sites could reduce the erosion potential of those sites. A value of 0 indicates that there is no potential for windblown sediment transport (greatest impact); a value of 1 indicates that conditions are best for windblown sediment transport (lowest impact). See Appendices B and H for a description of the index.

[c] The time off river index (TORI) is a 0 to 1 index that represents the potential for operations over the 20-year LTEMP period to provide conditions that increase the amount of time whitewater rafters would have to explore nearby archaeological sites during the day. A value of 0 indicates that there is the greatest potential for time of river (greatest impact); a value of 1 indicates that there is the least potential for time off river (lowest impact). See Appendices B and H for a description of the index.

event demonstrated that terrace bank erosion may occur as flow elevations increase, during the period of peak high flow, and following the decrease of high flows to normal operational levels. Under most of the LTEMP alternatives, the greatest flows would be 45,000-cfs flows lasting for 96 hr (Section 4.3); these would be comparable to or less than flows that have occurred historically that resulted in slumping. The only alternatives in which this duration could be exceeded are Alternatives D and G. Alternatives D and G allow for longer duration HFEs (up to 250 and 336 hr, respectively) when there is adequate sediment. However, flows will reach the lower threshold of 23,200 cfs under all alternatives. Under most alternatives, HFEs would be limited in magnitude and duration, but the cumulative effect of more than one HFE in a year and in sequential years is not known, and could result in an even higher risk of slumping compared to the effects of individual HFEs.

The results from the Glen Canyon flow effects metric are shown in Figure 4.8-1. Alternative A most closely represents the current operational conditions. Under the metric, Alternative F would have the highest number of days per year; flows would be >23,200 cfs with an average of 14 days per year more than under Alternative A. Alternative F, therefore, has the highest potential for impacts on terraces that contain cultural resources in Glen Canyon. The higher number of days under Alternative F results from the relatively high spring flows between May and June (Section 2.3.6). The remaining alternatives have an average number of days per year where flows would be >23,200 cfs within 4 days of those under Alternative A.

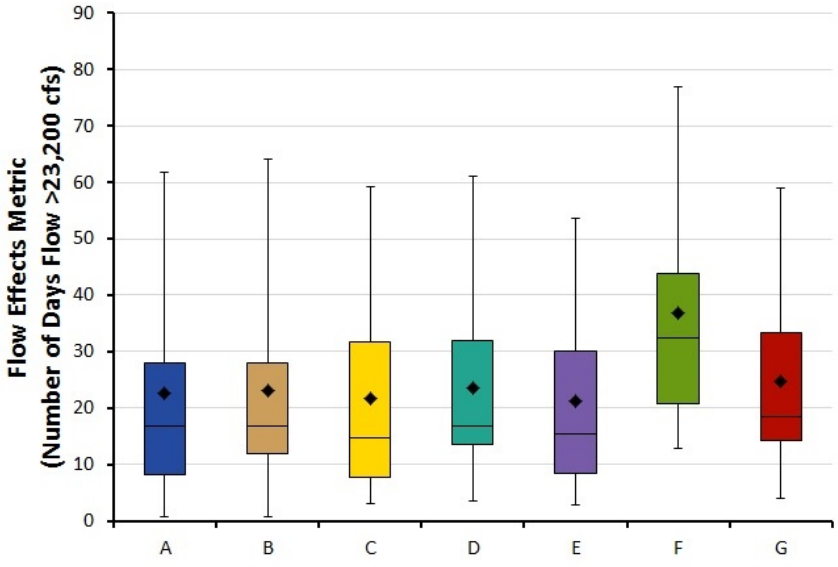

FIGURE 4.8-1 Number of Days per Year Flows Would Be >23,200 cfs under LTEMP Alternatives (letters). (Flows of this magnitude have the potential to affect cultural resources in Glen Canyon. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

Although there are differences among alternatives in the number of HFEs, these differences have little effect on the number of days per year flows would be >23,200 cfs. This is because HFEs are relatively brief, and the large volume released under the HFE must be compensated for by releasing less water, which results in lower flows, at other times of year. Since all alternatives must release the same annual volume of water, alternatives with HFEs may have lower releases at other times of years than those without. The effect on the metric would be greater in years of high volume (≥10 maf) when equalization flows would be implemented according to the Interim Guidelines (Reclamation 2007a).

A persistent source of impacts on cultural resources is visitors (Bulletts et al. 2008, 2012; Jackson-Kelly et al. 2013). The effects being identified include the moving of artifacts on archaeological sites and the defacing of inscriptions, pictographs, and petroglyphs. The LTEMP does not incorporate any specific recommendations or policies concerning visitors under any alternatives. The Colorado River Management Plan (CRMP) is the primary document addressing visitor policies related to cultural resources in GCNP (NPS 2005a). Because LTEMP alternatives do not alter any policies concerning visitors, they do not differ with respect to any direct effect caused by visitors on cultural resources. Visitor effects are discussed under cumulative impacts.

An indirect effect related to visitor disturbances to cultural resources concerns the amount of time boaters have off river to explore and potentially interact with archaeological sites. More time would be available when flows are higher during the tourist season (June–September), and this factor could vary among alternatives. Analysis determined that the time off river index for most alternatives did not vary much (<2%) among current conditions (Alternative A). However, Alternative F has higher flows during May and June, so it could provide for more time off river during those months; these higher flows are offset by lower flows in July, August, and September, when time off river would be less than for other alternatives. Overall, the time off river index under Alternative F was lower (8.9% lower than Alternative A), indicating that visitors could spend more time off river than under Alternative A.

The Spencer Steamboat, located in GCNRA, could be directly affected by flows. The steamboat lies in the river, is part of the Lees Ferry/Lonely Dell Ranch National Historic District, and has been subject to all past dam releases, including HFEs (2012, 2013, and 2014), extended-duration HFEs (1996), low flows (2002), fall steady flows (2011–2013), and higher fluctuation flows (pre-1992). Although the site appears to be receiving an ongoing accumulation of sediment, which is beneficial for site preservation, ongoing monitoring has demonstrated that the wet-dry cycling resulting from fluctuations at low flow levels has caused the most obvious and persistent impacts on the site, as predicted by Carrell (1987). The recent installation of submerged monitoring stations (Pershern et al. 2014) will allow the opportunity to systematically evaluate the nature and origin of sediment accumulating at the site, and determine how that mechanism of transport may be influenced or affected by dam operations. Because the proposed flows do not exceed or vary greatly from past flows, similar effects are anticipated under any of the alternatives. The cumulative effects of multiple HFEs and extended-duration HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

The results from the wind transport of sediment index under the various alternatives are shown in Figure 4.8-2. This index represents the potential for wind to transport sand from channel-margin sandbars to high elevation terraces in the Grand Canyon, which could in turn reduce erosion and stabilize archaeological sites in these terraces. Historic properties contained within the Grand Canyon River Corridor Historic District are most susceptible to both aggregation and erosion of sand, which could create adverse or beneficial effects as explained in Section 4.8.2. Alternative G scores the highest of all the alternatives, with an average index value nearly three times greater than Alternative A. Alternative G has the highest number of HFEs and the lowest maximum daily flows during the windy months. Alternative G has parameters that are ideal for wind transport of fluvial sediment to terraces that contain cultural resources. The second highest scoring alternative is Alternative D. Alternatives A and B scored the lowest on this index.

On the whole, the wind transport of sediment index is highly correlated to the number of HFEs and the corresponding sand load index. The relationship between the sand load index and HFEs is discussed in Appendix E. The wind transport of sediment index is highly correlated to the sand load index because the average maximum discharge between March and June for each of the alternatives is within 5,000 cfs. With minimal difference in flow, the amount of sediment for distribution becomes the determining factor for the index. The exception to this is Alternative F. Although Alternative F was determined to have the second highest potential sand

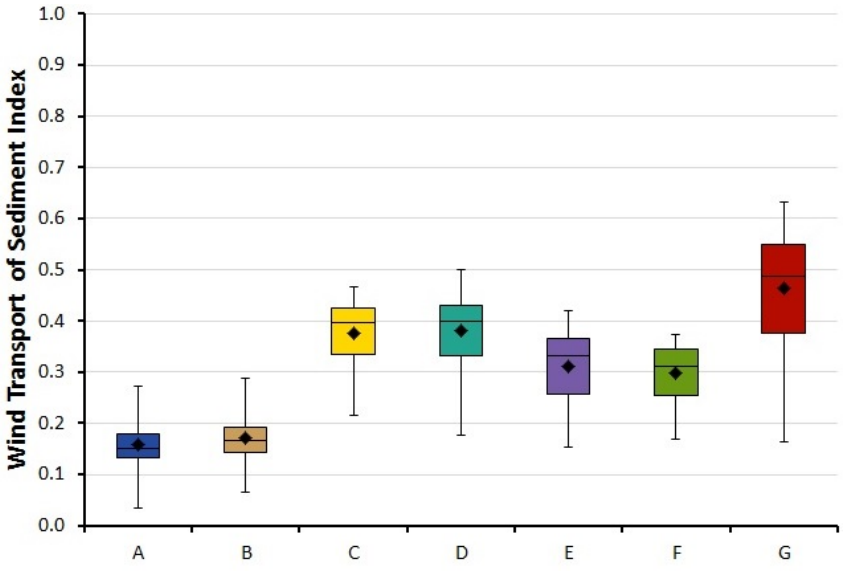

FIGURE 4.8-2 Wind Transport of Sediment Index Values for LTEMP Alternatives (letters) (Values of 1 are considered optimal. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

deposition (second highest sand load index, only less than Alternative G), it ultimately has an average index value lower than Alternatives C, D, E, and G because larger discharges of water create less ideal conditions for wind transport.

4.8.4 Alternative-Specific Impacts

4.8.4.1 Alternative A (No Action Alternative)

Dam operations under Alternative A are expected to continue to contribute to conditions that could affect terraces that contain cultural resources in Glen Canyon. Observations in Glen Canyon noted that effects on the toe of the resource-bearing terrace at Ninemile Terrace begin with flows above 23,200 cfs (Baker 2013). Under Alternative A, flows could exceed 23,200 cfs and create conditions that could affect the stability of resource-bearing terraces. However, based on no significant deterioration of the Ninemile site since the 1996 flows, the effects of HFEs and interim operations on terraces in Glen Canyon under Alternative A would not be expected to change from current conditions. However, the cumulative effects of daily flows and the lack of sediment availability remain factors which could affect the stability of the terraces and continue to create the potential for effects as identified under the current MLFF operation. There would be no change from current conditions with respect to the stability of Spencer Steamboat, but the cumulative effects of multiple HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

In the Grand Canyon, sandbar building that would result from HFEs under Alternative A could provide windblown sediment to high terraces; however, based on observations of existing conditions, this effect is expected to be small and would be reduced after HFEs were discontinued under this alternative in 2020. Alternative A is not expected to significantly improve the stability of archaeological sites.

In summary, operations under Alternative A could result in conditions which may contribute to slumping of terraces in Glen Canyon, although these effects are expected to be similar to those under current conditions. Operations under Alternative A are not expected to significantly improve the stability of archaeological sites in the Grand Canyon. There would be no change from current conditions with respect to the stability of Spencer Steamboat or visitor time off river and subsequent effects on cultural resources.

4.8.4.2 Alternative B

Dam operations under Alternative B are not expected to have additional effects on terraces that contain cultural resources in Glen Canyon. Daily fluctuations under Alternative B would be higher than under Alternative A. In addition, experimental hydropower improvement flows under this alternative could result in daily flows of 25,000 cfs between December and February, as well as between June and August. However, these wider daily fluctuations are not expected to result in increased erosion rates because the alternative results in only a slight

increase in the number of days when the base of the terraces in GCNRA would be inundated (i.e., flows >23,200 cfs) compared to Alternative A, which would result in a minor increase in the potential for slumping. There would be no change from current conditions with respect to the stability of Spencer Steamboat, but the cumulative effects of multiple HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

It is anticipated that there will be some increase in the amount of sediment available for wind transport under Alternative B; both Alternatives A and B are expected to have approximately the same number of HFEs. Alternative B is expected to have a smaller beneficial effect from windblown sediment in the Grand Canyon relative to other alternatives that have more frequent HFEs. With hydropower improvement flows, there is expected to be a minor decrease with respect to wind transport compared to Alternative A.

In summary, operations under Alternative B could result in conditions which may contribute to slumping of terraces in Glen Canyon, although these effects are expected to be similar to those under Alternative A. Operations under Alternative B are not expected to significantly improve the stability of archaeological sites in the Grand Canyon. There would be no change from current conditions with respect to the stability of Spencer Steamboat or visitor time off river and subsequent effects on cultural resources.

4.8.4.3 Alternative C

Dam operations under Alternative C are not expected to have any additional effects on terraces that contain cultural resources in Glen Canyon. Although HFEs under Alternative C would be limited to a maximum of 45,000 cfs for 96 hr, and erosion of the base of terraces was only observed after the 1996 HFE of 168 hr, the cumulative effect of multiple HFEs on the stability of terraces is not known. Compared to Alternative A, operations under Alternative C would not result in a substantial increase in the number of days when the base of the terraces in GCNRA would be inundated (i.e., flows ≥23,200 cfs; thus, there is no measurable difference in the potential for increased slumping. There would be no change from current conditions with respect to the stability of Spencer Steamboat, but the cumulative effects of multiple HFEs and extended-duration HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

The amount of sediment available for wind transport in the Grand Canyon under Alternative C is greater than under Alternative A because there would be more frequent HFEs through the entire 20-year LTEMP period, increased sediment retention resulting from lower daily fluctuations, proactive spring HFEs in wet years, and reduced fluctuations before and after HFEs.

In summary, operations under Alternative C could result in conditions which may contribute to slumping of terraces in Glen Canyon, although these effects are expected to be similar to those under Alternative A. There could be some improvement in the potential for windblown sediment to protect archaeological sites on terraces in the Grand Canyon. There

would be no change from current conditions with respect to the stability of Spencer Steamboat or visitor time off river and subsequent effects on cultural resources.

4.8.4.4 Alternative D (Preferred Alternative)[21]

Dam operations under Alternative D could result in some additional destabilization of terraces that contain cultural resources in Glen Canyon. This could result from the extended-duration HFEs (up to 250 hr) that would be implemented as an experimental treatment in years when large inputs of sediment from the Paria River occur. No more than four extended-duration HFEs would be implemented during the LTEMP period under Alternative D. Some slumping was observed in Glen Canyon as a result of the 1996 HFE, which had a magnitude of 45,000 cfs and duration of 168 hr. In addition, the cumulative effect of multiple HFEs on the stability of terraces is not known. Compared to Alternative A, operations under Alternative D would result is a slight increase in the number of days when the bases of the terraces in GCNRA would be inundated (i.e., flows ≥23,300 cfs), which would result in a slightly increased potential for slumping. There would be no change from current conditions with respect to the stability of Spencer Steamboat, but the cumulative effects of multiple HFEs and extended-duration HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

In the Grand Canyon, the amount of sediment available for wind transport under Alternative D is greater than under Alternative A because there would be more frequent HFEs through the entire 20-year LTEMP period, increased sediment retention resulting from more even monthly release volumes, and proactive spring HFEs in wet years.

In summary, operations under Alternative D could result in additional destabilization of terraces in Glen Canyon. There could be some improvement in the potential for windblown sediment to protect archaeological sites on terraces in the Grand Canyon. There would be a small decrease in the amout of time off river and subsequent effects on cultural resources, but no change from current conditions with respect to the stability of Spencer Steamboat.

4.8.4.5 Alternative E

Dam operations under Alternative E are not expected to have any additional effects on terraces that contain cultural resources in Glen Canyon. Although HFEs under Alternative E would be limited to a maximum of 45,000 cfs for 96 hr, and erosion of the base of terraces was only observed after the longer duration 1996 HFE (168 hr), the cumulative effect of multiple HFEs on the stability of terraces is not known. Compared to Alternative A, operations under Alternative E do not result in a substantial increase in the number of days when the base of the terraces in GCNRA would be inundated (i.e., flows ≥23,200 cfs),), which would result in no measurable difference in the potential for increased slumping. There would be no change from current conditions with respect to the stability of Spencer Steamboat, but the cumulative effects

[21] Adjustments made to Alternative D after modeling was completed (see Section 2.2.4) are not expected to result in a change in Alternative D's impacts on cultural resources.

of multiple HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

In the Grand Canyon, the amount of sediment available for wind transport under Alternative E is greater than under Alternative A because there would be more frequent HFEs through the entire 20-year LTEMP period (although fewer than under Alternatives C, D, F, and G).

In summary, operations under Alternative E could result in conditions which may contribute to slumping of terraces in Glen Canyon, although these effects are expected to be negligible. There could be some improvement in the potential for windblown sediment to protect archaeological sites on terraces in the Grand Canyon. There would be a small decrease in the amout of time off river and subsequent effects on cultural resources, but no change from current conditions with respect to the stability of Spencer Steamboat.

4.8.4.6 Alternative F

Alternative F is expected to have additional effects on terraces that contain cultural resources in Glen Canyon because there would be an increase in the number of days when the bases of terraces in GCNRA would be inundated. Flows in May and June would be sustained at higher levels under this alternative, resulting in an increased number of days in wetter years when the bases of the terraces would be inundated, compared to Alternative A. Although HFEs would be limited to a maximum of 45,000 cfs for 96 hr, and erosion of the bases of terraces was only observed after the longer duration 1996 HFE (168 hr), the cumulative effect of multiple HFEs on the stability of terraces is not known. Compared to Alternative A, operations under Alternative F would result in an increase in the number of days when the bases of the terraces in GCNRA would be inundated (i.e., flows ≥23,200 cfs), which would result in an increased potential for slumping. There would be no change from current conditions with respect to the stability of Spencer Steamboat, but the cumulative effects of multiple HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

Dam operations under Alternative F would allow faster travel times for boaters in May and June; therefore, boaters would have additional time off river to visit cultural resources during those months. This increase would be offset by the effects of lower flows in July–September. Alternative F is the only LTEMP alternative that, based on the analysis, could have any influence on visitor effects.

In the Grand Canyon, the amount of sediment available for wind transport under Alternative F is greater than under Alternative A because there would be more frequent HFEs through the entire 20-year LTEMP period and increased sediment retention from low steady flows throughout much of the year. However, the highest flows under Alternative F are in May, which reduces the potential for wind transport of sediment to terraces during this windy period.

In summary, operations under Alternative F could result in additional destabilization of terraces in Glen Canyon. There could be some improvement in the potential for windblown sediment to protect archaeological sites on terraces in the Grand Canyon. There would be no change from current conditions with respect to the stability of Spencer Steamboat; there could be a small increase in the visitor time off river in May and June, which could result in increased visitation and potential damage to cultural resources.

4.8.4.7 Alternative G

Dam operations under Alternative G could result in some destabilization of terraces that contain cultural resources in Glen Canyon. This could result from the extended-duration HFEs (up to 336 hr) that would be implemented in years when large inputs of sediment from the Paria River occur. Some slumping was observed in Glen Canyon as a result of the 1996 HFE, which had a magnitude of 45,000 cfs and duration of 168 hr. In addition, the cumulative effect of multiple HFEs on the stability of terraces is not known. Compared to Alternative A, operations under Alternative G would result in an increase in the number of days when the bases of the terraces in GCNRA would be inundated (i.e., flows ≥23,300 cfs), which would result in an increased potential for slumping. There would be no change from current conditions with respect to the stability of Spencer Steamboat, but the cumulative effects of multiple HFEs and extended-duration HFEs on the Spencer Steamboat are not known and could increase the risk of degradation.

In the Grand Canyon, the amount of sediment available for wind transport under Alternative G would be greater than under Alternative A because there would be more frequent HFEs through the entire 20-year LTEMP period, increased sediment retention from steady flows throughout the year, and proactive spring HFEs in wet years. Alternative G has the lowest spring operational flows when windy conditions are most typical. These factors create the best conditions under any of the alternatives for wind transport of sediment to the terraces.

In summary, operations under Alternative G could result in additional destabilization of terraces in Glen Canyon. There could be some improvement in the potential for windblown sediment to protect archaeological sites on terraces in the Grand Canyon. There would be a small decrease in the amout of time off river and subsequent effects on cultural resources, but no change from current conditions with respect to the stability of Spencer Steamboat.

4.9 TRIBAL RESOURCES

Assessing the comparative impacts of the LTEMP alternatives on Tribal resources presents a challenge both because of the Tribes' holistic view of the Canyons, in which all things are interconnected, and because there is no single "Tribal view" held by all members of all Tribes. The holistic view encompasses most of the subject areas considered in this EIS and perspectives of the Fort Mojave Tribe, Havasupai Tribe, Hopi Tribe, Hualapai Tribe, Navajo Nation, Pueblo of Zuni, and Southern Paiute Tribes on these resources are found throughout the document.

The values placed by these Tribes on the river and its Canyons are significant and real but may be intangible; thus, they are not easily quantifiable. In addition, many of the values and resources most important to the Tribes are not directly affected by the proposed action as defined by operational patterns of water releases from Glen Canyon Dam.

Issue: How do alternatives affect Tribal resources in Glen, Marble, and Grand Canyons?

Impact Indicators:

- Health of the ecosystem including vegetation, wildlife, fish, and wetlands
- Water rights
- Condition of traditional cultural places

Issue: How do alternatives affect the sacred integrity of and Tribal connections to the Canyons?

Impact Indicators:

- Stewardship and educational opportunities
- Independent access to Canyons
- Number of nonnative fish removed each year
- Economic opportunity
- Incorporating traditional knowledge into the LTEMP EIS

4.9.1 Tribal Resource Goals

As discussed in Section 3.9, the Tribes that have the closest ties to the Canyons and are most actively involved in the LTEMP EIS process are the Fort Mojave Tribe, Havasupai Tribe, Hopi Tribe, Hualapai Tribe, Navajo Nation, Pueblo of Zuni, and Southern Paiute Tribes. Eight important themes or values relative to the Colorado River and its Canyons emerged from meetings, workshops, and webinars held with individual Tribal representatives and from reviewing ethnographies and Canyon monitoring reports produced by or for the Tribes. These have been identified as Tribal resource goals for the LTEMP EIS and grouped according to whether they can be represented quantitatively and whether they would be differentially affected by alternative management practices at or related to the operation of Glen Canyon Dam. An initial evaluation was made based on Tribal sources, and the Tribes were afforded the opportunity to review and provide input.

For this discussion, Tribal resources are divided into two categories: (1) traditional cultural places—those elements with fixed and defined locations, and (2) traditional cultural resources—resources that are either widely scattered or mobile, such as riparian vegetation, birds, mammals, and fishes. For many Tribes, resources in these two categories may be considered TCPs or contributing elements to a TCP and may be differently affected by flow and non-flow elements of the seven LTEMP alternatives.

4.9.1.1 Increase the Health of the Ecosystem in Glen, Marble, and Grand Canyons

Tribes such as the Hopi express their perception of the state of the Canyons in terms of the Canyons' health (Yeatts and Huisinga 2003, 2006, 2009, 2010, 2011, 2012, 2013). For the Hopi, natural elements and resources are significant for creating a culturally significant, harmonious landscape. Without them, the landscape would not be whole. These resources, because they are either widely scattered or mobile, rather than existing in a fixed location, may be considered traditional cultural resources.

In general, the affected Tribes are concerned with the state of the Canyons as a whole. The determination of Canyon health from a Tribal point of view can be complex and can vary from Tribe to Tribe. For example, a recent survey of Hopi Canyon monitors showed that most respondents found the Canyons to be in good health, or at least better taken care of than in the past, in part because of Hopi participation in the adaptive management process by monitoring important sites such as the salt mine, and because of the offerings made in the Canyons by Tribal members (Yeatts and Huisinga 2013). Some aspects of Canyon health are quantifiable and parallel or reflect values that have been expressed by the Tribes or their representatives. These include riparian plant diversity, wetland abundance, and characteristics of native fish populations considered here. The interest of the Tribes extends beyond these measures to impacts on other aspects of Canyon health explored elsewhere in this chapter, including natural processes (Section 4.4), aquatic ecology (Section 4.5), vegetation (Section 4.6), wildlife (Section 4.7), hydropower (Section 4.13), and environmental justice (Section 4.14).

The Western concept of ecosystem has much in common with the Tribes' view of their place in an interconnected natural world. Plant communities form a fundamental aspect of any ecosystem, and vegetation health is an indicator of ecosystem health. Metrics for vegetation community diversity and wetland abundance in the riparian zone most directly affected by flow management at the Glen Canyon Dam have been developed based on the results of an existing state and transition model developed by GCMRC for Colorado River riparian vegetation downstream of Glen Canyon Dam; this is described by Ralston et al. (2014) and in Appendix G and discussed in Section 4.6.1. The metrics are on a scale relative to starting conditions where a higher value means greater vegetation community diversity or wetland abundance relative to starting conditions.

A healthy ecosystem from a Tribal perspective is characterized by a high degree of species diversity, represented here by diversity in vegetation community types. The model projects transitions over the 20-year LTEMP period for each alternative analyzed. During discussions with the Tribes, they often expressed their view that all forms of life have value, whether native or nonnative. To take this perspective into account, evaluation of diversity included nonnative (primarily tamarisk) as well as native vegetation, including the invasive arrowweed. The analysis indicated that all alternatives on average would result in a decrease in total vegetation diversity over the 20-year LTEMP period.

The loss in diversity would be greatest under Alternatives C, F, and G. Under these alternatives, the acreage occupied by the invasive tamarisk increases (Table 4.9-1). Alternatives under which tamarisk[22] would increase are characterized by spring high flows (HFEs or ≥30 days with flows >20,000 cfs), which serve to distribute seed, followed by low flows in the growing season (May–September) which would allow seedlings to establish themselves. Alternative B results in the least loss of diversity, followed by Alternatives A, D, and E. Under these alternatives, the area covered by tamarisk decreases.

Another indicator of Canyon health is the abundance of wetlands in the riparian zone. Although they make up only a small part of the riparian area of the river corridor (4.6 acres, or 0.5% of total area of all vegetation types), wetlands include plants of medicinal and cultural significance to some Tribes (Jackson et al. 2001) that continue to be harvested with care (Yeatts and Huisinga 2006). The Hopi generally see the marshes as healthy and well taken care of, but there is some indication in the Tribal monitoring reports that cattail and reed marshes are decreasing in size and number and that cattails are decreasing in number (Yeatts and Huisinga 2013).

TABLE 4.9-1 Vegetation Community Diversity and Change in Tamarisk Cover

Alternative	Mean Diversity Score[a]	Change in Tamarisk Cover (ac)
A	0.95	−58.4
B	0.97	−71.3
C	0.75	104.0
D	0.94	−22.4
E	0.93	−45.7
F	0.70	230.7
G	0.83	46.4

[a] Higher values of diversity indicate better condition relative to other alternatives. A value less than 1 indicates an expected reduction in diversity relative to current conditions over the 20-year LTEMP period. A value greater than 1 indicates an expected increase in diversity.

22 The model takes into account the effects of scouring, drowning, desiccation, and sediment deposition, but does not account for the effects of the tamarisk leaf beetle or tamarisk weevil. These two insect species are expected to result in a reduction in the amount of live tamarisk in the river corridor.

Based on the vegetation models discussed in Section 4.6, the change in abundance was determined for each of the wetland community types (common reed wet marsh and willow/baccharis/horsetail wetland). Wetlands would expand under hydrologic regimes that lack extended periods of high flows (≥30 days with maximum daily flows >20,000 cfs) and extended low flows (≥30 days with maximum daily flows <10,000 cfs), but are maintained with occasional extended high flows (in many cases) or HFEs and an absence of extended low flows during the growing season. Alternatives that include frequent extended low flows, such as the annual flows for Alternative F, or extended high flows followed by extended low flows tend to result in transitions of wetlands to other plant community types. All of the alternatives are expected to result in a decrease in wetland cover, with particularly large decreases under Alternative F.

The state of aquatic life in the Canyons is discussed in Section 4.5. Section 4.5.2 presents a summary of projected impacts on native and nonnative fishes and the aquatic food base. These projections correlate well with recent results from the Hopi monitoring program, which found the native fish populations in the Canyons, particularly the humpback chub, to be healthy (Yeatts and Huisinga 2013).

Impacts on riparian and terrestrial wildlife are discussed in Section 4.7.2. Impacts on indicators of wildlife and habitat health are expected to be limited, with no major differences among the alternatives. Alterations in riparian vegetation and the aquatic food base are not expected to be sufficient to adversely affect amphibians and reptiles over the long term; however, alternatives could produce changes in near-shore aquatic and wetland habitats that are important to amphibians and that serve as important food production areas for both amphibians and reptiles (Section 4.7.2.2). The distribution of woody riparian vegetation is not expected to vary enough under any alternative to disrupt the migration of riparian bird species or to have noticeable differences in impacts on species that nest in riparian vegetation; however, alternatives could produce changes in shoreline habitats that could affect waterfowl and wading birds (Section 4.7.2.3). Impacts on mammals such as muskrat and beaver would be negligible under all alternatives (Section 4.7.2.4). Larger mammals such as deer and bighorn sheep are mobile and able to adjust their use of different habitats along the corridor. Impacts on bighorn sheep under all alternatives are expected to be negligible (Section 4.7.2.4). A recent Hopi monitoring report found birds, mammals, insects, and snakes in the Canyons all to be healthy (Yeatts and Huisinga 2013).

4.9.1.2 Protect and Preserve Sites of Cultural Importance

Sites of cultural importance to the Fort Mojave Tribe, Havasupai Tribe, Hopi Tribe, Hualapai Tribe, Navajo Nation, Pueblo of Zuni, and Southern Paiute Tribes include archaeological sites, places associated with traditional narratives of Tribal identity, rock writing, sacred places, offering sites, springs, and traditional resource collection areas. Individually or collectively, these may be referred to as traditional cultural places. These places may also be contributing elements to a TCP such as the "rim-to-rim" TCP described in Section 3.9.6.

Expected effects of the alternatives on archaeological sites and historic properties are discussed in Section 4.8. Other cultural resources associated with specific locations are likely to

experience the same types of impacts as those on archaeological sites. Those Tribes that regularly monitor the condition of culturally important sites and resources in the Canyons most often list intentional and unintentional damage to sites from visitors to the Canyons as the prime threat to site integrity. Reported damage includes trailing, trampling, removal of vegetation, disturbance of artifacts, vandalism, and disruption of the sacred context through inappropriate behavior (Section 4.9.1.4). Bank erosion and inundation are mentioned less frequently in the monitoring reports. The majority of visitors to the river corridor arrive by boat. Higher flows have faster currents, so boaters travel more quickly between campsites, leaving more time to explore off-river, which could lead to more visitation of cultural sites and a greater potential for damage. Modeling of visitor time off the river indicates that there is almost no difference in expected amount of time off river among the LTEMP alternatives, with the exception of Alternative F. Under this alternative, boaters could spend slightly more time off the river in May and June when flows are relatively high and steady. Overall, impacts on these sites of importance are not expected to vary significantly as a result of visitation among the alternatives.

For the Fort Mojave Tribe, Havasupai Tribe, Hopi Tribe, Hualapai Tribe, Navajo Nation, Pueblo of Zuni, and Southern Paiute Tribes, all water is sacred and the places where it emerges from the ground as seeps and springs are particularly sacred. Tribal members travel to sacred springs in the Canyons to retrieve water for ritual use in their own communities (Dongoske 2011b; Jackson-Kelly et al. 2013). Warm mineral springs, such as Pumpkin Springs, are sacred and their waters are considered therapeutic (Austin et al. 2007). The Tribes are concerned with the purity of these sacred waters and exercise stewardship over them, which can include appropriate prayers and offerings at the springs and along sacred trails that lead to them. The Hopi largely consider the springs to be healthy, as a result of their having access to the springs and being able to perform appropriate stewardship activities (Yeatts and Huisinga 2009). Occasionally, spring sources, such as Pumpkin Springs, may take on a murky, polluted appearance and an HFE is welcome in order to flush out the muck and algae that have accumulated. This may disrupt access for a short amount of time, but water levels return to normal within a few weeks. During consultation, the Tribes that monitor Tribal resources in the Canyons—Hopi, Hualapai, Navajo, Southern Paiute, and Zuni—all have expressed more concern with damage to the springs and disrespect for the sanctity of the waters by non-Tribal visitors to the Canyons than with inundation resulting from flow management. Hopi monitoring reports suggest that the health of the springs is largely unaffected by the operation of Glen Canyon Dam. Overall, adverse impacts on springs and seeps from operation of Glen Canyon Dam are expected to be negligible, while the HFEs have some benefit.

Some adverse impacts can be mitigated through education and communication. All of the Tribes with ties to the Canyons are affiliates of Native Voices on the Colorado River (https://nativevoicesonthecolorado.wordpress.com), and many have their own outreach programs developed to educate visitors to the Canyons regarding Tribal histories and affiliations with the Canyons. This is discussed further in Section 4.9.1.4. Mitigation of potential effects on resources of Tribal concern will be subject to ongoing consultation.

4.9.1.3 Preserve and Enhance Respect for Canyon Life

For those Tribes that hold the Canyons to be a sacred space, the plant and animal life are integral elements without which its sacredness would not be complete. The Zuni, in particular, have established a lasting familial relationship with all aquatic life in the Colorado River and the other water sources in the Canyons (Dongoske 2011a). They consider the taking of life through the mechanical removal of trout to be offensive, and to have dangerous consequences for the Zuni. The confluence of the Colorado River and the Little Colorado River is considered a sacred area because of its proximity to places identified in traditional Tribal narratives as the locations of the Zuni and the Hopi emergence into this world and other important events. The killing of fish in proximity to sacred places of emergence is considered desecration, and would have an adverse effect on the Grand Canyon as a Zuni TCP. In addition, Pueblo of Zuni have identified significant social and psychological effects to their community during mechanical removal periods. For example, between 2003 and 2006, when the initial mechanical removal efforts occurred at the confluence of the Little Colorado and Colorado Rivers, the Zuni reported an increase in the use of taser guns by Zuni police on Zuni community members. The Zuni view this as a direct adverse effect on the Zuni community from mechanical removal events (Panteah 2016). The Zuni expressed their view on this subject in Section 3.9.6. In the past, the Zuni have expressed a willingness to consult with Reclamation in good faith in "seeking and reaching agreement with the Zuni to avoid, reduce, compensate for, or otherwise mitigate any adverse effects" (Zuni Tribal Council 2010).

Reclamation and the NPS are committed to continue to consult with the Tribes regarding nonnative fish control. Reclamation committed in agreements with Tribes in 2012 to consider live removal when feasible (Reclamation 2012b); however, the presence of whirling disease prohibits live removal of trout due to the risk of spreading the disease to other waters. Reclamation and the NPS have worked with the Tribes to determine a beneficial use of the removed fish on other projects and understand that what is considered beneficial use may not be the same for all Tribes. Reclamation and the NPS are committed to consult further with the Tribes to determine acceptable mitigation for nonnative fish control.

The purpose of trout management activities is to enhance the survival of the endangered humpback chub by reducing the numbers of trout in the river. Reducing the trout population would reduce competition with and predation on young-of-the-year chub near the confluence with the Little Colorado River from trout moving downstream from reaches just below Glen Canyon Dam (Section 4.5). Two forms of trout management have been proposed: TMFs and mechanical removal. Each is being considered as a management action that may be triggered when trout and/or chub populations are at specified levels. Trout management is included in all alternatives except Alternative F, and mechanical removal is only possible under Alternative A until 2020 (see Appendix J).

A TMF is a highly variable flow pattern of water releases at Glen Canyon Dam intended to control the number of young-of-the-year trout in the Glen Canyon reach of the Colorado River and, subsequently, the migration of trout to downstream areas such as the confluence of the Little Colorado River (Chapter 2). A typical TMF would consist of several days at a relatively high

sustained flow (e.g., 20,000 cfs) that would prompt young fish to move into the shallows along the channel margins and, depending on the time of year, would prompt spawning fish to construct redds and lay eggs in nearshore shallow areas. The high flows would be followed by a rapid drop to a low flow (e.g., 5,000 cfs), stranding young-of-the-year trout and, depending on the time of year, possibly exposing the eggs, thus preventing them from hatching. With the exception of Alternatives C and D, under which TMFs could be implemented early in the LTEMP period even if not triggered by predicted high trout recruitment, TMFs may be triggered during years in which trout recruitment in the Glen Canyon reach is anticipated to be high. Under each of the alternatives in which TMFs are included, they would initially be conducted as experiments; they would be implemented only if they prove to be successful in reducing the trout population in the Glen Canyon reach. In general, TMFs would most likely be triggered when spring HFEs, which can stimulate the food base and thus trout production, are followed by relatively high steady summer flows. Where the number of HFEs is limited, as in Alternative B, it is expected that TMFs would be triggered in fewer years. Modeling indicates TMFs would be triggered most often under Alternative G. If TMFs prove successful, they would reduce the number of times mechanical removal would be triggered.

Mechanical removal would employ electrofishing to stun and remove nonnative fish. Usually, the removed fish would then be euthanized and put to some beneficial use. For example, in one mechanical removal test, the trout were emulsified and used as fertilizer in the Hualapai Tribal gardens (Reclamation 2011a). In their Comprehensive Fisheries Management Plan, the NPS committed to put all removed nonnative fish (including trout) to beneficial use through human consumption (NPS 2013e). GCMRC has modeled the number of years in which mechanical removal would be triggered under various alternatives. In general, mechanical removal would be triggered in far fewer years than TMFs. In general, when TMFs are projected to be triggered in more years, mechanical removal of trout would be triggered in fewer years. Modeling indicates that under Alternative G (the alternative under which the most TMFs would be triggered), mechanical removal would never be triggered in more than 7 years out of 20.

With regard to fish management, the Tribes have expressed a preference for letting nature take its course rather than intervening to mitigate the consequences of past actions. For example, the Zuni have suggested that it could be that the emergence of whirling disease in trout is nature's way of tempering out-of-balance fish dynamics. The Zuni and Hopi have questioned the trout's level of impact on the humpback chub population and have urged additional studies of this relationship before undertaking the large-scale removal of fish (Zuni Tribal Council 2010; Yeatts and Huisinga 2013). For them, TMFs and mechanical removal are both offensive and would be considered an adverse effect on the Grand Canyon TCP. Likewise, the Hopi Tribe "recommends that efforts to understand what are the limiting factors for the humpback chub (both habitat issues in mainstem and Little Colorado River, and the life stage(s) where mortality rate is limiting) continue to be a focus of aquatic research. In addition, management actions such as the translocation should be continued as long as they are continuing to be successful" (Yeatts and Huisinga 2012).

4.9.1.4 Preserve and Enhance the Sacred Integrity of Glen, Marble, and Grand Canyons

The preservation of the sacred integrity of the Canyons is vitally important to the Tribes. Under the provisions of Executive Order 13007, both Reclamation and the NPS have obligations to accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners; to avoid adversely affecting the physical integrity of sacred sites; and to maintain the confidentiality of the location of sacred sites as requested by the Tribes. Inappropriate behaviors and activities within the Canyons can negatively affect the sanctity of the Canyons. Visitor impacts noted by Tribes include, but are not limited to, trampling of resources, lack of respect for sacred sites, trailing, illegal collection of artifacts, artifact movement, vandalism, and littering. Disruptive, boisterous behavior in the Canyons disturbs the spiritual ambiance that surrounds sacred trails and sites. Many Tribes have reported experiencing discomfort when performing ceremonies at certain sites within the river corridor because of the number and behavior of visitors present. In some cases, Tribal members have been approached by curious visitors during private ceremonies (Bulletts et al. 2008. 2012; Jackson-Kelly et al. 2013). During consultation meetings, Tribal representatives expressed concerns regarding integrity of the Canyons. For example, the Zuni expressed that from their perspective, any impact on the Canyons is an impact on the Zuni people, because the spirits that are disturbed can bring adverse consequences to the Zuni and their families; and the Navajo indicated that they have observed a reduction in the strength of plants gathered from sites along the river to be used for medicinal and ceremonial purposes, and have sought out other collection sites. In addition, visitor impacts could diminish the feeling, association, settings, and materials of important places, aspects used to evaluate the integrity of a traditional cultural place.

Non-Tribal visitors will continue to be present under all alternatives. As noted in Section 4.8, Alternative F is modeled to result in slightly more visitor time off-river, resulting in slightly more risk to sacred sites than the other alternatives. There is very little variation in the modeled time off river among the other alternatives

Possible adverse effects on sacred sites that result from tourists in the Canyons could be mitigated and in some cases prevented through communication and education. All of the Tribes with historical and cultural ties to the Canyons are affiliates of Native Voices on the Colorado River, an educational program that offers the Tribes a chance to share their historic and contemporary perspectives of the Colorado River and the Canyons with river guides, river outfitters, and the public. River guides and outfitters in turn share this information with their clients on river trips (NVCR undated). In addition, some Tribes have developed their own outreach programs. The Southern Paiute Consortium has developed outreach programs with Colorado River guides, local schools and universities, and civic organizations. When they are conducting monitoring trips or present in the corridor, the consortium also talks with Canyon visitors. The goal of the program is to educate non-Tribal members about the Southern Paiute history and broad cultural landscape of the Canyons (Bulletts et al. 2012). The Hualapai encourage public outreach and education as a means of teaching people about negative impacts on Hualapai resources (Jackson-Kelly et al. 2013). The Zuni have expressed interest in developing an educational program that would allow Zuni cultural advisors to inform river guides, boatmen, NPS, and Reclamation about the importance of Zuni history and traditional

issues as they are related to the Canyons (Dongoske 2011a). Reclamation and NPS are committed to continue working with the Tribes to develop or continue development of education and outreach programs. It is important that visitors to the Canyons understand the magnitude of the consequences their presence has on Tribal resources and Tribal members.

4.9.1.5 Maintain and Enhance Healthy Stewardship Opportunities and Maintain and Enhance Tribal Connections to the Canyons

During the development of the LTEMP DEIS, the Tribes expressed concern with maintaining and improving their connection to the Canyons, including the stewardship responsibilities given to them at creation or emergence. Stewardship is partly expressed through their participation in the Glen Canyon Dam Adaptive Management Work Group (AMWG) and Technical Work Group (TWG), which encourage participation in an open discussion of issues related to the operation of Glen Canyon Dam as well as the design of monitoring and research conducted by the GCMRC.

The Tribes regard maintaining their connection to the Canyon through traditional activities and fulfilling their stewardship responsibilities as vital. Tribal stewardship takes place on many levels, including participation in the management of Canyon resources through monitoring programs, ceremonial activities, and recounting oral histories. These stewardship activities are important for all Tribal members, but they are particularly important for passing down traditions and oral histories to Tribal youth. As discussed above, insensitive behavior by Canyon visitors and researchers may disrupt the Tribes' ritual activities of stewardship and passing cultural values connected to the Canyons to the next generation (Bulletts et al. 2008, 2012; Jackson-Kelly et al. 2013).

Adverse effects can be avoided or mitigated through continued communication; this includes communicating about the timing and duration of HFEs. Many of the Tribes are members of both the AMWG and TWG. Many Tribes also have their own monitoring programs whereby resources and sites of importance are monitored, the health of the Canyon is examined, sacred sites are visited, and respects are paid to the Canyon and its resources. Continued communication and collaboration between the Tribes and federal agencies will enhance stewardship opportunities for the Tribes, as will maintaining the Tribes' continued access to the Canyons to conduct important religious practices necessary for continued stewardship.

4.9.1.6 Economic Opportunity

As discussed in Section 4.14.2.1, economic ventures currently operated by the Tribes and Tribal members rely heavily on tourism both in and around the Canyons. These ventures include commercial rafting on the river, tourist facilities in or near the Canyons, and vendors of Native American crafts, such as jewelry, basketry, and ceramics, that rely heavily on trade with tourists. Within the Canyons, the Grand Canyon Resort Corporation, owned by the Hualapai Tribe, provides recreational facilities including river running below Diamond Creek. The Hualapai River Runners provide day and overnight whitewater rafting trips, and flat-water day trips. The

Tribe (working with GCNP) also issues some permits for private whitewater boating below Diamond Creek. The 1-day whitewater boating trips create the largest river recreation economic impacts within the Canyons (61 jobs and $1.4 million in annual regional income), while day-use flat-water trips also make a significant contribution (19 jobs and $0.4 million in annual regional income). The NPS CRMP (NPS 2006b), developed in consultation with the Hualapai Tribe, places limits on the number and size of trips below Diamond Creek. There are a fixed number of river trip launches allowed under the NPS plan and more demand than capacity. The number of trips would not change as a result of any of the alternatives, so the impacts on the river runners would be the same as Alternative A for all alternatives. The same annual economic impacts would be expected under each of the alternatives.

The Havasupai, Hualapai, and Navajo all operate land-based tourist facilities in or adjacent to the Canyons that are important contributors to their economic development. The Havasupai operate a lodge, café, trading post, and campground on their reservation, and offer Canyon tours. The Hualapai have a number of tourist and recreational facilities and opportunities including a river running operation, skywalk, helicopter rides, and hiking in the Western Grand Canyon. The Navajo have Tribal parks overlooking the Little Colorado River and Grand Canyon, and along Lake Powell. No difference in tourist use of land-based facilities or Native American craft vendors is expected among the LTEMP alternatives. However, Tribes have expressed the desire for communication before and during HFEs to enable them to communicate information to tourists as necessary.

The Navajo also operate the Antelope Point Marina on Lake Powell. Direct and indirect economic impacts of visitation to Lake Powell facilities are discussed in Section 4.14.2.1. There is very little difference among the alternatives regarding impacts on marinas on Lake Powell. Models indicate that all alternatives except Alternative F would result in negligible change in regional income, less than 0.6%. The largest potential decrease would be 1.1% under Alternative F because that alternative has higher releases in the spring and lower releases through the summer every year, and consequently slightly different reservoir levels in the summer months.

4.9.1.7 Maintain Tribal Water Rights and Supply

Reclamation is committed to operating Glen Canyon Dam so that all water obligations are met, including those to Tribes. Lake Powell supplies water to both the Navajo Chapter of LeChee and the City of Page, Arizona, which share a water intake system (NPS 2009b). Currently, two intakes provide water. There is an intake on the face of the dam at 3,480 ft above mean sea level and a second intake off the penstocks to Units 7 and 8 at 3,470 ft above mean sea level. In the current configuration, the minimum pool elevation necessary to supply LeChee and Page is 3,470 ft above mean sea level. The minimum power pool elevation is 3,490 ft above mean sea level, well above the water intakes (Grantz 2014). Plans now under consideration call for a new, lower intake at 3,373 ft above mean sea level. The modeling results for all of the alternatives show Lake Powell levels remaining above the existing and proposed intakes for the entire 20-year period (see Appendix J). The lowest pool level projected is 3,480.3 ft above mean sea level, about the level of the intake on the dam face and 10 ft above the penstock intake.

4.9.1.8 LTEMP Process

Tribes have been involved in the LTEMP development process and will continue to be involved in the implementation of LTEMP. Tribes have routinely expressed concern regarding how LTEMP decisions are made rather than what decision is made, the genuine incorporation of Tribal input, and the importance of learning to improve management over time. They have favored an experimental approach resulting in adaptive management.

Over the course of the development of the LTEMP DEIS, Reclamation and the NPS have sought to incorporate Tribal input into the LTEMP process. Cooperating and consulting Tribes were included in Cooperating Agency and stakeholder meetings. Reclamation and NPS have also held Tribal meetings, workshops, conference calls, and webinars. Various documents related to the development of the LTEMP DEIS have been provided to the Tribes for their review and input. When requested, there have been face-to-face meetings with the Tribes. Tribes were given the opportunity to contribute to the Tribal lands, affected environment, and environmental consequence sections of the EIS, and Tribal views have been incorporated throughout this EIS. A complete summary of Tribal consultation efforts is provided in Section 5 and Appendix N.

4.9.2 Analysis Methods

Two main issues emerged in analyzing how the proposed action would be likely to affect Tribal resources in the Canyons: (1) How would alternatives affect the continued existence of Tribal resources in the Canyons? and (2) How would alternatives affect the sacred integrity of and Tribal connections to the Canyons? Since the Tribes are the best judges of how the alternatives would affect them and because some Tribal resources are sacred and their locations confidential, the answers to these questions require input from the Tribes. The analysis presented here is based mainly on input from the Tribes, augmented with analysis of quantifiable impacts.

Input from the Tribes was sought and continues to be sought in a number of ways. Initially, NPS and Reclamation identified 43 federally recognized Tribes with potential historical and cultural ties to the Colorado River and its Canyons and invited them to participate in the LTEMP EIS process, as either Cooperating Agencies or consulting parties. NPS and Reclamation conducted meetings with groups of cooperating and consulting Tribes; these meetings included workshops, teleconferences, webinars, and face-to-face meetings with Tribal authorities in efforts to fully identify Tribal concerns about impacts of alternatives on resources. The agencies also consulted with Tribes during Cooperating Agency meetings. Tribes that chose to become Cooperating Agencies also were given the opportunity to contribute to the writing of the EIS. Chapter 5 and Appendix N provide descriptions and other information for the consultation process. Goals for resources of Tribal concern were developed from information obtained at these meetings, and Tribes had an opportunity to review, edit, and contribute additional information and concerns. Where possible, potential impacts on these resource goals were determined quantitatively, and modeling was used to quantify impacts. Modeling and analysis incorporated analyses from other resource areas such as aquatic resources, riparian vegetation, and economics. Tribes were invited to meetings where the results of the modeling were presented, and they were given a chance to ask questions and contribute comments.

Qualitative assessments of impacts were based on written information produced by or for the Tribes. Significant insight into Tribal priorities came from the Tribes that regularly monitor the state of resources in the Canyons that they consider significant. Tribal monitoring reports from the Hopi (Yeatts and Brod 1996; Dongoske 2001; Yeatts and Huisinga 2006, 2009, 2010, 2011, 2012, 2013), Hualapai (Jackson et al. 2001; Jackson-Kelly et al. 2009, 2010, 2011, 2013), Navajo (NNHPD 2012), Southern Paiute (Austin et al. 1999; Drye et al. 2000, 2001, 2002, 2006; Bulletts et al. 2003, 2004, 2008, 2010, 2011, 2012; Snow et al. 2007), and Zuni (Dongoske 2011a) were consulted for information on sites and resources of importance, as were ethnographies produced for the Tribes during previous related National Environmental Policy Act of 1969, as amended (NEPA) analyses (Ferguson and Lotenberg 1998; Lomaomvaya et al. 2001; Roberts et al. 1995; Yeatts and Huisinga 2003; Stoffle et al. 1994, 1995; Hart 1995).

4.9.3 Summary of Impacts

A summary of the impacts of the LTEMP alternatives on Tribal resources is presented in Table 4.9-2. In general, it is anticipated that there will be limited impacts on places and resources from the proposed action and the impacts that are anticipated do not vary greatly among the alternatives. Flow-related impacts on traditional cultural places include inundation by high flows (i.e., flows above the normal maximum operating flow of 25,000 cfs), resulting in erosion and temporary loss of access to such features as springs. Inundation impacts are temporary and can be mitigated through communication between Reclamation and the Tribes regarding scheduled high flows. The potential for the inundation of historic properties and erosion of terraces where historic properties are located is discussed above in Section 4.8. It is anticipated that traditional cultural resources most directly affected by flows would be riparian vegetation and fishes. Flow impacts on culturally important terrestrial wildlife would be minimal and do not vary among alternatives (see Section 4.7).

Some alternatives include non-flow actions that include trout removal and vegetation management. Proposed experimental vegetation management activities include the removal of nonnative species, clearing vegetation to expose sand for camping and distribution by wind, removing encroaching vegetation from campsites, and replacing removed nonnative species with native species, many of which have cultural importance to the Tribes. Vegetation management has the potential for both beneficial and adverse impacts (see Section 4.9.4). Increasing campable area by clearing campsites may not be seen as positive by Tribes that consider the Canyons a sacred space and are concerned with visitors disrespecting and interfering with important ceremonial and other cultural activities. All LTEMP alternatives would have the same overall level of visitation, set by the number of permits, so effects would be negligible in terms of a difference from No Action. In addition, there are potential positive effects that could result from using plants as barriers, closing off trails to culturally sensitive sites, and increasing native plants in treatment areas that are important to Tribes. Removing vegetation to open up sandy beaches has the potential for allowing wind to transport fine sediment to higher elevations and potentially shielding archaeological sites from erosion. These impacts would not vary among the action alternatives. Lethal removal of trout has been identified by the Zuni with the support of other affiliated Tribes as having an adverse effect on the TCP of the Grand Canyon, particularly when

TABLE 4.9-2 Summary of Impacts of LTEMP Alternatives on Tribal Resources

Resource	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Overall summary of impacts	Operations would result in no change in the amount of sand available for wind transport to cultural resource sites; a negligible loss of riparian diversity; a small loss of wetlands and no impact to Tribal water and economic resources. No TMFs, but mechanical trout removal could be triggered. After 2020, potential adverse impact to culturally important archaeological sites.	Compared to Alternative A, operations would result in a slight increase in the amount of sand available for wind transport to cultural resource sites except during hydropower improvement flows when there would be a slight decrease. There would be a slight loss in riparian diversity and slightly more loss in wetlands. There would be no impact on Tribal water and economic resources. TMFs and mechanical trout removal could be triggered. Small increase in sediment near Hualapai recreation operations; more frequent HFEs could affect docks.	Compared to Alternative A, operations would result in an increase in the amount of sand available for wind transport to cultural resource sites; the second largest loss in wetlands and a decrease in riparian plant diversity. Tribally operated marinas could experience a negligible drop in income. TMFs and mechanical trout removal could be triggered. Small increase in sediment near Hualapai recreation operations; more frequent HFEs could affect docks.	Compared to Alternative A, operations would result in an increase in the amount of sand available for wind transport to cultural resource sites; the least amount of wetlands loss across alternatives; and similar riparian plant diversity. Tribally operated marinas could experience a negligible drop in income. TMFs and mechanical trout removal could occur with or without triggers. Small increase in sediment near Hualapai recreation operations; more frequent HFEs could affect docks.	Compared to Alternative A, operations would result in an increase in the amount of sand available for wind transport to cultural resource sites; an increase in wetlands loss; and similar riparian plant diversity. Tribally operated marinas could experience a negligible drop in income. TMFs and mechanical trout removal could be triggered. Small increase in sediment near Hualapai recreation operations; more frequent HFEs could affect docks.	Compared to Alternative A, operations would result in an increase in the amount of sand available for wind transport to cultural resource sites but would result in an increase in the potential for river runners to explore and potentially damage places of cultural importance during May and June. The greatest loss of wetlands, largest increase in invasive species, and lowest riparian plan diversity occur under this alternative. Tribally operated marinas could experience a slight loss of income under this alternative. There would be no TMFs or mechanical trout removal. Small increase in sediment near Hualapai recreation operations; more frequent HFEs could affect docks.	Compared to Alternative A, operations would result in the greatest potential increase in the amount of sand available for wind transport to cultural resource sites; the third-largest wetlands loss across alternatives; and a decrease in riparian plant diversity. Tribally operated marinas could experience a negligible drop in income. TMFs and mechanical trout removal could be triggered. Small increase in sediment near Hualapai recreation operations; more frequent HFEs could affect docks.

TABLE 4.9-2 (Cont.)

Resource	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Traditional Cultural Places							
Visitation of culturally significant sites	No change in the potential for recreationists to visit culturally significant sites	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Compared to Alternative A, slight increase in the potential for recreationists to visit culturally significant sites in May and June.	Same as Alternative A.
Availability of sand for wind transport to protect culturally important archaeological sites	Negligible change in wind transport of sand; some increase in sand from HFEs until 2020, when HFEs are discontinued; potential adverse impact due to reduction in sediment availability after 2020.	Compared to Alternative A, slight potential increase (+7%) from HFEs continuing over entire LTEMP period; slight decrease (−10%) with implementation of hydropower improvement flows.	Compared to Alternative A, increased potential for wind transport of sand to cultural resource sites (+137%), resulting from increase in frequency of HFEs.	Compared to Alternative A, increased potential for wind transport of sand to protect cultural resource sites (+139%), resulting from increase in frequency of HFEs.	Compared to Alternative A, increased potential for wind transport of sand to cultural resource sites (+96%), resulting from increase in frequency of HFEs.	Compared to Alternative A, increased potential for wind transport of sand to cultural resource sites (+88%), resulting from increase in frequency of HFEs.	Compared to Alternative A, increased potential for wind transport of sand to cultural resource sites (+193%), resulting from increase in frequency of HFEs.

TABLE 4.9-2 (Cont.)

Resource	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Traditional Cultural Resources							
Riparian plant diversity	Slight loss of riparian plant diversity (0.95 diversity index).	Similar to Alternative A (0.97 diversity index).	Compared to Alternative A, decrease in riparian plant diversity (0.75 diversity index).	Similar to Alternative A (0.96 diversity index).	Similar to Alternative A (0.93 diversity index).	Compared to Alternative A, lowest riparian plant diversity (0.70 diversity index); largest acreage of invasive plants.	Compared to Alternative A, decrease in riparian plant diversity compared to Alternative A (0.83 diversity index).
Retention of wetlands (existing marsh is less than 5 ac total)	Approximately 3.6 ac retained; 28% loss.	Compared to Alternative A, approximately 4 ac retained (8% more). Under hydropower improvement, flows wetlands loss would be greater.	Compared to Alternative A, approximately 1.25 ac retained (47% less). Second-largest area of wetlands loss across alternatives.	Compared to Alternative A, approximately 4.2 ac retained (12% more). Least loss of wetlands across alternatives.	Compared to Alternative A, approximately 3.1 ac retained (10% less).	Compared to Alternative A, approximately 0.7 ac retained (58% less). Largest area of wetlands loss across alternatives.	Compared to Alternative A, approximately 1.5 ac retained (30% less). Third-largest area of wetlands loss.
Frequency of TMFs	No TMFs.	TMFs expected in 3 of 20 years	TMFs expected in about 6 of 20 years.	TMFs expected in 8 of 20 years.	TMFs expected in 3 of 20 years.	No TMFs.	TMFs expected in 11 of 20 years. Most TMFs of any alternative.
Frequency of mechanical removal of trout	Trout removal expected in <1 of 20 years.	Trout removal expected in <1 of 20 years.	Trout removal expected in about 0–3 of 20 years.	Trout removal expected in about 2–3 of 20 years.	Trout removal expected in about 0–2 of 20 years.	No trout removal. Least trout removal of any alternative.	Trout removal expected in 3 of 20 years. Most trout removal of any alternative.
Impacts on culturally important wildlife	Negligible adverse impact effects on culturally important wildlife.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.

TABLE 4.9-2 (Cont.)

Resource	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Economic and Water Resources							
Impact on Tribal recreation operations in Western Grand Canyon	No change from current sediment conditions; facilities may be affected by HFEs until 2020.	Compared to Alternative A, potential for small increase (<3%) in sediment deposited near Hualapai recreation operations; slightly greater impacts on docks due to slightly more frequent HFEs.	Compared to Alternative A, potential for small increase (<3%) in sediment deposited near Hualapai recreation operations; greater impacts on docks than Alternative A due to more frequent HFEs.	Compared to Alternative A, potential for small increase (<2%) in sediment deposited near Hualapai recreation operations; greater impacts on docks than Alternative A due to more frequent HFEs.[a]	Compared to Alternative A, potential for small increase (<3%) in sediment deposited near Hualapai recreation operations; greater impacts on docks than Alternative A due to more frequent HFEs.	Compared to Alternative A, potential for small increase (6%) in sediment deposited near Hualapai recreation operations; greater impacts on docks than Alternative A due to most frequent HFEs.	Compared to Alternative A, potential for small increase (<3%) in sediment deposited near Hualapai recreation operations; greater impacts on docks than Alternative A due to more frequent HFEs.
Impact on Tribal land-based vendors	No impact on land-based vendors.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.
Impact on Tribal marina operators	No change from current condition.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Compared to Alternative A, slight decrease in marina visitation (1.1%).	Same as Alternative A.
Water supply	Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.

[a] Adjustments made to Alternative D after modeling was completed included a prohibition of sediment-triggered and proactive spring HFEs in the same water year as an extended duration fall HFE. The number of spring HFEs would be reduced from 6.8 to 5.5 after the prohibition (1.3 fewer), and this reduction in frequency could reduce the impacts on Hualapai docks under Alternative D.

it takes place in proximity to the confluence of the Colorado River and the Little Colorado River, an area of special significance to the Zuni (Dongoske 2011b), the Hopi (Yeatts and Huisinga 2013), and the Navajo (Roberts et al. 1995). The lethal mechanical removal of trout and/or TMFs would be considered a significant adverse impact by some Tribes; however, if done in conjunction with mandated consultation with the Tribes, the impact may be reduced through beneficial uses and other practices that have been used for the Bright Angel fish removal efforts. For a discussion of alternative specific impacts see Section 4.9.4.

As discussed in Section 3.9, many of the Tribes that have been involved with this EIS consider portions of the Colorado River and its tributaries, the Canyons through which they flow, as well as elements within the river and Canyon corridors, as a TCP or part of a TCP. Any impact on any cultural place or cultural resource—be it an archaeological site, sacred place, traditional collection area, important plant or animal, or other element considered a TCP or contributing element to a TCP—is also considered an impact on the TCP, because these resources add to the overall traditional value of the TCP for these Tribes. As previously discussed, many Tribes have their own monitoring programs whereby resources and sites of importance are monitored, the health of the Canyon is examined, sacred sites are visited, and respects are paid to the Canyon and its resources. Any effect on the Canyons and their resources will likely be evaluated by each Tribe during the monitoring assessments. The Zuni in particular have stated that any action within the Grand Canyon will have to be assessed by the Zuni people for adverse effects that may be experienced in the Zuni Pueblo itself.

The Hualapai Tribe operates recreational facilities in the Western Grand Canyon, and their facilities and activities could be adversely affected by operation of Glen Cayon Dam. The Hualapai have expressed concern over dam operations they believe are increasing the amount of sediment collecting in the channel in their operational area below Diamond Creek. Their primary operations are centered in and around the Quartermaster area (RM 260). They have reported adverse impacts on their commercial operations from river sediment, including effects on equipment, access to their docks, and navigation in the river.

The Hualapai are concerned over the steep and unstable slopes previously inundated by Lake Mead that are now exposed due to reservoir levels retreating from the previous high-water line. The issues associated with the steep and unstable shorelines in the Lake Mead delta are related to the declining reservoir level, and will not be resolved until the level of Lake Mead either regains its previous high levels or until the banks naturally stabilize under new, lower reservoir levels.

The Hualapai are concerned with the effect of different flows on their boat docks. The number and duration of HFEs under LTEMP alternatives could affect boat docks and other facilities operated by the Hualapai Tribe. The dock structures were evaluated in 2012 by Reclamation engineers (Walkoviak 2012; see Section 4.10.2.6 for a discussion of the findings of this evaluation). LTEMP alternatives differ in the frequency and type of HFEs that would occur over the 20-year LTEMP period (Table 4.3-1; Sections 4.3.2 and 4.3.3). Alternative A would have the fewest (average of 5.5 HFEs over the LTEMP period, with HFEs not being conducted after 2020); Alternative F would have the most (average of 38.1 HFEs over the entire LTEMP period).

It is expected that dam operations, HFEs, equalization flows, and other flow events will continue to deliver sediment to the Western Grand Canyon and Lake Mead. Nearly all sediment that enters the Grand Canyon below Lake Powell will eventually move downstream. Higher flows, in general, do transport more sediment, and sediment transport will continue in the free-flowing portions of the river below Diamond Creek. Based on the analysis presented in Section 4.10.2.6, the increase in suspended sand at RM 225 under LTEMP alternatives relative to Alternative A is approximately 6% for Alternative F, 2% for Alternative D, and less than 3% for all other alternatives. This difference is significantly less than the differences under potential future hydrologic conditions. The location where this suspended sand deposits downstream of RM 225 will be a function of Lake Mead elevation and local hydraulic conditions. However, the amount will not be more that what is in suspension, so the sand deposition at RM 260 will be much less than the 2 to 6% increase in suspended sand expected under the LTEMP action alternatives.

4.9.4 Alternative-Specific Impacts

This section presents the impacts of the LTEMP alternatives on the Tribal resource goals presented in Section 4.9.1. Impacts are based on both quantitative and qualitative indicators of the status of resources that Tribes have indicated are culturally important. Factors considered include the state of riparian plant communities, riparian and terrestrial wildlife, and aquatic resources. Also considered are the time Canyon visitors spend off the river, potentially impacting traditional cultural places and economic opportunities for commercial Tribal river runners.

4.9.4.1 Alternative A (No Action Alternative)

Under Alternative A, the No Action Alternative, the modified fluctuating flows as defined in the 1996 ROD for the operation of Glen Canyon Dam would continue. Existing operations and recent decisions would be maintained. The existing HFE protocol and nonnative fish control actions and experimentation would continue until 2020 as specified in existing EAs. The HFE protocol EA (Reclamation 2011b) projected that access to and use of certain cultural properties could possibly be altered due to inundation in the area directly affected by an HFE. Less sand would be moved from Marble Canyon downstream under this alternative than under any other and it has the lowest sand load index score, which suggests there would be less building of sandbars, resulting in less sand being available for windborne transport to culturally important sites.

Alternative A is likely to result in a relatively even proportional distribution of plant community types, but a slight loss in plant community diversity. Modeling results suggest that 3.6 ac of wetland habitat will remain at the end of the 20-year LTEMP period, a decrease of 28% from the current wetland acreage (Section 4.6). An estimated 4.6 ac of wetlands occurs downstream from the dam.

Testing of TMFs is allowed under Alternative A, but since there has not been a decision to implement these flows, they are not considered a regular action under this alternative. Modeling of trout numbers suggests that mechanical removal trips would only rarely be triggered, resulting in the fewest removal trips of any alternative where mechanical removal is allowed, in part because removal actions would expire in 2020. As indicated by lack of significant changes in the riparian plant communities and the mobility of larger animals, impacts on terrestrial wildlife—including species important to Tribes, such as bighorn sheep, deer, snakes, amphibians, and yellow-feathered nesting birds (an important group of birds for the Hopi Tribe)—are likely to be negligible and would not differ among the alternatives (Section 4.7).

Time off river under this alternative would be the same as all other alternatives except Alternative F (Section 4.8.3).

No change from current conditions is expected with regard to recreational economic or water supply impacts on Tribes. There would be no change in current sediment conditions that could affect Hualapai recreation operations in the Western Grand Canyon, but existing Hualapai docks could be affected by HFEs until 2020. The Canyons are expected to continue to draw tourists who would patronize land-based Tribal tourist facilities and Native American craft vendors. These would not be affected by the flow alternatives. There would be no effect on the Navajo marina under this alternative (Sections 4.2 and 4.14.2.1; Reclamation 2011a). Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.

In summary, under Alternative A, there would be a relatively even distribution of plant community types, but a slight loss in plant diversity and wetland acreage. Trout removal trips are expected to be triggered in 1 year out of 20, the lowest expected number of trips among alternatives, which represents no change from current conditions. The availability of sand for wind transport could provide some benefit to some places of traditional cultural importance due to HFEs until 2020 when the HFE protocol expires, at which point these areas could experience an adverse impact due to lack of available sediment for wind transport. However, places of traditional cultural importance are present throughout the Canyons and vary in nature. Wind-transported sand may not always be considered a benefit for these resources. As stated in Section 4.8.2, the actual extent to which current sediment levels can stabilize archaeological sites on the terraces remains unknown. Sediment can also be removed from archaeological sites by wind and rain, a factor that could lead to loss of integrity of a traditionally important cultural place or resource. There would be no change in the potential for recreationists to visit culturally significant sites. Impacts on Tribally important riparian plant communities and terrestrial wildlife are expected to be negligible. There would be no change from current conditions related to Tribal recreation economics, Tribal land-based vendors, marinas operated by Tribal enterprises, or Navajo Nation water supply. Any impact on a Tribally important cultural place or resource is also considered an impact on a Tribe's TCP.

4.9.4.2 Alternative B

Alternative B would follow the same monthly water release volumes as Alternative A, but there would be greater fluctuations in 10 months of the year and increased down-ramp rates. Under this alternative, HFEs would be implemented over the entire 20-year LTEMP period, but they are limited to no more than one every other year. There is greater daily flow fluctuation than in Alternative A for most months. Hydropower improvement flows—operations with wider fluctuations in high electrical demand months—would be tested in 4 years when the annual release volume is ≥8.23 maf. TMFs would be tested and implemented if successful.

This alternative is likely to result in the maintenance of current levels of evenness and diversity of plant community distribution; slightly higher plant diversity is expected than under Alternative A. Due to a lack of extended high or low flows that scour or desiccate wetlands, approximately 4 ac of wetlands would be retained under Alternative B, 8% more than under Alternative A (Section 4.6), except under the hydropower improvement flows, in which case there would be increased loss of wetlands. An estimated 4.6 ac of wetlands occurs downstream from the dam.

The wider daily fluctuations under Alternative B would reduce the potential for bar-building, making less sand available for windborne transport to culturally important places relative to normal operations under Alternative B. Under typical operations, more sediment would be deposited above the 31,500 cfs level and the potential for sandbar building as reflected in the sand load index would be slightly greater (+7%) than under Alternative A, unless hydropower improvement flows are included, in which case the sand load index would be slightly less than under Alternative A (−10%).

Under this alternative, TMFs are expected to occur in about three of the 20 LTEMP years. This alternative and Alternative E likely would have the fewest TMFs among the alternatives that would test and implement TMFs (Alternative A allows testing and Alternative F does not). Low numbers of TMFs result from lower numbers of trout recruits in the Glen Canyon reach. Low trout numbers result from higher daily fluctuations and fewer spring HFEs. When trout numbers are low, mechanical removal is triggered in fewer years.

Based on the lack of significant changes in the riparian plant communities and the mobility of larger wildlife species, impacts on terrestrial wildlife—including species important to Tribes, such as big horn sheep, deer, snakes, amphibians, and yellow-feathered nesting birds (an important group of birds for the Hopi Tribe)—are likely to be negligible and not to differ across the alternatives (Section 4.7).

Time off river under this alternative would be the same as all other alternatives except Alternative F (see Section 4.8.3).

Few changes relative to current conditions are expected with regard to recreational economic impacts on Tribes; no impacts are expected on water supply. There could be a small (<3%) increase in the amount of sand that could be deposited near Hualapai recreation operations in the Western Grand Canyon. Existing Hualapai docks could be affected by HFEs during the

entire LTEMP period, but the total number of HFEs (7.2) would be comparable to the number under Alternative A (5.5). The Canyons are expected to continue to draw tourists who would patronize land-based Tribal tourist facilities and Native American craft vendors. These would not be affected by the flow alternatives. There would be no effect on reservoir elevation and the Navajo marina under this alternative. Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.

In summary, under Alternative B, current wetland acreage is expected to be retained and plant diversity would be slightly higher than under Alternative A, except under hydropower improvement flows, which would result in greater loss of wetlands. TMFs are expected to be triggered in 3 years out of 20; while trout removal trips are expected to potentially be triggered, if at all, in 1 year out of 20. The availability of sand for wind transport to potentially protect some places of traditional cultural importance would somewhat increase relative to Alternative A because HFEs would occur over the entire LTEMP period. However, the high fluctuations of hydropower improvement flow would potentially decrease the availability of sand. Places of traditional cultural importance are present throughout the Canyons and vary in nature. Wind-transported sand may not always be considered a benefit for these resources. As stated in Section 4.8.2, the actual extent to which current sediment levels can stabilize archaeological sites on the terraces remains unknown. Sediment can also be removed from archaeological sites by wind and rain, a factor that could lead to loss of integrity of a traditionally important cultural place or resource. There would be no change in the potential for recreationists to visit culturally significant sites. Impacts to Tribally important riparian plant communities and terrestrial wildlife are expected to be negligible. There would be no change from current conditions related to Tribal land-based vendors, marinas operated by Tribal enterprises, or Navajo Nation water supply. There is the potential for a minor increase in impacts on Hualapai docks related to a minor increase in the number of HFEs over the LTEMP period. Any impact on a Tribally important cultural place or resources is also considered an impact on a Tribe's TCP.

4.9.4.3 Alternative C

Under Alternative C, the highest water release volumes would occur in the high electric demand months of December, January, and July, with lower volumes from August through November to conserve sediment inputs during the monsoon period. The HFE protocol would be followed for the entire 20-year period, and some additional HFEs would be allowed. Proactive spring HFEs would be tested in years with a high volume of flow (>10 maf). Compared to Alternative A, more sediment would be deposited above the 31,500 cfs level and the potential for sandbar building as reflected in the sand load index would be greater (+137%), making more sand available for windborne transport to cultural sites (Section 4.3).

Operations under this alternative are expected to result in relatively low plant community diversity and evenness. High flows followed by growing season lows are likely to result in more loss of diversity than under Alternative A (Section 4.6). This alternative is expected to retain approximately 1.25 ac of wetlands, 47% less than that retained under Alternative A. This alternative results in more wetland loss than any other alternative except Alternative F. An estimated 4.6 ac of wetlands occurs downstream from the dam.

TMFs are expected to be triggered in about 6 out of 20 years under this alternative because of the relatively higher number of trout expected to be produced (Section 4.5). Mechanical trout removal is expected to be triggered in few if any of the 20 years modeled.

As under other alternatives, because of the types of changes expected in the riparian plant communities and the mobility of larger wildlife species, impacts on terrestrial wildlife—including species important to Tribes, such as bighorn sheep, deer, snakes, amphibians, and yellow-feathered nesting birds (an important group of birds for the Hopi Tribe)—are likely to be negligible and not to differ across the alternatives (Section 4.7).

Time off river under this alternative would be the same as all other alternatives except Alternative F (see Section 4.8.3).

Some changes relative to current conditions are expected with regard to recreational economic impacts on Tribes; no impacts are expected on water supply. There could be a small increase (<3%) in the amount of sand that could be deposited near Hualapai recreation operations in the Western Grand Canyon. Existing Hualapai docks could be affected by HFEs during the entire LTEMP period, and the total number of HFEs (21.3) would be higher than the number under Alternative A (5.5). The Canyons are expected to continue to draw tourists who would patronize land-based Tribal tourist facilities and Native American craft vendors. These would not be affected by the flow alternatives. There would be a minor effect on reservoir elevation that could result in a decrease (<0.6%) in income at the Navajo marina. Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.

In summary, under Alternative C, the diversity of riparian plant communities is expected to decrease, and this alternative is expected to result in the second-largest area of wetland loss when compared to Alternative A. TMFs are expected to be triggered in 6 out of 20 years, and trout removal trips could potentially to be triggered in 3 out of 20. Under Alternative C, there would be a slight increase in the potential for wind transport of sand to protect some places of traditional cultural importance when compared to Alternative A. However, places of traditional cultural importance are present throughout the Canyons and vary in nature. Wind-transported sand may not always be considered a benefit for these resources. As stated in Section 4.8.2, the actual extent to which current sediment levels can stabilize the archaeological sites on the terraces remains unknown. Sediment can also be removed from archaeological sites by wind and rain, a factor that could lead to loss of integrity of a traditionally important cultural place or resource. There would be no change in the potential for recreationists to visit culturally significant sites. Impacts on Tribally important riparian plant communities and terrestrial wildlife are expected to be negligible. There would be no change from current conditions related to Tribal land-based vendors or Navajo Nation water supply. There is the potential for an increase in impacts on Hualapai docks related to a minor increase in the number of HFEs over the LTEMP period, and a negligible loss of income (<0.6%) at Tribally operated marinas on Lake Powell. Economic effects on Tribal tourist enterprises would be the same as under Alternative A, except for Tribally operated marinas, which would experience a negligible drop in income. Any impact on a Tribally important cultural place or resources is also considered an impact on a Tribe's TCP.

4.9.4.4 Alternative D (Preferred Alternative)

Alternative D adopts characteristics of Alternatives C and E to achieve sediment retention characteristics and other resource benefits while reducing impacts on the value of hydropower generation and capacity, when compared to Alternatives C and E. Like Alternatives C and E, Alternative D includes a number of condition-dependent flow and non-flow actions that may be triggered by resource conditions. Alternative D differs from the other two in the specific trigger conditions and the actions that would be taken. Compared to Alternative A, more sediment would be deposited above the 31,500 cfs level and the potential for sandbar building as reflected in the sand load index would be greater (+139%), making more sand available for windborne transport to cultural sites (Section 4.3).

Under Alternative D, riparian plant community diversity and evenness would be virtually the same as under Alternative A and similar to Alternative E. These alternatives would result in only a slight loss of plant community diversity. There would be on average an overall loss of invasive species; both tamarisk and arrowweed would decrease under Alternative D. There would be somewhat less loss of tamarisk under Alternative D than under Alternatives A or E. Repeated extended high flows can remove tamarisk and arrowweed. The low number of growing season extended low flows would limit tamarisk establishment and the shifting of wetland communities to arrowweed (Section 4.6.3.4).

Approximately 4.2 ac of wetlands would be retained under Alternative D, 12% more than under Alternative A. This alternative would result in the least amount of wetland loss of all alternatives. Greater wetland acreage is associated with greater plant community diversity. Low numbers of extended low flows during the growing season would limit the occurrence of wetland communities shifting to arrowweed. An estimated 4.6 ac of wetlands occurs downstream from the dam.

Spring HFEs, which stimulate the food base, and steady summer flows are factors that tend to result in trout population growth. Spring HFEs would be more common under Alternative D than under Alternative A, and summer daily fluctuations would be slightly less under Alternative D than under Alternative A. Under Alternative D, TMFs are expected to be triggered in about 8 out of 20 years. This would be more often than under any alternative except Alternative G, partly because TMFs could be triggered during years in which the production of young-of-the-year rainbow trout in the Glen Canyon reach is anticipated to be high. Overall, because TMFs are expected to reduce the number of fish in the trigger reach, mechanical removal could be triggered in fewer years. Under Alternative D, modeling suggests that trout removal would occur in about 2 to 3 out of 20 years.

As under other alternatives, because of the types of changes expected in riparian plant communities and the mobility of larger wildlife species, impacts on terrestrial wildlife—including species important to Tribes, such as bighorn sheep, deer, snakes, amphibians, and yellow-feathered nesting birds—are likely to be negligible and not to differ across the alternatives (Section 4.7).

Time off river under this alternative would be the same as all other alternatives except Alternative F (Section 4.8.3).

Some changes relative to current conditions are expected with regard to recreational economic impacts on Tribes; no impacts are expected on water supply. There could be a small (<2%) increase in the amount of sand that could be deposited near Hualapai recreation operations in the Western Grand Canyon; existing Hualapai docks could be affected by HFEs during the entire LTEMP period, and the total number of HFEs (21.1)[23] would be higher than the number under Alternative A (5.5). The Canyons are expected to continue to draw tourists who would patronize land-based Tribal tourist facilities and Native American craft vendors. These would not be affected by the flow alternatives. There would be a minor effect on reservoir elevation that could result in a decrease (<0.6%) in income at the Navajo marina. Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.

In summary, under Alternative D, there would be a relatively even distribution of plant community types, but a slight loss in plant diversity, similar to Alternative A. The least amount of wetland acreage loss would occur under this alternative. TMFs are expected to be triggered in 8 years out of 20, and trout removal trips could potentially be triggered 3 years out of 20. Under Alternative D, there would be a slight increase in the potential for wind transport of sand to protect some places of traditional cultural importance when compared to Alternative A. However, places of traditional cultural importance are present throughout the Canyons and vary in nature. Wind-transported sand may not always be considered a benefit for these resources. As stated in Section 4.8.2, the actual extent to which current sediment levels can stabilize the archaeological sites on the terraces remains unknown. Sediment can also be removed from archaeological sites by wind and rain, a factor that could lead to loss of integrity of a traditionally important cultural place or resource. There would be no change in the potential for recreationists to visit culturally significant sites. Impacts on Tribally important riparian plant communities and terrestrial wildlife are expected to be negligible. There would be no change from current conditions related to Tribal land-based vendors or Navajo Nation water supply. There is the potential for a minor increase in impacts on Hualapai docks related to an increase in the number of HFEs over the LTEMP period, and a negligible loss of income (<0.6%) at Tribally operated marinas on Lake Powell. Any impact on a Tribally important cultural place or resources is also considered an impact on a Tribe's TCP.

4.9.4.5 Alternative E

Like Alternatives C and D, Alternative E includes a number of condition-dependent flow and non-flow actions that would be triggered by resource conditions. Alternative E differs from the other two in the specific trigger conditions and the actions that would be taken. Under Alternative E, the relatively high number of HFEs projected would result in a higher sand load

[23] Adjustments made to Alternative D after modeling was completed included a prohibition of sediment-triggered and proactive spring HFEs in the same water year as an extended-duration fall HFE. The estimated number of HFEs after this adjustment would be about 19.8 (1.3 fewer than were modeled). This reduced number of HFEs could reduce the impact of Alternative D on Hualapai docks in the Western Grand Canyon.

index (+96%) and significantly more sandbar building potential than under Alternative A, making more sand available for windborne dispersal to culturally important places.

This alternative would result in a slightly less diverse and even distribution of plant community types than under Alternatives A, B, and D, but more diversity and evenness than under Alternatives C, F, or G. This alternative is expected to retain approximately 3.1 ac of wetlands, 10% less relative to Alternative A. An estimated 4.6 ac of wetlands occurs downstream from the dam.

TMFs would be triggered in about the same number of years as under Alternative B. Fewer TMFs are expected because the number of trout in the Glen Canyon reach is expected to be lower under this alternative as a result of higher summer fluctuation levels and fewer spring HFEs. Mechanical removal would be triggered in up to 2 out of 20 years.

Because of the types of changes expected in riparian plant communities and the mobility of larger wildlife species, impacts on terrestrial wildlife—including species important to Tribes, such as bighorn sheep, deer, snakes, amphibians, and yellow-feathered nesting birds—are likely to be negligible and not to differ across the alternatives (Section 4.7).

Time off river under this alternative would be the same as all other alternatives except Alternative F (Section 4.8.3).

Some changes relative to current conditions are expected with regard to recreational economic impacts on Tribes; no impacts are expected on water supply. There could be a small (<3%) increase in the amount of sand that could be deposited near Hualapai recreation operations in the Western Grand Canyon. Existing Hualapai docks could be affected by HFEs during the entire LTEMP period, and the total number of HFEs (17.1) would be higher than the number under Alternative A (5.5). The Canyons are expected to continue to draw tourists who would patronize land-based Tribal tourist facilities and Native American craft vendors. These would not be affected by the flow alternatives. There would be a minor effect on reservoir elevation that could result in a decrease (<0.6%) in income at the Navajo marina. Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.

In summary, under Alternative E, diversity and evenness of plant community types would be slightly less than under Alternatives A, B, and D, but slightly more than under Alternatives C, F, or G. This alternative would retain more wetland acreage than Alternatives F, G, and C. TMFs are expected to be triggered in 3 years out of 20, and trout removal trips could potentially to be triggered 2 years out of 20. Under Alternative E, there is a slight increase in the potential for wind transport of sand to protect some places of traditional cultural importance when compared to Alternative A. However, places of traditional cultural importance are present throughout the Canyons and vary in nature. Wind-transported sand may not always be considered a benefit for these resources. As stated in Section 4.8.2, the actual extent to which current sediment levels can stabilize the archaeological sites on the terraces remains unknown. Sediment can also be removed from archaeological sites by wind and rain, a factor that could lead to loss of integrity of a traditionally important cultural place or resource. Impacts on Tribally important riparian plant communities and terrestrial wildlife are expected to be negligible. There would be no

change in the potential for recreationists to visit culturally significant sites. There would be no change from current conditions related to Tribal land-based vendors or Navajo Nation water supply. There is the potential for a minor increase in impacts on Hualapai docks related to an increase in the number of HFEs over the LTEMP period, and a negligible loss of income (<0.6%) at Tribally operated marinas on Lake Powell. Any impact on a Tribally important cultural place or resources is also considered an impact on a Tribe's TCP.

4.9.4.6 Alternative F

Alternative F is designed to re-create a more natural (pre-dam) flow pattern while limiting sediment transport and providing lower, stable base flows in summer, fall, and winter, and warmer temperatures in the summer. It allows both spring and fall HFEs, which should significantly increase the deposition and retention of sediment relative to Alternative A. Compared to Alternative A, more sediment would be deposited above the 31,500 cfs level and the potential for sandbar building as reflected in the sand load index would be greater (+88%), making more sand available for windborne transport to cultural sites (Section 4.3).

This alternative would result in the lowest degree of evenness and diversity and the greatest spread of tamarisk-dominated communities. This alternative would have high flows that spread tamarisk seeds followed by growing season low flows, which would allow seedlings to establish themselves. Similarly, this alternative is expected to result in the greatest amount of wetland loss of any alternative, retaining only 0.7 ac of wetlands, 58% less than under Alternative A. An estimated 4.6 ac of wetlands occurs downstream from the dam.

This alternative includes neither mechanical removal nor TMFs and would thus allow nature to take its course regarding the interaction of humpback chub and nonnative trout. The steady flows and frequent spring HFEs of this alternative are expected to produce larger numbers of trout relative to most other alternatives.

Because of the types of changes expected in the riparian plant communities and the mobility of larger wildlife species, impacts on terrestrial wildlife—including species important to Tribes, such as bighorn sheep, deer, snakes, amphibians, and yellow-feathered nesting birds—are likely to be negligible and not to differ across the alternatives (Section 4.7).

Under this alternative, visitors to the Canyons would spend slightly more time off the river than under any of the other alternatives (Section 4.8.3).

Some changes relative to current conditions are expected with regard to recreational economic impacts on Tribes; no impacts are expected on water supply. There could be a small (<6%) increase in the amount of sand that could be deposited near Hualapai recreation operations in the Western Grand Canyon; existing Hualapai docks could be affected by HFEs during the entire LTEMP although the total number of HFEs (38.1; highest of alternatives) would be much higher than the number under Alternative A (5.5). The Canyons are expected to continue to draw tourists who would patronize land-based Tribal tourist facilities and Native American craft vendors. These would not be affected by the flow alternatives. There would be a minor effect on

reservoir elevation that could result in a decrease (1.1%; highest of alternatives) in income at the Navajo marina. Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.

In summary, under Alternative F, plant diversity would be at its lowest, wetland loss would be at its highest, and the largest acreage of invasive species would occur. There would be no TMFs or mechanical trout removal trips under this alternative. Under Alternative F, there would be a slight increase in the potential for wind transport of sand to protect some places of traditional cultural importance when compared to Alternative A. However, places of traditional cultural importance are present throughout the Canyons and vary in nature. Wind-transported sand may not always be considered a benefit for these resources. As stated in Section 4.8.2, the actual extent to which current sediment levels can stabilize the archaeological sites on the terraces remains unknown. Sediment can also be removed from archaeological sites by wind and rain, a factor that could lead to loss of integrity of a traditionally important cultural place or resource. There would be a slight increase in the potential for recreationists to visit and potentially damage culturally significant sites during May and June. Impacts to Tribally important riparian plant communities and terrestrial wildlife are expected to be negligible. There would be no change from current conditions related to Tribal land-based vendors or Navajo Nation water supply. There is the potential for a minor increase in impacts on Hualapai docks related to an increase in the number of HFEs over the LTEMP period, and a negligible loss of income (<0.6%) at Tribally operated marinas on Lake Powell. Any impact on a Tribally important cultural place or resources is also considered an impact on a Tribe's TCP.

4.9.4.7 Alternative G

Alternative G targets the conservation of sediment through steady, equal monthly release volumes that would maximize retention of sediment, and the largest number of HFEs of any alternative, some with extended duration, which would distribute and retain sediment at higher elevations. Compared to Alternative A, more sediment would be deposited above the 31,500 cfs level and the potential for sandbar building as reflected in the sand load index would be greater (+193%), making more sand available for windborne transport to cultural sites (Section 4.3).

With more high flows, it is likely that this alternative would result in somewhat less diversity and evenness of plant communities than under Alternative A, but more diversity and evenness than under Alternatives C and F. The alternative would retain approximately 1.5 ac of wetlands, 30% less than Alternative A. Mean wetland acreage would be lower that of Alternatives A, B, D, and E, but above that of Alternatives C and F (see Appendix J). An estimated 4.6 ac of wetlands occurs downstream from the dam.

The steady summer flows and spring HFEs that characterized this alternative create favorable conditions for the growth of the trout population. As a consequence, TMFs are expected to occur more often under this alternative (11 out of 20 years) than under any other. Mechanical removal would also occur more often under this alternative than any other, on average about 3 out of 20 years.

Because of the types of changes expected in the riparian plant communities and the mobility of larger wildlife species, impacts on terrestrial wildlife—including species important to Tribes, such as bighorn sheep, deer, snakes, amphibians, and yellow-feathered nesting birds—are likely to be negligible and not to differ across the alternatives (Section 4.7).

Time off river under this alternative would be the same as all other alternatives except Alternative F (Section 4.8.3).

Some changes relative to current conditions are expected with regard to recreational economic impacts on Tribes; no impacts are expected on water supply. There could be a small (<3%) increase in the amount of sand that could be deposited near Hualapai recreation operations in the Western Grand Canyon; existing Hualapai docks could be affected by HFEs during the entire LTEMP although the total number of HFEs (24.5) would be much higher than the number under Alternative A (5.5). The Canyons are expected to continue to draw tourists who would patronize land-based Tribal tourist facilities and Native American craft vendors. These would not be affected by the flow alternatives. There would be a minor effect on reservoir elevation that could result in a decrease (<0.6%) in income at the Navajo marina. Lake Powell elevation would remain above the level of the water intakes used by the Navajo Nation.

In summary, under Alternative G, there would be a decrease in riparian plant diversity, and the third-largest wetland acreage loss across alternatives would occur. TMFs are expected to be triggered in 11 out of 20 years, and trout removal trips could potentially to be triggered 3 out of 20 years. Under Alternative G, there would be a slight increase in the potential for wind transport of sand to protect some places of traditional cultural importance when compared to Alternative A. However, places of traditional cultural importance are present throughout the Canyons and vary in nature. Wind-transported sand may not always be considered a benefit for these resources. As stated in Section 4.8.2, the actual extent to which current sediment levels can stabilize the archaeological sites on the terraces remains unknown. Sediment can also be removed from archaeological sites by wind and rain, a factor that could lead to loss of integrity of a traditionally important cultural place or resource. Impacts on Tribally important riparian plant communities and terrestrial wildlife are expected to be negligible. There would be no change in the potential for recreationists to visit culturally significant sites when compared to Alternative A. There would be no change from current conditions related to Tribal land-based vendors or Navajo Nation water supply. There is the potential for a minor increase in impacts on Hualapai docks related to an increase in the number of HFEs over the LTEMP period, and a negligible loss of income (<0.6%) at Tribally operated marinas on Lake Powell. Any impact on a Tribally important cultural place or resources is also considered an impact on a Tribe's TCP.

4.10 RECREATION, VISITOR USE, AND EXPERIENCE

This section presents the potential impacts of LTEMP alternatives on recreation, visitor use, and experience. Background information on the resources or resource attributes included in this analysis can be found in Section 3.10. There are also references to Sections 4.5 (Aquatic Ecology), Section 4.6 (Plant Communities), Section 4.14 (Socioeconomics and Environmental Justice), and the Recreation Economic Analysis in Appendix L, as they apply to visitor use and experience.

Issue: How do the alternatives affect recreation, visitor use, and experience?

Impact Indicators:

- Fish size and catch rate
- Flow fluctuation, water levels, and HFEs
- Navigability and safety
- Lost visitor opportunities
- Camping and recreation facilities on old sediment terraces
- Campsite area
- Campsite crowding
- Encounters with other groups
- Lake recreation
- Impacts on Tribal recreation operations in the Western Grand Canyon

4.10.1 Analysis Methods

The analysis of impacts on recreation, visitor use, and experience downstream of Glen Canyon Dam was based on assessment of alternative-specific differences in 10 indicators that were based on six quantitative metrics developed using recreational findings in published papers and reports, and quantified based on alternative-specific flow characteristics. The metrics were developed through consultation with subject matter experts and with consideration of comments from Cooperating Agencies.

Four of the metrics address issues important to visitor use and experience in GCNP, while the other two metrics focus on the Glen Canyon reach between the dam and Lees Ferry. Some information used for the assessment is not from measures of specific factors but is qualitative in nature. Most metrics were created as indices with values ranging from 0 to 1, where 1 is the optimal condition for that resource, and 0 represents the lowest possible value. An index with a relative scale was used because it was often impossible to quantify the condition of the resource, but it was possible to generate a relative scale that reflected that condition. For example, there is no current methodology that defines how specific camping areas in GCNP might respond to HFEs, but there is a basis for making conclusions about which conditions are likely to favor a general increase in camping area in the park. The exception to the 0 to 1 scale is the Glen Canyon Rafting Metric, which measures the number of potential lost rafting trips. All of the metrics except the Glen Canyon Rafting Metric are seasonally weighted to reflect seasonal differences in recreational use, with more weight given to conditions in the peak recreation period than in periods with less use. More information including assumptions and limitations of these metrics is in Appendix J. The six recreation-specific metrics are as follows:

- *Camping Area Index*—Accounts for optimal campsite area building and maintenance flows and sediment load (also used as input to the assessment of campsite crowding).

- *Time Off-River Index*—Relates the level of flows to visitors being able to spend time ashore visiting attractions.

- *Fluctuation Index*—Based on combinations of flows and fluctuations identified as preferable by experienced boat operators.

- *Navigation Index*—Based on the percentage of time minimum daily flows are less than 8,000 cfs (also used as input to the assessment of campsite crowding and encounters with other groups).

- *Glen Canyon Rafting Metric*—Estimates the number of visitors unable to participate in day rafting in Glen Canyon due to high flows; the metric is the mean annual number of lost visitor opportunities.

- *Glen Canyon Inundation Index*—Accounts for flows that impact recreational sites and recreational uses within the Glen Canyon reach.

An 8,000-cfs maximum daily fluctuation limit was established in the 1996 ROD (Reclamation 2006) to address safety, recreation, and sediment concerns (Reclamation 1995). The analysis conducted for the LTEMP EIS has not identified new evidence to suggest that these concerns and this fluctuation level do not still apply. The determination of 8,000 cfs as a maximum daily fluctuation level that is suitable for recreation was based on Bishop et al. (1995). Bishop et al. surveyed both the river guides and the general public regarding preferences, and the river guides reported a preference for a maximum of 8,000-cfs daily change for a "tolerable recreation experience" under relatively high average daily flows. The current river guide community and the public have continued to state the preference for retaining the 8,000-cfs maximum daily fluctuation that is currently in place under Alternative A.

In the discussions below, the anticipated impacts of the alternatives are compared to the effects of Alternative A, the No Action Alternative. Impacts on recreation were developed using these metrics as well as published literature to evaluate how recreation would be affected by the alternatives. Information used includes the number and seasonality of HFEs, daily flow information, economic analysis, and fishery and vegetation management information that is documented in other portions of this EIS. Metric values are based on 20-year simulations of Glen Canyon Dam releases under different hydrology and sediment conditions as determined for the various LTEMP alternatives.

The economic analysis conducted by Gaston et al. (2015) quantified the net economic use value (NEV) of recreation at Lakes Powell and Mead, and for three reaches of the Colorado River: Glen Canyon, the Upper Grand Canyon, and the Lower Grand Canyon under the LTEMP alternatives. The results of this analysis are presented in Section 4.14 and Appendix L.

4.10.2 Summary of Impacts

The impacts of LTEMP alternatives on visitor use and experience are summarized in Table 4.10-1. Graphs showing the performance of the alternatives for each of the metrics are shown in Figure 4.10-1. A more detailed analysis for each of the alternatives is presented in Section 4.10.3.

Differences in the alternatives' effects on recreation tend to be mostly related to differences in the frequency and characteristics of experimental flows, particularly HFEs and TMFs, but are also related to differences in operations such as fluctuating flow effects during high-demand seasons for hydropower. Effects are greater for actions that occur during peak recreational use months, for example certain spring HFEs that may occur during the peak rafting season. Some experimental flows and actions occur in only a few years; thus, for the majority of time, the LTEMP alternatives' experimental flows cause little difference for recreation effects. Differences in daily maximum and minimum flows under normal operations can, however, distinguish between alternatives with respect to potential effects on recreation. Daily maximum flows above 8,000 cfs increasingly reduce usable beach area, and would effectively submerge all beach area at flows above 31,500 cfs (Section J.2.1.1). In addition, daily fluctuations resulting in minimum flows below 8,000 cfs can affect river navigability and cause delays at rapids. Flow fluctuations can also affect shoreline angling, and rafters who camp may be forced to move to higher ground and to check boat moorings overnight. Such effects would not occur or would be less prominent under alternatives with reduced fluctuation or steady flows (e.g., Alternatives A, C, D, F, and G), while high steady flows under Alternative F in some spring and summer months would reduce usable camping area. Lastly, not all effects are experienced by all recreational users, and other effects are localized. For example, flow fluctuations may affect overnight boaters who camp more than day-only boaters, while vegetation management and mechanical trout removal are both localized actions that would affect recreation in only portions of the river at any given time.

4.10.2.1 Glen Canyon Fishing

Effects of Flow Fluctuations, Water Levels, and HFEs

Anglers in the Glen Canyon reach identified a preference for steady flows and flows between 8,000 and 15,000 cfs (Bishop et al. 1987). Stewart et al.'s (2000) follow-up of the Bishop et al. (1987) study after the implementation of MLFF flows in 1996 did not identify river level fluctuations as an issue, and in 2011 an AZGFD creel study found that angler satisfaction in the Glen Canyon reach was high (Anderson, M. 2012), indicating that the existing flow regime was favorable for Glen Canyon anglers.

TABLE 4.10-1 Summary of Impacts of LTEMP Alternatives on Recreation, Visitor Use, and Experience

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)[a]	Alternative E	Alternative F	Alternative G
Overall summary of impacts	No change from current conditions. Fewest HFEs, moderate fluctuations, intermediate trout catch rates, few navigability concerns, few lost day-rafting visitor days (49 over 20-year period), and declining camping area.	Compared to Alternative A, comparable number of HFEs and higher fluctuations result in more lost day-rafting visitor days (45% increase) in Glen Canyon, highest number of large trout (13% increase), lowest trout catch rates, most navigability concerns, and similar camping area (5% increase in index).	Compared to Alternative A, more HFEs and lower fluctuations result in more lost day-rafting visitor days in Glen Canyon (543% increase), similar number of large trout (3% decrease), higher trout catch rates; fewer navigation concerns, and more camping area (170% increase in index).	Compared to Alternative A, more HFEs and comparable fluctuations result in more lost day-rafting visitor days in Glen Canyon (610% increase), similar number of large trout (5% increase), similar trout catch rates, similar navigation concerns, and more camping area (158% increase in index).	Compared to Alternative A, more HFEs, higher fluctuations, and more frequent flows below 8,000 cfs result in more lost day-rafting visitor days in Glen Canyon (261% increase), more large trout (8% increase), lower trout catch rates, more navigation concerns, and more camping area (118% increase in index).	Compared to Alternative A and all other alternatives ,frequent HFEs, steady flows, and lack of trout management actions result in most lost day-rafting visitor days in Glen Canyon (1,776% increase), higher trout catch rates, but fewest large trout (22% decrease); very few navigability concerns, and more camping area (191% increase in index).	Compared to Alternative A, more HFEs and steady flows result in few additional lost day-rafting visitor days in Glen Canyon (4% increase), higher trout catch rates, but fewer large trout (9% decrease); very few navigability concerns, and greatest potential increase in camping area (220% increase in index).

TABLE 4.10-1 (Cont.)

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)[a]	Alternative E	Alternative F	Alternative G
Glen Canyon—Fishing							
Fluctuations, water levels, and HFEs	No change from current conditions; high angler satisfaction with flow levels and daily fluctuations; average 5.5 HFEs (lowest of alternatives) until 2020 (up to 8 days in a calendar year if both spring and fall HFEs were triggered) that may disrupt fishing during their implementation.	Compared to Alternative A, similar satisfaction with flow levels and fluctuations; average 7.2 HFEs over LTEMP period (up to 4 days in a calendar year) that may disrupt fishing during their implementation.	Compared to Alternative A, similar satisfaction with flow levels and fluctuations; average 21.3 HFEs over LTEMP period (up to 10 days in a calendar year if both a spring and an extended-duration fall HFE were triggered) that may disrupt fishing during their implementation.	Compared to Alternative A, similar satisfaction with flow levels and fluctuations; average 21.1 HFEs over LTEMP period (up to 10 days in a calendar year if an extended-duration fall HFE were triggered) that may disrupt fishing during their implementation.	Compared to Alternative A, similar satisfaction with flow levels and fluctuations; average 17.1 HFEs over LTEMP period (up to 8 days in a calendar year if both spring and fall HFEs were triggered) that may disrupt fishing during their implementation.	Compared to Alternative A, lower satisfaction with flow levels; average 38.1 HFEs (highest of alternatives) over LTEMP period (up to 8 days in a calendar year if both spring and fall HFEs were triggered) may disrupt fishing during their implementation.	Compared to Alternative A, similar satisfaction with flow rates; average 24.5 HFEs over LTEMP period (up to 18 days in a calendar year if both spring and extended-duration fall HFEs were triggered) that may disrupt fishing during their implementation.
Fish size and catch rate	No change from current conditions; intermediate catch rates and estimated 770 large trout (≥16 in.).	Compared to Alternative A, lowest angler catch rates, but 13% more large trout (870, most of any alternative).	Compared to Alternative A, slightly higher catch rates; 3% fewer large trout (750).	Compared to Alternative A, similar catch rates; 5% more large trout (810).	Compared to Alternative A, similar catch rate; 8% more large trout (830).	Compared to Alternative A, highest catch rate; 22% fewer large trout (600).	Compared to Alternative A, second highest catch rates; 9% fewer large trout (700)..

TABLE 4.10-1 (Cont.)

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)[a]	Alternative E	Alternative F	Alternative G
Glen Canyon—Fishing (Cont.)							
Navigability/ safety	No change from current conditions; intermediate number of days when flows below 8,000 cfs could affect navigability; minimal safety concerns from up-ramp rates.	Lowest navigability due to occasional flows below 8,000 cfs; slightly increased wading risk during tests of hydropower improvement flows.	Somewhat higher navigability than Alternative A; minimal safety concerns from up-ramp rates.	Same as Alternative A; minimal safety concerns from up-ramp rates.	Somewhat lower navigability than Alternative A; minimal safety concerns from up-ramp rates.	Somewhat higher navigability than Alternative A; minimal safety concerns, steady flows.	Highest navigability, with few if any flows below 8,000 cfs; minimal safety concerns, steady flows.
Glen Canyon—Day Rafting/Recreation							
Lost rafting visitor opportunities	No change from current conditions; estimated loss of 49 visitors/year out of a total of 50,000 due to HFEs (0.1%).	71 out of 50,000 fewer visitors/year due to HFEs.	315 out of 50,000 fewer visitors/year due to HFEs.	348 out of 50,000 fewer visitors/year due to HFEs.	177 out of 50,000 fewer visitors/year due to HFEs.	919 out of 50,000 fewer visitors/year because of large number of HFEs in peak rafting season.	51 out of 50,000 fewer visitors/year due to HFEs.
Camping and recreation facilities on old sediment terraces	No change from current conditions; lowest potential adverse impact on terraces; estimated 5.5 HFEs and no TMFs over the LTEMP period.	Intermediate potential impact on terraces; estimated 7.2 HFEs, 3 TMFs, and 4 years with hydropower improvement flows.	Intermediate potential impact on terraces; estimated 21.3 HFEs and 6 TMFs.	Intermediate potential impact on terraces; estimated 21.1 HFEs and 8 TMFs.	Intermediate potential impact on terraces; estimated 17.1 HFEs and 3 TMFs.	Highest potential impact on terraces; estimated 38.1 HFEs, but no TMFs.	Intermediate potential impact on terraces; estimated 24.5 HFEs and 11 TMFs.

TABLE 4.10-1 (Cont.)

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)[a]	Alternative E	Alternative F	Alternative G
Grand Canyon—Whitewater Boating							
Campsite area	No change from current conditions; lowest improvement of campsite area; would continue long-term decline since there are no HFEs after 2020; camping area index (CAI) = 0.14 out of 1.	Compared to Alternative A, effects of 2 more HFEs offset by higher fluctuations; overall campsite loss is expected to continue, CAI = 0.15, an increase of 5% over Alternative A.	Comared to Alternative A, more HFEs and moderate fluctuations would result in a potential increase in camping area (CAI = 0.38, an increase of 170%).	Comared to Alternative A, more HFEs and comparable fluctuations would result in a potential increase in camping area (CAI = 0.36, an increase of 158%).	Comared to Alternative A, more HFEs and higher fluctuations would result in a potential increase in camping area (CAI = 0.30, an increase of 118%).	Compared to Alternative A, most HFEs, no daily fluctuations, and high sustained spring flowswould result in a potential increase in camping area (CAI = 0.41, an increase of 191%).	Comared to Alternative A, more HFEs, even monthly volumes, and no daily fluctuations would result in the highest potential increase in camping area (CAI = 0.45, an increase of 224%).
River flow level and fluctuations as indicated by the navigation index (NI) and the fluctuation index (FI)	No change from current conditions; intermediate NI (0.50 out of 1) and intermediate FI (0.79 out of 1) indicate good river conditions for whitewater boating most of the time.	Compared to Alternative A, 22% decrease in NI and 47% decrease in FI (lowest of alternatives) indicate decrease in boating conditions.	Compared to Alternative A, 50% increase in NI and 18% increase in FI indicate improvement in boating conditions.	Compared to Alternative A, 10% decrease in NI and 6% decrease in FI indicate decrease in boating conditions.	Compared to Alternative A, 26% decrease in NI (lowest of alternatives) and 28% decrease in FI indicate decrease in boating conditions.	Compared to Alternative A, 42% increase in NI and 27% increase in FI (highest of alternatives) indicate improvement in boating conditions.	Compared to Alternative A, 92% increase in NI (highest of alternatives) and 24% increase in FI indicate improvement in boating conditions.

TABLE 4.10-1 (Cont.)

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)[a]	Alternative E	Alternative F	Alternative G
Lakes Powell and Mead—Recreation Access Issues Based on Reservoir Elevation							
Lake Powell (percent of seasons in which reservoir elevation drops below 3,580 ft)[b]	No change from current conditions; elevation drops below 3,580 ft in 21.8% of the seasons in the 20-year LTEMP period (percent of seasons with low reservoir elevations occurring in at least 1 month)	Compared to Alternative A, 2.6% increase in the percent of seasons elevation drops below 3,580 ft.	Compared to Alternative A, negligible increase (0.4%) in the percent of seasons elevation drops below 3,580 ft.	Compared to Alternative A, 5.1% increase in the percent of seasons elevation drops below 3,580 ft.	Compared to Alternative A, 5.1% increase in the percent of seasons elevation drops below 3,580 ft.	Compared to Alternative A, 4.7% increase the percent of seasons elevation drops below 3,580 ft.	Compared to Alternative A, 4.7% increase the percent of seasons elevation drops below 3,580 ft.
Lake Mead (percent of seasons in which reservoir elevation drops below 1,050 ft)[c]	No change from current conditions; elevation drops below 1,050 ft in 25.5% of the seasons in the 20-year LTEMP period (percent of seasons with low reservoir elevations occurring in at least 1 month)	Compared to Alternative A, 10.6% decrease in the percent of seasons during which elevation drops below 1,050 ft.	Compared to Alternative A, negligible (0.3%) decrease in the percent of seasons during which elevation drops below 1,050 ft.	Compared to Alternative A, 2.5% decrease in the percent of seasons during which elevation drops below 1,050 ft.	Compared to Alternative A, 1.2% decrease in the percent of seasons during which elevation drops below 1,050 ft.	Compared to Alternative A, 2.5% decrease in the percent of seasons during which elevation drops below 1,050 ft.	Compared to Alternative A, 1.9% decrease in the percent of seasons during which elevation drops below 1,050 ft.

TABLE 4.10-1 (Cont.)

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)[a]	Alternative E	Alternative F	Alternative G
Tribal Recreation Program							
Impacts on Tribal recreation operations in the Western Grand Canyon	No change from current sediment conditions; docks may be affected by HFEs until 2020 (average 5.5 over 20-year LTEMP period); lowest impact alternative.	Compared to Alternative A, approximately 2% increase in suspended sediment at RM 260; slightly greater impacts on Hualapai recreational facilities due to more frequent HFEs (average 7.2 over 20-year LTEMP period).	Compared to Alternative A, approximately 3% increase in suspended sediment at RM 260; greater impacts on Hualapai recreational facilities due to more frequent HFEs (average 21.3 over 20-year LTEMP period).	Compared to Alternative A, approximately 2% increase in suspended sediment at RM 260; greater impacts on Hualapai recreational facilities due to more frequent HFEs (average 21.1 over 20-year LTEMP period).	Compared to Alternative A, approximately 3% increase in suspended sediment at RM 260; greater impacts on Hualapai recreational facilities due to more frequent HFEs (average 17.1 over 20-year LTEMP period).	Compared to Alternative A, approximately 6% increase in suspended sediment at RM 260; greater impacts on Hualapai recreational facilities due to more frequent HFEs (average 38.1 over 20-year LTEMP period); highest impact alternative.	Compared to Alternative A, approximately 2% increase in suspended sediment at RM 260; greater impacts on Hualapai recreational facilities due to more frequent HFEs (average 24.5 over 20-year LTEMP period).
Park Facilities							
Impacts on park facilities at Pearce Ferry	No change from current conditions; facilities may be affected by HFEs; lowest impact alternative.	Slightly greater impacts than Alternative A due to slightly more frequent HFEs.	Greater impacts than Alternative A due to more frequent HFEs.	Greater impacts than Alternative A due to more frequent HFEs.	Greater impacts than Alternative A due to more frequent HFEs.	Greatest impact alternative due to most frequent HFEs.	Greater impacts than Alternative A due to more frequent HFEs.

[a] Adjustments made to Alternative D after modeling was completed included a prohibition of sediment-triggered and proactive spring HFEs in the same water year as an extended-duration fall HFE. The estimated number of HFEs after this adjustment would be about 19.8 (1.3 fewer than were modeled). This reduced number of HFEs could reduce Alternative D's impacts on Hualapai docks in the Western Grand Canyon.

[b] Percent of seasons with at least 1 month with Lake Powell elevations equal to or below 3,580 ft AMSL, the level below which boat ramp access is assumed to be impeded; based on 21 traces over 20 years for 12 months per year. Seasons were defined as summer (May, June, July, August), winter (November, December, January, February), and spring/fall (March, April, September, October). See Appendix J.

[c] Percent of seasons with at least 1 month with Lake Mead elevations equal to or below 1,050 ft AMSL, the level below which marinas and boat ramp function is assumed to be impeded; based on 21 traces over 20 years for 12 months per year. Seasons were defined as summer (May, June, July, August), winter (November, December, January, February), and spring/fall (March, April, September, October). See Appendix J.

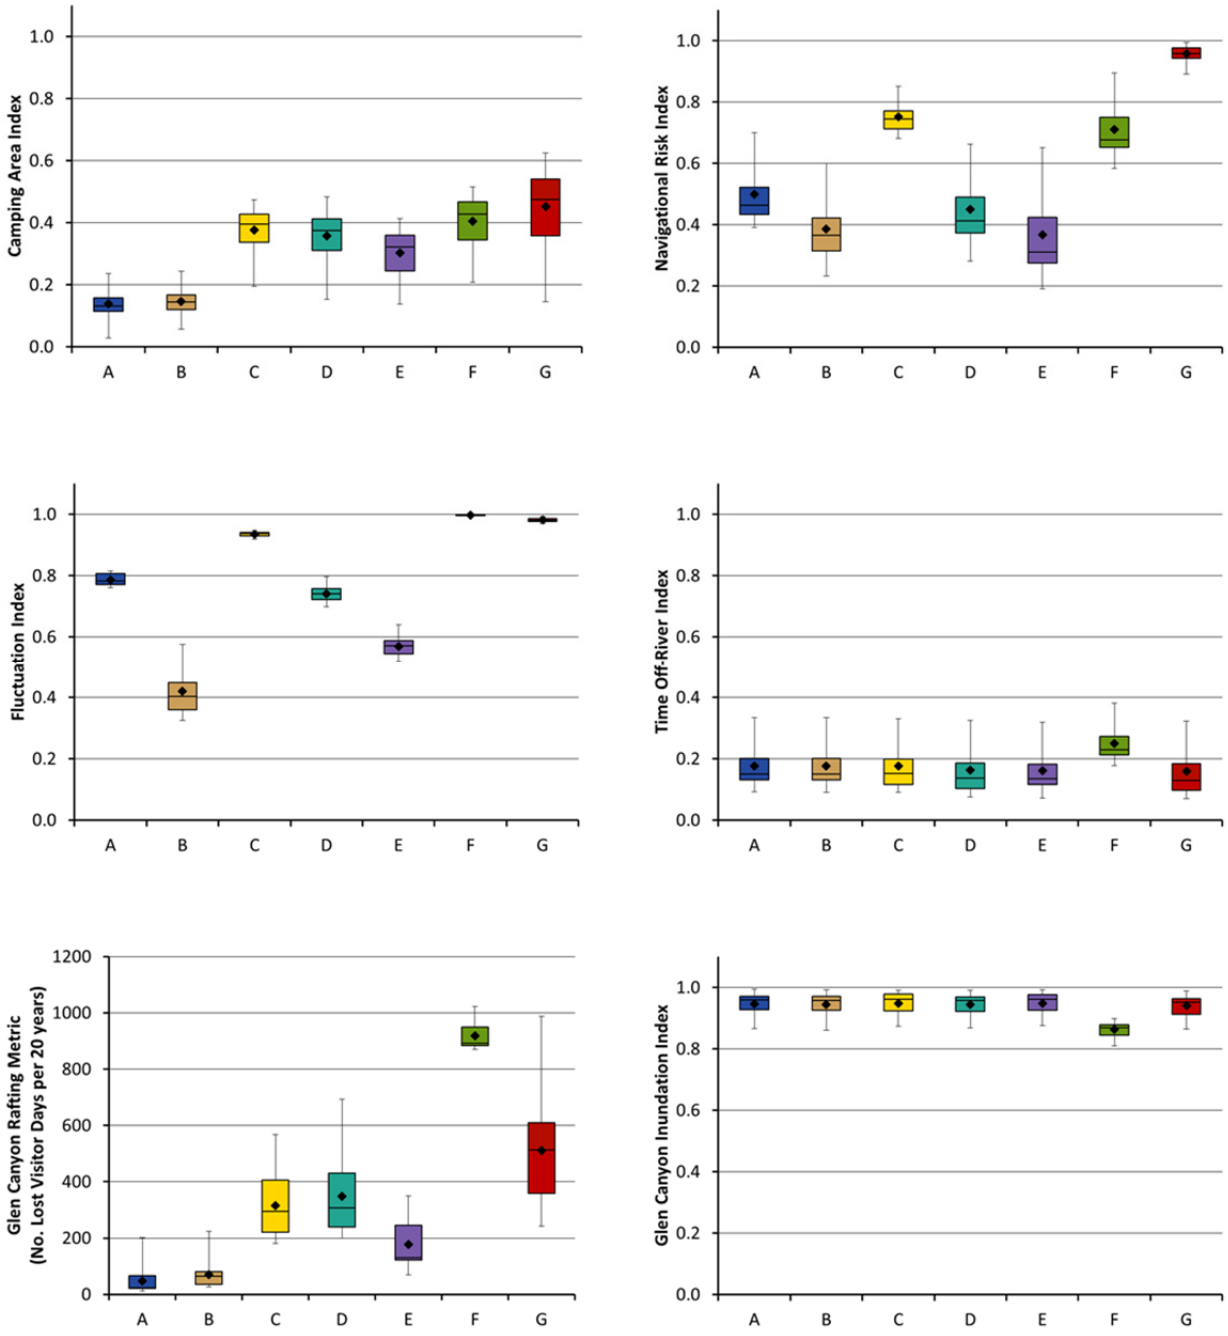

FIGURE 4.10-1 Recreation, Visitor Use, and Experience Metric Results for LTEMP Alternatives (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

Steady flow Alternative F and Alternative G provide daily flows with no fluctuations; Alternative G might be considered better for anglers because flows would be at preferred levels throughout the year, whereas Alternative F has higher-than-preferred flows during some of the most popular fishing months, April through June. The highest fluctuations of fluctuating flow Alternatives C, A, D, E, and B (listed in order from lowest to highest within-day fluctuations) may not occur during peak fishing months. Furthermore, because the daily fluctuations analyzed in Bishop et al. (1987) were greater with respect to angling than those under the proposed alternatives, little difference is expected in effects on angling between alternatives due to fluctuations. Stewart et al. (2000) found that current fluctuations under MLFF were not identified by anglers as an issue. The effects of flow and fluctuation levels on angler satisfaction under the alternatives are quantified in economic terms in Section 4.14.2.1, which indicates that Alternative A would have the highest angler use value by a small margin over all alternatives; Alternative F would have the lowest due to high flows in peak fishing months.

The Glen Canyon Inundation metric was developed to identify the percentage of time river flows were above certain elevations that affect boating, fishing, and shoreline access. The metric is a measure of the suitability of flows between 3,000 and 31,500 cfs. Most alternatives perform similarly with regard to this metric, with Alternative F having a slightly lower metric value as illustrated in Figure 4.10-1. However, because all of the alternatives perform so consistently on this metric, it will not be discussed further.

Fishing would be disrupted during HFEs under all alternatives. The average number of HFEs over the 20-year LTEMP period would vary among alternatives, and would range from 5.5 under Alternative A to 38.1 under Alternative F; Alternative D would have an average of 21.1 HFEs[24] over the 20-year period. The maximum number of days that HFEs would disrupt fishing in any year would range from 4 under Alternative B to 18 under Alternative G; Alternative G is highest because it includes the potential for extended-duration HFEs that are up to 14 days long (Alternative D would have a maximum of 10 HFE days within a calendar year). Extended-duration HFEs are expected to be triggered relatively infrequently and would be limited to no more than four under Alternative D (Section 4.3.3).

Effects of Fish Size and Catch Rates

Anglers in the Glen Canyon reach are almost evenly split in their preference for catching either large fish or for catching more fish (Anderson, M. 2012). Analysis described in more detail in Section 4.5.2.2 concludes there will likely be differences among the alternatives both in the percentages of larger fish (individuals exceeding 16 in. in length) in the population and in the angler catch rate. Among the alternatives, the estimated number of large trout was generally greatest under Alternative B and lowest under Alternatives F and G. Alternatives E, D, A, and C in descending order are expected to produce intermediate numbers of large trout. The modeled

[24] Adjustments made to Alternative D after modeling was completed included a prohibition of sediment-triggered and proactive spring HFEs in the same water year as an extended-duration fall HFE. The estimated number of HFEs after this adjustment would be about 19.8 (1.3 fewer than were modeled). This reduced number of HFEs is not expected to result in a change in Alternative D's impacts on recreation.

angler catch rates are greatest under Alternatives F and G because of their steadier flow regimes, and lowest under Alternative B, with the greatest fluctuations. It is anticipated that recreational angling use in the Glen Canyon Reach would be similar to current conditions under all alternatives and that angler satisfaction would likely remain high, but satisfaction for some alternatives would be based on the size of fish, while that of others would be based on the number of fish.

Navigability and Wading Safety in the Glen Canyon Reach

The ability for boats to navigate freely within the Glen Canyon reach was an issue when low flows of 1,000–3,000 cfs occurred prior to 1996. All alternatives now include a minimum 5,000 cfs flow between 7 PM and 7 AM, and 8,000 cfs from 7 AM to 7 PM (with the exception of Alternative F, which has flows near or somewhat below 8,000 cfs all day during the summer, fall, and winter). The Navigation Index (Figure 4.10-1) is based on the amount of time flows are above 8,000 cfs. Alternatives B and E have lower Navigation Index values than Alternative A due to more frequent low flows. Alternatives C, F, and G are higher than Alternative A, and Alternative D is about the same as Alternative A.

Wading anglers are always at risk from swift water and from rapidly rising water levels, and anglers are urged to exercise caution. Specifically, rapidly increasing flow is a safety concern with respect to the ability of wading anglers to move toward shore. At least three drownings in 12 years preceding the 1995 EIS possibly were related to river stage or stage change (Reclamation 1995). Implementation of the MLFF protocol limiting up-ramp rates to 4,000 cfs/hr for all fluctuating-flow alternatives has reduced the potential safety concerns for wading anglers. An up-ramp rate of 5,000 cfs/hr proposed under Alternative B during tests of hydropower improvement flows could result in an adverse impact on safety of anglers due to rapidly rising water levels. With respect to HFEs, Reclamation and NPS would coordinate to ensure that safety measures are implemented during an HFE, including restricting access immediately below Glen Canyon Dam, and providing public notice about the timing of an HFE. Each of the affected NPS units—GCNRA, GCNP, and Lake Mead National Recreation Area (LMNRA)—has clearly designated responsible parties, staffing needs, and actions that are required to occur prior to and during an HFE.

4.10.2.2 Glen Canyon Day Rafting

The 15-mi Glen Canyon reach hosts a large number of day rafters who use the pontoon-raft concession that departs from near Glen Canyon Dam and travels to Lees Ferry (Section 3.11.1.2). Bishop et al. (1987) established that day rafting participants express no preferences regarding either river flows or fluctuations. As a result, impacts on rafting use are related only to the occurrence of HFEs, which result in lost visitor recreation opportunities and lost revenue for the rafting concessioner. The variables influencing the level of impact are the number of HFEs and the time of year in which they occur. Spring HFEs have a greater impact than fall HFEs because visitor use is higher in the spring months. HFEs are scheduled only in

October, November, March, and April, with the exception of proactive spring HFEs (under Alternatives C, D, and G), which can occur in April, May, or June.

Because of the high number of HFEs, Alternative F would have by far the greatest adverse impact on day-use rafting with an anticipated mean annual loss of about 919 visitor opportunities over the LTEMP period out of a typical annual total of 50,000 such trips expected over the LTEMP period. Alternatives G, D, C, and E would have the next largest adverse impacts with 512, 348, 315, and 177 mean annual lost visitor use opportunities, respectively. Alternatives A and B would be similar in their impact and would result in 49 and 71 mean annual lost visitor use opportunities, respectively (Figure 4.10-1).

4.10.2.3 Glen Canyon Recreational Facilities

Glen Canyon contains both high-elevation sediment terraces, which are remnants of larger terraces that existed prior to construction of Glen Canyon Dam, and lower elevation terraces, which are still affected by dam operations. Glen Canyon has six designated campsites with fire pits and bathrooms along its 15-mi stretch. These recreational facilities are generally located above the high-water level of normal dam operations; however, HFEs are the principal flow actions that could affect these campsites through erosion of terraces combined with an absence of sediment sources in the Glen Canyon reach for possible deposition and rebuilding of terraces. Alternative F would have the largest adverse impact on these facilities from the projected number of HFEs and annual high releases (Table 4.3-1), followed by Alternatives G, C, D, E, B and A, in decreasing order. In addition, higher fluctuation levels, including during tests of hydropower improvement flows under Alternative B, could lead to increased campsite erosion relative to the other alternatives.

4.10.2.4 Whitewater Boating

The availability, size, and quality of campsites in the Grand Canyon is an important resource for whitewater boaters. As discussed in Section 3.11-2, total campsite area has undergone a long-term downward trend due to sandbar erosion and vegetation growth, having decreased by 56% from 1998 to 2006 (Kaplinski et al. 2010). Generally, alternatives with more sediment-triggered HFEs are expected to result in greater campsite area, although flow and fluctuation levels as well as vegetation control will affect the maintenance of campsite area. Alternatives G and F show the highest potential to create and maintain campsite area based on Camping Area Index values (Figure 4.10-1). These are followed by Alternatives C, D, and E which have index values more than two times greater than those of Alternatives A and B.

River flow levels and fluctuations are important for whitewater boaters (Bishop et al. 1987; Hall and Shelby 2000; Stewart et al. 2000; Roberts and Bieri 2001). The minimum daily flow levels of 5,000 cfs from 7 PM to 7 AM and 8,000 cfs from 7 AM to 7 PM provided by most alternatives are considered only minimally adequate for Grand Canyon boating. Transit times of morning flow increases to 8,000 cfs from 5,000 cfs overnight at the dam to downstream locations may delay the arrival of 8,000 cfs or higher desired at more

challenging rapids. Such concerns would arise only in low-volume months, however, when minimum flow limits would be applied. Flows on most days under the fluctuating flow alternatives would exceed these limits. Steady flow Alternatives F and G could feature daily flows of 5,000 cfs for extended periods of time; however, only four occurrences of 5,000 cfs flows for a period of a month or more appeared in LTEMP 20-year hydrology simulations for Alternative F, and there were none for Alternative G. Extended low flows of 5,000 cfs would adversely affect navigability and trip management in GCNP because of a greater risk of boating incidents. Conversely, the normal steady flows of Alternatives F and G would offer benefits to river trip planning over the alternatives with fluctuating flows because river travel time and off-river time is more predictable. Commercial and private whitewater trip leaders reported (Bishop et. al. 1987) a preference for steady flows in the 20,000–26,000 cfs range. Alternative F approaches these levels in April through June, and thus would have higher perceived value to rafters than would Alternative G, which limits flows to near 12,000 cfs or less year round in 8.23-maf years.

The Navigation Index and the Fluctuation Index both address aspects of the impact of fluctuations on whitewater boating (Figure 4.10-1). Both indices are designed to produce values that increase in the direction of improved boating conditions. Thus, a higher Navigation Index value indicates that an alternative presents relatively lower navigation risks due to low flows (below 8,000 cfs), while higher Fluctuation Index values indicate that an alternative will have fluctuations more often within a preferred range for whitewater boating (Bishop et al. 1987). Alternatives G, F, and C have the highest values for both indices (indicating the best conditions), while Alternatives B and E had the lowest index values (indicating the worst conditions). Alternatives A and D have intermediate values for these two indices.

The Time Off-River Index values indicate there would not be much difference in time available for off-river activities between the alternatives, likely due to similar mean annual flows of between 10,000 and 15,000 cfs. Because the index does not provide a meaningful distinction among the alternatives, it will only be referenced in special circumstances in Section 4.10.3.

4.10.2.5 Reservoir Activities and Facilities

Recreation on Lakes Powell and Mead can be affected by water levels dropping below the level at which ramps and marinas can function. In the case of Lake Powell, the Castle Rock cut is also a critical feature. Although the lowest boat ramp elevations on Lake Powell are not all the same, 3,580 ft AMSL is representative of the level below which major access issues occur. The frequency at which reservoir elevations would be above 3,580 ft AMSL at the end of the month seasonally has been analyzed to determine whether there is any significant difference among the alternatives. The same has been done for Lake Mead using an elevation of 1,050 ft AMSL, the level to which the NPS has committed in order to keep marinas and launch ramps functional.

Simulations were performed of end of the month reservoir elevations by season (summer [May, June, July and August], winter [November, December, January, and February], or spring/fall [March, April, September, and October]) for the 20-year CRSS simulations using

21 hydrology traces for both reservoirs. For Lake Powell, with respect to the 3,580 ft AMSL reference level for boat access, approximately 22% of all simulated seasons showed at least one month with end of the month elevations at or below this level for all alternatives. There was very little difference among the alternatives; all alternative means fall between 21.75% for Alternative A and 22.86% for Alternative E. Such differences by alternative are due to small changes in elevation when reservoir elevation is near the 3,580-ft reference level.

The results for Lake Mead simulations were similar to those for Lake Powell, with a slightly greater range of results. Alternative B, with 22.78%, had the lowest percentage of seasons with at least 1 month at or below the reference elevation, and Alternative A, with 25.48%, had the highest. Differences by alternative are due to small changes in elevation when reservoir elevation is near the 1,050-ft reference level.

As discussed in Section 4.2.2.1, the elevations of Lake Powell and Lake Mead are more affected by annual variation in inflow than by alternative. The dominating effect of hydrology was also observed in the analysis of reservoir elevations with respect to reservoir access, with relatively small effects attributable to differences in alternatives. With respect to ongoing drought conditions affecting operations at LMNRA, as noted in Section 3.10.3.1, an October 2005 NPS General Management Plan Amendment for Low Water Conditions and a Finding of No Significant Impact (NPS 2005b) identified the current strategy for low-water operations. This amendment articulated the intent to maintain boat-launch capacities established in the original General Management Plan of 1986 and a subsequent amendment in 2003, by either extending or relocating existing launch ramps and marinas to be functional down to an elevation of 1,050 ft AMSL. This amendment reflects the current management direction for low-water operations, and it assumes that NPS and concessionaires will continue to modify launching and marina facilities as necessary and possible, given time and budget to continue providing visitor services.

4.10.2.6 Tribal Recreation Operations

The Hualapai Tribe operates recreational facilities in the Western Grand Canyon, and their facilities and activities could be adversely affected by operation of Glen Cayon Dam. The Hualapai have expressed concern over dam operations they believe are increasing the amount of sediment collecting in the channel in their operational area below Diamond Creek. Their primary operations are centered in and around the Quartermaster area (RM 260). They have reported adverse impacts on their commercial operations from river sediment, including effects on equipment, access to their docks, and navigation in the river.

They are also concerned over the steep and unstable slopes previously inundated by Lake Mead that are now exposed due to reservoir levels retreating from the previous high-water line. The issues associated with the steep and unstable shorelines in the Lake Mead delta are related to the declining reservoir level, and will not be resolved until the level of Lake Mead either regains its previous high levels or until the banks naturally stabilize under new, lower reservoir levels.

The Hualapai are also concerned with the effect of different flows on their boat docks. The number and duration of HFEs under LTEMP alternatives could affect boat docks and other facilities operated by the Hualapai Tribe. LTEMP alternatives differ in the frequency and type of HFEs that would occur over the 20-year LTEMP period (Table 4.10-1; Sections 4.3.2 and 4.3.3). Alternative A would have the fewest (average of 5.5 HFEs over the LTEMP period, with HFEs not being conducted after 2020); Alternative F would have the most (average of 38.1 HFEs over the entire LTEMP period).

Reclamation engineers evaluated the Haulapai dock structures in 2012 to consider, among other things, the effect of high flows and related sediment on the dock structures (Walkoviak 2012). The conclusion of this assessment was that "the docks as designed and built are currently at risk of failure under essentially any Glen Canyon Dam operating regime, including normal operations" and the "docks are already at risk of failure regardless of future HFE implementation." Based on this assessment, Reclamation concluded that "there are no appropriate actions necessary regarding these [dock] structures in advance or following a HFE." Reclamation recommended that the operators undertake "a thorough structural, geotechnical, and hydraulic engineering review, and consider rebuilding the structures to standards that would allow certification by a licensed civil engineer."

Since the 2012 assessment, Reclamation has not been notified of any modifications to the dock structures to address the structural issues identified. Accordingly, concerning the potential effects of HFE-related sediment discussed above, Reclamation's position continues to be that there is "no appropriate mitigation for HFEs for the docks as currently built." If modifications are made, Reclamaton will consult with the Haulapai Tribe to discuss next steps.

Regarding the potential for differences among alternatives in their impacts on sediment issues near Hualapai facilities at RM 260, it is expected that dam operations, HFEs, equalization flows, and other flow events will continue to deliver sediment to the Western Grand Canyon and Lake Mead. Nearly all sediment that enters the Grand Canyon below Lake Powell will eventually move downstream to the area of concern. Higher flows, in general, do transport more sediment, and sediment transport will continue in the free-flowing portions of the river below Diamond Creek.

Transport of sand downstream from sources in Marble Canyon (RM 0–RM 61) under various LTEMP alternatives is discussed in Sections 4.3.2 and 4.3.3. The least amount of sand that would be transported would be under Alternative A, primarily because, under this alternative, the HFE protocol would expire in 2020; HFEs are the major source of sand transport under the alternatives. Sand transport would be second lowest under Alternative D and greatest under Alternatives F and G.

One metric that helps explain the potential for differences in sediment that would be relevant to Hualapai recreational operations is the amount of sediment leaving Marble Canyon at RM 61. Table 4.10-2 presents those values for each alternative, as determined from sediment

TABLE 4.10-2 Amount of Sediment Transported Out of Marble Canyon under the LTEMP Alternatives over the 20-Year LTEMP Period

	Alternative						
Indicators	A (No Action Alternative)	B	C	D (Preferred Alternative)	E	F	G
Sand leaving Marble Canyon (ktons)	17,900	18,800	19,200	18,600	19,100	20,500	19,000
Sand leaving Marble Canyon (% change from Alternative A)	0	5	7	4	7	15	6
% change in suspended sand at RM 225 relative to Alternative A	0	2	3	2	3	6	2

modeling. However, many factors must be considered when trying to assess how these values for RM 61 would relate to sediment settling out at Hualapai facilities near RM 260:

- Based on the results of quantitative modeling performed for the LTEMP, LTEMP alternatives would differ in the amount of suspended sediment transported out of Marble Canyon.

- The sediment model does not estimate transport past the end of Marble Canyon (RM 61). Data at the USGS gage (number 09404200) above Diamond Creek in GCNP (RM 225) was used to estimate values at RM 260.

- Approximately 50% of the sand that is in suspension at RM 225 (and presumably in suspension at the Hualapai facilities at RM 260) is from sources other than Marble Canyon; therefore more than half of the sand in suspension at RM 260 is independent of dam operations and comes from the Little Colorado River and other tributaries downstream of Marble Canyon.

- Some portion of the suspended sediment being transported may settle out in the channel at RM 260; that portion is dependent on a number of factors, including the elevation of Lake Mead and local hydraulic conditions (e.g., velocity and depth). Unless there is a significant geomorphic change near Quartermaster Canyon—such as a change in slope, width, or Lake Mead elevation— suspended sand would likely continue to travel downstream.

- Variability in sand transport out of Marble Canyon based on potential future hydrology is much larger than any variation in sand transport due to LTEMP alternatives considered in this EIS.

The average amount of suspended sand passing RM 225 is approximately 44,000 ktons over 20 years. The increase in suspended sand at RM 225 relative to Alternative A is approximately 6% for Alternative F, approximately 2% for Alternative D, and under 3% for all other alternatives (Table 4.10-2). This difference is significantly less than the differences under potential future hydrologic conditions. The location where this suspended sand deposits downstream of RM 225 will be a function of Lake Mead elevation and local hydraulic conditions. However, the amount will not be more that what is in suspension, so the sand deposition at RM 260 will be much less than the 2 to 6% increase in suspended sand expected under the LTEMP action alternatives.

4.10.2.7 Pearce Ferry

Park facilities at Pearce Ferry, managed by LMNRA, have been damaged in the past by HFEs and may be affected by HFEs in the future. Effects would vary among alternatives, and those with more frequent HFEs, particularly spring HFEs, could have greater impact. In the months following HFEs, there would be temporary impacts on both park operations and visitor access when there is damage, until the takeout ramp is repaired. Damage in April–June (following a spring HFE) would have greater impact on visitors than damage in November–January (following a fall HFE).

4.10.2.8 Park Operations and Management

As discussed in Section 3.10.4, potential effects on NPS staffing levels are related to recreation and resource concerns. For this analysis, staff levels were generally calculated as full-time equivalents, based upon known amounts of time currently dedicated to operational functions. To estimate the changes to staff levels that might be different among alternatives, an assumed relationship to a quantitative metric from modeling was used. For instance, if vegetation modeling indicated a 5% increase in nonnative invasive plants, it was assumed that there would be a 5% increase in the need for vegetation treatment work. Staff time for monitoring and maintenance of camping beaches and trails was estimated using the modeled Camping Area Index. Staff time related to special flows, such as HFEs or TMFs, was estimated based on the tracking of GCNRA and GCNP staff time for notification and coordination related to HFEs from 2011 to 2015. Flow patterns were looked at in terms of safety, and boating hazards and staff time for ranger patrols were analyzed, though this was looked at as trend information rather than quantitative contributions to the total as staff time for safety issues can vary greatly from year to year.

Another consideration that was evaluated was impacts on park facilities at Pearce Ferry, managed by LMNRA, as these facilities have been damaged in the past by HFEs and are likely to be damaged by HFEs in the future. Effects would vary between alternatives, as those with more frequent HFEs, particularly spring HFEs, may have more effects than those with fewer HFEs. There would be temporary impacts in the months following HFEs to both park operations and visitor access when there is damage, until the takeout ramp is repaired. Damage in April–

June (following a spring HFE) would have more impact on visitors than damage in November–January (following a fall HFE).

Based on the analysis conducted, the maximum difference between action alternatives (B through G) and Alternative A was a 1.8 full-time equivalent decrease (Alternative D), and the maximum was an increase of 0.1 full-time equivalent (Alternative B). However, factors such as safety response and repairs at Pearce Ferry, which were considered but were not possible to quantify, did not vary in the same direction as the quantified effects. Therefore, the differences among alternatives may be less than indicated by the quantified effects. Based on this analysis, it was determined that the variation among alternatives for park staffing for recreation and resource concerns would be negligible.

4.10.3 Alternative-Specific Impacts

The following section provides descriptions of impacts that are expected to occur under each of the LTEMP alternatives.

4.10.3.1 Alternative A (No Action Alternative)

Under Alternative A, trout abundance, size, and catch rates are expected to vary within the ranges that have been observed under MLFF operations over the past 20 years. About 770 large trout (a number intermediate among the alternatives; large trout are defined as individuals exceeding 16 in. in length) would be expected under Alternative A, as well as intermediate levels of angler catch rates (Section 4.5.3.1). Fishing would be disrupted during HFEs, but the number of HFEs under Alternative A is the lowest of all alternatives (5.5) and HFEs would not be conducted after 2020. The maximum number of days that HFEs would disrupt fishing in any year would be 8 if a spring and fall HFE were conducted in the same calendar year. Therefore, under Alternative A overall angler satisfaction is anticipated to remain the same as at present, with a consistent trend in the fishery toward more, but smaller, fish. Alternative A is expected to result in the highest angler satisfaction of all alternatives, by a small margin (Section 4.14.2.1).

The current MLFF maximum up-ramp rate of 4,000 cfs/hour under this alternative has been adopted for all LTEMP alternatives and it is not anticipated that this ramp rate would create angler safety issues. The down-ramp rate of 1,500 cfs is the same as the current rate and also does not create issues for anglers.

Because this alternative only allows for HFEs until 2020 and has the fewest total number of HFEs, Alternative A scores the best among alternatives in the Glen Canyon Rafting Metric, with a projected mean annual loss of only 49 visitor rafting trips (Figure 4.10-1), compared to a total mean annual visitor use of 50,000 visitors. This is a 0.01% reduction. In addition, the lower number of HFEs would result in the lowest anticipated impact on the sediment terraces and the recreational resources they support.

With respect to whitewater boating, about 80% of the time daily fluctuations would remain in a range preferred by whitewater boaters (FI = 0.79) (Figure 4.10-1). Navigational boating risks due to flows below 8,000 cfs under Alternative A, as reflected in the navigation index, would be about in the middle of the range for all alternatives (NI = 0.50) (Figure 4.10-1). Having the lowest mean number of HFEs over the LTEMP period, Alternative A has among the lowest potential for increasing campsite area of all alternatives, with a camping area index value of 0.14 (Figure 4.10-1). Based on observed effects under the current MLFF operating regime, this alternative is expected to lead to a continued loss of campsite area due to erosion and increased campsite crowding.

There would be no change in current sediment conditions that could affect Hualapai recreation operations in the Western Grand Canyon, but these facilities could be affected by HFEs until 2020 (average 5.5 HFEs over the 20-year LTEMP period). Reclamation will address any concerns related to these facilities in the manner stated in the 2012 letter between Reclamation and the Hualapai Tribe (Walkoviak 2012).

In addition to sediment-triggered spring and fall HFEs, several experimental elements are featured in Alternative A, including mechanical removal of trout in the Little Colorado River reach and testing TMFs. Mechanical trout removal activities are intensive activities that can last many days and over a period of several months (Reclamation 2011a). Mechanical trout removal activities would have a short-term impact to visitor experience from motorized use. Based on modeling of trout numbers, there is a low probability that this activity will occur under Alternative A during the LTEMP period.

In summary, there would be little change from current conditions under Alternative A. Alternative A would have the fewest HFEs (ending in 2020) that could affect fishing and boating, and moderate flow fluctuations. Anglers would expect to see intermediate numbers of large trout and intermediate catch rates. Few navigability concerns from low flows would occur. Concerns for angler safety from high up-ramp rates would be low. Alternative A would have the fewest lost day rafting trips in Glen Canyon resulting from HFEs. Ongoing loss of camping area would continue, leading to increased crowding. There would be very little interference with recreation from testing and implementing experimental elements under the alternative.

4.10.3.2 Alternative B

Of all the alternatives, Alternative B has the lowest estimated number of rainbow trout and trout emigrants in the trout fishery below Glen Canyon Dam, but it has the greatest estimated number of large rainbow trout (>16 in.), about 870 fish. Hydropower improvement flows, which may occur in 4 out of 20 years, would be expected to result in even lower trout abundance and emigration and an increase in the numbers of large trout (Section 4.5.3.2). Angler catch rates would be the lowest of all alternatives because of the relatively low number of trout under this alternative. Fishing would be disrupted during HFEs, but the number of HFEs under Alternative B (7.2) is comparable to the number under Alternative A (5.5). The maximum number of days HFEs would disrupt fishing in any year would be 4, because, under Alternative B, no more than one HFE would be conducted every other year. Alternative B is expected to

have angler satisfaction related to flow levels and fluctuations similar to that under Alternative A. High daily fluctuations (up to 66% higher), down-ramp rates as high as 4,000 cfs/hour (2.7 times higher than under Alternative A), and more frequent flows below 8,000 cfs result in relatively low navigability (Figure 4.10-1).

Alternative B is expected to have slightly more HFEs than Alternative A, and would result in an anticipated mean loss of 71 annual Glen Canyon day-rafting opportunities (Figure 4.10-1). Under Alternative B, there is a slightly increased likelihood of additional impacts on sediment terraces in the Glen Canyon reach that support recreation facilities and campsites.

There would be a slight increase (3%) in suspended sediment at Hualapai recreational facilities in the Western Grand Canyon. These facilities could be affected by HFEs during the entire LTEMP period, but the total number of HFEs would be comparable to the number under Alternative A (average 7.2 HFEs over the 20-year LTEMP period). Reclamation will address any concerns related to these facilities in the manner stated in the 2012 letter between Reclamation and the Hualapai Tribe (Walkoviak 2012).

Whitewater boating would be affected by high daily fluctuations under Alternative B; daily fluctuations would remain in a range preferred by whitewater boaters only about 42% of the time (FI = 0.42), the lowest of all alternatives. As reflected in a NI value of 0.39, navigational boating risks due to flows below 8,000 cfs under Alternative B would be the second highest. In addition, the down-ramp rate is 2 to 2.6 times higher than under Alternative A, which could lead to boats being stranded in both GCNRA and GCNP. Alternative B is expected to result in slightly more camping area than Alternative A (CAI = 0.15) (Figure 4.10-1) due to a higher number of HFEs, but there would be a continued declining trend in campsite area due to high flow fluctuations. Total number of campsites and campsite area would continue to decrease under Alternative B, potentially increasing competition and crowding at campsites.

In addition to HFEs, Alternative B includes experimental testing of mechanical removal of trout in the Little Colorado River reach, TMFs, and hydropower improvement flows in 4 years during the LTEMP period when annual volume is ≤8.23 maf (Section 2.2.2).

The impacts of mechanical trout removal activities would be similar to those described under Alternative A; however, based on modeling of trout numbers there is a low probability that this activity will be triggered under Alternative B during the LTEMP period.

TMFs are expected to be triggered relatively infrequently under this alternative (mean of three TMFs triggered over the 20-year LTEMP period); therefore the overall impact of TMFs on recreation is expected to be minimal. Such effects are expected to be fairly short term due to the dynamic nature of the fishery. TMFs are intended to decrease trout abundance in the fishery in the Glen Canyon reach, which could result in a reduced angler catch rate but could also increase the number of larger fish.

Tests of hydropower improvement flows in 4 years when annual volume is ≤8.23 maf would more closely resemble the operations at Glen Canyon Dam prior to the early 1990s, and

would produce daily fluctuations up 20,000 cfs (5,000 cfs nighttime to 25,000 cfs daytime). The daily minimum flow would be 5,000 cfs and the up- and down-ramp rates would each be 5,000 cfs/hr. High ramp rates, when combined with the overall level of fluctuations under Alternative B, would create additional difficulties in navigating rapids and managing boats tied to shore. In the 1995 EIS (Reclamation 1995), rapidly increasing flow was identified as a safety concern for wading fishermen with respect to their ability to move toward shore. This pattern of river fluctuations and high daytime flows would also adversely affect fishing and usable campsite area.

In summary, Alternative B would have the second fewest HFEs and the greatest flow fluctuations; the former would result in relatively few days that would disrupt angling and boating from river closings, similar to Alternative A, and the latter would result in reduced whitewater boater satisfaction due to high daily fluctuations compared to Alternative A. The number of large trout would be highest of all alternatives, but catch rates lowest. Navigability and boat stranding concerns would be the greatest of all alternatives due to high fluctuations and high down-ramp rates, but relatively low overall. There would be few lost day rafting trips in Glen Canyon due to HFEs, similar in number to Alternative A. Camping area is expected to continue to decrease due to erosion, similar to Alternative A. Interference with recreation from testing and implementing experimental elements would be low and similar to that under Alternative A, with the exception of hydropower improvement flows, which would produce greater impacts than under Alternative A.

4.10.3.3 Alternative C

Under Alternative C, about 750 large trout are predicted to be present below Glen Canyon Dam, similar to the number under Alternative A (770); angler catch rates would be similar to those under Alternatives A, D, and E, more than under Alternative B and less than under Alternatives F and G (Section 4.5.3.3). Fishing would be disrupted during HFEs, and the number of HFEs under Alternative C (21.3) is much higher than the number under Alternative A (5.5). The maximum number of days HFEs could disrupt fishing in any year would be 10 under Alternative C (if a spring HFE and extended-duration fall HFE were conducted in the same calendar year). Angler satisfaction related to flow levels and fluctuations under this alternative is expected to be similar to that of Alternative A. The down-ramp rate is 1.7 times that under Alternative A, but it is not expected to create an issue for anglers.

The more frequent HFEs under this alternative (including proactive spring HFEs and extended-duration fall HFEs) would result in an estimated 315 lost day-rafting visitor opportunities in Glen Canyon (Figure 4.10-1) as compared to a loss of 49 such opportunities under Alternative A. In addition, under Alternative C, the larger mean number of HFEs is expected to result in erosion of sediment terraces from wetting and undercutting in the Glen Canyon reach that support recreation facilities and campsites.

Daily fluctuations would remain in a range preferred by whitewater boaters most of the time (FI = 0.93). The low frequency of flows below 8,000 cfs results in good navigation (NI = 0.75), exceeded only by Alternative G. Because of the relatively high number of HFEs and

moderate fluctuations under Alternative C, it has a higher probability of producing an increase in campsite area compared to Alternative A (Figure 4.10-1).

There would be a slight increase (3%) in suspended sediment at Hualapai recreational facilities in the Western Grand Canyon. These facilities could be affected by HFEs during the entire LTEMP period, and the total number of HFEs would be higher than the number under Alternative A (average 21.3 HFEs over the 20-year LTEMP period). Reclamation will address any concerns related to these facilities in the manner stated in the 2012 letter between Reclamation and the Hualapai Tribe (Walkoviak 2012).

In addition to HFEs, Alternative C includes experimental testing of mechanical removal of trout in the Little Colorado River reach, TMFs, and low summer flows. Mechanical trout removal activities would be triggered infrequently and could temporaily limit visitor access to portions of the river for several days over several months when they occur.

TMFs are intended to decrease trout abundance, which might reduce angler catch rate, but could also result in an increased number of larger fish in the Glen Canyon reach. Such effects are expected to be fairly short term due to the dynamic nature of the fishery. TMFs are expected to be triggered six times during the 20-year LTEMP period under Alternative C, compared to no TMFs under Alternative A (Table 4.9-2).

The impacts of testing low summer flows would vary depending on the level of flows and the number of years they are employed. Flows of 8,000 cfs would result in a short-term increase in available camping area, a decrease in rafter time off river for exploration, and potentially more difficult navigation.

In summary, Alternative C would have almost four times the number of HFEs that could affect fishing and boating, compared to Alternative A, but lower daily fluctuation levels. Angler satisfaction with flow rate and fluctuations would be similar to that under Alternative A, and so would the number of larger trout and trout catch rates. Few navigation concerns would exist, similar to Alternative A. However, the number of lost day rafting trips in Glen Canyon due to HFEs would be about six times the number under Alternative A, but this is still a small fraction of total rafting trips. Camping area is expected to increase somewhat due to the effects of HFEs, while continued reduction is expected under Alternative A. Interference with recreation from testing and implementing experimental elements would be greater than under Alternative A.

4.10.3.4 Alternative D (Preferred Alternative)

Under Alternative D, an estimated 810 large trout are predicted to be present in the trout fishery below Glen Canyon Dam, with angler catch rates similar to those under Alternatives A, C, and E; this would be more than under Alternative B, and less than under Alternatives F and G (Section 4.5.3.4). Fishing would be disrupted during HFEs, and the number of HFEs under

Alternative D (21.1)[25] is much higher than under Alternative A (5.5). The maximum number of days that HFEs could disrupt fishing in any year would be 10 under Alternative D (if an extended-duration fall HFE were conducted). Angler satisfaction related to flow levels and fluctuations under Alternative D is expected to be similar to that under Alternative A. The down-ramp rate is 1.7 times that under Alternative A, but it is not expected to create an issue for anglers.

The more frequent HFEs under this alternative (including proactive spring HFEs and extended-duration fall HFEs) would result in an estimated 348 lost day-rafting visitor opportunities in Glen Canyon (Figure 4.10-1) as compared to a loss of 49 such opportunities under Alternative A. In addition, more frequent HFEs under Alternative D compared to Alternative A are expected to result in relatively greater erosion of sediment terraces due to wetting and undercutting the Glen Canyon reach that supports recreation facilities and campsites.

Daily flow fluctuations (FI = 0.74) and daily minimum flows that may affect navigability (NI = 0.45) under Alternative D are lower those under Alternative A, and intermediate among all alternatives for both metrics. Because of the relatively high number of HFEs and moderate fluctuations, Alternative D is expected to increase campsite area (CAI = 0.36) more than Alternatives A, B, and E, and less than Alternatives C, F, and G (Figure 4.10-1).

There would be a slight increase (2%) in suspended sediment at Hualapai recreational facilities in the Western Grand Canyon. These facilities could be affected by HFEs during the entire LTEMP period, and the total number of HFEs would be higher than the number under Alternative A (average 21.1 HFEs over the 20-year LTEMP period). Reclamation will address any concerns related to these facilities in the manner stated in the 2012 letter between Reclamation and the Hualapai Tribe (Walkoviak 2012).

In addition to HFEs, Alternative D includes experimental testing of mechanical removal of trout in the Little Colorado River reach, TMFs, macroinvertebrate production flows, and low summer flows. Although there can be direct effects of these experiments on recreation, long-term indirect benefits for recreation may accrue from the adoption of successful treatments, including potentially improved aquatic food base that supports the trout fishery.

Mechanical trout removal activities, although triggered infrequently, might limit visitor access to portions of the river for several days over several months when they occur.

TMFs are intended to decrease trout abundance, which might reduce angler catch rate; however, it could also result in an increased number of larger fish in the fishery in the Glen Canyon reach. Such effects are expected to be fairly short term due to the dynamic nature of the fishery. TMFs are expected to be triggered in 8 years over the 20-year LTEMP period, compared to no TMFs under Alternative A (Table 4.9-2).

---

25 Adjustments made to Alternative D after modeling was completed included a prohibition of sediment-triggered and proactive spring HFEs in the same water year as an extended-duration fall HFE. The estimated number of HFEs after this adjustment would be about 19.8 (1.3 fewer than were modeled). This reduced number of HFEs is could result in a decrease in Alternative D's impacts on Hualapai docks in the Western Grand Canyon.

Low summer flows would be tested only in the second 10 years of the 20-year LTEMP period. Flows of 8,000 cfs or less would result in a short-term increase in available camping area, a decrease in rafter time off river for exploration, potentially more difficult navigation, and potential loss of business by commercial rafters and fishing guides because of low flows. Testing macroinvertebrate production flows would feature steady flows on every weekend from May through August (34 days total). Under this experiment, the flow on weekends would be held to the minimum flow for that month. Effects on recreation would be similar to those for low summer flows.

In summary, Alternative D would have almost four times the number of HFEs that could disrupt fishing and boating and similar daily fluctuation levels, compared to Alternative A. Angler satisfaction with flow levels and fluctuations would be similar to that underAlternative A, as would the number of larger trout and trout catch rates. Few navigation concerns would exist, similar to Alternative A. However, the number of lost rafting trips due to HFEs would be about seven times that of Alternative A. Camping area is expected to increase somewhat due to the effects of HFEs, compared to an expected reduction under Alternative A. Interference with recreation from testing and implementing experimental elements would be greater than under Alternative A.

4.10.3.5 Alternative E

Alternative E is expected to result in an estimated number of rainbow trout and trout emigrants near the low end of alternatives and similar to Alternative A, with the second-highest expected number of large rainbow trout (about 830 fish) in the trout fishery below Glen Canyon Dam after Alternative B (Section 4.5.3.5). Angler catch rates similar to those under Alternative A would be expected. Fishing would be disrupted during HFEs, and the number of HFEs under Alternative E (17.1) is much higher than under Alternative A (5.5). The maximum number of days HFEs could disrupt fishing in any year would be 8 under Alternative E (if a spring HFE and fall HFE were conducted in the same calendar year). Angler satisfaction related to flow levels and fluctuations under Alternative E is expected to be similar to that under Alternative A. The down-ramp rate of this alternative is 1.7 times that of Alternative A, but it is not expected to create an issue for anglers.

The more frequent HFEs under this alternative would result in an estimated 177 lost day-rafting visitor opportunities in Glen Canyon (Figure 4.10-1), an increase of 146 over Alternative A. In addition, under Alternative E, the larger mean number of HFEs is expected to result in an increase in adverse impacts on sediment terraces in the Glen Canyon reach that supports recreation facilities and campsites, compared to Alternative A.

Daily fluctuations would be in the range preferred by whitewater boaters only about half of the time (FI = 0.57) and is lower than under all other alternatives except Alternative B, while flows would be below 8,000 cfs more frequently than all other alternatives (NI = 0.37), slightly more frequent that Alternative B. Because of the relatively high number of HFEs under Alternative E, this alternative is expected to increase campsite area (CAI = 0.30) more than Alternatives A and B, but somewhat less than Alternatives C, D, F and G.

There would be a slight increase (3%) in suspended sediment at Hualapai recreational facilities in the Western Grand Canyon. These facilities could be affected by HFEs during the entire LTEMP period, and the total number of HFEs would be higher than the number under Alternative A (average 17.1 HFEs over the 20-year LTEMP period). Reclamation will address any concerns related to these facilities in the manner stated in the 2012 letter between Reclamation and the Hualapai Tribe (Walkoviak 2012).

In addition to sediment-triggered spring and fall HFEs, several experimental elements are featured in Alternative E, including mechanical removal of trout in the Little Colorado Reach, testing and implementing TMFs, and testing low summer flows in the second 10 years of the LTEMP period.

The impacts of mechanical removal of trout in the Little Colorado reach would be similar to those described under Alternative A. Overall, there is a low probability that this action would be triggered during the LTEMP period based on the expected number of trout in the Little Colorado River reach.

TMFs are intended to decrease trout abundance, which might reduce angler catch rate; however, it could also result in an increased number of larger fish in the fishery in the Glen Canyon reach. Such effects are expected to be fairly short term due to the dynamic nature of the fishery. TMFs are expected to be triggered in 3 years over the 20-year LTEMP period, compared to no TMFs under Alternative A (Table 4.9-2).

The impacts of testing low summer flows would be the same as discussed under Alternative C. When they are tested, summer flows of 8,000 cfs would result in a short-term increase in available camping area, a decrease in rafter time off river for exploration, potentially more difficult navigation, and potential loss of business by fishing guides due to angler perception of less-desirable fishing conditions.

In summary, Alternative E would have three times as many HFEs that could affect fishing and boating and similar daily fluctuations, compared to Alternative A. Angler satisfaction with flow levels and fluctuations would be similar to that under Alternative A. The number of large trout would be higher than under Alternative A, while catch rates would be similar to those under Alternative A. Few navigation concerns would exist, but slightly more than under Alternative A. The number of lost rafting trips due to HFEs would be 3 to 4 times that of Alternative A, but still a small fraction of total rafting trips. Camping area is expected to increase somewhat due to the effects of HFEs, compared to an expected reduction under Alternative A. Interference with recreation from testing and implementing experimental elements would be greater than under Alternative A.

4.10.3.6 Alternative F

The steady daily flows of Alternative F are expected to result in higher numbers of trout and increased angler catch rates, but the lowest number of large trout of all alternatives (600 fish) (Section 4.5.3.6). In addition, this alternative does not include any trout management actions

(i.e., mechanical removal and TMFs). Angler satisfaction related to flow levels and fluctuations under Alternative F, however, is anticipated to be lowest of all alternatives due to high flows during peak fishing season (Section 4.14.2.1). In addition, Alternative F has the highest number of HFEs (38.1) of all alternatives, including a 1-day HFE in early May in all years without a sediment-triggered spring HFE. In addition, there would be an annual 7-day 25,000-cfs flow at the end of June that would occur during prime fishing months, which would also adversely impact fishing. The maximum number of days HFEs could disrupt fishing in any year would be 8, under Alternative F (if a spring HFE and fall HFE were conducted in the same calendar year).

An anticipated mean annual loss of 919 day-use rafting opportunities in Glen Canyon due to HFEs (Figure 4.10-1) is the largest such loss of any alternative and about 20 times that of Alternative A (loss of 49 rafting opportunities). In addition, the large number of HFEs in Alternative F would tend to increase erosion of sediment terraces in the Glen Canyon reach that support recreation facilities and campsites.

Under the steady flows of Alternative F, whitewater boaters would not be affected by daily flow fluctuations (FI = 1.0). With most daily flows near or above 8,000 cfs (NI = 0.71), navigability is expected to be higher than under Alternatives A, B, D and E and lower than under Alternatives C and G. Thus, conditions are anticipated to be satisfactory for boaters most of the time. With a high number of HFEs and steady monthly flows, Alternative F has a high likelihood of increasing campsite area (CAI = 0.41) (Figure 4.10-1). Steady daily flows would result in predictable availability of campsites. Usable campsite area would be reduced somewhat compared to Alternative G, due to high seasonal flows in March through June under Alternative F. Because Alternative F has lower flows in summer and fall months, that alternative may result in greater useable camping area during those months than under Alternative G.

There would be a small increase (6%) in suspended sediment at Hualapai recreational facilities in the Western Grand Canyon. These facilities could be affected by HFEs during the entire LTEMP period, and the total number of HFEs would be higher than the number under Alternative A or any other LTEMP alternative (average 38.1 HFEs over the 20-year LTEMP period). Reclamation will address any concerns related to these facilities in the manner stated in the 2012 letter between Reclamation and the Hualapai Tribe (Walkoviak 2012).

There are no experimental elements in this alternative, other than HFEs, that could affect recreation.

In summary, Alternative F would have the greatest number of HFEs of all alternatives that could affect fishing and boating. In addition, angler satisfaction with flow levels under Alternative F is anticipated to be lowest of all alternatives due to high flows during the peak fishing season. The fewest large trout are expected under this alternative, but highest catch rates. Very few navigability concerns would exist from low flows and no safety or convenience concerns from daily fluctuations. However, the most lost rafting trips due to HFEs would occur, about 20 times the number under Alternative A. Alternative F is expected to be the second most beneficial of all alternatives with respect to increasing camping area due to the effects of HFEs and reduced erosion. It would have no interference with recreation from testing and implementing experimental actions beyond those related to HFEs.

4.10.3.7 Alternative G

Alternative G would have the second-lowest number of large trout (700 fish), but trout abundance and angler catch rates would be high (Section 4.5.3.7). Fishing would be disrupted during HFEs, and the number of HFEs under Alternative G (24.5) is much higher than under Alternative A (5.5). The maximum number of days that HFEs could disrupt fishing in any year would be 18 under Alternative G (if a spring HFE and extended-duration fall HFE were conducted in the same calendar year). Angler satisfaction related to flow levels and fluctuations under this alternative is expected to be slightly less than that under Alternative A.

The relatively high number of HFEs under this alternative (including proactive spring HFEs and extended-duration fall HFEs) would result in an anticipated annual loss of 512 visitor day-rafting opportunities in Glen Canyon over the LTEMP period (Figure 4.10-1); this is more than 10 times larger than under Alternative A (loss of 49 rafting opportunities). The number of HFEs would result in a higher tendency to erode sediment terraces that support recreation facilities and campsites compared to all alternatives but Alternative F.

Under the steady flows of Alternative G, whitewater boaters would not be affected by daily flow fluctuations (FI = 0.98), and the steady monthly flows would be consistently above 8,000 cfs, reflecting high navigability (NI = 0.96). Because of the high number of HFEs under Alternative G, and its steady monthly and daily flows, it has the highest likelihood of any alternative of increasing campsite area (CAI = 0.45) (Figure 4.10-1).

There would be a slight increase (2%) in suspended sediment at Hualapai recreational facilities in the Western Grand Canyon. These facilities could be affected by HFEs during the entire LTEMP period, and the total number of HFEs would be higher than the number under Alternative A (average 24.5 HFEs over the 20-year LTEMP period). Reclamation will address any concerns related to these facilities in the manner stated in the 2012 letter between Reclamation and the Hualapai Tribe (Walkoviak 2012).

In addition to HFEs, Alternative G includes experimental testing of mechanical removal of trout in the Little Colorado Reach; and testing and implementation of TMFs. The impacts of mechanical trout removal activities would be similar to those described under Alternative A. Based on the expected number of trout in the Little Colorado River reach, Alternative G has an estimated three such removals, the greatest number triggered during the LTEMP period of all alternatives (Table 4.9-2).

TMFs are intended to decrease trout abundance, which might reduce angler catch rate; however, it could also result in an increased number of larger fish in the fishery in the Glen Canyon reach. Such effects are expected to be fairly short term due to the dynamic nature of the fishery. Based on the anticipated higher trout recruitment levels, Alternative G is expected trigger TMFs in 11 of 20 LTEMP years (Table 4.9-2), the highest number of all alternatives.

In summary, angler satisfaction with flow levels and fluctuations would be similar to that under Alternative A. Alternative G would have fewer large trout than Alternative A, but catch rates would be higher. Very few navigability concerns would exist from low flows and no safety

or convenience concerns from daily fluctuations. There would be about 10 times more lost rafting trips due to HFEs than under Alternative A. Alternative G is expected to be the most beneficial of all alternatives with respect to increasing camping area due to the effects of HFEs and reduced erosion. Interference with recreation from testing and implementing experimental elements would be greater than under Alternative A.

4.11 WILDERNESS

This section presents the potential impacts on wilderness and visitor wilderness experience. Although flows from Glen Canyon Dam would not be considered a prohibited use under the Wilderness Act, impacts are disclosed within this section for the purposes of their implications to NPS wilderness management. Background information on the wilderness qualities evaluated in this analysis appears in Section 3.15.

Issue: How do the alternatives affect wilderness and visitor wilderness experience?

Impact Indicators:

- Opportunities for solitude at campsites and on the river
- Preservation of natural conditions as reflected by naturalness of flow
- Rafters' time available for onshore exploration
- Visual and noise disturbances from administrative uses

As stated in Section 3.11, there is proposed wilderness in both Glen Canyon and the Grand Canyon within the Colorado River Ecosystem. The NPS has an obligation to manage the Colorado River corridor through GCNP to protect and preserve the resource in a wild and primitive condition and provide a wilderness river experience (as described in the 2006 Colorado River Management Plan). The proposed wilderness designation does not include areas upstream from Lees Ferry (including Glen Canyon Dam); moreover, the NPS management for wilderness values must remain consistent with the Section 1802 (b) of the GCPA. There are also references to Section 4.10: Recreation, Visitor Use, and Experience.

4.11.1 Analysis Methods

The analysis of impacts on wilderness and visitor wilderness experience downstream of Glen Canyon Dam was based on an assessment of alternative-specific differences in four indicators of the quality of visitor wilderness experience: opportunities for solitude at campsites and on the river; preservation of natural conditions as reflected by naturalness of flow; opportunities for experiencing wilderness as indicated by the amount of time rafters have for exploration; and visual and noise disturbances. These indicators are evaluated qualitatively and comparatively as they relate to the differing properties or features of the seven alternatives.

The effects of the alternatives on campsite crowding and its effect on visitor wilderness experience was evaluated through consideration of the tendency of flow patterns and experimental flows (mainly HFEs) under the various alternatives to build beaches and thus potentially increase campsite area. The likelihood of rafters encountering other groups at rapids

was evaluated based on the expected frequency of daily flows less than 8,000 cfs, a flow level associated with rafting delays at rapids as rafters scout conditions or wait for higher flows. Flows of 8,000–9,000 cfs have been identified by commercial guides as the minimum level necessary to safely run the river with passengers (Bishop et al. 1987; Stewart et al. 2000).

The naturalness of flows was evaluated by determining the magnitude of daily flow fluctuations under alternatives as compared to fluctuation levels perceived to be less natural, generally greater than 10,000 cfs as identified by Bishop et al. (1987). Stewart et al. (2000) found that daily fluctuations of 5,000–8,000 cfs under MLFF were not an issue for most recreational use, but they did not address fluctuations above 10,000 cfs. Opportunities for rafters to explore attraction sites or enjoy personal time at camp were evaluated by determining the effects of flow on river travel duration and the amount of off-river time available each day. Finally, the effects of noise and visual disturbance of wilderness values was evaluated by considering the number of HFEs, TMFs, trout removals, and the relative number of administrative trips expected under the alternatives.

The metrics described in Section 4.10 were used as input to the evaluation of effects on wilderness experience. The potential for beach building used the Camping Area Index to evaluate the effects of campsite availability and size on potential crowding and opportunities for solitude (Figure 4.10-1a); the Navigation Risk Index was used to evaluate potential crowding at rapids (Figure 4.10-1d); the Fluctuation Index was used to evaluate the naturalness of flows(Figure 4.10-1c); and the Time-Off-River Index was used to evaluate the opportunity for onshore exploration (Figure 4.10-1b). The effects of HFEs, TMFs, trout removal, and other experimental actions were evaluated from estimates of the expected frequency of such actions for the alternatives. Using these metrics and supporting information, it was possible to rank the alternatives with respect to their relative effects on associated wilderness values. The details of the methodology used to produce metric values and detailed results are presented in Appendix J.

4.11.2 Summary of Impacts

In Section 3.15, wilderness character is described as having four qualities: untrammeled, natural, undeveloped, and providing for outstanding opportunities for solitude or a primitive and unconfined form of recreation. In describing the wilderness values and visitor experiences within GCNP that are to be preserved and protected, GCNP's General Management Plan states that "Visitors traveling through the canyon on the Colorado River should have the opportunity for a variety of personal outdoor experiences, ranging from solitary to social. Visitors should be able to continue to experience the river corridor with as little influence from the modern world as possible. The river experience should help visitors to intimately relate to the majesty of the canyon" (NPS 1995).

Dam operations and management activities considered under LTEMP alternatives can affect these wilderness values and the quality of the wilderness river experience for river visitors. As dam operations affect beach retention or building, operations under the alternatives can affect campsite crowding and solitude. Similarly, low daytime flows less than 8,000 cfs can increase crowding at rapids. Although these are conceivable effects on wilderness experience and have

been modeled for the alternatives, such effects would detract only slightly from an overall wilderness experience in the study area, and differences in the effects of alternatives would be difficult to discern.

Wilderness experience may also be affected by high daily fluctuations that appear to be greater than what would occur naturally. Fluctuations in excess of 10,000 cfs have been identified as creating less natural conditions on the river (Bishop et al. 1987). TMFs and HFEs would also present less natural conditions to visitors. However, daily fluctuations under MLFF and the proposed alternatives are generally constrained to near or less than 10,000 cfs and thus would have at most a small effect on perceptions of naturalness, differences in which would be difficult to discern among fluctuating flow alternatives; the steady flow Alternatives F and G would have no such effects.

Overall flow level can also affect the wilderness experience through effects on the duration of rafting trips and thus the time available for onshore exploration. However, because there is little difference among the alternatives in time off river (Figure 4.10-1b), this measure is not discussed further in this analysis.

Finally, resource management actions, (i.e., administrative actions) including experimental vegetation treatment under all alternatives but Alternative A; mechanical removal of trout, which is allowed under some alternatives; and other experimental work and administrative trips common to all alternatives can affect visitor experience by increasing encounter rates, placement and use of equipment, and noise from motorized equipment. Such effects would be infrequent and short term and would affect relatively few visitors. Vegetation actions, even though they would conform to minimum tool use requirements, may have short-term negative effects during disturbance but long-term positive effects on wilderness by returning native vegetation and hence wilderness character. Effects on wilderness experience of the LTEMP alternatives are summarized and compared in Table 4.11-1 and analyzed in the discussions that follow.

Campsite crowding has been reduced since the implementation in 2006 of the CRMP (NPS 2005a), but campsite area and campsite size was decreasing (Kaplinski et al. 2010) prior to adoption of the HFE protocol in 2011 (Reclamation 2011b). Alternatives that do not reverse the trend of loss in campsite area eventually would have an adverse effect on wilderness qualities because of increases in crowding at remaining campsites. On the basis of the number of HFEs anticipated under each of the alternatives (Section 4.3), Alternatives F and G are expected to result in the greatest benefit to visitor wilderness experience with respect to opportunity for solitude, because of a greater likelihood of increasing and retaining campsite area (Section 4.10.2). Alternatives C, D, and E rank just below Alternatives F and G, while Alternatives A and B rank lowest with regard to camping area as a consequence of having the fewest HFEs. Under Alternative A (the No Action Alternative), HFEs would not be implemented after the HFE protocol expired in 2020.

On the basis of allowable within-day fluctuation, Alternatives B and E would have more frequent occurrences of very low flows (about 60% of days), including in the periods of peak recreational use, and therefore would tend to result in more crowding at rapids as rafters stop to

TABLE 4.11-1 Summary of Impacts of LTEMP Alternatives on Wilderness Experience

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Overall summary of impacts	No change from current conditions. Declining camping area following cessation of HFEs would reduce opportunity for solitude; intermediate effects on crowding at rapids and levels of fluctuations; lowest disturbance from experimental actions.	Compared to Alternative A, similar decline in camping area, somewhat more crowding at rapids, greatest level of fluctuations, greater disturbance from non-flow actions, especially under experimental hydropower improvement flows.	Compared to Alternative A, reversal of camping area decline, somewhat less crowding at rapids, lower level of fluctuations, greater disturbance from non-flow actions.	Compared to Alternative A, reversal of camping area decline, similar crowding at rapids, similar level of fluctuations, greater disturbance from non-flow actions.	Compared to Alternative A, reversal of camping area decline, most crowding at rapids, higher level of fluctuations, greater disturbance from non-flow actions.	Compared to Alternative A, reversal of camping area decline, less crowding at rapids, no fluctuations, greater disturbance from non-flow actions, but no mechanical removal of trout.	Compared to Alternative A, greatest reversal of camping area decline, least crowding at rapids, no fluctuations, greater disturbance from non-flow actions.
Campsite crowding as indicated by the camping area index (CAI)	No change from current conditions; lack of HFEs after 2020 would lead to continued declining size and number of campsites (CAI = 0.14 out of 1) and could result in further crowding and adverse effects on solitude.	Compared to Alternative A, continued declining trend in campsite area (CAI = 0.15) could result in crowding and adverse effects on solitude.	Compared to Alternative A, the expected increase in campsite area (CAI = 0.38) could reduce crowding and improve solitude.	Compared to Alternative A, the expected increase in campsite area (CAI = 0.36) could reduce crowding and improve solitude.	Compared to Alternative A, the expected increase in campsite area (CAI = 0.30) could reduce crowding and improve solitude, but would be lower than other alternatives except Alternatives A and B.	Compared to Alternative A, the expected increase in campsite area (CAI = 0.41) could reduce crowding and improve solitude. Steady flows also would aid trip planning, helping to avoid crowding.	Compared to Alternative A, greatest increase in campsite area (CAI = 0.45) could reduce crowding and improve solitude. Steady flows also would aid trip planning, helping to avoid crowding.

TABLE 4.11-1 (Cont.)

Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Encounters with other groups at rapids due to low flows (8,000 cfs) as indicated by the navigation index (NI)	No change from current conditions; intermediate rank among alternatives; NI = 0.50 out of 1.	More encounters than Alternative A; NI = 0.39.	Fewer encounters than Alternative A; NI = 0.75.	Similar effect as Alternative A; NI = 0.45.	Most encounters due to highest frequency of low flows; NI = 0.37.	Fewer encounters than Alternative A because steady flows mostly above 8,000 cfs; NI = 0.71.	Fewest encounters because of steady flows nearly always above 8,000 cfs; NI = 0.96.
Effect of daily fluctuations as indicated by the fluctuation index (FI)	No change from current conditions; intermediate effect among alternatives, FI = 0.79 out of 1.	Highest daily fluctuations, FI = 0.42.	Almost no effect, FI = 0.93.	Similar to Alternative A, FI = 0.74.	Second-highest daily fluctuations, FI = 0.57.	No effect; steady daily flows, FI = 1.0.	No effect; steady daily flows, FI = 0.98.
Disturbance from non-flow actions: vegetation management, mechanical removal of trout, and administrative trips	No change from current conditions; no vegetation treatments, few mechanical removals of trout.	Compared to Alternative A, greater impacts due to vegetation treatments; and few mechanical removals of trout.	Compared to Alternative A, greater impacts due to vegetation treatments and more mechanical removals of trout.	Compared to Alternative A, greater impacts due to vegetation treatments and more mechanical removals of trout.	Compared to Alternative A, greater impacts due to vegetation treatments and potentially more mechanical removals of trout.	Compared to Alternative A, less impact due to absence of mechanical removals of trout, but greater effects due to vegetation treatments.	Compared to Alternative A, greater impacts due to vegetation treatments and more mechanical removals of trout.

scout rapids or wait for flows to rise. Alternatives D and A would be similar to each other and comparable to current conditions (about 50% of days with low flows), while Alternatives F, C, and G would have the fewest days with low flows (about 5% to 30% of days), and would result in the lowest chances of encountering other groups. Although these comparisons are easily made on the basis of the flow patterns of the alternatives, the actual effects on crowding at rapids may be small overall, and small differences noted between alternatives may not be significant.

Daily flow fluctuations in excess of 10,000 cfs have been identified as creating less natural conditions on the river. The effect of such flow fluctuations on wilderness experience was evaluated using the fluctuation index (Section J.2.3 in Appendix J) developed from maximum "tolerable" fluctuations preferred by whitewater rafters (Table 3.10-2), which are generally less than 10,000 cfs and depend on overall flow level (Bishop et al. 1987). The fluctuation index is presented in Section 4.10, where it is used to evaluate effects of fluctuations on whitewater rafting. It is used here as a surrogate for effects on perceived natural conditions in the Grand Canyon. Alternatives F and G, which employ steady flows, have fluctuation index values near 1.0, indicating no within-day fluctuations. Fluctuating flow Alternatives A, C, and D would be similar to each other, with most fluctuations within the preferred range; they would have fluctuation index values of 0.79, 0.93, and 0.74, respectively. Alternatives B and E would have the lowest fluctuation index values, indicating the lowest frequency of fluctuations within the preferred range (Figure 4.10-1). Alternative D would include testing of macroinvertebrate production flows during weekend days from March through August, and these steady flows would reduce any impacts of fluctuations on wilderness experience on those days. Because most daily fluctuations under all alternatives are below the 10,000-cfs level (flows ≥10,000 cfs were identified as being perceived as less natural by Bishop et al. 1987), the fluctuation index, which was developed for whitewater rafting for effects of fluctuations on such factors as navigation and camping, is not a perfect surrogate for evaluating perceived naturalness of flows. Visitors would be expected to notice that high daily fluctuations are not natural; however, the overall effects of such perceptions on wilderness experience are likely fairly small.

A metric (time off river) was developed to quantify the relative amount of time rafters would have to explore and enjoy wilderness at the end of each day (Section 4.10.1). Roberts and Bieri (2001) demonstrated that groups spent 50% less time off river at a flow of 8,000 cfs, compared to a flow of 19,000 cfs. Evaluation of the flow patterns of the LTEMP alternatives demonstrated that there would be very little difference among alternatives for this metric, except under Alternative F, which has elevated flows during the peak boating season. This similarity among alternatives is likely due to the fact that each has similar mean annual flows of between 10,000 and 15,000 cfs.

Non-flow experimental actions, including mechanical removal of trout, experimental vegetation treatments, and administrative trips related to monitoring and data collection needed for the GCDAMP would also present less natural conditions to visitors related to noise and visual disturbances. Vegetation treatments, proposed by NPS as an experimental, pilot effort to determine the effectiveness of vegetation control and treatment efforts, would occur under all alternatives except for Alternative A. They would temporarily adversely affect wilderness experience while the activities were ongoing and until treatments were discontinued, either

because they had achieved a level of success that produced natural vegetation communities, or because they were ineffective.

Alternative A would have the lowest impacts from non-flow experimental actions, because vegetation treatment is not included in the alternative. Alternative F would have impacts that were slightly higher than Alternative A, but lower than the remaining alternatives, because this alternative does not employ mechanical trout removal. Alternatives B, C, D, E, and G would have the highest levels of such impacts, which would be comparable under these alternatives.

Considering the effects of flow fluctuation overall, the steady flow Alternatives F and G would rank as having generally lower adverse effects on wilderness experience than the fluctuating flow alternatives, because the latter alternatives have effects on a daily basis. This advantage is reduced somewhat, but not entirely, by the higher frequency of HFEs under Alternative F and of HFEs and TMFs under Alternative G as compared to the fluctuating flow Alternatives A–E. Of the fluctuating flow alternatives, Alternative A would have the lowest effects from fluctuating flows due to moderate daily fluctuations, few HFEs, and no TMFs. Alternatives B, C, D, and E would have comparable effects from fluctuations, with Alternative B having the greatest effect from high daily fluctuations, but the fewest HFEs of these alternatives.

Considering sand retention and potential increase in sandbar area, which is also an effect of flows and flow fluctuations, benefits related to sand retention and increases in sandbar area would be lowest under Alternatives A and B, which would have relatively few HFEs that would build bars and relatively high fluctuating flows that would erode bars. Benefits would be intermediate under Alternatives C, D, and E, which have more HFEs to build sandbar area than Alternatives A and B. Benefits would be greatest under Alternatives F and G, which would have steady flows and the most frequent HFEs. Crowding and loss of solitude would decrease with increasing sandbar area.

While the metrics discussed above provide an analytical tool to evaluate and differentiate the LTEMP alternatives with regard to effects on visitor wilderness experience, actual differences for most visitors would be small and many of the disturbances evaluated—including HFEs, TMFs, mechanical trout removals, and vegetation management—would be infrequent, short-term actions that would not affect most visitors. In addition, few visitors would be expected to experience more than one of these disturbances, as a given action of one type typically excludes the other actions at a given time (e.g., a TMF would not occur at the same time as an HFE or likely within the time period of a single trip).

4.11.3 Alternative-Specific Impacts

The following Section provides descriptions of impacts summarized above as they are expected to occur under each of the LTEMP alternatives. The alternatives are compared in terms of the relative rankings of the various wilderness experience effects and measures considered, rather than in absolute terms.

4.11.3.1 Alternative A (No Action Alternative)

Under Alternative A (the No Action Alternative), the HFE protocol would expire in 2020. It is expected that implementation of the protocol up to its expiration would help reverse the ongoing trend of declining campsite area, but the declining trend would resume after the protocol expired. Any increase in crowding would reduce opportunities for solitude and primitive, unconfined recreation under this alternative.

Alternative A, with a navigation index of 0.50 (Figure 4.10-1), ranks in the middle of the LTEMP alternatives, indicating a relatively high tendency for low flows to lead to encountering other groups at rapids under Alternative A. The navigation index is a seasonally weighted measure of the frequency of minimum daily flows greater than 8,000 cfs, identified as the flow below which navigation risks increase (Appendix J.2.2).

Similarly, Alternative A ranks in the middle of alternatives with regard to daily fluctuation levels, with a fluctuation index of 0.79 (Figure 4.10-1); a majority of days would be within the daily range of fluctuations preferred by whitewater rafters (Section J.2.3 in Appendix J), which would also maintain a sense of naturalness as identified by Bishop et al. (1987). This ranking is consistent with allowed daily fluctuations under the respective alternatives. With respect to experimental flows, Alternative A has the lowest projected number of HFEs and no TMFs that would negatively affect wilderness experience.

Alternative A would have the second lowest impacts on wilderness experience from non-flow actions overall among the alternatives. Alternative A has no TMFs, a low expected number of mechanical removal trips, and no experimental vegetation treatments. The number of administrative trips expected under this alternative would be comparable to that of other alternatives.

In summary, Alternative A has the lowest potential to increase campsite area and a corresponding decrease in visitor solitude, and a moderate tendency for crowding at rapids due to periods of lower flows. Alternative A would have moderate adverse effects from daily flow fluctuations and experimental flows on wilderness experience, and has the lowest adverse effects from non-flow experimental actions on wilderness experience as a result of having the lowest combined number of such actions.

4.11.3.2 Alternative B

Alternative B would have a relatively low potential to retain and build sandbar area, similar to that for Alternative A, and would be expected to continue a long-term trend of increasing campsite crowding due to erosion. The low tendency to retain sand and build beaches is attributable to the low number of projected HFEs over the 20-year LTEMP period (an average of 7.2) and high daily fluctuations. Any increase in crowding would reduce opportunities for solitude under this alternative.

Alternative B, with a navigation index of 0.39 (Figure 4.10-1), has one of the highest tendencies for low flows to lead to encountering other groups at rapids. Any such effect, however, would lead to only small effects on wilderness experience, because frequency of encounters would be slightly increased, short term, and low impact.

Alternative B, with a fluctuation index of 0.42 (Figure 4.10-1), would have the fewest days within the daily range of fluctuations preferred by whitewater rafters, which also maintains a sense of naturalness as identified by Bishop et al. (1987), resulting in a high relative potential to reduce a sense of naturalness among the alternatives. With respect to experimental flows, Alternative B has the second lowest projected number of HFEs and a moderate number of TMFs that would negatively affect wilderness experience.

The number of non-flow experimental actions and administrative trips under Alternative B would be higher than under Alternative A, but comparable to, or in the case of mechanical removals of trout less than, those under other alternatives. As for other alternatives, the effects of these actions on wilderness experience are expected to be localized and short-term and to affect relatively few visitors each year. Vegetation treatments would also have a slight long-term potential benefit from restoring wilderness character by promoting native vegetation.

In summary, Alternative B has the second lowest potential to increase campsite area and preserve visitor solitude, while having among the highest tendencies for crowding at rapids due to low flows. Alternative B would have among the highest adverse effects from daily flow fluctuations and experimental flows on wilderness experience, and is comparable to, or lower than, most other alternatives with respect to adverse effects of non-flow experimental actions on wilderness experience.

4.11.3.3 Alternative C

Alternative C is expected to have a relatively high potential to retain sand and build sandbar area (exceeded only slightly by Alternatives F and G) and is expected to reverse the trend in declining campsite area. This high potential results from the high frequency of HFEs (an average of 21.3 over the LTEMP period) and moderate within-day fluctuations in flow. This increase in camping area would improve opportunities for solitude.

Alternative C, with a navigation index of 0.75 (Figure 4.10-1), has a relatively low tendency for encounters at rapids, and thus a relatively low potential to affect solitude.

Alternative C, with a fluctuation index of 0.93 (Figure 4.10-1), ranks third among alternatives; most days would be within the daily range of fluctuations preferred by whitewater rafters, which also maintains a sense of naturalness as identified by Bishop et al. (1987) and a correspondingly low potential to reduce a sense of naturalness due to high daily flow fluctuations. With respect to experimental flows, Alternative C has the second-highest projected number of HFEs and a moderate to high number of TMFs that would negatively impact wilderness experience.

The number of non-flow experimental actions and administrative trips under Alternative C would be higher than under Alternative A, but comparable to those under other alternatives. As for other alternatives, the effects of these actions on wilderness experience are expected to be localized and short term, and to affect relatively few visitors each year. Vegetation treatments would also have a slight long-term potential benefit from restoring wilderness character by promoting native vegetation.

In summary, Alternative C has a relatively high potential to increase campsite area and preserve visitor solitude, while having a low tendency for crowding at rapids due to low flows. Alternative C would have among the lowest adverse effects on wilderness experience from daily flow fluctuations and experimental flows, and is comparable to most other alternatives with respect to adverse effects of non-flow experimental actions on wilderness experience.

4.11.3.4 Alternative D (Preferred Alternative)[26]

Alternative D is expected to have a relatively high potential to retain sand and build sandbar area, similar to Alternatives C, F, and G, and is expected to reverse the trend in declining campsite area. This high potential results from a high number of projected HFEs over the next 20 years (an average of 21.1), similar to Alternative C, and moderate within-day fluctuations. This increase in camping area would improve opportunities for solitude.

Alternative D, with a navigation index of 0.45 (Figure 4.10-1), would be comparable to Alternative A with regard to encounters at rapids, and would represent little change from current conditions.

Alternative D, with a fluctuation index of 0.74 (Figure 4.10-1), ranks fifth among alternatives, just below Alternative A; a majority of days would be within the daily range of fluctuations preferred by whitewater rafters, which also maintains a sense of naturalness as identified by Bishop et al. (1987) and a correspondingly low potential to reduce a sense of naturalness due to high daily flow fluctuations. With respect to experimental flows, Alternative D has a high number of HFEs (tied with Alternative C) and the second-highest number of TMFs, which could negatively affect wilderness experience.

The number of non-flow experimental actions and administrative trips under Alternative D would be higher than under Alternative A, but comparable to those under other alternatives. As for other alternatives, the effects of these actions on wilderness experience are expected to be localized and short term, and to affect relatively few visitors each year. Vegetation treatments would also have a slight long-term potential benefit from restoring wilderness character by promoting native vegetation.

In summary, Alternative D has a relatively high potential to increase campsite area and preserve visitor solitude, while having a moderate tendency for crowding at rapids due to low

[26] Adjustments made to Alternative D after modeling was completed (see Section 2.2.4) are not expected to result in a change in Alternative D's impacts on wilderness.

flows. Alternative D would have moderate adverse effects from daily flow fluctuations and experimental flows on wilderness experience, and is comparable to most other alternatives with respect to adverse effects of non-flow experimental actions on wilderness experience.

4.11.3.5 Alternative E

Alternative E is expected to have a moderate potential to retain sand and build sandbar area, slightly lower than Alternatives C, D, F, and G, and would be similarly expected to reverse the trend in declining campsite area. This moderate potential results from a medium number of projected HFEs over the next 20 years (an average of 17.1) and daily fluctuations somewhat higher than Alternatives A, C, and D, but lower than Alternative B. This increase in camping area would improve opportunities for solitude under this alternative.

Alternative E, with a navigation index of 0.37 (Figure 4.10-1), would have the highest tendency for low flows to lead to encountering other groups at rapids relative to the other alternatives.

Alternative E, with a fluctuation index of 0.57 (Figure 4.10-1), ranks sixth among alternatives, above only Alternative B; about half of days would be within the daily range of fluctuations preferred by whitewater rafters, which also maintains a sense of naturalness as identified by Bishop et al. (1987) and a high relative potential to reduce a sense of naturalness due to high daily flow fluctuations. With respect to experimental flows, Alternative E has a moderate number of HFEs and a moderate number of TMFs that would negatively affect wilderness experience

The number of non-flow experimental actions and administrative trips under Alternative E would be higher than under Alternative A, but comparable to those under other alternatives. As for other alternatives, the effects of these actions on wilderness experience are expected to be localized and short term, and to affect relatively few visitors each year. Vegetation treatments would also have a slight long-term potential benefit from restoring wilderness character by promoting native vegetation.

In summary, Alternative E has a moderate potential to increase campsite area and preserve visitor solitude, while having a relatively high tendency for crowding at rapids due to low flows. Alternative E would have relatively moderate to high adverse effects from daily flow fluctuations and experimental flows on wilderness experience, and is comparable to most other alternatives with respect to adverse effects of non-flow experimental actions on wilderness experience.

4.11.3.6 Alternative F

Alternative F is expected to have the second-highest potential to retain sand and build beach area and would be similarly expected to reverse the trend in declining campsite area. This high potential results from a high number of projected HFEs over the next 20 years (an average

of 38.1) and steady flows. This increase in camping area would improve opportunities for solitude under this alternative. Steady flows under this alternative will aid in trip planning, which will also help avoid crowding.

Alternative F, with a navigation index of 0.71 (Figure 4.10-1), would have lower tendency for low flows to lead to encountering other groups at rapids than other alternatives, except Alternatives C and G.

Alternative F, with a fluctuation index of 1.0 (Figure 4.10-1), ranks highest among alternatives; essentially all days would be within the daily range of fluctuations preferred by whitewater rafters, which also maintains a sense of naturalness as identified by Bishop et al. (1987) and effectively no potential to reduce a sense of naturalness due to high daily flow fluctuations under this steady-flow alternative. With respect to experimental flows, Alternative F has the highest number of HFEs but no TMFs that would negatively affect wilderness experience.

The number of non-flow experimental actions and administrative trips under Alternative F would be higher than under Alternative A, but lower than those under other alternatives because this alternative would not feature mechanical trout removal. As for other alternatives, the effects of these actions on wilderness experience are expected to be localized and short term, and to affect relatively few visitors each year. Vegetation treatments would also have a slight long-term potential benefit from restoring wilderness character by promoting native vegetation.

In summary, Alternative F has a high potential to increase campsite area and preserve visitor solitude, while having a low tendency for crowding at rapids due to low flows. Alternative F would have no adverse effects from daily flow fluctuations but some effects from the highest number of HFEs on wilderness experience, and is lower than most other alternatives with respect to adverse effects of non-flow experimental actions on wilderness experience.

4.11.3.7 Alternative G

Alternative G is expected to have the highest potential to retain sand and build sandbar area and would be most likely of all alternatives to reverse the trend in declining campsite area. This high potential results mainly from a high number of projected HFEs over the next 20 years (an average of 24.5) and steady flows. This increase in camping area would improve opportunities for solitude under this alternative. Steady flows will aid in trip planning, which will also help avoid crowding.

Alternative G, with a navigation index of 0.96 (Figure 4.10-1), would have the lowest tendency of all alternatives for low flows to lead to encountering other groups at rapids.

Alternative G, with a fluctuation index of 0.98 (Figure 4.10-1), ranks second among alternatives, slightly below Alternative F; nearly all days would be within the daily range of fluctuations preferred by whitewater rafters, which also maintains a sense of naturalness as identified by Bishop et al. (1987) and effectively no potential to reduce a sense of naturalness due to high daily flow fluctuations under this steady-flow alternative. With respect to experimental flows, Alternative G has the second-highest number of HFEs and highest number of TMFs that would negatively affect wilderness experience.

The number of non-flow experimental actions and administrative trips under Alternative G would be higher than under Alternative A, but comparable to those under other alternatives. As for other alternatives, the effects of these actions on wilderness experience are expected to be localized and short term, and to affect relatively few visitors each year. Vegetation treatments would also have a slight long-term potential benefit from restoring wilderness character by promoting native vegetation.

In summary, Alternative G has a high potential to increase campsite area and preserve visitor solitude, while having the lowest tendency for crowding at rapids due to low flows. Alternative G would have no adverse effects from daily flow fluctuations, but some effects from the second-highest number of HFEs on wilderness experience; it is comparable to all alternatives except Alternatives A and B with respect to adverse effects of HFEs and comparable to other alternatives with respect to effects of non-flow experimental actions on wilderness experience.

4.12 VISUAL RESOURCES

This section describes the assessment of the potential effects of the alternatives on visual resources, concentrating on changes that could occur to the water, select geological features, and areas of riparian vegetation along the shore lines of the Colorado River, Lake Powell, and Lake Mead.

Issue: How do the alternatives affect visual resources?

Impact Indicators:

- Exposure of lake deltas in Lake Mead and Lake Powell
- Changes in vegetation and sandbar size

Visual resources are important to visitor enjoyment of GCNRA, GCNP, and LMNRA, and the conservation of visual resources is an important component of federal management activities for these areas. For this reason, it is important to understand how dam operations and non-flow management actions may affect visual resources within the project area. Indictors of effects on visual resources include the height of the calcium carbonate ring surrounding Lake Mead and Lake Powell, the exposure of lake deltas in Lake Mead and Lake Powell, the exposure of Cathedral-in-the-Desert in Lake Powell, and potential impacts associated with changes in vegetation and water color, clarity, and surface appearance.

Calcium carbonate deposits form at the water line and are typically visible at reservoir elevations below full pool, where they create a bathtub ring effect. They are generally lighter in color than the walls without calcium carbonate deposits. This creates visual contrast that may

result in visual impacts. The calcium carbonate deposits around both Lake Powell and Lake Mead will be more or less exposed as reservoir levels rise and fall; however, the exposure will be most affected by future hydrology. In order to quantify the extent of visibility of the calcium carbonate rings, the average end-of-month elevation of each reservoir over the 20-year LTEMP period was modeled, and from this the potential range in height of the exposed calcium carbonate ring (the distance from the top of the ring to the water level) was determined. Projected elevations were compared against both reservoirs at full pool. Lake Powell is considered at full pool at 3,700 ft AMSL. Lake Mead is considered at full pool at 1,221 ft AMSL.

Our analysis indicates that the reservoir elevations would vary very little under the different alternatives, resulting in very little difference in the potential maximum height of the calcium carbonate ring. For Lake Powell, the potential difference in the maximum height of the ring varies approximately 1 ft among the alternatives for a short-term period within the year, but would be no different by the end of the water year. For Lake Mead, the potential difference in the maximum height of the ring varies approximately 3 ft for a short-term period within the year, but would be no different by the end of the water year among the alternatives. The calcium carbonate deposits produce a visual contrast regardless of their height and size and make up only a portion of the view in both reservoirs, and the overall difference in visual impacts among the alternatives as a result of exposure of the rings would be negligible.

Lake deltas appear as expansive, eroding sediment deposits that become more visible as the water level in the reservoir decreases. They are considered a visual detraction (Reclamation 2007a). The size of a lake delta is directly affected by the mass of sediment delivered to the delta, and its exposure is directly affected by reservoir elevation. Lake deltas within Lake Powell and Lake Mead will be more or less exposed as reservoir levels fall and rise; however, the exposure of the lake deltas will be most affected by future hydrology. The increased visibility of lake deltas creates increased visual contrast and may result in visual impacts. In order to quantify the extent of the visibility of lake deltas, the average end-of-month elevation of each reservoir over the 20-year LTEMP period was modeled to determine if lake deltas would be more or less exposed in each of the reservoirs.

The analysis indicates that Lake Powell elevations would vary approximately 1 ft among the alternatives, while Lake Mead elevations would vary approximately 3 ft among the alternatives. Lake deltas produce visual contrast regardless of their height and size and make up a very small part of the views in both reservoirs. On the basis of predicted variation in reservoir elevations, there would be little, if any, difference in the exposure of lake deltas in either reservoir among the alternatives, and the overall difference in visual impact among the alternatives as a result of exposure of lake deltas would be negligible.

Cathedral-in-the-Desert is a prominent geological feature in Lake Powell that attracts many visitors when exposed. The feature is exposed when the Lake Powell reservoir elevation is ≤ 3,550 ft AMSL (Reclamation 2007a). Because of the attention Cathedral-in-the-Desert receives when it is exposed, the exposure of this feature could be perceived as a positive impact or benefit. To determine the potential exposure of Cathedral-in-the-Desert, the average number of months per year that Lake Powell's end-of-month elevation was ≤ 3,550 ft AMSL over the

20-year LTEMP period was modeled. Our analysis indicates that Cathedral-in-the-Desert could be exposed an average of 2 months per year over the 20-year LTEMP period under all alternatives, and the overall difference in visual impact between the alternatives would be negligible for Cathedral-in-the-Desert and similar attractions within the reservoir basin.

Vegetation plays an important role in the scenic experience along the Colorado River. Vegetation increases the visual interest of many places where it occurs by adding variety in color and texture in contrast to the river, rocks, and bare canyon walls. Flow variations and non-flow management actions can alter the type and frequency of vegetation along the corridor (see Section 3.6.2 and Section 4.6). Changes in vegetation could result in different levels of color and texture in contrast to the surrounding landscape, but it is difficult to predict how this could affect a visitor's visual experience and is not expected to vary significantly among alternatives. It is not possible to predict what types of vegetation are more appealing than others to recreationists. Individuals are often influenced by their personal experiences and/or expectations, and what is visually pleasing to one individual may not be to another. Potential impacts on vegetation were assessed based on professional judgment and the riparian vegetation assessment presented in Section 4.6.

Although frequent visitors to the Canyons, such as Tribal members, river guides, scientists, and anglers, will likely notice a change in plant states and sandbar size, it is not certain that an individual participating in a once-a-year or once-in-a-lifetime river trip will notice any change unless there are vegetation management activities underway during visitor trips. Visitors standing at scenic overlooks with views of the river may notice vegetation or sandbars in the corridor, but they will be unlikely to notice a change in vegetation state or sandbar size from these locations, given their distance from the river. Therefore, visual impacts on the Canyons from changes in vegetation or sandbar size are expected to be negligible under all alternatives.

NPS management actions that are being proposed in the river corridor of Glen and Grand Canyons as well as on Hualapai lands, such as nonnative plant removal, native plant revegetation, and mitigation at cultural sites, may have effects on the visual environment. These effects are associated primarily with the alteration of the forms, colors, and textures of vegetation, both immediately after implementation of management activities and over longer time periods, because of changes in species composition, but, as discussed above, the visual effects of changes in vegetation type and cover would be negligible.

Based on this analysis, the effects are considered negligible and would not vary among the alternatives.

4.13 HYDROPOWER

This section describes the potential impacts of changes in Glen Canyon Dam operations on the economic value of the powerplant's capacity and energy production. Impacts are measured in terms of changes in regional power system capacity expansion pathways[27] and overall system-level electricity production costs. The amount of generation and associated economics at the Hoover Dam Powerplant is analyzed separately. This section discusses how changes in system resources and operations affect both wholesale electricity rates paid by utilities that purchase firm capacity and energy from WAPA. This section also presents analysis on the retail electricity rates produced by the Glen Canyon Dam Powerplant.

Issue: How do alternatives affect hydropower resources?

Impact Indicators:

- Changes in the amount (MWh) and dollar value of hydropower generation at Glen Canyon Dam
- Changes in SLCA/IP firm capacity
- Changes in capital and operating costs that WAPA's customers incur to serve their loads
- Changes in wholesale rates that WAPA charges its firm electric service customers
- Changes in residential electricity bills of WAPA's customers
- Changes in powerplant generation and economics at Hoover Dam.

4.13.1 Analysis Methods

This section describes the methods used to estimate the impact of alternative Glen Canyon Dam operating criteria on the economic value of its hydropower resources, to compute changes in the rate that WAPA charges its firm electric service (FES) customers, and to estimate the impacts on retail electricity rates charged by entities that purchase power from the Salt Lake City Area Integrated Projects (SLCA/IP or federal preference power). This section also describes the methods used to estimate the possible indirect impact of alternative operating criteria at Glen Canyon Dam on Hoover Dam generation and economics.

The LTEMP hydropower resources impact analysis was largely an economic analysis rather than a financial analysis. A financial analysis focuses on the revenues and costs accrued by a particular entity, including transfer payments, such as power transactions, taxes, and insurance. It also includes payments made by individual entities for previous investments. In contrast, an economic analysis focuses on societal costs and benefits. Transfer payments among entities are excluded because the total net change to society of these transactions is zero; that is, the amount paid by the buying entity equals the amount received by the selling entity. Also excluded from economic costs are past investments, such as those to construct power plants, because these expenditures have already been incurred on society and cannot be recovered. Similar to other power systems EIS analyses performed by Argonne, the economic analysis performed for LTEMP estimates changes to the U.S. economy as the result of altering operating criteria at Glen Canyon Dam. These economic costs include expenditures to build and operate new capacity in the future to replace Glen Canyon Dam Powerplant lost capacity and both fuel and variable

[27] A capacity expansion pathway is a specification of the size, timing, and type of generating units to be constructed over a specified planning horizon.

operation and maintenance (O&M) costs associated with altering the dispatch of Western Interconnection generating units. A financial analysis was performed for the LTEMP EIS to estimate the wholesale (see Section 4.13.1.2) and retail rate impacts (see Section 4.13.1.3) on individual affected entities (e.g., individual FES utilities and their retail customers).

4.13.1.1 Hydropower Resource and Capacity Expansion Impacts

For each of the proposed alternative operating criteria, the hydropower impact analysis estimated the net present value (NPV) of the cost of meeting future energy and capacity demands of utilities (customers) that have long-term firm (LTF) contracts to purchase power from WAPA's SLCA/IP facilities (Section 3.13) and compared these costs to the NPV of costs under the existing operating criteria (Alternative A, the No Action Alternative).

A number of models and spreadsheet tools were used for the analysis, including:

- *Colorado River Simulation System (CRSS)* simulated future monthly operations for the six large SLCA/IP facilities that include the Seedskadee Project (Fontenelle) and the five Colorado River Storage Project (CRSP) facilities; namely, Glen Canyon Dam, Flaming Gorge Dam, and the Aspinall Cascade (Blue Mesa, Morrow Point, and Crystal Dams).

- *Sand Budget Model (SBM)* scheduled the type and timing of HFEs at Glen Canyon Dam and reallocated monthly water release volumes from CRSS, and revised monthly elevations to enable higher water releases during months with HFEs. Another type of experiment at Glen Canyon Dam, TMFs, were also added at this stage.

- *GTMax-Lite* optimized the economic value of hourly energy produced at the five largest CRSP power facilities based on monthly results from CRSS. This model determined an hour-by-hour pattern of both generation (in MWh) and water releases (in cfs) that satisfied the operating constraints imposed by each alternative, such as up/down ramp rates, maximum change in the release over a rolling 24-hour period, maximum hourly release, and others. This model consists of two configurations: one for Glen Canyon Dam and one for the remaining four CRSP facilities and Fontenelle.

- *AURORAxmp (Aurora)* simulated the operation of the modeled power system and projected hourly spot market prices in the Western Interconnection. The model was run in the capacity expansion mode to project system capacity expansion paths that would reliably meet future electricity demands, and in the unit dispatch mode to simulate powerplant unit operations to serve the load while minimizing total electricity production cost. The model was developed by EPIS, Inc., and is commonly used by utilities throughout the United States.

- *Other specialized models and spreadsheet models* developed for the LTEMP analysis included:
  - Representative Trace Tool: selected the most representative trace or hydrological future of all traces simulated by CRSS and the SBM.
  - Hydropower Outage Model: simulated unit outages, both scheduled maintenance and forced outages, at the six large SLCA/IP facilities.
  - Hourly Load Forecast Algorithm: determined hourly loads of WAPA's customers over the study period.
  - Firm Marketable Capacity spreadsheet: estimated the amount of firm capacity from all SLCA/IP facilities that WAPA could offer its customers at an assumed risk preference or exceedance level.

More detail on each model and tool can be found in Appendix K, Sections K.1.4 and K.1.5.

A number of simplifying assumptions were made for the hydropower analysis, as follows:

- The geographic scope of the analysis was limited to the service territories of utilities with which WAPA currently has LTF electricity contracts. Limiting the analysis to WAPA's customers allows the analysis to concentrate on the systems most affected by an LTEMP alternative with an adequate level of fidelity to obtain good estimates of economic impacts. In addition, the hourly economic value of energy which drives much of SLCA/IP operations was estimated by a tangential modeling task that encompasses the entire Western Interconnection.

- Given the amount of power generated at Glen Canyon Dam relative to the amount of electricity in the Western Interconnection power grid, the analysis assumes that the operation of Glen Canyon Dam does not have a significant influence on the marginal value of electricity at locations outside of the large utilities that WAPA serves.

- WAPA's customers are separated into two categories: large and small. Large customers, which comprise about 75% of firm capacity and energy sales, were modeled more rigorously than small customers. The eight largest customers are Deseret Generation and Transmission Cooperative (Deseret), the Navajo Tribal Utility Authority (NTUA), Salt River Project (SRP), Utah Associated Municipal Power Systems (UAMPS), Utah Municipal Power Agency (UMPA), Platte River Power Authority, Tri-State Generation and Transmission Association (Tri-State), and Colorado Springs Utilities (CSU). There are about 130 remaining "small customer" entities accounting for the remaining 25% of LTF sales. Individually, each small customer receives less than 2.5% of WAPA's total SLCA/IP LTF capacity and energy sales.

- The CRSS model was used to project operations under 105 monthly hydrological traces over a 48-year period from 2013 through 2060 for three

sediment traces, namely, high, moderate, and low. Each trace contains a unique historical chronological time sequence of hydrological conditions. Therefore, hydrological conditions are deterministic, and it is extremely unlikely that any one trace will ever be repeated. Of these 105 traces, a common set of 21 was used to estimate the level of firm capacity of the CRSP plants and the Fontenelle powerplant. To estimate the hourly value of Glen Canyon Dam energy production, the AURORA model was run in dispatch mode using a representative hydrological trace. The trace chosen best met a set of criteria for being "representative," and included a significant distribution of hydrological conditions that are very similar to the hydrological distribution of the 21 traces. In addition, the mean of the representative trace is approximately equal to the mean of all 21 traces. Furthermore, the AURORA model run will only use the moderate sediment trace, which was estimated to have a 63.1% chance of occurring. Using a single sediment trace greatly expedites model runs by reducing the number of cases to be examined.

- This analysis uses the GTMax-Lite model to simulate the hourly operation of Glen Canyon Dam and the remaining hydropower facilities that comprise both the CRSP and Fontenelle powerplant. This model was designed specifically for the LTEMP EIS and consists of two configurations. One configuration models only the operation of Glen Canyon Dam, and the other configuration models the remaining aforementioned facilities. This is a simplification for power production because WAPA schedules and Reclamation dispatches all of the CRSP power units concurrently and incorporate some operating goals and guides that are not represented by GTMax-Lite.

- The methodology assumes that the electrical utilities being modeled engage in unfettered exchange with perfect information about the entire system when it comes to exchanging electrical energy and sharing capacity. In reality, each utility makes its own autonomous decisions with imperfect knowledge about both the future and the actions of competing utilities. Transmission constraints are also not explicitly modeled; neither are institutional nor regulatory obstacles to trade.

Figure 4.13-1 shows the modeling sequence and data flows for the power systems analysis. The following section briefly describes the methodology; a more detailed discussion of the methodology can be found in Appendix K, Sections K.1.4 and K.1.5.

Another noteworthy assumption is that "emergency exception criteria" as stipulated under the 1996 Record of Decision will continue under all LTEMP alternatives. Therefore, in accordance with the criteria, Glen Canyon Dam will be allowed to operate outside of minimum and maximum flow limits, daily change constraints, and both maximum hourly up- and down-ramp rates in the event of a power system emergency (e.g., grid energy imbalance events).

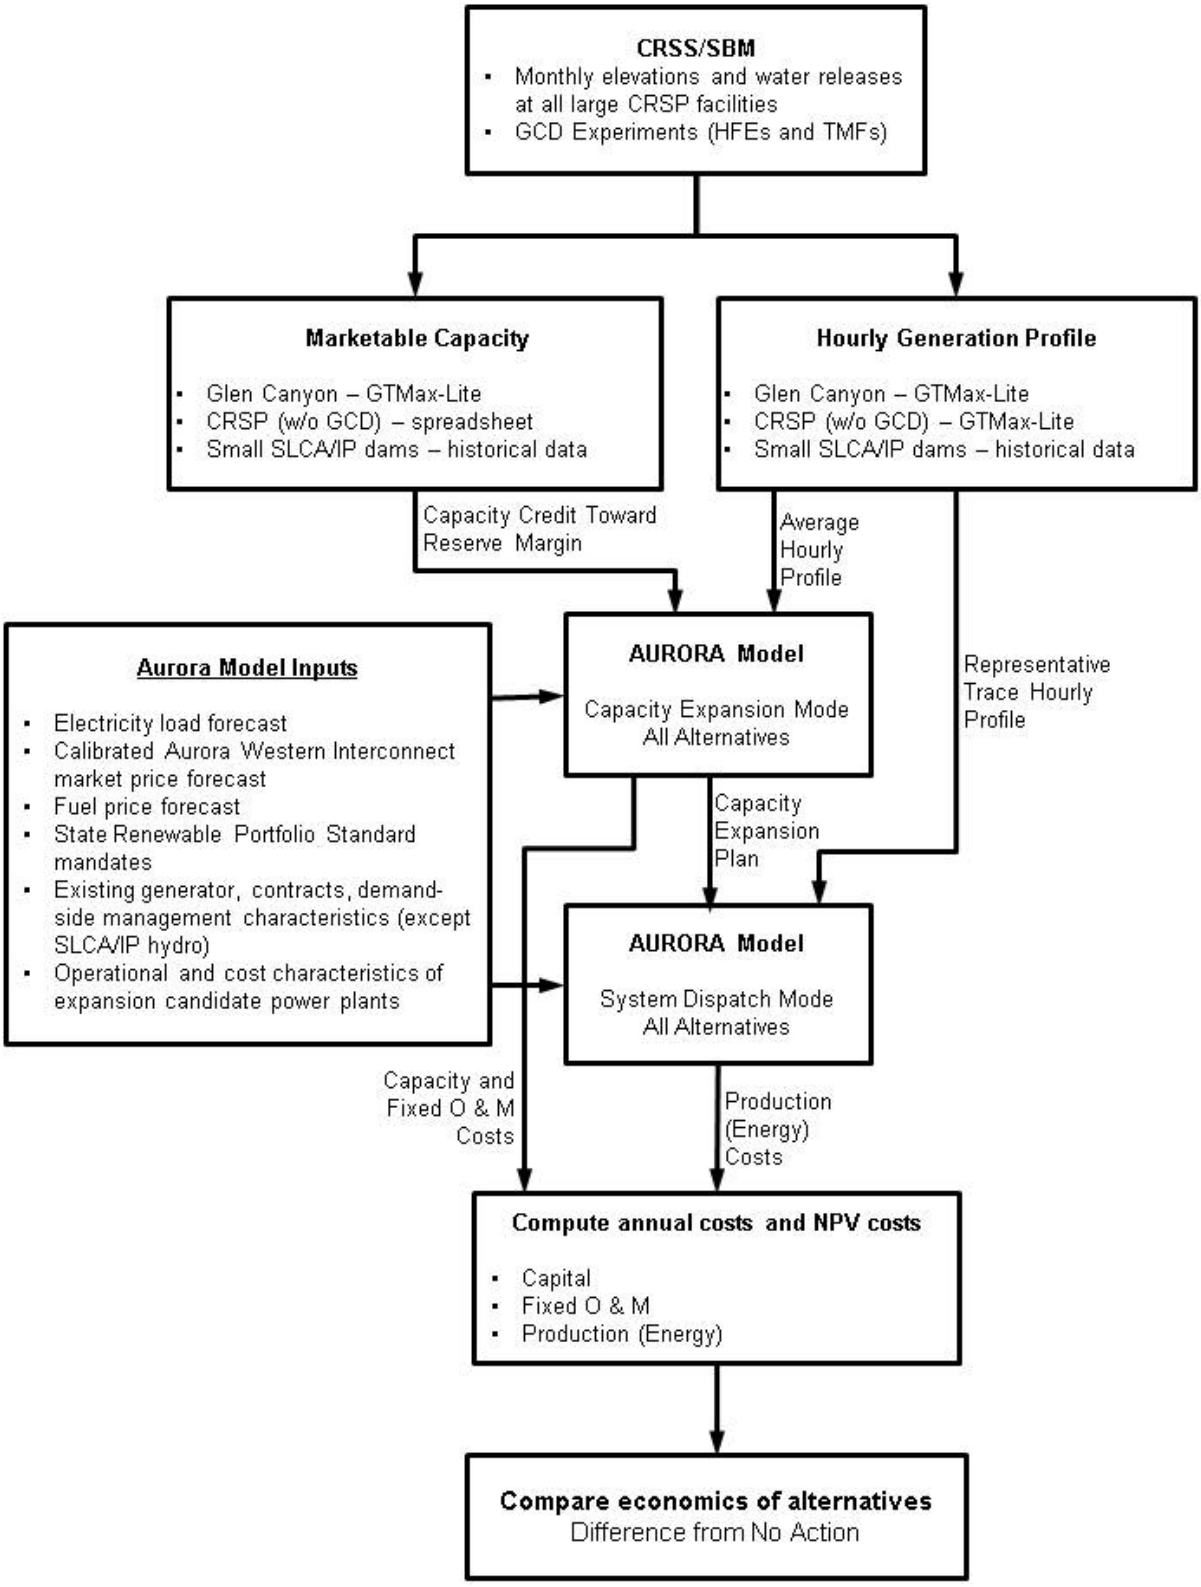

FIGURE 4.13-1 Flow Diagram of the Power Systems Methodology Used in the LTEMP EIS

Alternative-specific Glen Canyon Dam operating criteria would affect the timing and amount of powerplant additions in the SLCA/IP system and system operation. Both would result in economic impacts that are measured by the AURORA model—the core tool used for power systems analysis. If the operating criteria under each alternative result in a reduction in the maximum output from Glen Canyon Dam during the time of peak system load, new generating capacity would be needed elsewhere in the SLCA/IP system to meet SLCA/IP peak loads. Alternative operating criteria could also change the timing of Glen Canyon Dam generation on both a monthly and hourly basis (i.e., less power generated in the high price peak periods and more generated in the low price off-peak hours). Such a change in hydropower operation may cause other powerplants, typically fossil-fuel thermal units, to increase expensive generation in peak hours and decrease relatively inexpensive generation in off-peak hours. The differences in the timing of new resources and in the way the system is dispatched mean that the cost of serving SLCA/IP loads over the 20-year LTEMP period would differ from system operations under the existing operating criteria. Therefore, for each alternative, AURORA was used for two major purposes: (1) to determine the capacity expansion pathway over time during the study period for a joint WAPA/LTF customer system; and (2) to perform a least-cost unit commitment and system dispatch for a given expansion pathway using a single representative hydrology future or trace.

Considerable amounts of data were needed for the AURORA model runs, including:

- Hourly electricity load forecasts for all WAPA's LTF customer utilities
- Western Interconnection electricity market price forecasts (spot market prices were projected using a configuration of AURORA representing the entire Western Interconnection and a spreadsheet model that calibrated those prices to historical 2013 observations at the Palo Verde market hub, which is a key Western Interconnection marketing hub often used as driver for SLCA/IP operations)
- Fuel price projections
- Renewable resource targets; from state renewable portfolio standards and/or from utility-specific goals as stated in their integrated resource plans (IRPs)
- Characteristics of contracts that customer utilities have with other utilities and with other WAPA offices other than SLCA/IP
- Characteristics of demand-side management programs
- Operational and cost characteristics of powerplants owned by customer utilities
- Operational and cost characteristics of candidate generating unit technologies for capacity expansion to reliably meet future SLCA/IP system loads

More details on data sources and how data was generated can be found in Appendix K, Sections K.1.6.1 and K.1.6.3.

Although the AURORA model has its own database of powerplant characteristics, fuel price projections, and hourly load profiles for a number of areas within the entire Western Interconnection, these data were compared to publicly available data sources to verify data accuracy and consistency. Such data sources include those available from the Energy Information Administration (EIA), as well as IRPs that WAPA's customers provide WAPA or post on their company website. Since the methodology modeled WAPA's eight large customers in detail, it was necessary to carefully examine the powerplant characteristics in the AURORA inventory and benchmark them against data compiled by EIA and in IRPs.

Due to the complexities of SLCA/IP hydropower operating criteria and mandates unrelated to power production, AURORA could not model the dispatch of these resources at a level of detail that is required for this study. Therefore, the GTMax-Lite model and other spreadsheet models were used to project powerplant-specific hourly production levels over the study period. The results of these models were input to AURORA as a time series of fixed hourly energy injections into the power grid. Input data for GTMax-lite and the spreadsheet models for each alternative came from the CRSS model and SBM models that include monthly reservoir elevations and water release volumes, as well as the type and timing of experiments at Glen Canyon Dam. Other inputs include both scheduled maintenance outages and forced outages at Glen Canyon Dam and the other large SLCA/IP facilities. Since alternatives only targeted the operation of Glen Canyon Dam, the generation at all other SLCA/IP was typically the same in every alternative. However, in some situations, when Glen Canyon Dam could not provide spinning reserves and/or regulation services, a portion or all of these grid services were provided by powerplants in the Aspinall Cascade, affecting the operations of these facilities.

SLCA/IP firm capacity was an input to the AURORA expansion model. It represents the amount of hydroelectric capacity WAPA is obligated to provide to LTF customers regardless of the state or condition of SLCA/IP resources. It is also the amount of capacity credited toward meeting the SLCA/IP system reserve margin; that is, the spare capacity above the annual coincidental peak of the electric power system. For this study, the reserve margin was assumed to be 15%, which is a typical value in the Western Interconnection. Because WAPA markets the capacity and energy produced by all 11 SLCA/IP facilities as a package, firm capacity was determined for the entire facility group. The GTMax-Lite model results were used to compute the capacity contribution from Glen Canyon Dam, while a spreadsheet using CRSS and SBM results were used to compute the contribution from the other large CRSP facilities. Historical data were used to compute firm capacity from the small SLCA/IP facilities; namely, Deer Creek, Elephant Butte, Towaoc, McPhee, and Molina. Because alternatives only affected Glen Canyon Dam's operation under almost all circumstances, only the contribution of Glen Canyon Dam to firm capacity varied by alternative.

This LTEMP analysis used an exceedance level of 90% to determine firm capacity; that is, 90% of the time that amount of capacity or more is available from SLCA/IP facilities at the time of system peak load. This exceedance level was selected based on a retrospective study performed by Argonne. It shows that the level of SLCA/IP capacity marketed and offered by

WAPA to its FES customers over the last 10 years is approximately at a 90% exceedance level. That is, WAPA has enough SLCA/IP capacity to meet its obligation 90% of the time. Firm capacity at 50% and 99% exceedance levels were also modeled. These results are presented in this section and detailed in Appendix K, Section K.1.10.4.

Hourly generation profiles from all SLCA/IP facilities were an input to both the AURORA expansion and dispatch models. The hourly profile based on the average of all 21 hydrology traces is input to the expansion model, and the hourly profile based on the representative trace is input to the dispatch model. The appropriate configuration of GTMax-Lite is used to compute the hourly generation profiles for Glen Canyon Dam and for the other large CRSP facilities.

The results from the AURORA model run in expansion mode show capacity expansion plans for each alternative over the study period. The plans specify the type of technology built (such as combustion turbines, combined cycle plants, coal plants, nuclear powerplants, etc.), the capacity of the unit, and the year it begins operating. A post-processor spreadsheet written by Argonne computed the annual capacity investment and fixed O&M costs for the new units over the study period. The AURORA model was given a wide selection of technologies from which to choose future capacity additions, including conventional and advanced natural gas combustion turbines, conventional and advanced gas/oil combined cycle units, scrubbed and pulverized coal units, integrated gasification combined cycle units, nuclear units, wind turbines, and solar thermal and photovoltaic facilities. More details on expansion technology candidates and their cost and performance characteristics are provided in Appendix K, Section K.1.6.3.

The capacity expansion plan for each alternative was an input to the AURORA run in dispatch mode to simulate the operation of the system for every hour in the entire study period for a single hydrological future or trace, which is known as the representative trace. Because the dispatch was run for only a single hydrological trace, selection of the trace is very important. Trace 14 was selected as the representative trace. More detail on the method used to select the representative trace can be found in Appendix K, Attachment K.3.

Results of the AURORA dispatch model consisted of costs to produce the electrical energy to meet the system load demand. Production costs are the sum of powerplant fuel costs, variable O&M costs, unit start-up costs, and cost of power purchased from the spot market. Spot sales are subtracted from total system costs. Results from the AURORA expansion and dispatch models (namely, capital, fixed O&M, and production or energy costs) were combined to determine the total annual costs for each alternative over the study period. The net present value stream of annual costs was also calculated to facilitate comparison of each alternative to Alternative A. This single lump-sum value was based on a discount rate of 3.375%, a rate that is used by Reclamation for cost-benefit studies of projects.

Sensitivity analyses were performed to determine the effect of several power systems model assumptions on the estimated cost of LTEMP alternatives. These sensitivity analyses evaluated the effect of differing assumptions for exceedance values (50, 90, and 99%), discount rates (1.4 vs. 3.375%), expansion pathways (various combinations of new combustion turbines and combined cycle plants), hydrology (representative 20-year trace vs. average of 21, 20-year

traces), and ancillary services (increasing [103 to 160 MW] vs. stable [67 MW] ancillary service provision). These analyses indicated that the cost alternatives may be either lower or higher for changes in grid operations and/or capacity replacement than those for the baseline assumption set. The analyses also demonstrated that results are more sensitive to some model assumptions than others. An overview of results is presented in Section 4.13.2.3; details are presented in Appendix K (Sections K.1.10.4 through K.1.10.9).

4.13.1.2 Wholesale Rate Impacts

The economic impact of changed operations at the Glen Canyon Dam Powerplant on electrical power production and value is the impact—measured in dollars—on the economy. It includes the system cost of changing the value of electrical power produced at Glen Canyon Dam as a result of changing the timing and routing of water releases (i.e., turbine and bypass). It also includes the expense of constructing (or savings resulting from forgoing construction of) additional electrical generators because of changes in firm SLCA/IP hydropower capacity. Wholesale rates[28] impacts describe how these economic impacts are distributed to utilities that purchase Glen Canyon Dam electrical power from WAPA at the SLCA/IP rate. The change in SLCA/IP rate among alternatives reflects the economic costs of altered Glen Canyon Dam operations.

WAPA sets rates as low as possible consistent with sound business principles to repay the federal government's investment in generation and transmission facilities in addition to specific non-power costs that power users are legislatively required by Congress to repay, such as irrigation costs that are beyond the irrigators' ability to repay. Sales of federal electric power and transmission repay all costs (including interest) associated with generating and delivering the power. WAPA prepares a power repayment study (PRS) for each specific power project to ensure the rates are sufficient to recover expenses.

It was assumed that WAPA will adjust its FES rates as necessary to address costs associated with LTEMP operations, including all net purchased energy, federal capital costs, fixed O&M costs, and interest expense. Interest expense is calculated by multiplying each investment's prior year unpaid balance by the appropriate interest rate. Computations of total purchase energy for each alternative are based on projections of total hourly generation from all SLCA/IP hydropower resources and hourly FES customer loads. The difference between hourly generation and load is resolved by hourly non-firm energy transactions at an energy price projected by the power systems economic analysis described in Section 4.13.1.1. All capital costs and fixed O&M costs associated with a reduction in Glen Canyon Dam Powerplant capacity are also paid by WAPA and passed on to its customers via adjustments to FES wholesale rates. See Appendix K, Section K.2, for more detailed information on the PRS and wholesale rate modeling process.

---

28 The term "rate" is used rather than "price." This is the standard convention for wholesale electrical commodities. Rate is the price charged for an energy unit, whether capacity or energy. Rate is often used to describe wholesale prices because it is the price of wholesale units and not necessarily the units used for retail sales.

Several calculations were performed to determine the impact of the LTEMP EIS alternatives on the SLCA/IP rate. Three rates were calculated for each of the seven alternatives: (1) a firm energy rate, (2) a firm capacity rate, and (3) a composite rate. The SLCA/IP FES rate is the price paid per unit of product sold by WAPA's CRSP Management Center to its SLCA/IP FES customers. These calculations and analyses were performed by WAPA CRSP Management Center staff.

WAPA markets SLCA/IP electrical power under firm, long-term contracts. Under these contracts, WAPA is required to deliver this electrical power to federal points of delivery regardless of hydrological conditions, status of generating units, or changes in the operational criteria of the SLCA/IP hydropower plants. The current FES marketing contracts expire on September 30, 2024. For the period following 2024, WAPA is currently engaged in developing a marketing plan. This requires a formal public process in compliance will applicable federal law.

Several assumptions had to be made in order to estimate LTEMP impacts. First, it was assumed that WAPA will continue with its current SLCA/IP obligations until the current marketing period ends and the existing contracts expire.[29] This requires that WAPA deliver the same amount of electrical power and energy to SLCA/IP customers until the end of fiscal year (FY) 2024, regardless of the alternative analyzed. Recognizing uncertainties about WAPA's future marketing of SLCA/IP resources between 2025 and 2034, net firming expenses for the post-2024 time period were analyzed under two sets of assumptions. These are as follows:

1. A continuation of existing SLCA/IP FES contract commitments between FY 2025 and FY 2034 (referred to as No Change or "NC" in Section 4.13.2.4); and

2. A reduction in SLCA/IP FES contract commitments so that net firming expenses are equal to $0 between FY 2025 and FY 2034. This means, for the numbers included in the SLCA/IP power repayment study, zero dollars of firming expense and zero additional dollars of revenue from market sale or from available hydropower sales (referred to as Resource Available or "RA" in Section 4.13.2.4).

These two assumptions constitute "bookends" regarding the outcomes possible in the development of the post-2024 marketing plan.[30] These bookends are for modeling purposes only. They represent a very broad range of possible FES obligations of electrical power in the post-2024 marketing period. The bookends will almost certainly encompass the actual rate impact, once the post-2024 marketing plan is completed. It should be noted that the

[29] There is a provision in the existing SLCA/IP contracts to modify the FES obligations upon a 5-year notice to SLCA/IP customers. However, considering the probable timing of new operating criteria for the Glen Canyon Dam following the completion of the LTEMP EIS and the issuance of a ROD, a 5-year notice would not be significantly different than the end of the current marketing period.

[30] Western could choose a post-2024 SLCA/IP FES obligation of electric power that exceeds its current obligation. However, prior to completion of the required public process it would be difficult to determine what the higher obligation would be that could be considered a reasonable bookend.

establishment of these bookends is not an attempt to predict or to anticipate WAPA's choice prior to the conclusion of the required public process.

4.13.1.3 Retail Rate Impacts

WAPA markets power to utilities serving approximately 5.8 million retail customers in Arizona, Colorado, Nebraska, Nevada, New Mexico, Utah, and Wyoming (Reclamation 2012d). Customers include small and medium-sized towns that operate publicly owned electrical systems, irrigation cooperatives, and water conservation districts; rural electrical associations or generation and transmission cooperatives who are wholesalers to these associations; federal facilities such as Air Force bases, universities, and other state agencies; and American Indian Tribes.

The effect of reductions in available generating capacity at Glen Canyon Dam under each of the alternatives on retail electricity rates and bills for customers of municipal, cooperative, and other entities receiving power from WAPA was estimated in four steps. First, a detailed database of retail revenues and sales was developed for 226 utility systems that directly or indirectly receive an allocation of SLCA/IP preference power including American Indian Tribes. This database was combined with aggregate production costs (variable O&M costs, purchased power, and fuel expenses), capital investments for capacity additions, and fixed O&M costs derived from the AURORA analysis. Second, capacity additions were converted to revenue requirements using a carrying charge analysis (see Appendix K, Section K.3.1) along with the capital cost of different investments. Third, the cost of changing Glen Canyon Dam operations under each alternative was distributed to each retail utility system by simulating the WAPA SLCA/IP capacity and energy allocation process. Fourth, overall rate impacts to individual utility systems (including Tribal Systems) were allocated to residential and non-residential consumers to compute retail rate and bill impacts. The process of using a carrying charge analysis along with aggregate production costs does not require SLCA/IP wholesale rates. This methodology, which uses production costs and carrying charges, results in somewhat higher rate impacts than one that uses SLCA/IP wholesale rates.

The objective of the retail rate impact analysis is to measure the change in electric bills that consumers who use electricity in their homes or businesses will ultimately incur because of changes in the way Glen Canyon Dam operates. Retail rate impacts can be measured directly from the change in capacity and energy costs that are computed in the power systems analysis along with the utility carrying charges. This direct method of computing retail rate impacts involves allocating changes in energy and capacity cost to distribution systems and then dividing the cost changes by retail revenues. All of the economic impacts come from the capacity cost (including fixed O&M) and energy cost changes (including ancillary service values). Using this method, additional evaluation of WAPA wholesale rates was unnecessary to derive retail rate impacts, and the wholesale rate analysis presented in Section K.2 of Appendix K was not used as the basis of the retail rate analysis presented here. The power systems simulations combined with the carrying charge rate analysis applied to new capacity resulting from Glen Canyon Dam operation changes measures impacts on wholesale power cost that must ultimately be attributed directly to retail ratepayers. Appendix K demonstrates that the methodology that computes retail

rates using a multi-step process with economic capacity and energy costs results in an appropriate estimate of retail rate impacts.

While the process of computing retail rate impacts from the capacity and energy cost changes implies changes in capacity allocation, under current contract provisions with customer utilities, WAPA may maintain the same capacity allocation to each customer entity. Given this contractual obligation, WAPA rather than the individual utilities may have to replace the lost capacity at Glen Canyon Dam by purchasing the shortfall from other sources. Eventually, these increased costs would be passed on to entities who are allocated preference power and rates would have to be increased because of higher capacity and energy cost. This process of assuming that WAPA would pay for the capacity and energy costs associated with changes in Glen Canyon Dam operations results in the same retail rate impacts as the assumption that the wholesale cost impacts are simply paid by the utilities themselves as long as WAPA would pass on the costs as they are incurred. If WAPA would defer the cost increases, the changes in energy and capacity costs would still be paid, but with a temporary deferral that would presumably include financing costs. Attempting to incorporate potential deferral strategies in WAPA's wholesale rate policy is neither appropriate nor practical in assessing retail rate impacts. For example, if capacity costs and production costs increase, but WAPA incurs the cost for a period of years but then later increases the rate including cost of capital, it would not be appropriate to include the deferral in the rate impacts. Finally, in order to provide a relative benchmark indication of the effects of Glen Canyon Dam capacity cost changes on costs incurred to purchase power, the average aggregate capacity and energy costs are measured relative to amount of money that WAPA currently collects from capacity and energy allocations (see Appendix K for details).

4.13.1.4 Hoover Dam Impacts

Hoover Dam is located about 370 mi downstream of Glen Canyon Dam. Its powerhouse has 17 turbines that have a combined hydropower nameplate capacity of approximately 2,074 MW. Hoover Dam operating criteria are unaffected by LTEMP EIS alternatives. Its energy production and economic value, however, will be impacted primarily by temporary changes in Lake Mead elevation that are projected to occur within a water year. In addition, alternatives will occasionally result in reallocation of Lake Mead monthly water release volumes within a year, when changes in projected December end-of-month Lake Mead elevations result in a different operating condition. Alternatives B, D, and E have the same Glen Canyon Dam October through December total release volumes as Alternative A, and therefore do not affect the Lake Mead operating condition and thus release volumes from Hoover Dam.

Changes in Lake Powell monthly water releases among LTEMP alternatives will affect pool elevations in Lake Mead, and these in turn will affect the Hoover Dam Powerplant derated capacity and energy generation. A modeling tool of Hoover Powerplant monthly operations was developed for the LTEMP EIS to estimate these impacts on Hoover Powerplant economics. The tool, referred to here as the Hoover Powerplant Model, computes and compares two economic metrics; namely, energy and firm capacity that could be used as a capacity credit in utility integrated resource plans. Both are measured in terms of NPV for each alternative.

To perform the analysis, projections of monthly water releases from Hoover Dam were obtained from CRSS, and Lake Mead end-of-month elevation projections were obtained from the SBM for all 21 hydrology traces for each alternative over the study period. Using information from Reclamation, algorithms were developed that relate reservoir elevation and reservoir storage to water-to-power conversion efficiencies and derated powerplant capacity. The Hoover Powerplant Model used this information to determine the difference in monthly generation between Alternative A and each of the other alternatives for all 21 hydrology traces. The Western Interconnection electricity market price forecasts, which are identical to the prices used in the Aurora model simulation of the SLCA/IP system, were used in the Hoover Powerplant Model to compute the value of the generation from the Hoover Powerplant. The value of monthly generation was computed by multiplying the monthly energy generation by the market price of electricity, accounting for the difference in price between energy generated in peak hours versus off-peak hours. Based on information from Reclamation, it was assumed that 95% of generation at the Hoover Powerplant takes place in peak hours and only 5% in off-peak hours. There were no projected changes in firm capacity.

The Hoover Powerplant Model uses methods that are simpler than the ones used to measure the economic impacts of the SLCA/IP system, and it uses a monthly rather than hourly time resolution. In addition, many of the assumptions that drive model results are uncertain. More details on the modeling methodology and the results are presented in Appendix K, Section K.5.

4.13.2 Summary of Hydropower Impacts

This section and Table 4.13-1 summarize the potential impacts of alternative operating criteria on Glen Canyon Dam's hydropower resources. These impacts are measured in terms of changes in both powerplant capacity and generation and associated economic value. Impacts are analyzed from an overall systems perspective in which least-cost electricity production costs are computed and regional power system capacity expansion pathways are determined. This section also discusses how changes in system resources and operations, caused by operational changes at Glen Canyon Dam, impact the wholesale rate that WAPA charges it FES customers and the retail electricity rate that FES customers charge to their end-use customers. Table 4.13-1 does not include the rate impacts on American Indian Tribes; they are discussed separately in Appendix K, Section K.3.

4.13.2.1 Monthly Water Release Impacts

Differences among LTEMP alternatives do not occur from annual water release volumes, but rather from the routing and timing of these water releases during monthly, daily, and hourly timeframes. The total volume of water released from Glen Canyon Dam over the 20-year LTEMP period is essentially identical under all LTEMP alternatives. Also, differences among alternatives in annual water release volumes are less than 1%. However, alternatives significantly impact the timing of water releases within a year. For example, as compared to Alternative A, Alternative F releases much higher water volumes during March, April, May, and June and much

TABLE 4.13-1 Summary of Impacts of LTEMP Alternatives on Hydropower Resources[a]

Impact Indicator	Alternative A (No Action Alternative)	Alternative B	Alternative C[b]	Alternative D (Preferred Alternative)[c]	Alternative E[d]	Alternative F	Alternative G
Overall summary of impacts resulting from changes in operations at Glen Canyon Dam	No change from current condition; second highest firm capacity and sixth-lowest total cost to meet electric demand over the 20-year LTEMP period; no change in average electric retail rate or average monthly residential electricity bill.	Compared to Alternative A, 0.3% decrease in average daily generation (MWh) and 3.8% increase in firm capacity (MW); 0.02% decrease in the cost of generation, 0.45% decrease in the cost of capacity, and 0.04% decrease in total cost to meet electric demand over the 20-year LTEMP period; small decreases in the average electric retail rate (–0.27%) and the average monthly residential electricity bill (–$0.27) in the year of maximum rate impact.	Compared to Alternative A, 0.8% decrease in average daily generation (MWh) and 17.5% decrease in firm capacity (MW); 0.08% increase in the cost of generation, 6.09% increase in the cost of capacity, and 0.41% increase in total cost to meet electric demand over the 20-year LTEMP period; small increase in average retail electric rate (0.43%) and average monthly residential electricity bill ($0.40) in the year of maximum rate impact.	Compared to Alternative A, 1.1% decrease in average daily generation (MWh) and 6.7% decrease in firm capacity (MW); 0.12% increase in the cost of generation, 3.12% increase in the cost of capacity, and 0.29% increase in total cost to meet electric demand over the 20-year LTEMP period; small increase in average retail electric rate (0.39%) and average monthly residential electricity bill ($0.38) in the year of maximum rate impact.	Compared to Alternative A, 0.7% decrease in average daily generation (MWh) and 12.2% decrease in firm capacity (MW); 0.06% increase in the cost of generation, 3.52% increase in the cost of capacity, and 0.25% increase in total cost to meet electric demand over the 20-year LTEMP period; small increase in average retail electric rate (0.50%) and average monthly residential electricity bill ($0.47) in the year of maximum rate impact.	Compared to Alternative A, 1.9% decrease in average daily generation (MWh) and 42.6% decrease in firm capacity (MW) (lowest of alternatives) ; 0.42% increase in the cost of generation, 4.03% increase in the cost of capacity, and 1.17% increase (highest of alternatives) in total cost to meet electric demand over the 20-year LTEMP period; highest change in average retail electric rate (1.21%) and average monthly residential electricity bill ($1.02) in the year of maximum rate impact.	Compared to Alternative A, 1.7% decrease in average daily generation (MWh) and 24.2% decrease in firm capacity (MW); 0.34% increase in the cost of generation, 7.39% increase in the cost of capacity, and 0.73% increase in total cost to meet electric demand over 20-year LTEMP period; small increase in average retail electric rate (0.64%) and average monthly residential electricity bill ($0.59) in the year of maximum rate impact.

TABLE 4.13-1 (Cont.)

Impact Indicator	Alternative A (No Action Alternative)	Alternative B	Alternative C[b]	Alternative D (Preferred Alternative)[c]	Alternative E[d]	Alternative F	Alternative G
Impacts on Electric Retail Rate Payers Resulting from Changes in Operations at Glen Canyon Dam							
Percent change in retail rates (maximum impact year)[m]	No change from current conditions	–0.27%	0.43%	0.39%	0.50%	1.21%	0.64%
Change in monthly residential bill (maximum impact year)[n]	No change from current conditions	–$0.27	$0.40	$0.38	$0.47	$1.02	$0.59
Impacts on Hoover Dam Power Systems Economics Resulting from Changes in Operations at Glen Canyon Dam							
Total NPV of generation ($million)[o]	2,362.3	2,362.3	2,408.6	2,384.2	2,390.2	2,451.1	2,392.0
Change in NPV of generation ($million)	No change from current conditions	No change from current conditions	46.4 (2.0% increase)	21.9 (1.0% increase)	27.9 (1.2% increase)	88.8 (4.1% increase)	29.7 (1.4% increase)

[a] Assumptions employed in models used to estimate impacts in this table were based on best available information. Sensitivity analyses were performed to determine the possible effect of these assumptions on the estimated cost of LTEMP alternatives. These analyses indicated that costs of alternatives could vary based on particular assumptions made. The analyses also illustrated that results are more sensitive to some model assumptions than others. An overview of results is presented in Section 4.13.2.3; details are presented in Appendix K (Sections K.1.10.4 through K.1.10.9).

[b] The results presented here do not include the cost of experimental low summer flows. Adding these costs would increase the relative cost of Alternative C compared to Alternative A, estimated at $148 million, by about $24.5 million, resulting in a total cost difference of about $173 million over a 20-year period. This addition increases the percent difference relative to Alternative A from a 0.41% increase in cost to a 0.48% increase in cost. The relative ranking of Alternative C compared to other alternatives would not change as a result of adding the cost of experimental low summer flows.

Footnotes continued on next page.

TABLE 4.13-1 (Cont.)

[c] The results presented here are based on the modeling conducted prior to making several adjustments to Alternative D, and they do not include the cost of experimental low summer flows. As presented in Section 4.13.3.4, experimental low summer flows would increase costs by $15 million, while the adjustments would reduce costs by $58.9 million. Combined, the cumulative effect of these adjustments may reduce the relative cost of Alternative D compared to Alternative A, estimated at $104 million, by approximately $44 million over a 20-year period; the resulting difference from Alternative A would be $60 million. These adjustments reduce the percent difference relative to Alternative A from a 0.29% increase in cost to a 0.17% increase in cost. These adjustments would also result in slight reductions to the retail rate costs. The relative ranking of Alternative D compared to other alternatives would change from fourth to third lowest cost.

[d] The results presented here do not include the cost of experimental low summer flows. Adding these costs would increase the relative cost of Alternative E compared to Alternative A, estimated at $91 million, by about $9.95 million, resulting in a total cost difference of about $101 million over a 20-year period. This addition increases the percent difference relative to Alternative A from a 0.25% increase in cost to a 0.28% increase in cost. The relative ranking of Alternative E compared to other alternatives would change from third to fourth lowest cost.

[e] Average daily Glen Canyon Dam generation under representative hydrological conditions.

[f] Firm capacity is calculated based on all 21 hydrology traces with median sediment input (sediment trace 2), which has the highest likelihood of occurrence. It is calculated at the 90% exceedance level, which means that at least that amount of SLCA/IP federal hydropower plant capacity is available in the peak month of August 90% of the time.

[g] Replacement capacity is the difference between the firm capacity in Alternative A and the firm capacity of another alternative; it represents the capacity that would need to be replaced somewhere in the power system if that alternative was implemented.

[h] Additional generation capacity required under the LTEMP alternatives for WAPA's customers over the 20-year LTEMP period to not only meet future load demand but also account for loss/gain in capacity at Glen Canyon Dam due to the alternative operating constraints.

[i] Net present value ($million 2015) of costs to meet total system electric demand over 20-year study period for all SLCA/IP customers under representative trace. Discount rate is 3.375%.

[j] Net present value of electricity generated at Glen Canyon Dam over the 20-year LTEMP period ($million 2015).

[k] NC = no change from current LTF commitment levels.

[l] RA = "resource available" (i.e., commitment level would equal available SLCA/IP federal hydropower resource).

[m] The unweighted average percent changes in retail rates relative to Alternative A across all systems with available data for the year with the highest percentage impact.

[n] The average change in residential electric bills (2015 dollars) relative to average residential bills in Alternative A for the year with the maximum rate impact (residential bills are not weighted by utility size).

[o] Net present value of electricity generated at Hoover Dam over the 20-year LTEMP period ($million 2015).

lower water volumes during July and August. Alternatives also impact the daily profile of water releases. Changes in operating criteria such as maximum and minimum release restrictions and mandates that limit water release changes over time result in very different release patterns during most days. For example, Alternative F requires water releases from Glen Canyon Dam to be at a constant rate an entire day. In contrast, Alternative A allows powerplant operators to change water release levels during a day such that power production more closely matches FES customer energy requests and/or in response to the market price of electricity.

Lastly, alternatives affect the routing of water releases from the dam. Water is typically released through one or more of the powerplant's eight turbines to produce electricity. However, dependent on the pressure exerted by the water elevation in Lake Powell, turbines have a limited amount of water that can flow through them during an hour. In addition, the generating capacity of a unit and the operational status (e.g,, online or out-of-service) limits the flow of water through it. Therefore, whenever a water release is required to exceed the combined flow capabilities of the generating units that are in operation (i.e., emergency, spill avoidance, and approved experiments), some of the water is released through bypass tubes and spillways. Releases such as this that produce no energy are referred to as non-power releases. Each alternative has a unique set of HFE specifications that affect the frequency and duration of Glen Canyon Dam non-power water releases.

Non-power releases can also occur under very low (i.e., dry) hydropower conditions when the Lake Powell elevation is below a minimum turbine water intake level (minimum power pool). All of the water is released through bypass tubes and, therefore, no electricity is produced until the water level rises above the minimum power pool level. All non-power water releases are considered an irretrievable loss of hydropower generation.

4.13.2.2 Hydropower Power Generation and Capacity Impacts

Table 4.13-1 summarizes the impacts of changes in Glen Canyon Dam operations under each alternative on hydropower generation and capacity. Under Alternative A, the average daily generation at Glen Canyon Dam over the 20-year study period is projected to be 11,599 MWh under representative conditions; that is, the monthly water releases and generation levels expected under one of the 21 analyzed hydrology traces, trace 14, which was considered representative of the full range of annual inflow volumes over the 20-year LTEMP period. On average, this represents 72.8% of the generation produced by all SLCA/IP hydropower resources over the 20-year LTEMP study period. With the remaining alternatives, generation would vary between 11,567 MWh under Alternative B (a reduction of 0.3% compared to Alternative A) to 11,379 MWh under Alternative F (a reduction of 1.9%) under representative conditions (Table 4.13-1). These relatively small differences (i.e., less than 2%) in average daily generation among the alternatives are not due to the amount of water released from the dam, but largely attributed to differences in the amount of water routed through bypass tubes to conduct HFEs, which, as described in the previous section, does not generate electricity and requires replacement resources. In addition, differences in monthly reservoir elevations affect both water-to-power conversion efficiency and bypass releases when reservoir elevation is below minimum power level.

Although there is little difference in annual average daily generation at Glen Canyon Dam among the alternatives, there are monthly differences. Under representative hydrological conditions, average daily generation under Alternative A ranges from 8,640 MWh in March to 15,410 MWh in August, before falling to 9,375 MWh in November, and then increasing to 11,511 MWh in January (Figure 4.13-2). Although generation under Alternative B would be similar to Alternative A between June and August, slightly less electricity would be generated during January through May, and during October through December. In contrast with Alternatives A and B, all other alternatives (except for Alternative F, which is discussed later) have less average daily generation in the summer months of June, July, and August when electricity demand is at its peak. Alternatives C, D, E, and G have a higher average daily generation in the spring months of March, April, and May than Alternatives A and B, with Alternative C generally having the highest values. Alternatives D, E, and G have higher average daily generation in the fall months of October and November compared to Alternatives A and B. However, in September, October, and November, Alternative C has a considerably lower average daily generation than almost any other alternative. In the winter months of December, January, and February, Alternatives A and B typically have a higher average daily generation than most other alternatives.

Generation under Alternative F would result in the most deviation from Alternative A, with a shifting of annual peak generation from the mid-summer months to late spring/early summer, producing a maximum of 19,995 MWh in June, significantly higher than the peak output under Alternative A (Figure 4.13-2). By contrast, generation during the summer would fall considerably, to a low of 9,708 MWh in July, exceeding 9,000 MWh in August, September, and November and falling to just over 6,900 MWh in December and January.

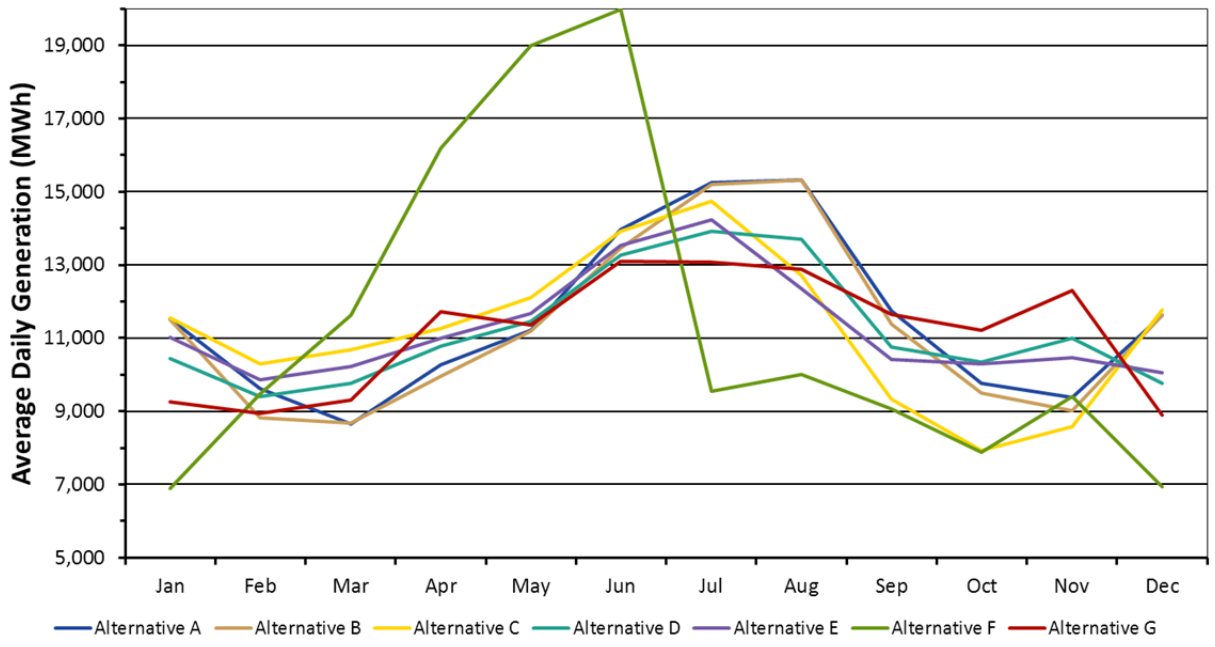

FIGURE 4.13-2 Average Daily Glen Canyon Dam Generation under Representative Hydrological Conditions under LTEMP Alternatives

Although the Glen Canyon powerplant is rated at 1,320 MW, it has been operationally restricted since 1996 and is rarely allowed to produce power at this capacity level (Veselka et al. 2010). This is due to several factors such as the number of units that are operable, the reservoir elevation, grid reliability considerations, and reservoir operating criteria. The latter is most important for the purposes of estimating economics under different LTEMP alternatives. However, it can produce at rated capacity during extremely high hydropower conditions and during high peak release HFEs when the reservoir is relatively high (i.e., about 33,000 cfs and higher).

As shown in Table 4.13-1, under Alternative A, there would be about 737 MW of firm capacity available from the entire SLCA/IP to meet peak system loads. This capacity is based on the assumption that 90% of the time this amount of capacity or more would be available when the system peak loads occur. Under Alternatives C, D, E, F, and G, the firm capacity would decrease to between 687.6 MW under Alternative D to 423.1 MW under Alternative F.

Except for Alternative B, under which the capacity is 28.1 MW higher than Alternative A, all other alternatives would provide approximately 50 MW to 314 MW less capacity—that is, a reduction that ranges from of 6.7% to 42.6% compared to Alternative A. Capacity differences mainly stem from the level of Glen Canyon Dam operational flexibility (daily change, ramp rates, etc.) and monthly water release volumes that are allowed under each alternative in conjunction with both reservoir elevations and monthly water release levels. Operations under Alternative B allow the highest level of flexibility, while Alternatives F and G, which require steady flows each day, restrict capacity. This lost capacity would need to be replaced somewhere in the SLCA/IP system or purchased from an entity outside of the SLCA/IP system footprint.

For LTEMP, it is assumed that the SLCA/IP system will build Glen Canyon Dam replacement capacity. SLCA/IP firm capacity affects the amount and timing of generating units that will be constructed in the future to reliably meet forecasted increases in electricity demand in the service territories of WAPA's FES customer utilities and to replace the retirement of existing powerplant generating capacity. Under Alternative A, an estimated 4,820 MW of new capacity would be built by WAPA's customer utilities. System capacity expansion additions are phased in over time such that a minimum 15% capacity reserve margin is attained in each year of the 20-year LTEMP period. Under alternatives with less SLCA/IP firm capacity, more new generating capacity must be built and system capacity expansion would need to begin sooner. Under Alternative B, 4,820 MW of new capacity would also be added by the end of the LTEMP period; however, because Alternative B has slightly more firm capacity available, one new generating unit would need to be constructed a year later than under Alternative A. All other alternatives have less firm capacity than Alternative A. Under Alternatives C, D, E, and G, 5,050 MW of new capacity would be required (an increase of 230 MW, or 4.8%, compared to Alternative A), and under Alternative F, 5,280 MW of new capacity would be required (an increase of 460 MW, or 9.5%) (Table 4.13-1). Also note that because the capacity is built in sizes/increments that exceed the amount lost, system capacity expansion differences among the alternatives do not typically match the amount of lost capacity. Appendix K, Section K.1.10.2, provides more details and illustrations of alternative impacts on capacity expansion timing and total new construction.

It is assumed that WAPA's eight largest wholesale customers make decisions and function as a single aggregate system, and that they would build enough capacity to reliably meet their total aggregate demands. The modeling of this power system assumes a very high level of cooperation and coordination among WAPA and its LTF power customers. Capacity expansion planning, unit commitment schedules, and least-cost hourly dispatch for the entire system were based on a "single operator/decision maker" model. This is a higher level of cooperation and coordination than what actually occurs and may tend to underestimate capacity replacement costs (or, in the case of Alternative B, benefits). On the other hand, because of siting, permitting, licensing, consruction time, and other factors, it may not be possible to bring units online as soon as indicated by the models. Later capacity replacement dates would lower the NPV of capacity replacements.

4.13.2.3 Economic Impacts

This section presents the anticipated economic impacts of LTEMP alternatives on hydropower resources. Included is a discussion of energy and capacity costs of operational characterisitcs of the LTEMP alternatives, the cost of experiments under Alternative D, and the results of sensitivity analyses performed to determine the effects of modeling assumptions on model results. The impacts of Alternative D on hydropower resources that are presented in this section were based on modeling performed prior to several changes in Alternative D, including an increase in the August volume (from 750 to 800 kaf in an 8.23-maf year, and a corresponding 25-kaf decrease in both May and June [changed from 657 to 632 kaf and 688 to 663 kaf, respectively] with proportional changes in drier and wetter years), reduction in the number of spring HFEs based on the prohibition of spring HFEs in the same water year as extended HFEs, and elimination of experimental load-following curtailment after fall HFEs. For hydropower resources, these adjustments to Alternative D would reduce the percent difference relative to Alternative A from 0.29% to 0.17%..

Energy and Capacity Costs

The power systems economic analysis primarily measures the impacts of LTEMP alternatives on the cost of generating energy to meet system electricity demands and to build sufficient capacity to meet these demands reliably. In doing so, the analysis accounts for system interactions and reactions. For example, when Glen Canyon Dam increases its output, power models estimate the generation response (i.e., decrease) of other online powerplants in the system. The economic impacts are not limited to any one individual system component, but rather to the collective impacts on all components in the system over the entire study period. Impacts measured include production costs that are incurred hourly on a continuous, ongoing basis and capacity expansion costs that occur as needed, and are therefore much less frequent. Focus is also placed on economic differences among alternatives rather than on their absolute values. Comparative analyses such as this one usually reduce modeling errors such as assumptions about high levels of system cooperation because errors occur in all alternatives and tend to cancel (or diminish) in the final calculations.

Capacity expansion cost components include capital investment costs, interest, and other expenses that are accrued during the time period that a generating unit is constructed ,in addition to fixed O&M costs that are incurred after the powerplant has been constructed. Since newly constructed capacity will operate long past the end of the 20-year LTEMP period, these costs along with interest during construction (IDC) are annualized and incurred from the time the unit comes on-line until the end of the study period. Similarly, O&M costs for new units are only incurred during the study years that the units operate. Because the primary focus of the analysis is on cost differences among alternatives, fixed O&M costs for existing powerplants are not included. It is assumed that these costs are identical among all alternatives because the AURORA model retirement schedule is identical across all alternatives.

The cost of serving system loads (system production cost) under each alternative over the 20-year LTEMP period is shown in Table 4.13-1. Costs are expressed in NPV to allow differences in the timing of generation to be normalized, using a 3.375% discount rate. Except for Alternative B, total energy production cost would increase under all alternatives compared to Alternative A, with increases varying from $21 million (a 0.06% increase) under Alternative E to $145 million (a 0.4% increase) under Alternative F. System-level production cost differences are a function of timing and routing of Glen Canyon Dam water releases and reservoir pool elevation effects.

In general, turbine water releases and associated generation occur when they have the highest economic value to decrease overall systemwide production costs. System energy value in this context is the amount of money that is expended to serve all of the system electricity demand. When the demand is low, it is served by generating units that have low production costs; however, as electricity demand increases, units that are more expensive to operate are brought on-line to serve this higher (or incremental) load. Therefore, there is a direct relationship between the cost of serving more demand and the incremental cost to serve it. In this economic analysis, the incremental cost to serve one more MWh of demand, electricity price, and economic value are used synonymously.

When Glen Canyon Dam produces energy during periods of the year when loads and prices are high, the power its produces offsets generation from more expensive units that would have otherwise been utilized. In effect, this lowers overall system production costs. Likewise, system production costs are lower when Glen Canyon generates energy during times of the day when it has the highest economic value. Alternatives with the most operational flexibility also have the highest economic value. This flexibility allows Glen Canyon Dam operators to generate more energy (that is, release more of the limited water resource) during times of the day when prices are highest and reduce generation when prices are low. Appendix K, Section K.1.10, provides more details on market prices and the timing of Glen Canyon Dam power production under each alternative.

Last, it should be noted that because water releases are limited, releases that bypass the generators (such as in the case of most HFEs) not only have zero power system economic value during the time of release, but also reduce future turbine water releases, and hence both energy production and value. In summary, the economic value of Glen Canyon Dam power generation is highest when water is released through powerplant turbines to produce energy which offsets

generation that would have otherwise been produced by generating units that are expensive to operate. The economic impacts of HFEs and other experiments, including low summer flows, TMFs, and sustained low flows for invertebrate production, are included in the impact estimates under each alternative and bundled with all other cost components into a single NPV cost.

The cost of building new capacity (or capital costs) to meet the 15% system reserve margin discussed in the previous section is shown in Table 4.13-1. The table also shows fixed O&M costs associated with the new construction. Both costs are expressed in NPV.

Based on AURORA model runs and a review of both WAPA's customers' IRPs and the IRPs of surrounding utility systems, new capacity additions consist of advanced natural gas-fired combined cycle plants (400 MW) and advanced natural gas-fired combustion turbines (230 MW). Capacity expansion pathways are carefully chosen for each alternative and consist of a mix of new technologies that is consistent with those found in the IRPs of WAPA's large customers and also with Energy Information Administration (EIA) forecasts of future generation capacity in the Western Interconnection (see Appendix K, Section K.1.6.2, for more details).

Total cost, including capital, fixed O&M, and production costs, is shown in Table 4.13-1. The cost is expressed in NPV using a 3.375% discount rate. Based on representative hydrological conditions, the total system cost to reliably supply electric demand during the 20-year LTEMP period under Alternative A would be just over $36.2 billion, with a decrease of about $16 million (or 0.04%) in the cost under Alternative B. Although Alternative B has slightly lower monthly generation than Alternative A, its total system cost is lower because it has a higher firm capacity. The higher firm capacity delays the construction of a natural gas combustion turbine plant by a year compared to Alternative A. With slightly higher spring and slightly lower summer average daily flows under Alternatives C, D, E, and G compared to Alternative A, total costs would be slightly higher, ranging from about $36.3 billion under Alternatives D and E (an increase of about 0.3% compared to Alternative A) to over $36.6 billion under Alternative F (an increase of 1.2%), which would have higher spring and early summer flows, and lower late summer and fall flows, than Alternative A.

The local value of only Glen Canyon Dam energy production under each alternative is presented in Table 4.13-1. It is based on hourly Glen Canyon Dam generation levels and the local value of energy from the dam. The ranking and cost differences among these alternatives for this local value do not match overall system results because they only focus on Glen Canyon Dam. There is no consideration of system-level interactions and reactions. Note that capital and fixed O&M costs are also not included. All alternatives have reductions in the local value of electricity generated by Glen Canyon Dam over the 20-year LTEMP period compared to Alternative A. Smaller reductions in value occur under Alternatives B, C, D, and E; losses in value vary from $5 million (a 0.2% reduction) under Alternative B to $49 million (a 1.9% reduction) under Alternative D. Alternatives F and G have larger reductions in value; namely, $122 million (a 4.6% reduction) and $106 million (a 4.0% reduction), respectively.

Cost of Experiments

A technique to "unbundle" the economic costs of several types of experiments was developed. Estimates of the cost of experiments were computed by comparing the estimated effects of long-term strategies of alternatives that differ only in inclusion of a particular experiment. The one element that differs between the two alternatives is the element for which the economic impacts are measured. For example, to measure the economic cost of low summer flows, two long-term strategies[31] for Alternative D are compared: long-term strategies D1 and D4. Both have identical operating criteria and the same experimental elements, except that under long-term strategy D1 low summer flows are included in the second 10 years of the LTEMP period, while under long-term strategy D4 low summer flow experiments would not be conducted. Subtracting NPV results for long-term strategy D4 from long-term strategy D1 yields the NPV cost of conducting the experiments over the 20-year LTEMP period. Using this methodology, the approximate cost of conducting different types of experimental elements can be "unbundled" from the total aggregate costs. The economic evaluations from the Structured Decision Analysis (Appendix C) provided the basis for this analysis because it modeled all 19 alternatives and long-term strategies.

The estimated NPV cost for each low summer flow experiment ranges from $21.01 million under Alternative D to $13.93 million under Alternative E.The NPV cost for each TMF on average ranges from $0.41 million under Alternative E to $0.45 million under Alternative D. The average NPV cost of each fall HFE ranges from $1.62 million under Alternative C to $1.65 million under Alternative E.

Macroinvertebrate production flows would, on average, increase the combined energy and capacity value by about $1.62 million per 4-month experiment. This experiment results in an increase because in the months of May through August, weekend flows are limited to the minimum flow for that month. Because there is no change in monthly releases for this experiment, lower weekend water releases result in larger water releases, more electric generation, and higher capacity on weekdays when demand and value is higher.

Additional discussion of the cost of experiments is presented in Section K.1.10.3 of Appendix K.

Sensitivity Analyses

Sensitivity analyses were performed on assumptions related to several factors including exceedance values, discount rates, capacity expansion pathways, hydrology, and ancillary services assumptions. These sensitivity analyses estimated how much the results would change if different assumptions were made regarding these factors. Of the factors evaluated, the type of technology used to replace lost capacity, exceedance value, and discount rate had the largest impact on the cost of generation and capacity. In most cases, the relative ranking of alternatives

[31] See Section 4.1 and Appendix C for descriptions of the long-term strategies analyzed for the LTEMP EIS and their relationship to the LTEMP EIS alternatives.

was unaffected by the assumptions used, but the absolute cost levels were either higher or lower than those presented for the baseline in the previous section. Details of these analyses and results are presented in Appendix K (Sections K.1.10.4 through K.1.10.9).

Exceedance Level. The sensitivity analysis for exceedance level was based on the relatively detailed AURORA modeling approach. It compares the baseline 90% exceedance level (i.e., the amount of capacity that is available 90% of the time) to 50% and 99% exceedance levels (i.e., the amount of capacity that is available 50% and 99% of the time, respectively). The higher the exceedance level, the lower the firm capacity credit assigned to SLCA/IP federal hydropower resources. In addition, in the 50–99% exceedance range, the higher the exceedance level, the lower the firm capacity difference among alternatives. Therefore, the higher the exceedance level, the smaller the difference in capital and fixed O&M costs among alternatives. Change in capacity expansion also impacts system production costs, but this tends to have only minor impacts. At 50% exceedance, the NPVdifference compared to Alternative A increased by $0 to $71 million (or 0% to 79%), depending upon the alternative. At 99% exceedance, the cost difference compared to Alternative A decreased by $0 to $59 million (or 0% to 60%), depending upon the alternative. The relative ranking of alternatives changed only slightly across the three exceedance levels. Alternatives D and E switched places at both the 50% and 99% exceedance levels. At 90% exceedance, Alternatives D and E were the fourth and third lowest, respectively, but at both the 50% and 99% exceedance levels they were third and fourth lowest, respectively.

Discount Rate. The discount rate is the rate of return used to make the value of costs or benefits that occur at different points in time commensurate with each other. The sensitivity analysis for discount rates was based on the AURORA modeling approach. To determine the sensitivity of results to discount rate, a model run was made using a discount rate of 1.4% and compared to results for the baseline discount rate of 3.375%. When using a lower discount rate, the NPV costs of alternatives relative to Alternative A are larger because costs at the end of the study period have a larger contribution to the NPV. The costs increase by about $4 to $84 million (or 20% to 25%), depending upon the alternative; the greater an alternative's cost difference relative to Alternative A, the greater the cost increase with the lower discount rate. However, the relative ranking of alternatives and relative percent difference from Alternative A did not change for these two discount rates.

Expansion Pathway. The expansion pathway for an alternative describes the size, timing, and type of generating units that would be constructed over a specified planning horizon. Sensitivity analyses of the expansion pathway were performed using two methodologies; one used the AURORA model and the other the GTMax-Lite model. They each explored different aspects of changes in the power system expansion and their effect on costs and rankings of alternatives.

Base Expansion Mix. A sensitivity analysis was performed on the baseline capacity expansion path using the AURORA model. In the baseline expansion, both advanced combustion

turbines and advanced combined cycle units were chosen by AURORA for new future additions under Alternative A. This is referred to as the base pathway. Adjustments to the timing and number of new advanced combustion turbines were then made to the base pathway to accommodate changes in Glen Canyon Dam capacity under the other alternatives.

The sensitivity study tested two extreme pathways for Alternative A. One base pathway built exclusively advanced combustion turbines and the second one built exclusively advanced combined cycle plants. The base construction pathway (i.e., the type and timing of additions) for Alternative A was used as the starting point for each of the other alternatives. Advanced combustion turbines were added to (or in the case of Alternative B, subtracted from)[32] a base expansion pathway to accommodate capacity changes at Glen Canyon Dam. Costs of the alternatives for each pathway varied slightly, both higher and lower, from the baseline expansion; there was no consistent trend toward higher or lower values in either of the two extreme base pathways as compared to the mixed pathway used for the baseline. Relative to the baseline pathway, the advanced combustion turbines yielded NPV changes that ranged from a decrease of $36 million (less expensive to implement than the alternative) for Alternative F to an increase of $15 million for Alternative C (more expensive). The advanced combined cycle sensitivity analysis produced NPVs that were between $27 million lower (Alternative G) and $51 million higher (Alternative D) than the baseline. These fluctuations in cost are primarily due to the lumpy nature of capacity additions. Alternative rankings for both pathways remain basically the same as the baseline.

Capacity Replacement Technology. A sensitivity analysis was performed on the baseline capacity replacement technology using the GTMax-Lite model. All lost capacity replacements under the baseline and sensitivity analyses described above relied exclusively on the advanced combustion turbine technology. However, models make many simplifying assumptions, and may not consider other factors beyond cost that a utility may use when determining thermal power plant additions. Consequently, a sensitivity analysis was performed to address uncertainties regarding the replacement of future capacity replacement.

The analysis considered a separate case in which capacity expansion changes relative to Alternative A would be made using a mix of 60% advanced natural gas combined-cycle plants and 40% advanced combustion turbines in terms of megawatts of capacity. This mix is approximately equal to the current average thermal capacity expansion mix contained in the IRPs of WAPA's LTF customers and other utilities in the surrounding area. It was derived from a review of IRPs that were available online in May 2016. Attachment K.11 of Appendix K provides a summary of capacity additions through the end of calendar year 2034. The GTMax-Lite model was used for this sensitivity analysis because it can exactly match the desired mix of capacity replacements. In addition, GTMax-Lite runs more rapidly with far fewer resources than AURORA, yet it produces similar results in terms of both differences in total NPV among alternatives and alternative ranking.

[32] This involved building combustion turbines sooner and/or building more combustion turbine capacity for an alternative as compared to Alternative A. Under Alternative B, the construction of a combustion turbine was delayed.

Using a mix of 60% natural gas combined-cycle plants and 40% combustion turbines for capacity replacement increases costs relative to the baseline for all alternatives except for Alternative B. Alternative B has a lower NPV of approximately $11.0 million, while the costs for all other alternatives increase from $17.1 million under Alternative D (the Preferred Alternative) to $93.4 million under Alternative F. The new mix of capacity replacements does not change alternative rankings.

Hydrological Condition. In this case, hydrologic condition refers to the daily, monthly, and yearly pattern of dam releases under different simulated 20-year periods that are based on the historical record. A sensitivity analysis was performed on hydrology assumptions using the AURORA model. As discussed earlier, Trace 14 was selected as the representative trace and used for the AURORA dispatch run for the baseline analysis. Because impacts of alternatives are dependent on hydrology condition, a study was performed on the sensitivity of results to hydrological condition. An additional hydrological condition was run; this condition used the average hourly generation from all 21 traces as projected by GTMax-Lite runs. Capital and fixed O&M costs were identical for both hydrology conditions and there were only slight differences in the production costs. Differences in NPV relative to the baseline ranged from a cost decrease of $15 million under Alternative G to a cost increase of $18 million under Alternative F.

Ancillary Services. Ancillary services are electricity grid services necessary to support the transmission of electric power from seller to purchaser given the obligations of control areas and transmitting utilities within those control areas to maintain reliable operations of the interconnected transmission system (FERC 1995). Services include spinning reserve, non-spinning reserve, replacement reserve, regulation/load following, black start, and voltage support. A sensitivity analysis was performed on ancillary service assumptions for Alternatives A, D, and F using the GTMax-Lite model. Ancillary services included in this analysis consisted of regulation and fast spinning reserves. It was performed on two possible cases: one in which total ancillary services requirements would increase from 103 MW in 2013 to 160 MW by 2030, and another where the current level of 67 MW would remain the same during the entire LTEMP study period. The analysis showed firm capacity and energy at capacity exceedance levels of 50, 90, and 99% would differ by less than 0.8% under low and high ancillary services levels. The difference in total NPV between the two scenarios for Alternatives A and D is $2.8 million (0.08%) and $4.71 million (0.14%), respectively. There is no difference in total NPV between scenarios for Alternative F.

4.13.2.4 Change in FES Wholesale Rates

Through some combination of changed SLCA/IP rates under the No Change (NC) bookend or lower SLCA/IP commitment levels under the Resource Available (RA) bookend, FES utilities that receive SLCA/IP preference power will be impacted as a result of changed operations at Glen Canyon Dam. Under the NC bookend, WAPA would absorb the economic costs (or reap the benefits) of an alternative and adjust FES rates accordingly, passing costs/benefits to its customers. At the other end of the spectrum, SLCA/IP commitment levels

would be adjusted to reflect hydropower resource attributes/capabilities under the RA bookend and FES customers would respond through adjustments to their system dispatch and future resource expansion paths.

For each alternative, WAPA computed the impact of each alternative in terms of single energy and capacity rates that are applied over the entire 2015 through 2034 LTEMP period. This deviates from WAPA's normal 5-year forecast in order to accurately capture each alternative's rate impacts. Table 4.13-1 shows FES customer rates estimated by WAPA RPS studies under both NC and RA bookend marketing structures. The energy and capacity rates reflect WAPA's current method of setting FES rates. SLCA/IP FES customers are billed monthly for the amount of energy used and for their capacity allocation. See Appendix K, Section K.2, for more detailed information on FES wholesale rate results.

This analysis is not a description of policy or an attempt to predict WAPA's post-2024 marketing plan. This set of bookend results is intended to reflect the range of reasonable possibilities.

4.13.2.5 Retail Rate and Bills Impacts

Systemwide production costs, fixed operation and maintenance costs of new capacity and the financing cost associated with building new plants is assumed to be incurred ultimately by entities that receive SLCA/IP preference power.[33] Costs associated with replacing generation capacity no longer provided at Glen Canyon Dam ultimately increases retail rates and bills of residential and non-residential customers. The retail rate impacts experienced by utility systems are not uniform across different utility systems that receive federal preference power. Differential retail rate impacts on particular systems from LTEMP alternatives are largely driven by the amount of power that is allocated from SLCA/IP relative to the quantity of other power that is produced or purchased by a particular system. If utility systems are allocated a large amount of SLCA/IP capacity and energy, but because of their large size, this allocation is a small fraction of the overall amount of power purchased, the retail rate impacts tend to be small. The relative dependence on SLCA/IP capacity and energy varies by a wide margin across entities that receive allocations. SLCA/IP energy allocation as a percent of retail sales range from 0.05% for SRP up to 62% for the City of Meadow (a member of UAMPS). Impacts on the utility systems that are most impacted are presented in Appendix K, Section K.3. This appendix also describes impacts on Tribal systems.

Table 4.13-1 shows impacts on retail electric rates and monthly residential electricity bills for WAPA's preference power customers compared to Alternative A. The change in retail rates and the average change in monthly residential bills are both in the year of maximum rate impact. Both metrics are not weighted by utility size; that is, each utility serving retail customers has the same weight. Note that the estimated retail rate impacts presented here were derived independently by Argonne and did not use the wholesale rates described in Section 4.13.2.4 as input. Wholesale rates were not used because: (1) by using data from the power systems model,

[33] The cost of experimental releases such as HFEs are currently considered to be non-reimbursable expenses.

the direct connection between power system costs and rate impacts could be observed and the process was transparent; and (2) the capital cost of constructing new capacity incurred by utility systems was directly estimated rather than assuming WAPA would carry the burden of replacing the capacity. Retail rate impacts were directly computed from projected wholesale power costs derived from the power systems analysis in Section 4.13.2.3. Rate impact calculations were based on the assumption that the capital, operating, and administrative costs of Glen Canyon Dam operations do not substantively change under different LTEMP alternatives when the energy output from the dam changes. These costs are not expected to be affected by differences in operations under LTEMP alternatives. Because these operating and administrative costs are not affected by the LTEMP alternatives, rate impacts result from changes in the cost associated with replacing capacity and/or energy with changes in dam operations. This approach may have produced somewhat higher estimates of retail rate impacts than if the wholesale rate impacts developed by WAPA in Section 4.13.2.3 had been used. More detailed analyses of retail rates and residential bills are provided in Appendix K, Section K.3.

The average change in the retail rate varies from a decrease of 0.27% in Alternative B to an increase of 1.21% in Alternative F. The average change in the monthly residential electricity bill varies from a decrease of $0.27 in Alternative B to an increase of $1.02 in Alternative F. Both metrics are the average in the year of maximum rate impact and are therefore higher than the average impact over the study period. The electric bill reduction in Alternative B is due to a delay of one year in constructing a new natural gas-fired combustion turbine compared to Alternative A. Similarly the electric bill increase in Alternative F is due to the construction of two new natural gas-fired combustion turbines over the 20-year LTEMP period compared to Alternative A. Retail rate and residential bill impacts are computed from adjusting data in the power systems analysis for municipal and cooperative carrying costs and not from SLCA/IP wholesale prices. If estimated wholesale prices are used instead of adjusting power systems cost, the measured rate impacts would be lower.

4.13.2.6 Impacts of LTEMP Alternatives on Hoover Dam Power Economics

Hoover Dam operating criteria are unaffected by LTEMP EIS alternatives. Its energy production and economic value, however, will be impacted primarily by temporary changes in Lake Mead elevation that are projected to occur within a water year. In addition, alternatives will occasionally result in reallocation of Lake Mead monthly water release volumes within a year, when changes in projected December end-of-month elevations result in a different operating condition, which would also affect Hoover Dam power economics. The Hoover Powerplant Model used projected Lake Mead reservoir elevations over the 20-year LTEMP period to estimate the monthly maximum operational capacity for the Hoover Powerplant for all 21 hydrology traces. Assuming the firm capacity at the Hoover Powerplant is based on the 90% exceedance level in the peak load month of August, the model found that for all alternatives the Lake Mead elevation is below the minimum pool level of 1,050 ft more than 10% of the time. Therefore, because more than 10% of the time in August no generation is possible, no firm capacity (or a firm capacity of zero) was assigned to all of the alternatives (see Section K.5 in Appendix K).

The Hoover Powerplant Model computed the change in economic value of Hoover Powerplant energy production attributed to each LTEMP alternative by multiplying the change in monthly energy production by monthly market prices of energy as projected by the AURORA model. Estimates are made for each month of the 20-year LTEMP period for all 21 hydrology traces. To compare LTEMP alternative economics on a consistent basis, the NPV of Hoover Dam energy was computed using a 3.375% annual discount rate, which is the same rate used for computing the NPV of SLCA/IP costs. The NPV of Hoover Powerplant energy is shown for each alternative in Figure 4.14-4 and presented in Table 4.13-1. The increase in NPV for Hoover Dam energy, relative to Alternative A, ranges from nearly zero for Alternative B to about $89 million for Alternative F.

As discussed in more detail in Section K.5 of Appendix K, the model used to compute Hoover Dam energy value considered fewer factors than the one used to estimate impacts at Glen Canyon Dam. For example, Hoover Dam estimates primarily use a monthly time step, while Glen Canyon Dam estimates are based on a model that optimizes hourly operations. In addition, Hoover Dam model results are highly sensitive to assumptions, particularly the assumed minimum power pool elevation, which affects the economic results for both energy and firm capacity because most of the estimated increases in value are due to lower non-power releases under LTEMP alternatives.

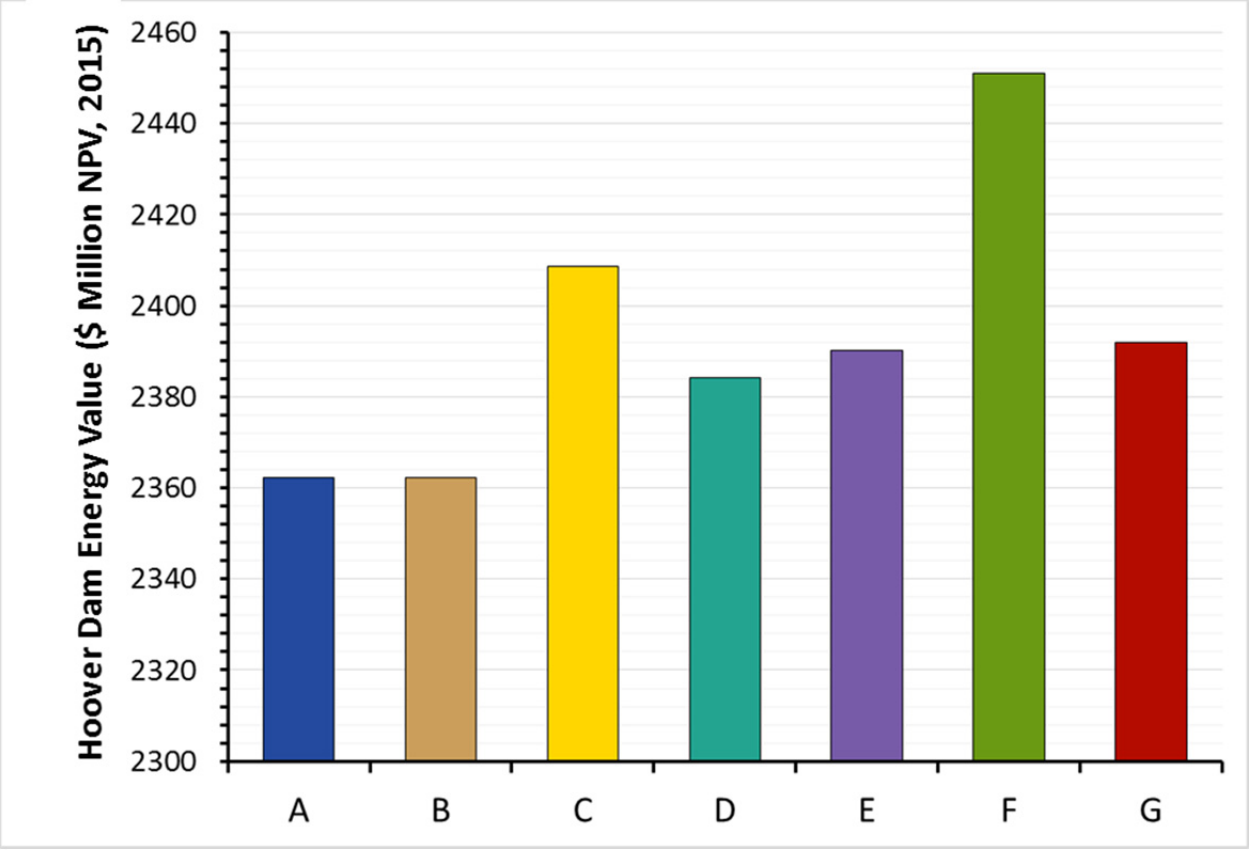

FIGURE 4.13-3 Total NPV of Hoover Powerplant Energy over a 20-Year Period under LTEMP Alternatives

4.13.3 Alternative-Specific Impacts

4.13.3.1 Alternative A (No Action Alternative)

Average annual daily generation at Glen Canyon Dam is currently 11,599 MWh under representative hydrological conditions. Average daily generation ranges from 8,640 MWh in March to 15,410 MWh in August, before falling to 9,375 MWh in November, and then increasing to 11,606 MWh in December (Figure 4.13-2). The local NPV of electricity generated by Glen Canyon Dam over the 20-year LTEMP period under representative conditions would be $2,662 million, and would not change under Alternative A. SLCA/IP marketable capacity is currently 737.2 MW at the 90% exceedance level. Average annual daily generation and hydropower value at Glen Canyon Dam and SLCA/IP firm capacity would not change under Alternative A.

Forecasted increases in electricity demand in the service territories of WAPA's customer utilities and the planned retirement of existing powerplants result in 4,820 MW of new capacity built under Alternative A over the 20-year LTEMP period. Assuming representative hydrological conditions, the total NPV of all costs (including capital, fixed O&M, and systemwide production costs) to meet system electric demand under Alternative A would be just over $36.2 billion.

Because there would be no change in Glen Canyon Dam operations as a result of Alternative A, there would be no impact on the wholesale rates WAPA charges its FES utility customers, retail rates charged by WAPA's customer utilities, or the electric bills paid by their residential customers. The average wholesale energy rate of the two bookend cases was estimated to be $13.46/kWh and the average capacity rate was estimated to be $5.72/kW.

In summary, Alternative A would have the second-highest firm capacity from SLCA/IP and tied with Alternative B for the smallest amount of new capacity needed over the 20-year LTEMP period. It also would have the second-lowest total cost to meet electric demand over that period, and there would be no change in either the average electric retail rate or the average monthly residential electricity bill. There would be no change in the value of generation produced at Hoover Dam.

4.13.3.2 Alternative B

Average annual daily generation at Glen Canyon Dam would be 11,567 MWh under representative hydrological conditions. Average daily generation under representative hydrological conditions would range from 8,665 MWh in March to 15,405 MWh in August, before falling to 9,046 MWh in November, and then increasing to 11,608 MWh in December (Figure 4.13-2). The local NPV of electricity generated by Glen Canyon Dam over the 20-year LTEMP period under representative conditions would be $2,657 million, a decrease of $5 million, or 0.2%, compared to Alternative A as explained below. SLCA/IP firm capacity would be 765.3 MW at the 90% exceedance level, which is a 28 MW, or 3.8%, increase compared to Alternative A. There would therefore be slight decreases in average annual daily

generation and hydropower value at Glen Canyon Dam and a slight increase in SLCA/IP firm capacity under Alternative B compared to Alternative A.

Forecasted increases in electricity demand in the service territories of WAPA's customer utilities and the planned retirement of existing powerplants result in 4,820 MW of new capacity built under Alternative B over the 20-year LTEMP period. Assuming representative hydrological conditions, the total NPV of all costs (including capital, fixed O&M, and systemwide production costs) to meet electric demand under Alternative B would be $36.2 billion.

Under Alternative B, there would be a small reduction in capital and fixed O&M costs associated with new capacity relative to Alternative A. Although the total amount of capacity added over the 20-year LTEMP period is the same as Alternative A, there would be a 1-year delay in constructing a new natural gas-fired combustion turbine. This delay accounts for the slightly lower total cost of Alternative B compared to Alternative A. Also because of the construction delay, the average electricity retail rate could drop by 0.27% and the average monthly residential electricity bill could be reduced by an average of $0.27. Both metrics are the average in the year of maximum rate impact.

The average wholesale energy rate was estimated to be $13.38/kWh, which is a decrease of $0.08/kWh (–0.6%) compared to Alternative A. The average wholesale capacity rate was estimated to be $5.69/kW, which is a decrease of $0.03/kW (–0.5%) compared to Alternative A.

The economic value of energy produced at Hoover Dam under this alternative would be the same as under Alternative A over the 20-year LTEMP period because there would be no difference in monthly releases between the two alternatives.

In summary, Alternative B would have the highest firm capacity from SLCA/IP federal hydropower resources of any alternative and would be tied with Alternative A for the smallest amount of new capacity needed over the 20-year LTEMP period. It also would have the lowest total cost to meet electric demand over that period. Both the wholesale energy and capacity rates charged by WAPA would decrease compared to Alternative A. There would be a decrease in the average electric retail rate and in the average monthly residential electricity bill compared to Alternative A in the year of maximum rate impact. There would be no change in the value of generation produced at Hoover Dam compared to Alternative A.

4.13.3.3 Alternative C

Average annual daily generation at Glen Canyon Dam would be 11,506 MWh under representative hydrological conditions. Average daily generation under would range from 10,292 MWh in February to 14,855 MWh in July, before falling to 7,971 MWh in October, and then increasing to 11,739 MWh in December (Figure 4.13-2). The local NPV of electricity generated by Glen Canyon Dam over the 20-year LTEMP period under representative conditions would be $2,614 million, a decrease of $48 million, or 1.8%, compared to Alternative A. SLCA/IP firm capacity would be 608.1 MW at the 90% exceedance level, which is a 129-MW, or 17.5%, decrease compared to Alternative A. There would therefore be slight decreases in

average annual daily generation and hydropower value at Glen Canyon Dam and SLCA/IP firm capacity under Alternative C compared to Alternative A.

Forecasted increases in electricity demand in the service territories of WAPA's customer utilities and the planned retirement of existing powerplants result in 5,050 MW of new capacity built under Alternative C over the 20-year LTEMP period. An additional gas turbine would be needed during the LTEMP period compared to Alternative A. Assuming representative hydrological conditions, the total NPV of all costs (including capital, fixed O&M, and systemwide production costs) to meet system electric demand under Alternative C would be almost $36.4 billion. Including the estimated cost of experimental low summer flows would result in an average increase in cost of about $24.5 million over a 20-year period, assuming the average number of low summer flows anticipated to be triggered (1.8). This would not change the relative rank of Alternative C compared to other alternatives.

Because of the additional gas turbine the average retail electric rate would increase about 0.43% and the average monthly residential electricity bill would increase by an average of $0.40. Both metrics are the average in the year of maximum rate impact.

The average wholesale energy rate was estimated to be $14.27/kWh, which is an increase of $0.81/kWh (6.0%) compared to Alternative A. The average wholesale capacity rate was estimated to be $6.06/kW, which is an increase of $0.35/kW (6.0%) compared to Alternative A.

The NPV of energy produced at Hoover Dam under this alternative is $46 million more than that under Alternative A over the 20-year LTEMP period. This increase in value is due primarily to the changes in Lake Mead reservoir elevations, which result from changes in monthly water releases upstream at Glen Canyon Dam.

In summary, Alternative C would have the fifth-highest firm capacity from SLCA/IP of the alternatives and would be tied for the third-smallest amount of new capacity needed over the 20-year LTEMP period. It also would have the fifth-lowest total cost to meet electric demand over that period. Both the wholesale energy and capacity rates charged by WAPA would increase compared to Alternative A. It would have the fourth-lowest change in both average retail electric rate and average monthly residential electricity bill in the year of maximum rate impact. It would have the second-largest increase in the value of generation at Hoover Dam compared to Alternative A.

4.13.3.4 Alternative D (Preferred Alternative)

Average annual daily generation at Glen Canyon Dam would be 11,477 MWh under representative hydrological conditions. Average daily generation would range from 9,392 MWh in February to 14,051 MWh in July, before falling to 10,381 MWh in October, and then increasing to 11,052 MWh in November (Figure 4.13-2). The local NPV of electricity generated by Glen Canyon Dam over the 20-year LTEMP period under representative conditions would be $2,613 million, a decrease of $49 million, or 1.8%, compared to Alternative A. SLCA/IP firm capacity would be 687.6 MW at the 90% exceedance level, which is a 49.6 MW, or 6.7%,

decrease compared to Alternative A. There would therefore be slight decreases in average annual daily generation and hydropower value at Glen Canyon Dam and SLCA/IP firm capacity under Alternative D compared to Alternative A.

Forecasted increases in electricity demand in the service territories of WAPA's customer utilities and the planned retirement of existing powerplants result in 5,050 MW of new capacity built under Alternative D over the 20-year LTEMP period. An additional gas turbine is built during the LTEMP period compared to Alternative A. Assuming representative hydrological conditions, the total NPV of costs (including capital, fixed O&M, and systemwide production costs) to meet system electric demand under Alternative D would be just over $36.3 billion.

Because of the additional gas turbine the average retail electric rate would increase about 0.39% and the average monthly residential electricity bill would increase by an average of $0.38. Both metrics are the average in the year of maximum rate impact.

The average wholesale energy rate was estimated to be $13.86/kWh, which is an increase of $0.4/kWh (3.0%) compared to Alternative A. The average wholesale capacity rate was estimated to be $5.89/kW, which is an increase of $0.17/kW (3.0%) compared to Alternative A.

As noted in Section 4.13.2.3, a technique was used to "unbundle" the economic costs of several types of experiments so the cost of each experiment could be estimated. Alternative D has low summer flows, TMFs, macroinvertebrate production flows, and both spring and fall HFEs.

The estimated average NPV cost for each low summer flow experiment in Alternative D is $21.01 million. This value includes an NPV energy cost of $2.76 million and a capacity cost of $18.25 million (see Table K.1-11 in Appendix K). Each TMF in Alternative D has an average energy cost of $0.45 million; there is no capacity cost because TMFs do not occur in August and monthly reallocations of water are not required to support these experiments.

Each 4-month macroinvertebrate production flow experiment has, on average, a net increase in value of $1.62 million, which consists of an energy value decrease of $871,000 and a capacity value increase of $2.49 million. The capacity increase occurs because water releases are minimized on weekends, which makes more water available for power production during weekdays when the peak load would most likely occur. The estimate provided here differs from that presented in the DEIS. After the DEIS was published, discussions with WAPA indicated that they would implement macroinvertebrate production flows in a different way than under normal operations, and the difference would maximize the benefit of lower weekend flows and capacity production during weekdays. Rather than a net cost of macroinvertebrate flows as presented in the DEIS, a net benefit to hydropower generation and capacity would be realized.

Finally, the average cost for each fall HFE $\leq$96 hr for Alternative D (based on an average of HFEs from the long-term strategies analyzed) is expected to range from approximately $1.62 million to $1.65 million (average of $1.64 million). The cost of fall HFEs consists of an energy component only because they do not occur in August and do not affect monthly water releases during August. Assuming a cost of a fall HFE under Alternative D of $1.64 million, the

per-hour cost would be $17,083 and the total cost for the longest possible extended-duration fall HFE (250 hr) would be $4.27 million. Note that this estimate assumes the costs for each hour would be equal, but in reality there would be some hours of ramp up and ramp down at the beginning and end of the HFE when cost would be less. In addition, a 250-hr HFE would have some additional cost associated with reducing reservoir elevation more than a 96-hr HFE. The cost of a spring HFE is expected to be similar in cost to a fall HFE.

The NPV of energy produced at Hoover Dam under this alternative is $22 million more than under Alternative A over the 20-year LTEMP period. This increase in value is due primarily to the changes in Lake Mead reservoir elevations resulting from the monthly water releases upstream at Glen Canyon Dam.

The results presented in Table 4.13-1 are from modeling conducted prior to making the adjustments to Alternative D described in Section 2.2.4, including prohibition of sediment-triggered and proactive spring HFEs in the same water year as an extended-duration fall HFE; elimination of experimental load-following curtailment after fall HFEs; and an adjustment in the monthly release volumes. Based on these modifications, the actual number of HFEs would be about 19.8 (1.3 fewer), which is estimated to reduce the cost of the alternative on hydropower generation by about $2.1 million over a 20-year period, using the estimated cost of HFEs presented in Section K.1.10.3.

Based on modeling that was performed after the DEIS was published,[34] the change in monthly release volumes would result in decreases in the NPV of the cost of production and capacity of about $5.3 million and $27.6 million, respectively, over the 20-year period. Elimination of load-following curtailment would result in a decrease in NPV of the production cost of about $4.0 million over the 20-year period, but would have no effect on capacity.

In addition to these adjustments to Alternative D, changes in the way macroinvertebrate production flows would be implemented and inclusion of the cost of low summer flows in the total cost of Alternative D would result in changes to the estimated total cost of Alternative D. Implementation of experimental macroinvertebrate production flows were modified based on input from WAPA after the DEIS was published. As described above, this modification would result in a net reduction in cost of individual experiments, producing a total reduction in cost of $19.8 million over a 20-year period rather than the original estimated increase of $94 million. Including the costs of low summer flows results in an average increase in cost of about $15.0 million over a 20-year period assuming the average number of low summer flows anticipated to be triggered (0.714).

[34] This modeling was performed using the screening tool described in Section 2.1, whose hydropower module was based on the GTMax-lite model, but incorporated several simplifying assumptions (e.g., constant flow to power conversion factor, constant within-month daily generation pattern). Unlike the modeling used to estimate costs of alternatives on energy and capacity shown in Table 4.13-1, which used GTMax-lite and Aurora models to estimate systemwide effects of LTEMP alternatives, the modeling used to estimate the effects of Alternative D adjustments focused only on Glen Canyon Dam energy and capacity rather than systemwide effects.

The cumulative effect of all of these adjustments and inclusion of low summer flows may reduce the total cost of Alternative D by approximately $44 million over a 20-year period; the original estimated increase in cost of $104 million relative to Alternative A would be reduced to $60 million. These adjustments to Alternative D reduce the percent difference relative to Alternative A from 0.29% to 0.17%.

These estimates may differ from the results that would be obtained had the integrated modeling been used to assess modifications to Alternative D. The streamlined modeling results are, however, considered representative of the expected effects of the adjustments, and they are provided here as an estimate of the approximate magnitude of the effects these adjustments may have on the actual impacts of Alternative D. Because the streamlined modeling results show that the adjustments to Alternative D are small and positive (i.e., reducing the impact), further analysis under the integrated model would not produce information to assist in making a reasoned choice among alternatives, particularly given the time and cost of further integrated modeling. Alternative D was chosen as the preferred alternative based on the original modeling performed on Alternative D prior to making modifications. It was determined that Alternative D provided an appropriate balance between protection of downstream resources while minimizing impacts on hydropower. The streamlined modeling of the effects of adjustments indicates that those adjustments would continue to provide for the protection of downstream resources while reducing even further the effects of the alternative on hydropower.

In summary, Alternative D would have the third-highest firm capacity from SLCA/IP of the alternatives and would be tied for the third-smallest amount of new capacity needed over the 20-year LTEMP period. It also has the fourth-lowest total cost to meet electric demand over that period (third lowest, considering the effects of adjustments discussed above). Both the wholesale energy and capacity rates charged by WAPA would increase compared to Alternative A. It has the third-lowest change in both average retail electric rate and average monthly residential electricity bill in the year of maximum rate impact. It would have the fifth-largest increase in value of generation at Hoover Dam compared to Alternative A.

4.13.3.5 Alternative E

Average annual daily generation at Glen Canyon Dam would be 11,521 MWh under representative hydrological conditions. Average daily generation would range from 9,858 MWh in February to 14,352 MWh in July, before falling to 10,332 MWh in October, and then increasing to 11,008 MWh in January (Figure 4.13-2). The NPV of local electricity generated by Glen Canyon Dam over the 20-year LTEMP period under representative conditions would be $2,620 million, a decrease of $42 million, or 1.6%, compared to Alternative A. SLCA/IP firm capacity would be 647.0 MW at the 90% exceedance level, which is a 90 MW, or 12.2%, decrease compared to Alternative A. There would therefore be slight decreases in average annual daily generation and hydropower value at Glen Canyon Dam and SLCA/IP firm capacity under Alternative E compared to Alternative A.

Forecasted increases in electricity demand in the service territories of WAPA's customer utilities and the planned retirement of existing powerplants result in 5,050 MW of new capacity

built under Alternative E over the 20-year LTEMP period. An additional gas turbine is built during the LTEMP period compared to Alternative A. Assuming representative hydrological conditions, the total NPV of all costs (including capital, fixed O&M, and systemwide production costs) to meet system electric demand under Alternative E would be just over $36.3 billion. Including the estimated cost of experimental low summer flows would result in an average increase in cost of about $9.95 million over a 20-year period, assuming the average number of low summer flows anticipated to be triggered (0.71). This would not change the relative rank of Alternative D compared to other alternatives (but note that other adjustments to Alternative D would change Alternative E's rank as described in the summary paragraph below).

Because of the additional gas turbine the average retail electric rate would increase about 0.50% and the average monthly residential electricity bill would increase by an average of $0.47. Both metrics are the average in the year of maximum rate impact.

The average wholesale energy rate was estimated to be $13.93/kWh, which is an increase of $0.47/kWh (3.5%) compared to Alternative A. The average wholesale capacity rate was estimated to be $5.92/kW, which is an increase of $0.2/kW (3.5%) compared to Alternative A.

The NPV of energy produced at Hoover Dam under this alternative is $28 million more than under Alternative A over the 20-year LTEMP period. This increase in value is due primarily to the changes in Lake Mead reservoir elevations resulting from the monthly water releases upstream at Glen Canyon Dam.

In summary, Alternative E would have the fourth-highest firm capacity from SLCA/IP of the alternatives and would be tied for the third-smallest amount of new capacity needed over the 20-year LTEMP period. It also would have the third-lowest total cost to meet electric demand over that period (fourth lowest, considering the effects of Alternative D adjustments discussed above). Both the wholesale energy and capacity rates charged by WAPA would increase compared to Alternative A. It would have the fifth-lowest change in both average retail electric rate and average monthly residential electricity bill in the year of maximum rate impact. It would have the fourth-largest increase in value of generation at Hoover Dam compared to Alternative A.

4.13.3.6 Alternative F

Average annual daily generation at Glen Canyon Dam would be 11,379 MWh under representative hydrological conditions. Average daily generation under representative hydrological conditions would range from 6,918 MWh in January to 19,995 MWh in June, before falling to 7,891 MWh in in October, and then increasing to 9,495 MWh in November and falling to 6,911 MWh in December (Figure 4.13-2). The local NPV of electricity generated by Glen Canyon Dam over the 20-year study period under representative conditions would be $2,540 million, a decrease of $122 million, or 4.6%, compared to Alternative A. SLCA/IP firm capacity would be 423.1 MW at the 90% exceedance level, which is a 314 MW, or 42.6%, decrease compared to Alternative A. There would therefore be large decreases in average annual

daily generation in summer and winter months that have the highest electricity prices and a large decrease in SLCA/IP firm capacity under Alternative F compared to Alternative A.

Forecasted increases in electricity demand in the service territories of WAPA's customer utilities and the planned retirement of existing powerplants result in 5,280 MW of new capacity built under Alternative F over the 20-year LTEMP period. Two additional gas turbines are built during the LTEMP period compared to Alternative A. Assuming representative hydrological conditions, the total NPV of all costs (including capital, fixed O&M, and systemwide production costs) to meet system electric demand under Alternative F would be just over $36.6 billion.

Because of the two additional gas turbines the average retail electric rate would increase about 1.21% and the average monthly residential electricity bill would increase by an average of $1.02. Both metrics are the average in the year of maximum rate impact.

The average wholesale energy rate was estimated to be $16.27/kWh, which is an increase of $2.81/kWh (21%) compared to Alternative A. The average wholesale capacity rate was estimated to be $6.91/kW, which is an increase of $1.2/kW (21%) compared to Alternative A.

The NPV of energy produced at Hoover Dam under this alternative is $89 million more than under Alternative A over the 20-year LTEMP period. This increase in value is due primarily to the changes in Lake Mead reservoir elevations resulting from the monthly water releases upstream at Glen Canyon Dam.

In summary, the operating constraints of Alternative F would require a steady flow from Glen Canyon Dam every month of the year. This alternative would have the lowest firm capacity (or the seventh highest) from SLCA/IP of all alternatives and the most new capacity needed over the 20-year LTEMP period. It also would have the highest total cost to meet electric demand over that period. Both the wholesale energy and capacity rates charged by WAPA would increase compared to Alternative A; in fact, this alternative would have the largest increase in wholesale rates of all alternatives. It would the highest change in both average retail electric rate and average monthly residential electricity bill in the year of maximum rate impact. It would have the largest increase in value of generation at Hoover Dam compared to Alternative A.

4.13.3.7 Alternative G

Average annual daily generation at Glen Canyon Dam would be 11,403 MWh under representative hydrological conditions. Average daily generation under would range from 8,932 MWh in February to 13,256 MWh in June, before falling to 8,827 MWh in December (Figure 4.13-2). The local NPV of electricity generated by Glen Canyon Dam over the 20-year LTEMP period under representative conditions would be $2,556 million, a decrease of $106 million, or 4.0%, compared to Alternative A. SLCA/IP firm capacity would be 558.2 MW at the 90% exceedance level, which is which is a 179 MW, or 24.3%, decrease compared to Alternative A. There would therefore be slight decreases in average annual daily generation and hydropower value at Glen Canyon Dam and a large decrease in SLCA/IP firm capacity under Alternative G compared to Alternative A.

Forecasted increases in electricity demand in the service territories of WAPA's customer utilities and the planned retirement of existing powerplants result in 5,050 MW of new capacity built under Alternative G over the 20-year LTEMP period. An additional gas turbine is built during the LTEMP period compared to Alternative A. Assuming representative hydrological conditions, the total NPV of all costs (including capital, fixed O&M, and systemwide production costs) to meet system electric demand under Alternative G would be almost $36.5 billion.

While the capital and operating costs borne by WAPA customer utilities to replace generation capacity no longer provided at Glen Canyon Dam would mean changes in retail rates charged by customer utilities under Alternative G and, consequently, changes in the electric bills of residential customers, impact on electric bills paid by residential customers of WAPA's customer utilities would be less than 1%.

Because of the additional gas turbine the average retail electric rate would increase about 0.64% and the average monthly residential electricity bill would increase by an average of $0.59. Both metrics are the average in the year of maximum rate impact.

The average wholesale energy rate was estimated to be $15.65/kWh, which is an increase of $2.19/kWh (16%) compared to Alternative A. The average wholesale capacity rate was estimated to be $6.67/kW, which is an increase of $0.95/kW (17%) compared to Alternative A.

Finally, the NPV of energy produced at Hoover Dam under this alternative is $30 million more than under Alternative A over the 20-year LTEMP period. This increase in value is due primarily to the changes in Lake Mead reservoir elevations that result from the monthly water releases upstream at Glen Canyon Dam.

In summary, the operating constraints of Alternative G would require a steady flow from Glen Canyon Dam every month of the year. This alternative would have the sixth-highest firm capacity from SLCA/IP of all alternatives (the second lowest after Alternative F) and would be tied for the third smallest amount of new capacity needed over the 20-year LTEMP period. It also would have the sixth-lowest total cost to meet electric demand over that period. Both the wholesale energy and capacity rates charged by WAPA would increase compared to Alternative A; in fact, this alternative would have the second-largest increase in wholesale rates of all alternatives. It would have the sixth-lowest change in both average retail electric rate and average monthly residential electricity bill in the year of maximum rate impact. It would have the second-largest increase in value of generation at Hoover Dam compared to Alternative A.

4.14 SOCIOECONOMICS AND ENVIRONMENTAL JUSTICE

This section describes the potential impacts of changes in dam operations on the recreational use values and nonuse values placed on recreational resources by individuals that visit, or may never visit, Lake Powell, Lake Mead, and the Grand Canyon. It also describes the potential regional economic impacts of changes in recreational visitation in a six-county region, and the potential impacts on low-income and minority populations in an 11-county region in the vicinity of the reservoirs and river corridor, and in eastern Arizona and northwestern New Mexico. The section also describes the regional economic impacts of changes in customer utility electricity bills and of expansion in electricity generation capacity that would occur as a result of changes in dam operations, as well as the potential impacts of changes in utility bills on low-income and minority populations, including Tribal populations, in the seven-state region in which power generated at the Glen Canyon powerplant is marketed.

Issue: How do alternatives affect socioeconomics and environmental justice?

Impact Indicators:

- Recreational use values associated with current and potential levels of visitation
- Nonuse (or passive use) economic value associated with the preferences of nonusers
- Employment and income impacts resulting from changes in recreational visitation, customer utility electricity generation capacity expenditures, and residential electricity bill expenditures
- High, adverse, and disproportionate impacts of changes in dam operations on low-income and minority populations

4.14.1 Analysis Methods

This section describes the methods used to estimate changes in recreational use values and non-use (or passive use) economic value that would result from changes in dam operations; the methods used to estimate the economic impacts of change in recreational visitation, customer utility electricity generation capacity expenditures, and residential electricity bill expenditures; and methods used to estimate the impacts of changes in dam operations on low-income and minority populations.

4.14.1.1 Recreational Use and Environmental Non-Use Values

The economic significance of recreational resources on the Colorado River can be measured both in terms of economic welfare, or consumer surplus, which is the amount of value a consumer of a good or service receives over and above that which would be paid for the good or service in the marketplace. However, as recreational activities are often not a market good, the characteristics of the demand for recreational resources cannot be based on the demand for recreational resources in the marketplace. Accordingly, consumer surplus is often referred to as *non-market value*, which includes both use value and non-use value (also called passive use value).

Estimation of recreational use values associated with potential changes in recreational resources under each of the alternatives relies on the benefits transfer method. This method involves the application of existing recreational use value estimates for a particular time period, site, level of resource quality, or combination thereof to a situation for which data are not available. The traditional benefits transfer approach to valuing recreation has been to employ existing use values studies conducted at an existing site, adjusting estimates to account for inflation. Transferring use value estimates from older studies rely on finding a study area with the same recreation activity in a similar geographic area as the study site, meaning that the preferred approach is to employ statistical recreation models developed for a study site; such models are used in conjunction with coefficients from an existing site to estimate recreation visitation and/or value at the study site, allowing the model transfer technique to improve the validity of the results compared to the use value transfer approach.

Because statistical models have been developed for estimating recreation value per trip for two of the three river reaches in the LTEMP study area—Glen Canyon and Upper Grand Canyon—and models estimating recreation use have been developed for Lake Powell and Lake Mead, while other studies have estimated values per trip for recreation use of Lake Powell and Lake Mead, the benefits transfer methods provides a useful and reliable approach to estimating river use values and reservoir visitation.

Visitation levels at the reservoirs were estimated using Neher et al. (2013) and then evaluated using the approach described in Gaston et al. (2014). The net economic value of recreation was then estimated for Lake Powell and Lake Mead, using the Lake_Full program; the GCRec_Full program was used to estimate the economic value for recreation on the three reaches of the Colorado River—Glen Canyon (from Glen Canyon Dam to Lees Ferry at RM 0), Upper Grand Canyon (from Lees Ferry to Diamond Creek at RM 225), and Lower Grand Canyon (from Diamond Creek to Lake Mead). These programs and the benefits transfer method are described in Appendix L. A review of use value estimates associated with Lake Powell, Glen Canyon, Upper Grand Canyon, Lower Grand Canyon, and Lake Mead can be found in Gaston et al. (2014).

In addition to use values, there may also be significant non-use values associated with reservoir and river resources in the Grand Canyon. A review of non-use valuation studies is provided in Section L.1.2 of Appendix L. NPS conducted a survey to determine non-use values associated with the impacts of Glen Canyon Dam operations on the endangered humpback chub, sandbars in the Grand Canyon, populations of large trout in Glen Canyon, and hydropower. The survey used a discrete choice model to estimate household and aggregate willingness to pay for various environmental outcomes associated with operations. These outcomes were then mapped to specific LTEMP alternatives to determine willingness to pay for each alternative. Survey data were collected from two samples of households—a national sample including all U.S. households, and a regional sample, including a sample of households purchasing power from Glen Canyon Dam. More information on the survey methods can be found in Neher et al. (2016), which is summarized in Appendix L.

4.14.1.2 Recreational Economic Impacts

The economic impacts of changes in recreational activity under each alternative are estimated using changes in visitor expenditures associated with various types of recreational activities, including angling, rafting, and boating, as well as spending on food and beverages, restaurants, fishing and boating equipment, gasoline for vehicles and boats, camping fees or motel expenses, guide services, and fishing license fees. Impacts occurring under each alternative are estimated for the six-county region in which the majority of recreational expenditures are likely to occur, and includes Coconino County and Mohave County in Arizona, and Garfield County, Kane County, San Juan County, and Washington County in Utah. Although a large number of visitors to Lake Mead come from the western side of the Colorado River in Clark County, Nevada, their share of expenditures on reservoir recreation in Clark County is not known. Expenditures are therefore assumed to occur in the six counties included in the analysis. Although the addition of Clark County to the analysis would likely produce slightly larger reservoir recreation employment and income impacts under each of the alternatives, it would not affect relative differences among the alternatives. Economic impacts include both direct and secondary effects of changes in expenditures that may occur on employment and income, and were estimated using the IMPLAN analysis tool (IMPLAN Group, LLC 2014). More information on the data and methods used, and a review of studies of the economic impacts of recreation activities in Glen Canyon, Grand Canyon and the surrounding area can be found in Section L.1.3 of Appendix L.

4.14.1.3 Electricity Bill Increase and Generation Capacity Expansion Impacts

Under each LTEMP alternative, the regional economic impacts of the eight largest WAPA customer utilities constructing and operating additional powerplants to replace energy and capacity losses from Glen Canyon Dam, and the resulting changes in customer utility electricity prices, were analyzed for the seven-state region in which WAPA markets power. This region includes Arizona, Colorado, Nebraska, Nevada, New Mexico, Utah, and Wyoming. Estimates of the required additional powerplant capacity were taken from the AURORAex model results (see Appendix K), and data on gas powerplant construction and operating expenditures, including materials, equipment, services, direct and indirect labor, by technology, size, and location were taken from the JEDI model (NREL 2015). Data on changes in retail electricity rates charged by the eight largest WAPA customer utilities, and the resulting changes in residential customer bills, were also included in the analysis (see Appendix K for a description of the retail rate analysis). IMPLAN input-output models (IMPLAN Group, LLC, 2014) (see Section L.1 of Appendix L), were used to estimate the regional economic impacts of additional generating capacity and changes in electricity prices; a separate IMPLAN model represents each of the seven states in the WAPA power marketing area. Note that the alternatives could affect the seasonal pattern of Lake Mead elevations, and thus power generation and capacity at Hoover Dam. However, such effects at Hoover Dam are anticipated to be relatively small (Section 4.13).

4.14.1.4 Environmental Justice

The analysis of potential environmental justice impacts follows guidelines described in the Council on Environmental Quality's (CEQ's) *Environmental Justice Guidance under the National Environmental Policy Act* (CEQ 1997). Environmental justice impacts on Tribes could occur through impacts on Tribal values or through impacts on Tribal economics. Impacts on values could result from temporary changes in access to culturally important Tribal resources, and there may be an adverse impact on Tribal values from trout management actions. Tribal economics may be affected by alternative-specific differences in impacts on recreation in Glen Canyon and the Grand Canyon and in the surrounding area, or from changes in the retail rates of hydropower sold to Tribes.

The analysis of environmental justice issues considered impacts within the 11-county region in which disproportionately high and adverse human health and environmental effects on minority and low-income populations may occur (including Apache County, Coconino County, Mohave County, and Navajo County in Arizona; Cibola County, McKinley County, and San Juan County in New Mexico; and Garfield County, Kane County, San Juan County, and Washington County in Utah). Other potential impacts related to environmental justice include changes in Tribal electricity retail rates, and impacts on Tribal resources and values. Using CEQ guidelines, the impact assessment determined whether each alternative would produce impacts that are high and adverse. If impacts were high and adverse, a determination was made as to whether these impacts would disproportionately affect minority and low-income populations by comparing the proximity of locations where any high and adverse impacts are expected with the location of low-income and minority populations. If impacts are not high and adverse, there can be no disproportionate impacts on minority and low-income populations.

4.14.2 Summary of Impacts on Socioeconomics and Environmental Justice

Table 4.14-1 summarizes the impacts for recreational use values, environmental non-use values, recreational economic impacts, and environmental justice.

4.14.2.1 Recreational Use Values

Recreational resources in Lake Powell, Lake Mead, and the Grand Canyon produce significant mean annual use values, with recreational activities in Lake Mead and Lake Powell constituting almost 97% of overall use value under each alternative (Table 4.14-2). Use values are presented in terms of net present value, to allow for differences in the distribution of use values between activities over time. Total mean annual use value created by all reservoir and river recreational activities amounts to $14,619.8 million under Alternative A (No Action Alternative), values which would decline slightly to between $14,598.7 million under

TABLE 4.14-1 Summary of Impacts of LTEMP Alternative on Socioeconomics and Environmental Justice[a]

Socioeconomic Impact Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Overall summary of socioeconomic impacts	No change from current conditions in use values, or economic activity with no change in reservoir levels or river conditions. Lowest non-use value of alternatives.	Compared to Alternative A, no change in use values and economic activity associated with Lake Powell recreation, and declines in use values (up to 5.2%) associated with most forms of river recreation. No change in economic activity for most forms of river recreation except angling, with declines during HFEs. Minimal decrease in use values (less than 0.1%) and no change in economic activity associated with Lake Mead recreation. Minimal increase in economic activity (less than 0.1%) from lower residential electric bills compared to Alternative A.	Compared to Alternative A, declines (0.7%) in use values and economic activity (0.6%) associated with Lake Powell recreation, and in use values (up to 11.5%) associated with most forms of river recreation. No change in economic activity for most forms of river recreation except angling, with declines during HFEs. Annual increase in non-use value of $2,353 million at national level.	from higher residential electric bills (less than 0.1%). Annual increase in non-use value of $3,524 million at national level.
Use Values[a]							
Lake Powell	No change from current conditions in use values ($5,016 million) because no change in water levels (lowest impact of alternatives).	Same as Alternative A	Compared to Alternative A, potential declines in use values of 0.7% (to $4,983 million) associated with lower water levels.	Compared to Alternative A, potential declines in use values of less than 0.4% (to $4,997 million) associated with lower water levels.	Compared to Alternative A, potential declines in use values of less than 0.5% (to $4,990 million) associated with lower water levels.	Compared to Alternative A, potential declines in use values of 1.1% (to $4,961 million) associated with lower water levels (highest impact of alternatives).	Compared to Alternative A, potential declines in use values of 0.4% (to $4,997 million) associated with lower water levels.
Glen Canyon	No change from current conditions in use values ($68.8 million) with no changes in river conditions (lowest impact of alternatives).	Compared to Alternative A, potential decline in use values for angling of 3.4% (to $19.4 million) and no change in day-use rafting ($48.7 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for angling of 6.2% (to $18.9 million) and no change in day-use rafting ($48.7 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for angling of 4.7% (to $19.2 million) and no change in day-use rafting ($48.7 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for angling of 3.4% (to $19.4 million) and no change in day-use rafting ($48.7 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for angling of 13.3% (to $17.4 million) and no change in day-use rafting ($48.7 million) associated with changes in river conditions (highest impact of alternatives).	Compared to Alternative A, potential decline in use values for angling of 6.2% (to $18.9 million) and no change in day-use rafting ($48.7 million) associated with changes in river conditions.

TABLE 4.14-1 (Cont.)

Socioeconomic Impact Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Upper Grand Canyon	No change from current conditions in use values ($355.8 million) with no changes in river conditions (lowest impact of alternatives).	Compared to Alternative A, potential decline in use values for private whitewater boating of 3.5% (to $66.5 million) and commercial whitewater boating of 5.8% (to $270.2 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for private whitewater boating of 1.5% (to $67.9 million) and commercial boating of 9.0%, (to $261.2 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for private whitewater boating of 1.3% (to $68.0 million) and commercial boating of 11.3%, (to $254.4 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for private whitewater boating of 2.3% (to $67.4 million) and commercial boating of 12.9%, (to $249.9 million) associated with changes in river conditions (highest impact of alternatives).	Compared to Alternative A, potential increase in use values for private whitewater boating of 0.4% (to $69.2 million) and decline for commercial boating of 2.3%, (to $280.2 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for private whitewater boating of 0.6% (to $68.5 million) and commercial boating of 13.7%, (to $247.6 million) associated with changes in river conditions.

TABLE 4.14-1 (Cont.)

Socioeconomic Impact Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Use Values*[a] *(Cont.)							
Lower Grand Canyon	No change from current conditions in use values ($64.8 million) with no changes in river conditions.	Compared to Alternative A, potential decline in use values for private whitewater boating of 2.0%, (to $3.6 million) for commercial 1-day boating of 4.6% (to $44.0 million); for overnight trips of 5.2% (to $0.52 million); no change for commercial flat-water boating ($14.5 million) associated with changes in river conditions.	Compared to Alternative A, potential decline in use values for private whitewater boating of 3.4% (to $3.6 million), for commercial 1-day boating of 9.6% (to $41.7 million), for overnight trips of 11.5% (to $0.49 million); no change for commercial flat-water boating ($14.5 million) associated with changes in river conditions.	Compared to Alternative A, potential increase in use values for private whitewater boating of 1.9% (to $3.8 million), decrease for commercial 1-day boating of 8.1% ($42.3 million), decrease for overnight trips of 11.7% (to $0.48 million); no change for commercial flat-water boating ($14.5 million) associated with changes in river conditions.	Compared to Alternative A, potential increase in use values for private whitewater boating of 0.6% (to $3.7 million), decrease for commercial 1-day boating of 10.0% (to $41.5 million), decrease for overnight trips of 14.0% (to $0.47 million); no change commercial flat-water boating ($14.5 million) associated with changes in river conditions.	Compared to Alternative A, potential increase in use values for private whitewater boating of 13.3% (to $4.2 million), decrease for commercial 1-day boating of 1.2% (to $45.5 million), decrease for overnight trips 8.9% ($0.46 million); no change for commercial flat-water boating ($14.5 million) associated with changes in river conditions.	Compared to Alternative A, potential increase in use values for private whitewater boating of 6.8% (to $3.9 million), decrease for commercial 1-day boating of 8.0% (to $42.4) million); decrease for overnight trips of 13.2% (to $0.42 million); no change commercial flat-water boating ($14.5 million) associated with changes in river conditions.
Lake Mead	No changes from current conditions in use values ($9,114.5 million) with no change in water levels (highest impact of alternatives).	Same as Alternative A.	Compared to Alternative A, potential increase in use values of 0.3% (to $9,145.2 million) associated with higher water levels.	Compared to Alternative A, potential increase in use values of 0.3% (to $9,139.7 million) associated with higher water levels.	Compared to Alternative A, potential increase in use values of 0.3% (to $9143.5 million) associated with higher water levels.	Compared to Alternative A, potential increase in use values of 0.5% (to $9,157.5 million) associated with higher water levels (lowest impact of alternatives).	Compared to Alternative A, potential increase in use values of 0.3% (to 9,143.3 million) associated with higher water levels.

Socioeconomic Impact Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Environmental Non-Use Values							
Willingness to pay (national level)	No change in non-use values (highest impact of alternatives).	Compared to Alternative A, $1.5 billion increase.	Compared to Alternative A, $4.0 billion increase.	Compared to Alternative A, $4.5 billion increase (lowest impact of alternatives).	Compared to Alternative A, $4.0 billion increase.	Compared to Alternative A, $2.5 billion increase.	Compared to Alternative A, $3.5 billion increase.
Willingness to pay (regional level)	No change in non-use values (highest impact of alternatives).	Compared to Alternative A, $9 million increase.	Compared to Alternative A, $22 million increase.	Compared to Alternative A, $25 million increase (lowest impact of alternatives).	Compared to Alternative A, $23 million increase.	Compared to Alternative A, $11 million increase.	Compared to Alternative A, $19 million increase.
Economic Impacts[b]							
Lake Powell	No change in direct and indirect employment (2,444 jobs) and income ($99.7 million) (lowest impact of alternatives).	Same as Alternative A.	Compared to Alternative A, declines in direct and indirect employment (to 2,430 jobs) and income (to $99.1 million) of 0.6%.	Compared to Alternative A, declines in direct and indirect employment (to 2,435 jobs) and income (to $99.3 million) of 0.4%.	Compared to Alternative A, declines in direct and indirect employment (to 2,433 jobs) and income (to $99.2 million) of 0.5%.	Compared to Alternative A, declines in direct and indirect employment (to 2,418 jobs) and income (to $98.6 million) of 1.1% (highest impact of alternatives).	Compared to Alternative A, declines in direct and indirect employment (to 2,435 jobs) and income ($99.3 million) of 0.4%.

TABLE 4.14-1 (Cont.)

Socioeconomic Impact Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Glen Canyon, Upper and Lower Grand Canyon	No change in direct and indirect employment (156 jobs) and income ($3.6 million) associated with river-based recreational activities.	Same as Alternative A.	Compared to Alternative A, negligible change in direct and indirect employment (<1 job) and income (<$20,000) associated with HFE effects on angling.	Compared to Alternative A, negligible change in direct and indirect employment (<1 job) and income (<$20,000) associated with HFE effects on angling.	Compared to Alternative A, negligible change in direct and indirect employment (<1 job) and income (<$20,000) associated with HFE effects on angling.	Compared to Alternative A, negligible change in direct and indirect employment (<1 job) and income (<$20,000) associated with HFE effects on angling.	Compared to Alternative A, egligible change in direct and indirect employment (<1 job) and income (<$20,000) associated with HFE effects on angling.
Lake Mead	No change in direct and indirect employment (5,099 jobs) and income ($208.0 million) (highest impact of alternatives).	Same as Alternative A.	Compared to Alternative A, increases in direct and indirect employment (to 5,116 jobs) and income (to $208.6 million) of 0.3%.	Compared to Alternative A, increases in direct and indirect employment (to 5,114 jobs) and income (to $208.6 million) of 0.3%.	Compared to Alternative A, increases in direct and indirect employment (to 5,115 jobs) and income (to $208.6 million) of 0.3%.	Compared to Alternative A, increases in direct and indirect employment (to 5,124 jobs) and income (to $209.0 million) of 0.5% (highest impact of alternatives).	Compared to Alternative A, increases in direct and indirect employment (to 5,115 jobs) and income (to $208.6 million) of 0.3%.

Socioeconomic Impact Indicators	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Environmental Justice							
Overall summary of environmental justice impacts	No change from current conditions. No disproportionately high and adverse impacts on minority or low-income populations.	TMFs and mechanical removal triggered in 3 years and <1 year, respectively, of LTEMP period; financial impacts related to electricity sales similar to those under Alternative A. No disproportionately high and adverse impacts on minority or low-income populations.	TMFs and mechanical removal triggered in 6 years and 0–3 years, respectively, of LTEMP period; financial impacts related to electricity sales would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A. No disproportion-ately high and adverse impacts on minority or low-income populations.	TMFs and mechanical removal triggered in 8 years and 2–3 years, respectively, of LTEMP period; financial impacts related to electricity sales would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A. No disproportion-ately high and adverse impacts on minority or low-income populations.	TMFs and mechanical removal triggered in 3 years and 0–2 years, respectively, of LTEMP period; financial impacts related to electricity sales would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A. No disproportion-ately high and adverse impacts on minority or low-income populations.	No impact; TMFs and mechanical removal not allowed under this alternative; financial impacts related to electricity sales would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and would be greater (as much as $3.26/MWh) than those under Alternative A. No disproportion-ately high and adverse impacts on minority or low-income populations.	Highest impact of all alternatives; TMFs and mechanical removal triggered in 11 years and 3 years, respectively, of LTEMP period; financial impacts related to electricity sales would be slightly higher (as much as $1.34/MWh) than those on non-Tribal customers, and would be greater (as much as $2.84/MWh) than those under Alternative A. No disproportionately high and adverse impacts on minority or low-income populations.
Tribal commercial and flat-water boating river boat rentals	No impacts expected with no changes in river visitation.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.	Same as Alternative A.

TABLE 4.14-1 (Cont.)

Environmental Justice (Cont.)							
Effects on Tribal values associated with TMFs and mechanical extraction of trout in proximity to sacred places of emergence	Negligible impacts, with no TMFs and infrequent trout removal actions (in <1 year of LTEMP period).	TMFs and mechanical removal triggered in an average of 3 years and <1 year, respectively, of LTEMP period.	TMFs and mechanical removal triggered in an average of 6 years and 1 to 3 years, respectively, of LTEMP period.	TMFs and mechanical removal triggered in an average of 11.0 years and 2 years, respectively, of LTEMP period.	TMFs and mechanical removal triggered in an average of 3 years and 2 years, respectively, of LTEMP period.	No impact; TMFs and mechanical removal not allowed under this alternative (lowest impact of alternatives).	Highest impact of all alternatives; TMFs and mechanical removal triggered in an average of 11 years and 3 years, respectively, of LTEMP period (highest impact of alternatives).
Financial impacts on Tribes related to electricity sales	No impacts expected.	Impacts would be similar to those on non-Tribal customers and those under Alternative A (lowest impact of alternatives).	Impacts on Tribes would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A.	Impacts on Tribes would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A.	Impacts on Tribes would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A.	Impacts would be slightly higher (<$1.00/MWh) from those on non-Tribal customers, and would be greater (as much as $3.26/MWh) than those under Alternative A (highest impact of alternatives)	Impacts would be slightly higher (as much as $1.34/MWh) than those on non-Tribal customers, and would be greater (as much as $2.84/MWh) than those under Alternative A

[a] Use values for alternatives are presented in Table 4.14-2.

[b] Employment and income values associated with recreational expenditures are presented in Tables 4.14-4 and 4.14-5, respectively. Employment and income associated with generation capacity are presented in Table 4.14-6, and residential electricity bills are presented in Table 4.14-7.

TABLE 4.14-2 Mean Annual Net Economic Value of Recreation Associated with LTEMP Alternatives[a]

Location and Activity	Mean Annual Net Economic Value ($ Million Net Present Value, 2015) for each Alternative						
	A (No Action Alternative)	B	C	D (Preferred Alternative)	E	F	G
Lake Powell							
General recreation	5,016.0	5,016.0	4,983.3	4,996.6	4,990.1	4,961.0	4,997.1
Glen Canyon							
Angling	20.1	19.4	18.9	19.2	19.4	17.4	18.9
Day-use rafting	48.7	48.7	48.7	48.7	48.7	48.7	48.7
Upper Grand Canyon							
Private whitewater boating	68.9	66.5	67.9	68.0	67.4	69.2	68.5
Commercial whitewater boating	286.9	270.2	261.2	254.4	249.9	280.2	247.6
Lower Grand Canyon							
Private whitewater boating	3.7	3.6	3.6	3.8	3.7	4.2	3.9
Commercial whitewater boating, 1-day trips	46.1	44.0	41.7	42.3	41.5	45.5	42.4
Commercial whitewater boating, overnight trips	0.55	0.52	0.49	0.48	0.47	0.46	0.42
Commercial flat-water boating	14.5	14.5	14.5	14.5	14.5	14.5	14.5
Lake Mead							
General recreation	9,114.5	9,114.3	9,145.2	9,139.7	9,143.5	9,157.5	9,143.3
All activities	14,619.8	14,598.0	14,585.3	14,587.6	14,579.1	14,598.7	14,585.3

[a] Use values are based on historical direct natural flow hydrology, weighted by sediment flow condition.

Source: Gaston et al. (2014).

Alternative F and $14,579.1 million under Alternative E, the latter of which is a decline of 0.3% compared to Alternative A.

Mean annual use values for general recreation in Lake Powell would fall slightly from $5,016 million under Alternative A to between $4,997.1 million under Alternative G and $4,961.0 million under Alternative F the latter of which represents a decline of 1.1%. Potential declines in use values under each alternative would come primarily as a result of lower reservoir water levels, which would mean exposed beaches and mudflats, reducing the quality of the recreational experience. There would be no change in use values associated with Alternative B compared to Alternative A. For Lake Mead, general recreation use values would increase slightly, from $9,114.5 million under Alternative A to between $9,139.7 million under Alternative D to $9,157.5 million under Alternative F, the latter of which is an increase of 0.5%. Higher use values would primarily result from higher reservoir water levels covering previously exposed mudflats and beaches, improving the quality of the recreational experience. There would be a slight decrease in use values associated with Alternative B compared to Alternative A.

Although river-based recreation activities produce less mean annual use value than reservoir-based activities, there would be more variation among alternatives. Differences between each alternative and Alternative A, where high flow experiments are restricted, are primarily due to the extent to which larger fluctuations in flow associated with each alternative are shifted to seasons of the year that are more popular with visitors.

Angling use values in Glen Canyon would decline from $20.1 million under Alternative A to between $19.4 under Alternative E to $17.4 million under Alternative F, the latter representing a decline of 13.3%. Use values associated with commercial whitewater boating in the Upper Grand Canyon would fall from $286.9 million under Alternative A to between $280.2 million under Alternative F and $247.6 million under Alternative G, the latter representing a 13.7% decline. Mean annual use value generated by 1-day commercial whitewater boating trips in the Lower Grand Canyon would fall from $46.1 million under Alternative A to between $45.5 million under Alternative F and $41.5 million under Alternative E, the latter of which represents a decline of 10.0%.

Private whitewater boating in the Upper Grand Canyon produces $68.9 million in use values under Alternative A, values that would increase to $69.2 million under Alternatives F, an increase of 0.4%, and fall to between $68.5 million under Alternative G and $66.5 million under Alternative B, a decrease of 3.5%. Private whitewater boating in the Lower Grand Canyon would decrease from $3.7 million under Alternative A to $3.6 million for Alternative B and C, and increase to between $3.7 million under Alternative E, and $4.2 million under Alternative F, an increase of 13.3%,

Day-use rafting in Glen Canyon would generate $48.7 million in use value under each of the alternatives, commercial boating overnight trips would produce $0.5 million under each alternative, while commercial flat-water boating in the Lower Grand Canyon would produce $14.5 million under each alternative. Use values for either activity would not change under any of the alternatives, because demand for these activities would not be affected by river levels or fluctuations in river flow.

With the exception of changes in use value associated with commercial whitewater overnight boating trips and commercial flat-water boating in the Lower Grand Canyon, changes in use value for all other forms of river recreation were statistically significant at the 90% confidence level under each alternative, while changes in use value associated with reservoir recreation were not statistically significant under any of the alternatives.

4.14.2.2 Environmental Non-Use Values

NPS conducted a survey to determine non-use values associated with the impacts of Glen Canyon Dam operations on the endangered humpback chub, sandbars in the Grand Canyon, populations of large trout in Glen Canyon, and hydropower (Neher et al. 2016). The survey used a discrete choice model to estimate household and aggregate willingness to pay for various environmental outcomes associated with operations. These outcomes were then mapped to specific LTEMP alternatives to determine willingness to pay for each alternative. These outcome results were based on the primary modeling metrics used in the LTEMP EIS for these resource areas. For sediment, the metric used was the sand load index. For humpback chub, the metric used was from the coupled rainbow trout–humpback chub model. For the purposes of this quantative study, the simplication of using these main modeling metrics was necessary; however, additional quantitative and qualitative analyses are fully discussed in the LTEMP EIS Sections 4.3 and 4.5. It should also be noted that the survey respondents seemed to value the status quo for trout populations most highly and provided no solid trend regarding increasing trout populations; therefore the trout results were deemed inconclusive and not used for the final outcomes listed below.

Survey data were collected from two samples of households, a national sample including all U.S. households, and a regional sample including a sample of households purchasing power from Glen Canyon Dam, and including all utilities receiving power from the Glen Canyon Dam.

The results from the national and regional samples indicated that, based on the estimated willingness to pay for environmental outcomes, Alternative D (the preferred alternative) would be the most highly valued of the alternatives with an aggregate annual willingness to pay value of $4,486 million, and a regional aggregate annual value of $25 million (Table 4.14-1) (Neher et al. 2016). The next highest rated alternatives were Alternatives C and E. Alternative B was associated with the lowest willingness to pay value based on expected outcomes.

A recently published study (Jones et al. 2016) offers an alternative total economic value analysis to that presented by Neher et al. (2016). The Jones et al. analysis relied on the contingent valuation methodology, which is similar to the methodology used by Welsh et al. (1995), but different from the methodology used by Neher et al. The Neher et al. analysis relied on the choice experiment methodology, which incorporates recent methodological advances in non-market valuation. However, the Jones et al. analysis is also different from the Neher et al. analysis because it included two additional attributes: (1) impacts on Tribes and rural western communities that depend on hydroelectric production, and (2) increases in air pollution by switching to nonrenewable fossil fuels in the power generation system. The Jones et al. study concluded that including these additional attributes would “significantly decrease willingness to

pay for changing Glen Canyon Dam operations, and demonstrate a significant fraction of the population with a positive willingness to pay for maintaining dam operations at current levels."

The Jones et al. (2016) study was a pilot study that relied on an internet panel rather than a randomized mail survey; the Tribe and rural western community attributes did not identify specific causal relationships or quantified values to ensure consistent respondent interpretation, and potential air quality impacts associated with increased fossil fuel use may be overstated for the range of alternatives analyzed for LTEMP (see Sections 4.15 and 4.16). While this study created a new framework that provided a different way of evaluating some of the attributes that would not have been analyzed otherwise, the issues discussed above limit the application of this study to the LTEMP EIS.

4.14.2.3 Recreational Economic Impacts

The regional economic impacts of recreation in Lake Powell, Lake Mead, and the Grand Canyon are closely tied to visitation levels for each recreational activity. By far the most significant recreational resource is Lake Mead, which drew almost 6 million individual trips in 2012, 72.0% of the total number of trips to these areas (Table 4.14-3). Lake Powell drew 1.9 million trips, or 23.0% of the total, while there were 0.2 million individual Grand Canyon river trips in 2012 (2.5% of the total). Of the river-based recreational activities, commercial flat-water boating in the Lower Grand Canyon, below Diamond Creek, drew the largest number of individual trips (95,520 individual trips, or 46.0% of the total number of individual river trips), followed by day-use rafting in Glen Canyon (53,578 individual trips, 25.8% of the total) and 1-day white water boating below Diamond Creek (28,748 individual trips, 13.8% of the total). Commercial whitewater boating in the Upper Grand Canyon drew 17,384 individual trips, or 8.4% of total river trips.

Recreational expenditures by visitors to Lake Powell and Lake Mead, and to the Upper and Lower Grand Canyon, create substantial employment and income in the six-county area in Arizona and Utah (Tables 4.14-4 and 4.14-5). Boating in Lake Mead currently produces 5,099 total (direct and indirect) jobs and $208 million in total income (direct and indirect) annually; boating on Lake Powell produces 2,444 total jobs and $99.7 million in income. Over the 20-year LTEMP period, annual direct and indirect economic activity would fall to between 2,435 jobs and $99.3 million in income for Alternative G and 2,418 jobs and $98.6 million in income for Alternative F, for Lake Powell, with increases of between 5,115 jobs and $208.6 million in income for Alternative G, and 5,124 jobs and $209.0 million in income for Alternative F for Lake Mead. Changes in employment under Alternative F resulting from changes in recreation at Lake Powell would represent a decrease of 1.1% in compared to Alternative A, and an increase of 0.5% under Alternative F at Lake Mead. There would be no change in recreational economic impacts associated with Alternative B compared to Alternative A.

Because current NPS regulations restrict the number of river boating trips that can be taken, and demand consistently exceeds the number of available permits (Gaston et al. 2014), the analysis assumes that the number of whitewater boating trips would not change as a result of any

TABLE 4.14-3 Recreational Visitation by Activity in Lake Powell, Upper and Lower Grand Canyon, and Lake Mead, 2012

Location	Activity	Number of Annual Individual Trips
Lake Powell	General recreation	1,914,768

Source: IMPLAN Group, LLC (2014).

of the alternatives, meaning that the regional economic impacts for river recreation under each of the alternatives would be the same as for Alternative A.

Angling trips could be affected under each of the alternatives, especially if HFEs occur during prime fishing months. High flows would mean poor fishing conditions, limited or no beach or shoreline access, and no wading; these restrictions and limitations could affect annual visitor spending (including spending on lodging, boat fuel, groceries, guide fees, and fishing licenses) and consequently could affect the regional economy. The number of HFEs would vary among alternatives, and would range from 5.5 under Alternative A to 38.1 under Alternative F (Alternative D would have an average of 21.1 HFEs).[35] The maximum number of days HFEs would disrupt angling in any year would range from 4 under Alternative B to 18 under Alternative G; Alternative G is highest because it includes the potential for extended-duration HFEs up to 14 days long (the maximum number of HFE days within a calendar under Alternative D would be 14 days). Note that extended-duration HFEs are expected to be triggered relatively infrequently and would be limited to no more than four under Alternative D (see Section 4.3.3). Although the variation in HFE frequency and duration would mean larger impacts under Alternatives D and G, because of the relatively small number of HFE days, and the timing of the proposed HFEs compared to that of the majority of angler trips, the overall economic impact of HFEs on angling and on the regional economy would be negligible, with less than one job and less than $20,000 in income lost annually in the six-county area.

[35] Adjustments made to Alternative D after modeling was completed included a prohibition of sediment-triggered and proactive spring HFEs in the same water year as an extended-duration fall HFE. The estimated number of HFEs after this adjustment would be about 19.8 (1.3 fewer than were modeled). This reduced number of HFEs is not expected to result in a change in Alternative D's impacts on socioeconomics.

Similarly, although the impacts of HFEs on license revenues would be slightly larger under Alternatives D and G, as would the economic impact of the spending of these revenues, the economic impacts are expected to be negligible for all alternatives, less than one job and $2,500 annually in income in the six-county area.

The largest river recreation impacts are from 1-day commercial whitewater boating trips below Diamond Creek, which produces 61 jobs annually and $1.4 million in income, and commercial whitewater trips in the Upper Grand Canyon (37 jobs and $0.8 million in income). Angling (19 jobs and $0.5 million in income) in Glen Canyon, and day-use rafting (commercial flat-water boating) (19 jobs and $0.4 million in income) below Diamond Creek would produce smaller impacts. A total of 156 jobs and $3.6 million in income are currently produced annually across all river recreational activities under Alternative A, with the same annual impacts expected under each alternative.

4.14.2.4 Customer Utility Electricity Generation Capacity and Residential Rate Increase Impacts

Although there would be no change in Glen Canyon Dam capacity under Alternative A, forecasted increases in the demand for electricity and the planned retirement of existing powerplant generating capacity would mean that an estimated 4,820 MW of new capacity would be built by the eight largest WAPA customer utilities under Alternative A over the 20-year study period. Under Alternative B, 4,820 MW of additional capacity would also be added, while a reduction in available generating capacity at Glen Canyon Dam under Alternatives C, D, E, and G would mean that alternative generating capacity would be required by WAPA customer utilities to replace lost hydropower capacity. An additional 5,050 MW would be required under Alternatives C, D, E, and G (an increase of 4.8% compared to Alternative A), with 5,280 MW needed under Alternative F (an increase of 9.5%) (see Section 4.13.2.3).

Using estimated capital and operating costs associated with providing additional capacity under each alternative for the eight largest WAPA customer utilities, the economic impacts of construction and operation of additional capacity are shown in Table 4.14-6. Under Alternative A, powerplant construction would produce an estimated 9,519 total (direct and indirect) jobs in the seven-state region, and $841.7 million in earnings. Operation of new powerplants under Alternative A would create 1,019 total jobs and $69.4 million in annual earnings. Alternative B would also require the same capacity as Alternative A, with 9,519 jobs and $841.7 million in earnings created directly and indirectly in the seven states. Operations would produce 1,019 total jobs and $69.4 in earnings per year. Alternatives C, D, E, and G would require slightly more additional capacity than Alternative A, producing 9,895 total construction and 1,065 total operations jobs, an increase of 3.9%, $875.3 million in construction earnings, and $72.5 annually during operations. The largest impacts of capacity additions would be under Alternative F, where 10,286 total jobs, an increase of 8.1%, and $909.6 million in earnings would be produced during construction, and 1,114 jobs and $75.7 million would be produced annually in earnings during operations. It should be noted that the alternatives could affect the seasonal pattern of Lake Mead elevations and, thus, power generation and capacity at

TABLE 4.14-6 Seven-State Economic Impacts[a] under LTEMP Alternatives of Additional Generating Capacity for the Eight Largest Customer Utilities, 2015–2033

	Alternative						
Parameter	A	B	C	D	E	F	G
Construction							
Employment (FTEs)	9,519	9,519	9,895	9,895	9,895	10,286	9,895
Earnings ($Million 2015)	841.7	841.7	875.3	875.3	875.3	909.6	875.3
Operations							
Employment (FTEs)	1,019	1,019	1,065	1,065	1,065	1,114	1,065

[a] Impacts assume average hydrological conditions, and that powerplants would use advanced oil/gas combined cycle or advanced combustion turbine technology. Construction impacts are total impacts over a 3-year construction period; operations impacts are average annual impacts.

Source: IMPLAN Group, LLC (2014).

Hoover Dam, and the associated impacts described here for Glen Canyon Dam. However, such effects related to Hoover Dam generation are anticipated to be relatively small (Section 4.13).

Costs associated with replacing generation capacity no longer provided at Glen Canyon Dam would mean changes in retail rates charged by WAPA customer utilities, and consequently, changes in the electric bills of residential customers. Although there is considerable variation in the amount of power sold by WAPA to customer utilities, ranging from 0.8% of customer utility power sales with Salt River Project to 23.7% with Navajo Tribal Utility Authority among the eight largest customer utilities, only 7.3% of power sales for all eight of the largest customer utilities comes from WAPA, meaning that the cost of additional capacity required under each alternative to replace capacity lost at Glen Canyon Dam has only negligible impacts (average less than 2% in maximum impacts year) on electric bills paid by residential customers of the eight largest WAPA customer utilities. Two groups of utilities that are allocated a large fraction of their generation resources from SLCA/IP projects are Tribal utilities and other small utilities. These groups would be affected more by capacity expansion differences among alternatives than others; Tribal utilities (Navajo and Cocopah) would experience up to a 2.8% increase in retail rates, while small utilities with the largest impact would experience up to a 3.1% increase in retail rates (see Appendix K for additional detail).

Although the economic impacts of changes in retail electricity rates and the corresponding impacts on residential customer bills would be dependent on the timing and magnitude of capacity expansion required under each alternative, changes in customer rates under each alternative are small. Table 4.14-7 shows the average annual losses in economic activity in the seven-state region for the eight largest customer utilities. Impact data are based on the aggregation of bill increases across the eight largest customer utilities, weighting by

TABLE 4.14-7 Average Annual Impacts on Economic Activity from Changes to Residential Electricity Bills of Largest Eight Customer Utilities, 2015–2033, Relative to Alternative A

	Alternative					
Parameter	B	C	D	E	F	G
Changes to employment (FTE jobs) compared to Alternative A	An increase in up to 10 new jobs	A reduction of 23 jobs	A reduction of 10 jobs	A reduction of 10 jobs	A reduction of 41 jobs	A reduction of 25 jobs
Changes to earnings (in millions of 2015 dollars) compared to Alternative A	An increase of $0.1 in earnings	A loss of $1.0 in earnings	A loss of $0.4 in earnings	A loss of $0.3 in earnings	A loss of $1.9 in earnings	A loss of $1.2 in earnings

Source: IMPLAN Group, LLC (2014).

individual utility power sales compared to total power sales for all eight utilities. Changes in retail rates range from a decrease of 0.27%% under Alternative B to an increase of 1.21% under Alternative F (Table 4.13-1).

The impact of these increases on employment and income in the seven-state region would range from less than 10 total (direct and indirect) jobs lost and $0.3 million in earnings lost under Alternative E to 41 jobs and $1.9 million in earnings lost under Alternative F. A slight decrease in electric bills under Alternative B would mean small increases in employment (less than 10 jobs) and earnings (an increase of $0.1 million).

4.14.2.5 Environmental Justice Impacts

Changes in river and reservoir recreational visitation might disproportionately impact low-income and minority populations including Tribal communities, both in the counties in the vicinity of the GCNRA and GCNP, and in the seven-state area in which power from Glen Canyon Dam is marketed.

Eleven-County Region

There were a large number of low-income and minority individuals in the 11-county region as a whole in the 2010 Census, with 38.0% of the population classified as minority, and 12.7% classified as low-income using data from the 2008–2012 American Community Survey. According to CEQ guidelines, however, environmental justice concerns should be evaluated where there are minority and low-income *populations*, where the number of minority and low-income *individuals* present in a geographic area are compared to a reference population (the number of minority and low-income individuals in a state, for example), rather than only on the number of minority and low-income *individuals* present in a geographic area. The number of

minority or low-income individuals does not exceed state averages by 20 percentage points or more, and does not exceed 50% of the total population in the area. This means that for the 11-county region as a whole, there are no minority or low-income populations based on the 2010 Census, the 2008–2012 American Community Survey data, and CEQ guidelines. The number of minority individuals exceeds the state average by 20 percentage points or more in Apache County, Arizona; McKinley County, New Mexico; and San Juan County, Utah. Minority individuals exceed 50% of the total population in Apache County and Navajo County, Arizona; Cibola County, McKinley County, and San Juan County, New Mexico; and in San Juan County, Utah, indicating that there are minority populations in each of these counties based on county level data in the 2010 Census, the 2008–2012 American Community Survey data, and CEQ guidelines. Because the number of low-income individuals does not exceed the state average by more than 20 percentage points, or does not exceed 50% of the total population in any of the 11 counties, there are no low-income populations based on county-level data in the 11-county region.

A large number of census block groups in the vicinity of the GCNRA and GCNP with low-income and minority populations could be affected if changes in visitation levels produced impacts that were high and adverse. In Coconino County, Arizona, a number of block groups have populations where the percentage of minorities is more than 20 percentage points higher than the state average. These are located in the eastern part of the county on the Navajo Nation Indian Reservation and Hopi Indian Reservation, in the western part of the county, including the Havasupai Indian Reservation and the Hualapai Indian Reservation, which are also located in one block group in eastern Mohave County, Arizona. One census block group in Page, Arizona, also has a minority population which is more than 50% of the total. There are a number of census block groups in San Juan County, Utah, where more than 50% of the total population is minority. These are located in the southern portion of the county and include the Navajo Nation Indian Reservation and the Ute Mountain Indian Reservation.

There are a large number of census block groups in the vicinity of GCNRA and GCNP where the percentage of low-income individuals is more than 20 percentage points higher than the state average. These are located in (1) Coconino County, Arizona, on the Navajo Nation Indian Reservation and the Hopi Indian Reservation; (2) Navajo County, Arizona, on the Navajo Nation Indian Reservation, which also contains the Fort Apache Indian Reservation; (3) eastern Mohave County, Arizona, on the Hualapai Indian Reservation; and (4) southeastern and southwestern San Juan County, Utah, on the Navajo Nation Indian Reservation and the Ute Mountain Indian Reservation. There are also a number of census block groups in the 11-county area where more than 50% of the total population is below the poverty level. These are located in (1) the eastern part of Coconino County, Arizona, on the Navajo Nation Indian Reservation and Hopi Indian Reservation; (2) southwestern San Juan County, Utah, on the Navajo Nation Indian Reservation and the Ute Mountain Indian Reservation; (3) the northern parts of Navajo County and Apache County, Arizona; and (4) southwestern Navajo County on the Fort Apache Indian Reservation.

Changes to river recreation could impact Tribes in the vicinity of GCNRA and GCNP. Commercial whitewater and flat-water boating below Diamond Creek is important to the Hualapai Tribe, for employment and income, but as Table 4.14-5 shows, there are negligible

differences expected among the alternatives. NPS regulates the number of river boating trips that can be taken, with a set number of river trip launches per year, meaning that none of the alternatives are expected to impact overall levels of recreational river visitation. Although differences in time off river for river trips among the alternatives, or differences in stage levels, could change visitation patterns, either of these leading to potential damage and reduced access to culturally important plants and resources, these impacts are expect to be negligible for all alternatives except Alternative F, which may have a slight increase in the potential for effects to cultural sites based on more time off river (see Table 4.14-5). Changes to river stage levels, such as those caused by HFEs, could temporarily restrict Tribal access to culturally important resources, such as springs, minerals, and plants. Similar impacts may also occur if recreational visitors spend more time away from destination campsites with inundation by higher water levels (Section 4.8), but these impacts are expected to be small. Higher water levels may have positive impacts from flushing out springs that have cultural significance to Tribal members, such as Pumpkin Springs (Section 4.9).

Temporary changes in access to culturally important Tribal resources and other areas of significance to tribes may also impact Tribal members. As described in Section 4.9, for those Tribes that hold the Canyons to be a sacred space, the plant and animal life are integral elements without which its sacredness would not be complete. The Zuni, in particular, have established a lasting familial relationship with all aquatic life in the Colorado River and the other water sources in the Canyons (Dongoske 2011a). They consider the taking of life through the mechanical removal of trout or TMFs to be offensive, and to have dangerous consequences for the Zuni. The confluence of the Colorado River and the Little Colorado River is considered a sacred area because of its proximity to places identified in traditional Tribal narratives as the locations of the Zuni and the Hopi emergence into this world and other important events. The killing of fish in proximity to sacred places of emergence is considered desecration, and would have an adverse effect on the Grand Canyon as a Zuni Traditional Cultural Property. The Zuni have expressed their view on this subject in Section 3.9.6. As shown in Table 4.14-1, there are differences among alternatives in the frequency of TMFs and mechanical removal of trout; Alternatives A and F would have the fewest of these actions, and Alternatives D and G the most.

In addition, fluctuations in reservoir levels could impact Tribes and resources managed by them, such as the Navajo Antelope Point marina operations. As shown in Section 4.8, there are negligible differences among all alternatives for impact to the Antelope Point marina, except under Alternative F, which shows a small difference from Alternative A (1.1%). As presented in Table 4.8-3, impacts on tradespeople making and selling jewelry and souvenirs to the traveling public along various routes in the region, primarily those in the vicinity of GCNRA and GCNP, are likely to be negligible, with no differences between the alternatives.

Seven-State Region

A large number of minority and low-income individuals are located in the seven-state region in which electricity from Glen Canyon Dam is marketed. In the region as whole, 35.7% of the population is classified as minority, while 15.1% is classified as low income. According to CEQ guidelines, however, environmental justice concerns should be evaluated where there are

minority and low-income *populations*, where the number of minority and low-income *individuals* present in a geographic area are compared to a reference population (the number of minority and low-income individuals in the nation, for example), rather than only on the number of minority and low-income *individuals* present in a geographic area. The number of minority or low-income individuals does not exceed the respective national averages by 20 percentage points or more, and does not exceed 50% of the total population in the area, meaning that for the seven-state region as a whole, there are no minority or low-income populations based on 2010 Census, the 2008–2012 American Community Survey data, and CEQ guidelines. Within one state in the region, New Mexico, 59.5% of the total population is minority, meaning that according to 2010 Census and 2008–2012 American Community Survey data and CEQ guidelines, there is a minority population in the state.

Although there are no minority populations in any of the seven states except for New Mexico, and no low-income populations, there are a large number of Tribal members in the seven-state area, many of whom reside on Indian Reservations. Many of these individuals have low-income status.

Tribal members receive a significant portion of their electricity from WAPA, which currently targets an allocation of 65% of total Tribal electrical use to the 57 Tribes or Tribal entities currently receiving an allocation of power from SLCA/IP; this includes power from Glen Canyon Dam (see Section K.4 in Appendix K). Nine Tribes operate their own electric utilities and receive power directly from WAPA; the remaining 48 have a benefit crediting arrangement. In a benefit crediting arrangement, the Tribe's electric service supplier takes delivery of the SLCA/IP allocation and in return gives an economic benefit or a payment to the tribe.

Tribes may be financially affected in one of three ways by the LTEMP alternatives: (1) a change in the rate they pay for SLCA/IP electric power if they operate their own utility; (2) a change in the payment they receive from their electric service provider if they have a benefit crediting arrangement; or (3) a change in both the payment they receive from their supplier for the benefit crediting arrangement and the electric rate their supplier charges if their supplier also receives an SLCA/IP allocation.

The benefit credit is computed by taking the difference between the SLCA/IP rate and the supplier rate and multiplying it by the Tribe's SLCA/IP allocation. Because the SLCA/IP rate is generally lower than the supplier's rate, the difference between the rates is considered a benefit by the Tribe and is the financial equivalent of a direct delivery of electricity.

Tribes whose supplier also receives a SLCA/IP allocation have a second financial impact. The retail electricity rate their supplier charges could change as a result of an alternative. The retail rate impact is computed by taking the difference in retail rates between an alternative and Alternative A and multiplying by the total electrical use on the Tribe's reservation. Therefore, the financial impact on these Tribes is the sum of the Tribal benefit credit and the retail rate impact.

The financial impact of all alternatives would be relatively small, but the impact on Tribal members would be greater than on non-Tribal residential customers (Table 4.14-8; see Section K.4 in Appendix K for a description of the analysis and results). Differences in impacts on the three groups are as follows:

- Tribal customers receiving power from a non-Tribal utility with an associated benefit credit: Financial impacts (increases in retail rates and reductions in benefit credit) would range from an average increase (compared to Alternative A) of $0.00/MWh under Alternative B to $1.63/MWh under Alternative G. Alternatives C, D, E, and F would produce an increase in financial impact of $0.37, $0.31, $0.24, and $1.53/MWh, respectively. The Tribe with the maximum impact would experience financial impacts of –$0.05 (net benefit), $0.91, $0.68, $0.58, $3.26, and $2.84/MWh under Alternatives B, C, D, E, F, and G, respectively.

- Tribal customers that purchase from Tribal-owned utilities: Financial impacts (increases in retail rates) would range from an average increase (compared to Alternative A) of $0.00/MWh under Alternative B to $1.72/MWh under Alternative G. Alternatives C, D, E, and F would produce an increase in financial impact of $0.37, $0.31, $0.24, and $1.53/MWh, respectively. The Tribe with the maximum impact would experience financial impacts of $0.02, $0.44, $0.39, $0.30, $2.00, and $2.37/MWh under Alternatives B, C, D, E, F, and G, respectively.

- Non-Tribal customers: Financial impacts (increases in retail rates) would range from an average increase (compared to Alternative A) of –$0.02/MWh (net benefit) under Alternative B to a $0.67/MWh increase under Alternative F. Alternatives C, D, E, and G would produce an increase in financial impact of $0.22, $0.15, $0.13, and $0.38/MWh, respectively. The Tribe with the maximum impact would experience financial impacts of –$0.07 (net benefit), $0.62, $0.41, $0.38, $1.86, and $1.07/MWh under Alternatives B, C, D, E, F, and G, respectively.

In summary, for the majority of resource areas, impacts on minority and low-income individuals are likely to be negligible. Commercial whitewater and flat-water boating below Diamond Creek is important to the Hualapai Tribe for employment and income, but there are expected to be negligible economic differences expected among the alternatives. Fluctuations in reservoir levels affecting the Navajo Antelope Point marina operations are expected to be negligible under all alternatives except Alternative F, which shows a small difference from Alternative A. Impacts also are likely to be negligible on tradespeople making and selling jewelry and souvenirs to the traveling public along routes in the vicinity of the Grand Canyon itself, with no differences between the alternatives.

TABLE 4.14-8 Financial Impacts on Tribal and Non-Tribal Electricity Customers

Parameter	Average Value under Alternative A ($/MWh)	Change from Alternative A					
		Alternative B	Alternative C	Alternative D	Alternative E	Alternative F	Alternative G
Tribal Customers with Benefit Credit (48 Utilities)							
Average Retail Rate ($/MWh)	91.82	–0.01	0.08	0.05	0.05	0.23	0.13
Average Benefit Credit ($/MWh)	8.84	–0.01	–0.27	–0.24	–0.18	–1.23	–1.45
Total of Retail and Benefit Impacts ($/MWh)	82.98	0.00	0.37	0.31	0.24	1.53	1.63
Maximum Impact: Hopi Tribe	72.67	–0.05	0.91	0.68	0.58	3.26	2.84
Tribal Customers without Benefit Credit (nine Utilities)							
Average Retail Rate ($/MWh)	95.09	0.00	0.40	0.33	0.26	1.63	1.72
Maximum Impact: Ak-Chin Indian Community	83.10	0.02	0.44	0.39	0.30	2.00	2.37
Non-Tribal Customers (142 Utilities)							
Average Retail Rate ($/MWh)	92.15	–0.02	0.22	0.15	0.13	0.67	0.38
Maximum Impact	73.74	–0.07	0.62	0.41	0.38	1.86	1.07

Differences in time off river and differences in stage levels, such as those caused by inundation during HFEs, could lead to damage and reduced Tribal access to culturally important plants and resources. However, the impacts are expected to be negligible for all alternatives except Alternative F, which may lead to a slight increase in impacts on cultural sites.

The financial impacts on Tribal members would be greater than those on non-Tribal residential customers, especially under Alternatives F and G. Financial impacts of other alternatives are all less than $1.00/MWh.

4.14.3 Alternative-Specific Impacts

4.14.3.1 Alternative A (No Action Alternative)

Use values associated with recreation in Lake Powell, Lake Mead, and the Upper and Lower Grand Canyon are substantial and current use values would not change under Alternative A. Use values associated with general recreational activities in Lake Mead ($9,114.4 million) and Lake Powell ($5,016 million) constitute almost 97% of the value created by reservoir and river resources in the affected area under Alternative A. Under Alternative A, commercial and private whitewater boating would produce $286.9 million and $68.9 million in use value, respectively, in the Upper Grand Canyon; other activities in the Lower Grand Canyon would produce lower use values.

There would be no change in the estimated per-household willingness to pay values associated with the impact of dam operations under Alternative A on humpback chub populations and sandbars in the Grand Canyon.

Recreational expenditures by visitors to Lake Powell, Lake Mead, and the Upper and Lower Grand Canyon create substantial employment and income in the six-county area in Arizona and Utah. Private boating in Lake Mead and Lake Powell would produce the largest number of jobs and the largest amount of income, amounting to 7,543 jobs and $307.7 million in income annually over the 20-year LTEMP period.

The largest river recreation impacts are from 1-day commercial whitewater boating trips below Diamond Creek, which produces 61 jobs and $1.4 million in income, and commercial whitewater trips in the Upper Grand Canyon (37 jobs and $0.8 million in income). Angling (19 jobs and $0.5 million in income) in Glen Canyon, and day-use rafting (commercial flat-water boating) (19 jobs and $0.4 million in income) below Diamond Creek would produce smaller impacts.

A total of 7,699 jobs and $311.3 million in income would be produced annually across all reservoir and river recreational activities under Alternative A over the 20-year LTEMP period.

Under Alternative A, there would be an estimated average 5.5 HFEs over the LTEMP period and a maximum of 8 HFE days in a calendar year; there would be no HFEs after 2020. Although HFEs would preclude angling during their implementation, their impact on employment and income generated by shore and boat angling, and from angler spending on fishing licenses, is expected to be negligible.

Although no additional generating capacity would be required under Alternative A as a result of changes in Glen Canyon Dam operations among the eight largest WAPA customer utilities, forecasted increases in the demand for electricity in the service territories of the eight largest customer utilities and the planned retirement of existing powerplant generating capacity would mean that an estimated 4,820 MW of new capacity would be built under Alternative A over the 20-year LTEMP period. Using estimated capital and operating costs associated with

providing additional capacity, powerplant construction would produce 9,519 total (direct and indirect) jobs in the seven-state region, and $841.7 million in earnings. Operation of new powerplants with Alternative A would create 1,019 total jobs and $69.4 million in annual earnings associated with new jobs.

Because there would be no change in Glen Canyon Dam operations as a result of Alternative A, there would be no impact on retail rates charged by the eight largest WAPA customer utilities or the electric bills paid by their residential customers, or subsequent impacts on employment or income, in the seven-state region.

In summary, with no change in reservoir levels or river conditions under Alternative A, there would be no change from current conditions in use values, economic activity, residential electricity bills, or environmental justice.

4.14.3.2 Alternative B

Under Alternative B, total use values associated with recreation in Lake Mead and the Upper and Lower Grand Canyon would decrease slightly relative to Alternative A, while remaining unchanged for Lake Powell (Table 4.14-2). General recreational activities in Lake Mead would produce $9,114.3 million in use value and $5,016.0 million at Lake Powell, while commercial and private whitewater boating would produce $270.2 million (5.8% decrease) and slightly less than $66.5 million (3.5% decrease), respectively, in the Upper Grand Canyon; other activities in the Lower Grand Canyon would produce lower use values.

Estimated per-household willingness-to-pay values associated with the impact of dam operations under Alternative B on humpback chub populations and sandbars in the Grand Canyon are estimated to be $1.5 billion at the national level and $9 million at the local (eight-county) level.

Under Alternative B, recreational expenditures by visitors and the number of jobs and income that would be created would be the same as under Alternative A (Tables 4.14-4 and 4.14-5). Private boating in Lake Mead and Lake Powell would produce the largest number of jobs and income, amounting to 7,543 jobs and $307.7 million in income annually over the 20-year LTEMP period. Impacts on river-based recreational activities would be the same as those under Alternative A.

Under Alternative B, there would be an estimated average 7.2 HFEs over the LTEMP period and a maximum of 4 HFE days in a calendar year. Although HFEs would preclude angling during their implementation, their impact on employment and income generated by shore and boat angling, and from angler spending on fishing licenses, is expected to be negligible.

Because Alternative B would feature the same monthly volumes as Alternative A, there would be no change in use value and economic impact associated with reservoir-based recreational activities. Changes in use values associated with Glen Canyon angling and Upper and Lower Grand Canyon private whitewater boating and commercial whitewater boating 1-day

trips would be primarily due to larger fluctuations in flow that would occur in seasons of the year more popular with visitors. Use values for Glen Canyon day-use rafting, Lower Grand Canyon commercial overnight boating trips, and commercial flat-water boating would not change, because demand for these activities would not be affected by river levels or fluctuations in flow under this alternative. With no changes in visitation for any of the river-based activities, there would be no change in the economic impact of these activities under Alternative B compared to Alternative A.

Although additional generating capacity would not be necessary under Alternative B as a result of changes in Glen Canyon Dam operations among the eight largest WAPA customer utilities, forecasted increases in the demand for electricity in the service territories of the eight largest customer utilities and the planned retirement of existing powerplant generating capacity would mean that an estimated 4,820 MW of new capacity would be built under Alternative B over the 20-year LTEMP period, as would be the case for Alternative A. Using estimated capital and operating costs associated with providing additional capacity, powerplant construction would produce 9,519 total (direct and indirect) jobs in the seven-state region, and $841.7 million in earnings. Operation of new powerplants under Alternative B would create 1,019 total jobs and $69.4 million in annual earnings associated with new jobs.

Because there would be slightly more Glen Canyon Dam generation capacity under Alternative B, retail rates charged by the eight largest WAPA customer utilities and the electric bills paid by their residential customers would fall, meaning the addition of less than 10 total (direct and indirect) jobs and an increase of $0.1 million in earnings in the seven-state region.

With no change in river visitation there would be no impacts on Tribal river boat rental operators and Tribal retailing in the vicinity of GCNRA and GCNP under Alternative B, and the impacts of changes in reservoir visitation on Tribal marina operators would be negligible. Access or damage to culturally important plants and resources would be negligible, but impacts on Tribal values related to implementation of TMFs and mechanical removal of trout would be adverse. Financial impacts on Tribes related to electricity sales would be similar to those on non-Tribal customers, and those under Alternative A.

In summary, under Alternative B, there would be a decline in use values associated with Glen Canyon angling, Upper Grand Canyon private and commercial whitewater boating, Lower Grand Canyon private whitewater boating commercial whitewater 1-day trips, and Lake Mead recreation compared to Alternative A. There would be no change in use values associated with Lake Powell recreation, Glen Canyon day-use rafting, Lower Grand Canyon commercial whitewater boating overnight trips, or commercial flatwater boating. There would also be no change in economic activity associated with Lake Powell and Lake Mead recreation, or river recreation. There would be an increase in economic activity as a result of lower residential electric bills compared to Alternative A.

4.14.3.3 Alternative C

Under Alternative C, total use values associated with recreation in Lake Powell and the Upper and Lower Grand Canyon would decrease slightly relative to Alternative A, while increasing for Lake Mead (Table 4.14-2). General recreational activities would produce $9,145.2 million (0.3% increase) in use value at Lake Mead and $4,983.3 million (0.7% decrease) at Lake Powell, while commercial and private whitewater boating would produce $261.2 million (9.0% decrease) and $67.9 million (1.5% decrease), respectively, in the Upper Grand Canyon; other activities in the Lower Grand Canyon would produce lower use values.

Estimated per-household willingness-to-pay values associated with the impact of dam operations under Alternative C on humpback chub populations and sandbars in the Grand Canyon are estimated to be $4.0 billion at the national level and $22 million at the local (eight-county) level.

Under Alternative C, recreational expenditures by visitors and the number of jobs and income that would be created in the six-county area in Arizona and Utah would be similar to those under Alternative A (Tables 4.14-4 and 4.14-5). Private boating in Lake Mead and Lake Powell would produce the largest number of jobs and income, amounting to 7,544 jobs and $307.7 million in income annually over the 20-year LTEMP period, a difference of 0.04% compared to Alternative A. Impacts on river-based recreational activities would be the same as those under Alternative A. A total of 7,700 jobs and $311.3 million in income would be produced annually across all reservoir and river recreational activities under Alternative C over the 20-year LTEMP period.

Under Alternative C, there would be an estimated average 21.3 HFEs over the LTEMP period and a maximum of 10 HFE days in a calendar year. Although HFEs would preclude angling during their implementation, their impact on employment and income generated by shore and boat angling, and from angler spending on fishing licenses, is expected to be negligible.

Differences in use value and economic impact associated with reservoir-based recreational activities under Alternative C compared to Alternative A would result primarily from changes in reservoir water levels, which would mean differences in exposure of beaches and mudflats, and consequently a change in the quality of recreational experience, and reduced visitor spending. Changes in use values associated with Glen Canyon angling and Upper and Lower Grand Canyon private whitewater boating and commercial whitewater boating 1-day trips would be primarily due to the shifting of monthly volumes away from seasons of the year that are more popular with visitors. Use values for Glen Canyon day-use rafting, Lower Grand Canyon commercial overnight boating trips, and commercial flat-water boating would not change, because demand for these activities would not be affected by river levels or fluctuations in flow under this alternative. With no changes in visitation for any of the river-based activities, there would be no change in the economic impact of these activities under Alternative C compared to Alternative A.

In addition to changes in generation and marketable capacity resulting from changes in Glen Canyon Dam operations under Alternative C, there would also be forecasted increases in the demand for electricity in the service territories of the eight largest WAPA customer utilities, and the planned retirement of existing powerplant generating capacity, meaning that an estimated 5,050 MW of new capacity would be built under Alternative C over the 20-year LTEMP period. Using estimated capital and operating costs associated with providing additional capacity, powerplant construction would produce 9,895 total (direct and indirect) jobs in the seven-state region, and $875.3 million in earnings. Operation of new powerplants under Alternative C would create 1,065 total jobs, a difference of 3.9% compared to Alternative A, and $72.5 million in annual earnings associated with new jobs.

Although costs associated with replacing generation capacity no longer provided at Glen Canyon Dam would mean changes in retail rates charged by WAPA customer utilities, and consequently changes in the electric bills of residential customers, the cost of additional capacity required to replace capacity lost at Glen Canyon Dam under Alternative C would only have negligible impacts on electric bills paid by residential customers of the eight largest WAPA customer utilities, and would mean the loss of 23 total (direct and indirect) jobs and $1.0 million in earnings in the seven-state region.

With no change in river visitation there would be no impacts on Tribal river boat rental operators and Tribal retailing in the vicinity of GCNRA and GCNP under Alternative C, and the impacts of changes in reservoir visitation on Tribal marina operators would be negligible. Access or damage to culturally important plants and resources would be negligible, but impacts on Tribal values related to TMFs and mechanical removal of trout would be adverse. Financial impacts on Tribes related to electricity sales would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A.

In summary, under Alternative C there would be a decline in use values associated with Lake Powell recreation, Glen Canyon angling, Upper Grand Canyon private and commercial whitewater boating, Lower Grand Canyon private whitewater boating, and commercial whitewater 1-day trips compared to Alternative A. There would also be a decline in economic activity associated with Lake Powell recreation. There would be no change in use values associated with Glen Canyon day-use rafting, Lower Grand Canyon commercial whitewater boating overnight trips, or commercial flatwater boating. There would also be no change in economic activity associated with river recreation. There would be an increase in use values and economic activity associated with Lake Mead recreation. Increased economic activity would result from customer utility capacity expansion compared to Alternative A, and reduced economic activity would come as a result of higher residential electric bills.

4.14.3.4 Alternative D (Preferred Alternative)[36]

Under Alternative D, total use values associated with recreation in Lake Powell, and the Upper and Lower Grand Canyon would decrease slightly relative to Alternative A, while increasing for Lake Mead (Table 4.14-2). General recreational activities in Lake Mead would produce $9,139.7 million (0.3% increase) in use value and $4,996.6 million (0.4% decrease) at Lake Powell, while commercial and private whitewater boating would produce $254.4 million (11.3% decrease) $68.0 million (a 1.3% decrease), respectively, in the Upper Grand Canyon; other activities in the Lower Grand Canyon would produce lower use values.

Estimated per-household willingness-to-pay values associated with the impact of dam operations under Alternative D on humpback chub populations and sandbars in the Grand Canyon are estimated to be $4.5 billion at the national level and $25 million at the local (eight-county) level. These are the highest values of any alternative.

Under Alternative D, recreational expenditures by visitors and the number of jobs and income that would be created in the six-county area in Arizona and Utah would be similar to those under Alternative A (Tables 4.14-4 and 4.14-5). Private boating in Lake Mead and Lake Powell would produce the largest number of jobs and income, amounting to 7,546 jobs and $307.8 million in income annually over the 20-year study period, a difference of 0.1% compared to Alternative A. Impacts on river-based recreational activities would be the same as those for Alternative A. A total of 7,702 jobs and $311.4 million in income would be produced annually across all reservoir and river recreational activities under Alternative D over the 20-year LTEMP period.

Under Alternative D, there would be an estimated average 21.1 HFEs over the LTEMP period and a maximum of 14 HFE days in a calendar year. Although HFEs would preclude angling during their implementation, their impact on employment and income generated by shore and boat angling, and from angler spending on fishing licenses, is expected to be negligible.

Reductions in use value and economic impact associated with reservoir-based recreational activities under Alternative D compared to Alternative A would come primarily as a result of changes in reservoir water levels, which would mean differences in exposure of beaches and mudflats, and consequently a change in the quality of recreational experience, as well as reduced visitor spending. Changes in use values associated with Glen Canyon angling and Upper and Lower Grand Canyon private whitewater boating and commercial whitewater boating 1-day trips would be primarily related to the shifting of monthly volumes away from seasons of the year more popular with visitors. Use values for Glen Canyon day-use rafting, Lower Grand Canyon commercial overnight boating trips, and commercial flat-water boating would not change, because demand for these activities would not be affected by river levels or fluctuations in flow under this alternative. With no changes in visitation for any of the river-based activities, there would be no change in the economic impact of these activities under Alternative D compared to Alternative A.

[36] Adjustments made to Alternative D after modeling was completed (see Section 2.2.4) are not expected to result in a change in Alternative D's impacts on socioeconomic or environjmental justice impacts.

In addition to changes in generation and marketable capacity resulting from changes in Glen Canyon Dam operations under Alternative D, there would also be forecasted increases in the demand for electricity in the service territories of the eight largest WAPA customer utilities and the planned retirement of existing powerplant generating capacity, meaning that an estimated 5,050 MW of new capacity would be built under Alternative D over the 20-year LTEMP period. Using estimated capital and operating costs associated with providing additional capacity, powerplant construction would produce 9,895 total (direct and indirect) jobs in the seven-state region, a difference of 3.9% compared to Alternative A, and $875.3 million in earnings. Operation of new powerplants under Alternative D would create 1,065 total jobs and $72.5 million in annual earnings associated with new jobs.

Although costs associated with replacing generation capacity no longer provided at Glen Canyon Dam would mean changes in retail rates charged by WAPA customer utilities, and consequently changes in the electric bills of residential customers, the cost of additional capacity required to replace capacity lost at Glen Canyon Dam under Alternative D would have impacts on electric bills paid by residential customers of the eight largest WAPA customer utilities and would mean the loss of less than 10 total (direct and indirect) jobs and $0.4 million in earnings in the seven-state region.

With no change in river visitation there would be no impacts on Tribal river boat rental operators or Tribal retailing in the vicinity of GCNRA and GCNP under Alternative C, and the impacts of changes in reservoir visitation on Tribal marina operators would be negligible. Access or damage to culturally important plants and resources would be negligible, but impacts on Tribal values related to TMFs and mechanical removal of trout would be adverse. Financial impacts on Tribes related to electricity sales would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A.

In summary, under Alternative D there would be a decline in use values associated with Lake Powell recreation, Glen Canyon angling, Upper Grand Canyon private and commercial whitewater boating, and Lower Grand Canyon commercial whitewater 1-day trips compared to Alternative A. There would also be a decline in economic activity associated with Lake Powell recreation. There would be no change in use values associated with Glen Canyon day-use rafting, Lower Grand Canyon commercial whitewater boating overnight trips, or commercial flatwater boating. There would also be no change in economic activity associated with river recreation. There would be an increase in use values for Lower Grand Canyon private whitewater boating and use values and economic activity associated with Lake Mead recreation. There would be increased economic activity from customer utility capacity expansion compared to Alternative A, and reduced economic activity as a result of higher residential electric bills.

4.14.3.5 Alternative E

Under Alternative E, total use values associated with recreation in Lake Powell and the Upper and Lower Grand Canyon would decrease slightly relative to Alternative A, while increasing for Lake Mead (Table 4.14-2). General recreational activities in Lake Mead would produce $9,143.5 million (0.3% increase) in use value and $4,990.1 million (0.5% decrease) at

Lake Powell, while commercial and private whitewater boating would produce $249.9 million (12.9% decrease) and $67.4 million (a 2.3% decrease), respectively, in the Upper Grand Canyon; other activities in the Lower Grand Canyon would produce lower use values.

Estimated per-household willingness-to-pay values associated with the impact of dam operations under Alternative E on humpback chub populations and sandbars in the Grand Canyon are estimated to be $4.0 billion at the national level and $23 million at the local (eight-county) level.

Under the Alternative E, recreational expenditures by visitors and the number of jobs and income that would be created in the six-county area in Arizona and Utah would be similar to those under Alternative A (Tables 4.14-4 and 4.14-5). Private boating in Lake Mead and Lake Powell would produce the largest number of jobs and income, amounting to 7,546 jobs and $307.8 million in income annually over the 20-year study period, a difference of 0.1% compared to Alternative A. Impacts on river-based recreational activities would be the same as those under Alternative A. A total of 7,702 jobs and $311.4 million in income would be produced annually across all reservoir and river recreational activities under Alternative E over the 20-year LTEMP period.

Under Alternative E, there would be an estimated average 17.1 HFEs over the LTEMP period and a maximum of 8 HFE days in a calendar year. Although HFEs would preclude angling during their implementation, their impact on employment and income generated by shore and boat angling, and from angler spending on fishing licenses, is expected to be negligible.

Small reductions in use value and economic impact associated with reservoir-based recreational activities under Alternative E compared to Alternative A would result primarily from changes in reservoir water levels, which would mean differences in exposure of beaches and mudflats, and consequently a change in the quality of recreational experience and reduced visitor spending. Changes in use values associated with Glen Canyon angling and Upper and Lower Grand Canyon private whitewater boating and commercial whitewater boating 1-day trips would be primarily related to the shifting of monthly volumes away from seasons of the year that are more popular with visitors. Use values for Glen Canyon day-use rafting, Lower Grand Canyon commercial overnight boating trips, and commercial flat-water boating would not change, because demand for these activities would not be affected by river levels or fluctuations in flow under this alternative. With no changes in visitation for any of the river-based activities, there would be no change in the economic impact of these activities under Alternative E compared to Alternative A.

In addition to changes in generation and marketable capacity resulting from changes in Glen Canyon Dam operations under Alternative E, there would also be forecasted increases in the demand for electricity in the service territories of the eight largest WAPA customer utilities and the planned retirement of existing powerplant generating capacity, meaning that an estimated 5,050 MW of new capacity would be built under Alternative E over the 20-year LTEMP period. Using estimated capital and operating costs associated with providing additional capacity, powerplant construction would produce 9,895 total (direct and indirect) jobs in the seven-state region, a difference of 3.9% compared to Alternative A, and $875.3 million in earnings.

Operation of new powerplants under Alternative E would create 1,065 total jobs and $72.5 million in annual earnings associated with new jobs.

Although costs associated with replacing generation capacity no longer provided at Glen Canyon Dam would mean changes in retail rates charged by WAPA customer utilities, and consequently changes in the electric bills of residential customers, the cost of additional capacity required to replace capacity lost at Glen Canyon Dam under Alternative E would only have negligible impacts on electric bills paid by residential customers of the eight largest WAPA customer utilities, and would mean the loss of less than 10 total (direct and indirect) jobs and $0.3 million in earnings in the seven-state region.

With no change in river visitation there would be no impacts on Tribal river boat rental operators and Tribal retailing in the vicinity of GCNRA and GCNP under Alternative E, and the impacts of changes in reservoir visitation on Tribal marina operators would be negligible. Access or damage to culturally important plants and resources would be negligible, but impacts on Tribal values related to TMFs and mechanical removal of trout would be adverse. Financial impacts on Tribes related to electricity sales would be slightly higher (<$1.00/MWh) than those on non-Tribal customers, and those under Alternative A.

In summary, under Alternative E there would be a decline in use values associated with Lake Powell recreation, Glen Canyon angling, Upper Grand Canyon private and commercial whitewater boating, and Lower Grand Canyon commercial whitewater 1-day trips compared to Alternative A. There would also be a decline in economic activity associated with Lake Powell recreation. There would be no change in use values associated with Glen Canyon day-use rafting, Lower Grand Canyon private whitewater boating, commercial whitewater boating overnight trips, or commercial flatwater boating. There would also be no change in economic activity associated with river recreation. There would be an increase in use values and economic activity associated with Lake Mead recreation. There would be increased economic activity from customer utility capacity expansion compared to Alternative A, and reduced economic activity as a result of higher residential electric bills.

4.14.3.6 Alternative F

Under Alternative F, total use values associated with recreation in Lake Powell, and the Upper and Lower Grand Canyon would decrease slightly relative to Alternative A, while increasing for Lake Mead (Table 4.14-2). General recreational activities in Lake Mead would produce $9,157.5 million (0.5% increase) in use value and $4,961.0 million (1.1% decrease) at Lake Powell, while commercial and private whitewater boating in the Upper Grand Canyon would produce $280.2 million (2.3% decrease) and $69.2 million (0.4% increase), respectively; other activities in the Lower Grand Canyon would produce lower use values.

Estimated per-household willingness-to-pay values associated with the impact of dam operations under Alternative F on humpback chub populations and sandbars in the Grand Canyon are estimated to be $2.4 billion at the national level and $11 million at the local (eight-county) level.

Under Alternative F, recreational expenditures by visitors and the number of jobs and income that would be created in the six-county area in Arizona and Utah would be similar to those under Alternative A (Tables 4.14-4 and 4.14-5). Private boating in Lake Mead and Lake Powell would produce the largest number of jobs and income, amounting to 7,542 jobs and $307.6 million in income annually over the 20-year LTEMP period, a difference of 0.02% compared to Alternative A. Impacts on the various river-based recreational activities would be the same as those under Alternative A. A total of 7,697 jobs and $311.2 million in income would be produced annually across all reservoir and river recreational activities under Alternative F over the 20-year LTEMP period.

Under Alternative F, there would be an estimated average 38.1 HFEs over the LTEMP period and a maximum of 8 HFE days in a calendar year. Although HFEs would preclude angling during their implementation, their impact on employment and income generated by shore and boat angling, and from angler spending on fishing licenses, is expected to be negligible.

Small reductions in use value and economic impact associated with reservoir-based recreational activities under Alternative F compared to Alternative A would come primarily as a result of changes in reservoir water levels, which would mean differences in exposure of beaches and mudflats, and consequently a change in the quality of recreational experience and reduced visitor spending. Changes in use values associated with Glen Canyon angling and Upper and Lower Grand Canyon private whitewater boating and commercial whitewater boating 1-day trips would be primarily related to the large shifts in monthly volumes; although the high volumes of May and June would result in higher use value during those months, the very low flows for much of the rest of the year would result in lower use value at those times. Use values for Glen Canyon day-use rafting, Lower Grand Canyon commercial overnight boating trips, and commercial flat-water boating would not change, because demand for these activities would not be affected by river levels under this alternative. With no changes in visitation for any of the river-based activities, there would be no change in the economic impact of these activities under Alternative F compared to Alternative A.

In addition to changes in generation and marketable capacity resulting from changes in Glen Canyon Dam operations under Alternative F, there would also be forecasted increases in the demand for electricity in the service territories of the eight largest WAPA customer utilities, and the planned retirement of existing powerplant generating capacity, meaning that an estimated 5,280 MW of new capacity would be built under Alternative F over the 20-year study period. Using estimated capital and operating costs associated with providing additional capacity, powerplant construction would produce 10,286 total (direct and indirect) jobs in the seven-state region, a difference of 8.1% compared to Alternative A, and $909.6 million in earnings. Operation of new powerplants under Alternative F would create 1,114 total jobs and $75.7 million in annual earnings associated with new jobs.

Although costs associated with replacing generation capacity no longer provided at Glen Canyon Dam would mean changes in retail rates charged by WAPA customer utilities, and consequently changes in the electric bills of residential customers, the cost of additional capacity required to replace capacity lost at Glen Canyon Dam under Alternative F would only have negligible impacts on electric bills paid by residential customers of the eight largest WAPA

customer utilities, and would mean the loss of 41 total (direct and indirect) jobs and $1.9 million in earnings in the seven-state region.

With no change in river visitation there would be no impacts on Tribal river boat rental operators and Tribal retailing in the vicinity of GCNRA and GCNP under Alternative F, although changes in reservoir visitation would be sufficient to affect Tribal marina operators. Access or damage to culturally important plants and resources would also be affected under Alternative F. No impacts on Tribal values related to TMFs or mechanical removal of trout would occur because these actions are not allowed under this alternative. Financial impacts on Tribes related to electricity sales would be slightly higher (<$1.00/MWh) from those on non-Tribal customers, and would be greater (as much as $3.26/MWh) than those under Alternative A.

In summary, under Alternative F there would be a decline in use values associated with Lake Powell recreation, Glen Canyon angling, Upper Grand Canyon commercial whitewater boating, and Lower Grand Canyon commercial whitewater 1-day trips compared to Alternative A. There would also be a decline in economic activity associated with Lake Powell recreation. There would be no change in use values associated with Glen Canyon day-use rafting, Lower Grand Canyon commercial whitewater boating overnight trips, or commercial flatwater boating. There would also be no change in economic activity associated with river recreation. There would be an increase in use values in Upper and Lower Grand Canyon private whitewater boating and in use values economic activity associated with Lake Mead recreation. There would be increased economic activity from customer utility capacity expansion compared to Alternative A, and reduced economic activity as a result of higher residential electric bills.

4.14.3.7 Alternative G

Under Alternative G, total use values associated with recreation in Lake Powell, and the Upper and Lower Grand Canyon would decrease slightly relative to Alternative A, while increasing for Lake Mead (Table 4.14-2). General recreational activities in Lake Mead would produce $9,143.3 million (0.3% increase) in use value and $4,997.1 million (0.4% decrease) at Lake Powell, while commercial and private whitewater boating would produce $247.6 million (13.7% decrease) and $68.5 million (a 0.6% decrease), respectively, in the Upper Grand Canyon; other activities in the Lower Grand Canyon would produce lower use values.

Estimated per-household willingness-to-pay values associated with the impact of dam operations under Alternative G on humpback chub populations and sandbars in the Grand Canyon are estimated to be $3.5 billion at the national level and $19 million at the local (eight-county) level.

Under Alternative G, recreational expenditures by visitors and the number of jobs and income that would be created in the six-county area in Arizona and Utah would be similar to those under Alternative A (Tables 4.14-4 and 4.14-5). Private boating in Lake Mead and Lake Powell would produce the largest number of jobs and income, amounting to 7,550 jobs and $308.0 million in income annually over the 20-year LTEMP period, a difference of 0.1% compared to Alternative A. Impacts on river-based recreational activities would be the same as

those under Alternative A. A total of 7,706 jobs and $311.6 million in income would be produced annually across all reservoir and river recreational activities under Alternative G over the 20-year LTEMP period.

Under Alternative G, there would be an estimated average 24.5 HFEs over the LTEMP period and a maximum of 18 HFE days in a calendar year. Although HFEs would preclude angling during their implementation, their impact on employment and income generated by shore and boat angling, and from angler spending on fishing licenses, is expected to be negligible.

Small reductions in use value and economic impact associated with reservoir-based recreational activities under Alternative G compared to Alternative A would come primarily as a result of changes in reservoir water levels, which would mean differences in exposure of beaches and mudflats, and consequently a change in quality of recreational experience and reduced visitor spending. Changes in use values associated with Glen Canyon angling and Upper and Lower Grand Canyon private whitewater boating and commercial whitewater boating 1-day trips would be primarily related to the equal monthly volumes that would occur year-round, and consequently lower flows during the more popular summer months. Use values for Glen Canyon day-use rafting, Lower Grand Canyon commercial overnight boating trips, and commercial flat-water boating would not change, because demand for these activities would not be affected by river levels under this alternative. With no changes in visitation for any of the river-based activities, there would be no change in the economic impact of these activities under Alternative G compared to Alternative A.

In addition to changes in generation and marketable capacity resulting from changes in Glen Canyon Dam operations under Alternative G, there would also be forecasted increases in the demand for electricity in the service territories of the eight largest WAPA customer utilities and the planned retirement of existing powerplant generating capacity, meaning that an estimated 5,050 MW of new capacity would be built under Alternative G over the 20-year study period. Using estimated capital and operating costs associated with providing additional capacity, powerplant construction would produce 9,895 total (direct and indirect) jobs in the seven-state region, a difference of 3.9% compared to Alternative A, and $875.3 million in earnings. Operation of new powerplants with Alternative G would create 1,065 total jobs and $72.5 million in annual earnings associated with new jobs.

Although costs associated with replacing generation capacity no longer provided at Glen Canyon Dam would mean changes in retail rates charged by WAPA customer utilities, and consequently changes in the electric bills of residential customers, the cost of additional capacity required to replace capacity lost at Glen Canyon Dam under Alternative G would have impacts on electric bills paid by residential customers of the eight largest WAPA customer utilities, and would mean the loss of 25 total (direct and indirect) jobs and $1.2 million in earnings in the seven-state region.

With no change in river visitation there would be no impacts on Tribal river boat rental operators and Tribal retailing in the vicinity of GCNRA and GCNP under Alternative G, and the impacts of changes in reservoir visitation on Tribal marina operators would be negligible. Access or damage to culturally important plants and resources would be negligible, but impacts on

Tribal values related to TMFs and mechanical removal of trout would be adverse. Financial impacts on Tribes related to electricity sales would be higher (as much as $1.34/MWh) from those on non-Tribal customers, and would be greater (as much as $2.84/MWh) than those under Alternative A.

In summary, under Alternative G there would be a decline in use values associated with Lake Powell recreation, Glen Canyon angling, Upper Grand Canyon private and commercial whitewater boating, and Lower Grand Canyon commercial whitewater 1-day trips compared to Alternative A. There would also be a decline in economic activity associated with Lake Powell recreation. There would be no change in use values associated with Glen Canyon day-use rafting, Lower Grand Canyon commercial whitewater boating overnight trips, or commercial flatwater boating. There would also be no change in economic activity associated with river recreation. There would be an increase in use values for Lower Grand Canyon private whitewater boating and in use values and economic activity associated with Lake Mead recreation. There would also be increased economic activity from customer utility capacity expansion, compared to Alternative A, and reduced economic activity as a result of higher residential electric bills.

4.15 AIR QUALITY

This section describes potential impacts of the LTEMP alternatives on ambient air quality in the immediate vicinity of GCNP and over the 11-state study area within the Western Interconnection, where the air quality would potentially be affected by the proposed action. The regional air quality setting is described in Section 3.15.

Issue: How do alternatives affect emissions from other facilities and air quality in the Grand Canyon area and in the 11-state study area?

Impact Indicators:

- Visibility effects from sulfates and nitrates
- SO_2 and NO_x emissions

4.15.1 Analysis Methods

Glen Canyon Dam hydropower generation does not generate air emissions. However, dam operations can affect emissions within the SLCA/IP system, which is referred to here as "the system." It also impacts emissions and ambient air quality over the 11-state Western Interconnection region, which includes Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming, because hydropower generation offsets generation from other generating facilities (i.e., coal-fired, natural gas-fired,) in the Western Interconnection. Differences among alternatives in the amount of generation at peak demand hours could affect regional air emissions, if lost generation was offset by generation from coal, natural gas, or oil units.

Air quality issues within the study area are discussed in Section 3.15 and notably include visibility degradation in Federal Class I areas. Coal, natural gas, and oil units emit SO_2 and NO_x, which are precursors to sulfate and nitrate aerosols, respectively. These aerosols play an important role in visibility degradation by contributing to haze. Among anthropogenic sources,

sulfate is a primary contributor to regional haze in the Grand Canyon, and nitrate is a minor contributor. Effects on visibility are analyzed through a comparison of regional SO_2 and NO_x emissions under the various alternatives.

To compute total air emissions under the alternatives, emissions were summed from all generating facilities in the SLCA/IP system. This analysis was based on the analysis performed for hydropower, which estimated electrical power contributions for the same facilities (results are discussed in Section 4.13). Emissions were computed according to the estimated electricity generation of each facility and for electricity traded on the spot market under each alternative by calendar year. The spot market represents the interface of the system with the greater Western Interconnection region and accounts for effects of Glen Canyon Dam operations outside of the system. For individual powerplants in the system, pollutant emission factors (in pounds per megawatt-hour [lb/MWh]) available in the *Emissions & Generation Resource Integrated Database* (eGRID) (EPA 2014a) were used to compute emissions. For unspecified powerplants (e.g., long term contract), composite emission factors were employed that are representative of power generation from all types of powerplants currently in operation over the Western Interconnection. Composite emission factors are estimated to be 0.74 and 1.07 lb/MWh for SO_2 and NO_x, respectively. For spot market purchases and sales, composite emission factors were used that are representative of power generation from gas powerplants currently in operation over the Western Interconnection, based on the assumption that spot market generation is primarily to serve peak loads. Composite emission factors are estimated to be 0.0083 and 0.266 lb/MWh for SO_2 and NO_x, respectively. For advanced natural-gas-fired simple cycle and combined cycle generating units to be built in the future, emission factors in EIA (2013) were used: 0.001 lb/MMBtu for SO_2 for both simple cycle (0.0098 lb/MWh) and combined cycle (0.0064 lb/MWh); 0.03 lb/MMBtu (0.29 lb/MWh) for simple cycle and 0.0075 lb/MMBtu (0.048 lb/MWh) for combined cycle for NO_x. Note the difference in the expression of emission factors employed from different sources. Emission factors for existing plants and the spot market are based on emissions per electricity output, while those for future plants are based on emissions per heat energy input (fuel burned). To make comparable estimates, the thermal efficiency of the plant must be taken into account for the latter case.

Potential impacts on regional ambient air quality associated with dam operations are compared in terms of air emissions among alternatives relative to air emissions for Alternative A (No Action Alternative).

4.15.2 Summary of Impacts

The geographic area of potential impacts consists of the GCNP vicinity and the 11-state Western Interconnection region. Table 4.15-1 presents potential impacts on ambient air quality that would likely result from each alternative. Due to very small differences in SO_2 and NO_x precursor emissions, negligible differences are expected among the alternatives with regard to visibility and haze in the region.

TABLE 4.15-1 Summary of Impacts of LTEMP Alternatives on Visibility and Regional Air Quality

Air Quality	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Overall summary of impacts	No change from current conditions	Negligible increase (0.01%) in SO_2 and NO_x emissions compared to Alternative A	Negligible decrease (–0.01%) in SO_2 emissions and no change in NO_x emissions compared to Alternative A	No change in SO_2 emissions and negligible increase in NO_x emissions compared to Alternative A	Negligible increase (<0.005%) in SO_2 and NO_x emissions compared to Alternative A	Negligible decrease (–0.04%) in SO_2 and NO_x emissions compared to Alternative A	Negligible decrease (–0.03%)in SO_2 and negligible increase in NO_x emissions compared to Alternative A
Visibility[a]	No change from current conditions	No change from Alternative A	No change from Alternative A	No change from Alternative A	No change from Alternative A	No change from Alternative A	No change from Alternative A
Air Quality in 11-State Western Interconnection Region							
SO_2 emissions (tons/yr)[b]	42,465	42,471	42,463	42,465	42,466	42,448	42,453
	No change from current conditions	Negligible increase (0.01%)	Negligible reduction (–0.01%)	No change from current conditions	Negligible increase (<0.005%)	Negligible reduction (–0.04%)	Negligible reduction (–0.03%)
NO_x emissions (tons/yr)[b]	78,496	78,501	78,496	78,503	78,500	78,487	78,498
	No change from current conditions	Negligible increase (0.01%)	No change from current conditions	Negligible increase (0.01%)	Negligible increase (<0.005%)	Negligible reduction (–0.01%)	Negligible increase (<0.005%)

[a] Visibility effects are estimated from expected changes in the emissions of sulfate and nitrate precursors, SO_2 and NO_x.

[b] Total air emissions and percent change in emissions (compared to Alternative A) from combustion-related powerplants in the system averaged over the 20-year LTEMP period.

Source: EPA (2014b).

Differences in emissions, and thus in impacts on air quality, under the LTEMP alternatives depend on four factors that may act to increase or decrease total emissions under a given alternative. These factors include:

- Total electricity generation at Glen Canyon Dam;
- Generation profile as characterized by the hourly, daily, and monthly release pattern;
- Amount and timing of needed replacement capacity needed to offset reduced Glen Canyon Dam capacity; and

- Amount of exports and imports of electricity to and from the spot market.

As total generation decreases, overall emissions increase because compensating generation includes a component of combustion sources within the system. The differences among the alternatives in total generation are relatively small (<2%), and are related to differences in the amount of water that bypasses the turbines during HFEs.

The generation profile of alternatives reflects the degree to which generation can meet peak demand. During low load periods Glen Canyon Dam electricity production displaces generation from baseload units such as coal-fired units that tend to have high emission rates in pounds (lb) of emissions per MWh generated; on-peak Glen Canyon generation displaces peaking unit production, typically natural gas-fired combustion turbines, which have lower emission rates than coal plants. Alternatives that have greater Glen Canyon Dam peaking generation have reduced Glen Canyon Dam baseload generation and vice versa, given approximately equal total flow volumes among the alternatives. Thus, fluctuating flow alternatives with greater Glen Canyon Dam peaking power and lower baseload power tend to result in higher SO_2 and NO_x emissions system-wide due the greater use of coal-fired facilities within the system to compensate for reduced baseload generation at Glen Canyon Dam. Coal-fired facilities have approximately an order of magnitude higher SO_2 and significantly higher NO_x emissions than gas-fired facilities for a given amount of generation. Coal plants also produce more CO_2, a greenhouse gas, than do gas-fired plants. Effects of greenhouse gas emissions are discussed in Section 4.16.

The amount and timing of needed replacement capacity can also have an effect on total emissions. Steady flow alternatives, which do not include load following have reduced effective capacity, or maximum generating level, which must be compensated for by the construction and operation of new generation facilities in the system to meet current and future demands during peak load periods. New capacity is required sooner under steady flow alternatives (Section K.1.10.2 in Appendix K). New units would tend to be cleaner, more efficient, and less expensive to operate and therefore would tend to displace generation from higher emitting old units that serve the same type of duty (i.e., peaking unit) and would thus tend to reduce system emissions slightly relative to fluctuating flow alternatives. Construction of new capacity and retirement of existing plants are included in the hydropower analysis (Section 4.13) and in this air quality analysis.

The relative amounts of exports and imports to and from the spot market also can affect total emissions. Alternatives with greater net exports (sales) from the SLCA/IP system to the spot market tend to have greater total emissions since fossil-fired powerplants in the SLCA/IP system tend to have higher emission rates than Western Interconnection powerplants in states which purchase the electricity, mostly in California. When the system buys external energy to serve electricity demand, it needs to produce less power from its own internal resources thereby reducing pollutants emitted by the system. Conversely, when the system sells power to the Western Interconnection, it increases power production to support the spot energy transaction. Emissions associated with spot market sales are accounted for because unit-level generation for all facilities in the system (including the amount required for a sale) is multiplied by plant-level

emission factors. On the other hand, this exported energy via a spot market transaction will reduce both generation and emissions in the overall 11-state Western Interconnection.

These factors have relatively small effects on emissions, and operate in sometimes opposing directions with regard to total system emissions of SO_2, NO_x and CO_2. Thus, although total emissions under the various alternatives are relatively similar, the relative differences result from a complex combination of these four factors that can only be understood through detailed modeling of emissions from individual generating facilities within the system under each of the alternatives. The following paragraphs present the results of such modeling.

Electricity generation averaged over the LTEMP period at Glen Canyon Dam for each alternative is shown in Figure 4.15-1. Little difference exists among alternatives, which range from 4,178 to 4,255 GWh per year. Other powerplants in the system can be fossil fuel–fired, renewable, hydro, or nuclear, and they depend on Glen Canyon Dam to provide uninterrupted power to their customers; power generation is thus similarly unchanged among alternatives. Under Alternative A, total SO_2 and NO_x emissions in the system averaged over the 20-year LTEMP period are estimated to be about 42,465 tons/yr and 78,496 tons/yr, which amount to about 10% and 3.0%, respectively, of total SO_2 and NO_x emissions over the Western Interconnection region (see Table 3.16-3). Thus, air emissions from power generators in the system are moderate contributors to total emissions in the Western Interconnection region. As shown in Table 4.15-1, air emissions under other LTEMP alternatives are similar to those under Alternative A. Differences from Alternative A range from –0.04 to 0.01% for SO_2 and from –0.01 to 0.01% for NO_x. Differences in average annual emissions range from –18 to 5 tons/yr for SO_2 and –10 to 6 tons/yr for NO_x, compared to those for Alternative A. Therefore, potential impacts of dam operations under various alternatives on regional air quality would be very small.

Table 4.15-2 presents a breakdown of emission sources by generation technology type for the generation facilities within the system and includes emissions for energy traded on the spot market using a composite emission factor for facilities in the Western Interconnection region. The table also shows power generation from Glen Canyon Dam under the various alternatives relative to Alternative A, which produces the most energy. Alternatives F and G produce relatively less hydropower energy than Alternative A (98.3% and 98.2%, respectively) because they have more HFEs in which a portion of released water bypasses the powerplant turbines.

SO_2 and NO_x emissions within the system are dominated by steam turbine technologies, mainly coal-fired powerplants (Table 4.15-2). Considering generation by facilities within the system (approximately 35 primary facilities), the differences among alternatives in estimated emissions are miniscule, ranging over only 0.05% for SO_2 and 0.02% for NO_x (system subtotal). Estimated differences among alternatives reflect slight differences in the contributions from various powerplant technologies; these are attributed to small differences in baseload and peaking energy provided by Glen Canyon Dam. Gas turbine peaking plant technologies produce lower SO_2 and lower NO_x emissions than baseload coal-fired plants. Thus, offsetting gas turbine peaking power with hydropower from Glen Canyon Dam has a lower effect on total system emissions than does offsetting coal-fired baseload with baseload energy from Glen Canyon Dam.

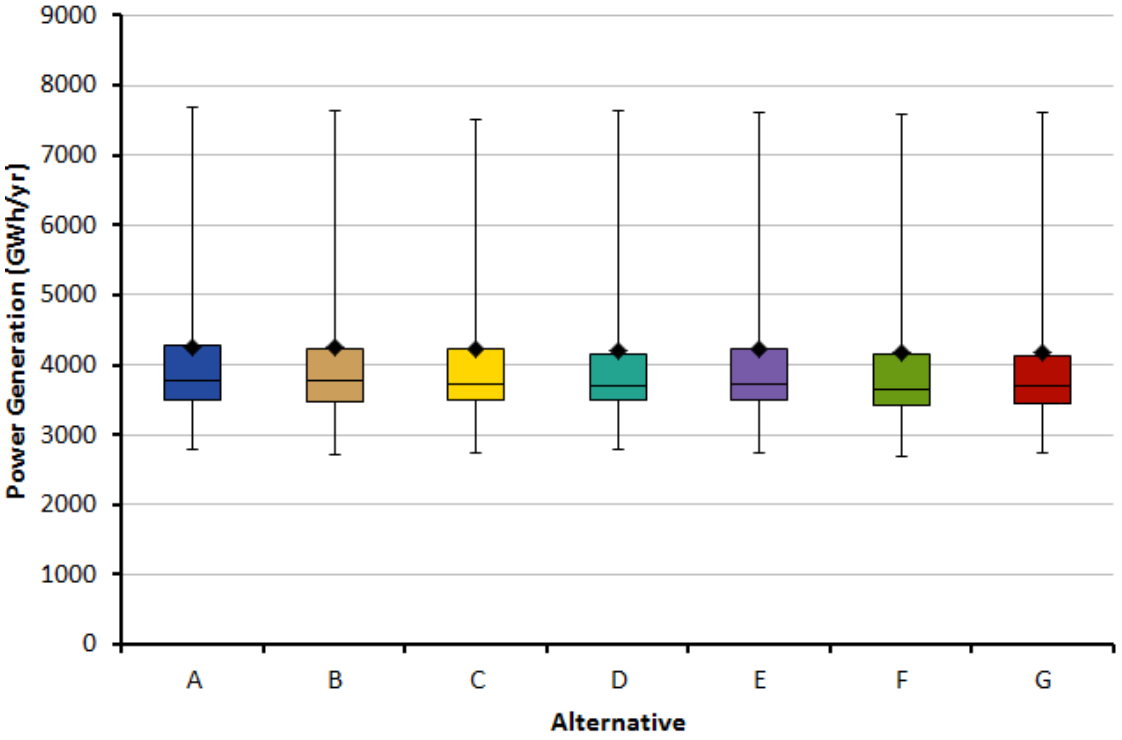

FIGURE 4.15-1 Annual Power Generation by Alternative over the 20-Year LTEMP Period (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

This effect may be seen by comparing emissions subtotals by technology type under fluctuating flow and steady flow alternatives. For both SO_2 and NO_x, steam turbine (coal plant) emissions are slightly lower under Alternatives F and G, reflecting possible reductions in baseload emissions from coal plants offset by increased baseload energy from Glen Canyon Dam, even though these two alternatives generate <2% less Glen Canyon Dam energy than the fluctuating flow alternatives. Likewise, SO_2 emissions for gas technologies are slightly higher for Alternatives F and G, reflecting increased peaking generation from gas plants compensating for lack of peaking ability under these two alternatives.

The effects of the spot market on total system emissions are shown in Table 4.15-2. The spot market contribution to emissions is small (about <0.2% of total emissions from the system); however, for NO_x the spot market contributes about 60% more than the in-system component to differences among alternatives (21 tons/yr and 13 tons/yr, respectively). The spot market has no effect on differences in SO_2 emissions, since spot market emissions are very small and similar (4 tons/yr) (Table 4.15-1). The spot market component is shown as a negative value in the table, reflecting a net export of power from the system. When power is exported (i.e., sold) to a utility outside of the system, it is assumed that the purchaser will generate less energy from its own power resources, resulting in lower total emissions in the Western Interconnection region. Therefore, we apply an emissions credit for energy that is bought by utilities outside of the system. Because we do not model external utilities in detail, we cannot pinpoint the exact source

TABLE 4.15-2 Distributions of SO_2 and NO_x Emissions Averaged over the 20-Year LTEMP Period by Alternative

	Alternative						
Generation Type	A (No Action Alternative)	B	C	D (Preferred Alternative)	E	F	G
Total Glen Canyon Dam Power Generation Relative to Alternative A (MW-hr/day) (% of Alternative A)	11,650 (100%)	11,616 (99.7%)	11,566 (99.3%)	11,525 (98.9%)	11,571 (99.3%)	11,449 (98.3%)	11,438 (98.2%)
SO_2 Emissions (tons per year)							
System Power Generation							
Combined Cycle	44	44	44	44	44	44	44

[a] Unspecified generation type.

[b] "Sales" refers to sales of power by system utilities to non-system utilities within the Western Interconnection. Sales result in a net credit to total Western Interconnection emissions, because the sales result in a reduction in emissions from those non-system utilities that are purchasing the power. "Purchases" refers to purchases by system utilities from non-system utilities within the Western Interconnection. Emissions related to these purchases are added to the total emissions in the Western Interconnection.

of this emission reduction. Therefore, we use composite emission factors representative of power generation in the 11-state Western Interconnection region. Note, however, that since we model all generating resources within the system we are accounting for the increased generation and hence emissions associated with the exported energy.

Net NO_x emissions related to spot market sales and purchases are lowest (greatest negative value) for the steady flow Alternatives F and G, and highest for the fluctuating flow Alternatives B and A. Net SO_2 spot market emissions are essentially the same across alternatives. This result can be explained by considering in-system generation selling to the spot market. Under steady flow Alternatives F and G, the Glen Canyon Dam powerplant does not provide peaking power, while under fluctuating flow Alternatives A-E it does. Since spot market sales typically serve peak demand, NO_x emissions from sales to the spot marker are therefore higher for Alternatives F and G, since other, typically gas-fired, facilities in the system provide peak generation. Such facilities generate NO_x emissions, but very little SO_2, so there is no effect on the latter emission.

Given the very small differences in the estimated emissions after considering all of the factors discussed above and in light of the uncertainty of emissions modeling, it may be concluded that emissions would be similar under all of the alternatives.

4.15.3 Alternative-Specific Impacts

Although differences are expected in potential ambient air quality and associated impacts among the various alternatives, potential air quality impacts are anticipated to be negligible. The modeled differences among alternatives are presented below. Detailed information on alternatives and hydropower assumptions and modeling can be found in Sections 2.3 and 4.13, respectively.

4.15.3.1 Alternative A (No Action Alternative)

Under Alternative A (No Action Alternative), annual power generation at Glen Canyon Dam would range from 2,781 to 7,677 GWh, with an average of 4,225 GWh, over the 20-year LTEMP period. Coal-fired steam plants account for the vast majority of these emissions; that is about 98% of both SO_2 and NO_x emissions. In addition, total LTEMP-related annual air emissions from power generation, system emissions plus changes in the Western Interconnection would range from 41,392 to 42,991 tons/yr with an average of 42,465 tons/yr for SO_2, and from 77,121 to 80,005 tons/yr with an average of 78,496 tons/yr for NO_x. These annual-average emissions for SO_2 would be about 10% and for NO_x would be about 3.0% of the total air emissions over the Western Interconnection region (see Table 3.16-3).

4.15.3.2 Alternative B

Under Alternative B, total LTEMP-related annual-average air emissions are 42,471 tons/yr for SO_2 and 78,501 tons/yr for NO_x; these values are about 0.01% higher than

those under Alternative A. Annual-average power generation at Glen Canyon Dam under this alternative is estimated to be about 99.7% of that under Alternative A. Total annual emissions from power generation in the region are slightly higher than those under Alternative A, due to the combined effects of the four factors described in Section 4.15.2. Consequently, there would be negligible differences in impacts on regional ambient air quality between Alternative B and Alternative A.

4.15.3.3 Alternative C

Under Alternative C, total LTEMP-related annual-average air emissions are 42,463 tons/yr for SO_2 and 78,496 tons/yr for NO_x; these values are about 0.01% lower than and the same as those under Alternative A, respectively. Annual-average power generation at Glen Canyon Dam under this alternative is estimated to be about 99.3% of that under Alternative A. Total annual emissions from power generation in the region are slightly lower than or the same as those under Alternative A, due to the combined effects of the four factors described in Section 4.15.2. Consequently, there would be negligible differences in impacts on regional ambient air quality between Alternative C and Alternative A.

4.15.3.4 Alternative D (Preferred Alternative)[37]

Under Alternative D, total LTEMP-related annual-average air emissions are 42,465 tons/yr for SO_2 and 78,503 tons/yr for NO_x; these values are the same as and about 0.01% higher than those under Alternative A, respectively. Annual-average power generation at Glen Canyon Dam under this alternative is estimated to be about 98.9% of that under Alternative A. Total annual emissions from power generation in the region are the same as or slightly higher than those under Alternative A, due to the combined effects of the four factors described in Section 4.15.2. Consequently, there would be negligible differences in impacts on regional ambient air quality between Alternative D and Alternative A.

4.15.3.5 Alternative E

Under Alternative E, total LTEMP-related annual-average air emissions are 42,466 tons/yr for SO_2 and 78,500 tons/yr for NO_x; these values are about <0.005% higher than those under Alternative A, respectively. Annual-average power generation at Glen Canyon Dam under this alternative is estimated to be about 99.3% of that under Alternative A. Total annual emissions from power generation in the region are slightly higher than those under Alternative A, due to the combined effects of the four factors described in Section 4.15.2. Consequently, there would be negligible differences in impacts on regional ambient air quality between Alternative E and Alternative A.

---

[37] Adjustments made to Alternative D after modeling was completed (see Section 2.2.4) are not expected to result in a change in Alternative D's impacts on air quality.

4.15.3.6 Alternative F

Under Alternative F, total LTEMP-related annual-average air emissions are 42,448 tons/yr for SO_2 and 78,487 tons/yr for NO_x; these values are about 0.04 and 0.01%, respectively, lower than those under Alternative A. Annual-average power generation at Glen Canyon Dam under this alternative is estimated to be about 98.3% of that under Alternative A. Total annual emissions from power generation in the region are slightly lower than those under Alternative A, due to the combined effects of the four factors described in Section 4.15.2. Consequently, there would be negligible differences in impacts on regional ambient air quality between Alternative F and Alternative A.

4.15.3.7 Alternative G

Under Alternative G, total LTEMP-related annual-average air emissions are 42,453 tons/yr for SO_2 and 78,498 tons/yr for NO_x; these values are about 0.03 and <0.005%, respectively, lower and higher than those under Alternative A. Annual-average power generation at Glen Canyon Dam under this alternative is estimated to be about 98.2% of that under Alternative A. Total annual emissions from power generation in the region are slightly lower or higher than those under Alternative A, due to the combined effects of the four factors described in Section 4.15.2. Consequently, there would be negligible differences in impacts on regional ambient air quality between Alternative G and Alternative A.

4.16 CLIMATE CHANGE

Issue: How could the LTEMP affect or be affected by climate change?

Impact Indicators:

- Changes in CO_2 and other GHG emissions under different LTEMP alternatives
- Climate-driven changes in hydrology and sediment inputs over the 20-year LTEMP period

There is the potential for the LTEMP to affect climate change indirectly through changes in dam operations, and for dam operations under the LTEMP to be affected by climate change. Although each of the LTEMP alternatives would generate approximately the same amount of electrical power,[38] there are relatively large differences in the monthly and within-day pattern of releases that affect hydropower capacity. These differences in available capacity affect how other power facilities in the region respond to changes in demand, and in this way can affect the total system emission of carbon dioxide (CO_2) and other greenhouse gases (GHGs) (Section 4.15 describes the effect of Glen Canyon Dam operations on the power system and the emissions of criteria pollutants). In addition to these potential effects on climate change, operations over the 20-year LTEMP period could be

[38] The relatively small expected differences among alternatives in the amount of total annual generation relate to the alternative-specific frequency of HFEs. Approximately 14,000 cfs of a 45,000-cfs HFE would be released through the bypass tubes, which do not generate power. Alternatives differ substantially in the frequency of HFEs (Section 4.2).

affected by climate-driven changes in hydrology (inflow patterns and evaporation rates) and sediment inputs. Reductions in inflow due to changes in precipitation and increases in evaporation rates resulting from increases in temperature could result in decreases in the elevation of Lake Powell, with subsequent reductions in power generation resulting from decreased head, and potentially an increase in the frequency of dropping below the power pool.

4.16.1 Analysis Methods

The analysis of GHG emissions and climate change was conducted based on the latest CEQ Guidance (CEQ 2016). The guidance recommends that NEPA analyses take into account available data and use GHG quantification tools for determining projected GHG emissions, which can be used as a proxy for assessing potential climate change effects of a proposed action and alternatives. In addition, when addressing climate change, agencies should consider: (1) the potential effects of a proposed action on climate change as indicated by changes in GHG emissions; and (2) the effects of climate change on a proposed action and its environmental impacts. These two components of the climate change analysis are provided in Sections 4.16.1.1 and 4.16.1.2, respectively.

4.16.1.1 Effects of LTEMP Alternatives on Climate Change

The buildup of heat-trapping GHGs can over time warm Earth's climate and result in adverse effects on ecosystems and human health and welfare. Thus, cumulative GHG emissions can be used as a surrogate to assess climate-change impacts. Such effects would be global and are not particularly sensitive to GHG source locations because GHGs are mostly long-lived and spread across the entire globe.

Glen Canyon Dam operation does not generate GHG emissions, but dam operations can indirectly affect climate change, regionally and globally, through varying contributions to the total mix of power generation in the region, which also includes coal-fired, natural gas–fired, hydroelectric, nuclear, and renewable generation sources. For the purposes of this analysis, the principal GHG of concern is CO_2, which accounts for more than 99% of GHG emissions related to power generation. However, facility- or technology-specific GHG emission factors also consider other GHGs, such as methane (CH_4) and nitrous oxide (N_2O), albeit to a small degree.

To compute total GHG emissions under the alternatives, emissions were summed from all generating facilities primarily affected by Glen Canyon Dam operations, referred to as "the system," as was done for SO_2 and NO_x for the air quality analysis (Section 4.15). This analysis was based on the analysis performed for hydropower, which estimated electrical power contributions for the same facilities, the results of which are discussed in Section 4.13. GHG emissions were computed according to the estimated annual electricity generation of each facility and for electricity traded on the spot market under each alternative. For individual powerplants, GHG emission factors (in lb/MWh) available in eGRID (EPA 2014a) were used to compute

GHG emissions. For unspecified powerplants (e.g., long-term contract), composite emission factors representative of power generation from all types of powerplants that are currently in operation over the 11-state Western Interconnection region (Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming) were employed. A composite emission factor for GHGs is estimated to be 963 lb/MWh (0.437 MT/MWh) for CO_2 equivalent (CO_2e).[39] For spot market purchases and sales, a composite GHG emission factor for gas powerplants operating in the Western Interconnection was used, and was estimated to be 888 lb/MWh (0.403 MT/MWh) CO_2e. For advanced natural gas–fired generating units projected to be built in the future, an emission factor from the EIA (2013) of 117 lb/MMBtu (0.053 MT/MMBtu) for CO_2 was used for both simple-cycle (1,141 lb/MWh [0.518 MT/MWh]) and combined cycle (752 lb/MWh [0.341 MT/MWh]) units.

Potential impacts on climate change associated with dam operations are evaluated for the LTEMP alternatives though a comparison of GHG emissions to those for Alternative A (no action alternative).

4.16.1.2 Effects of Climate Change on Hydrology and Downstream Resources

The effects of climate change on hydrology were treated as an uncertainty in the analyses of hydrology and downstream resource impacts, rather than by means of a full-fledged climate analysis and adaptation approach. The LTEMP EIS has the more limited scope of evaluating future dam operations, management actions, and experimental options to provide a framework for adaptively managing Glen Canyon Dam over the next 20 years to protect and minimize adverse impacts on downstream natural and cultural resources in GCNRA and GCNP. Accordingly, DOI used a sensitivity analysis approach to see how robust the alternatives would be with regard to their impact on resources under climate change.

The Basin Study (Reclamation 2012e) suggested there could be significant increases in temperature and decreases in water supply to the Colorado River system below Glen Canyon Dam over the next 50 years, driven by global climate change. The magnitude of these changes is uncertain. In addition, there could be changes to sediment input (especially from the Paria and Little Colorado Rivers), driven by complex local and regional climate changes, but the direction and magnitude of these changes are uncertain. Water supply, sediment supply, and temperature are important factors that affect all of the resources under consideration in the LTEMP EIS.

The approach used in this EIS treats climate change as an external uncertainty and analyzes the robustness of the alternatives to uncertainties in the water and sediment inputs. This approach required: (1) use of 21 hydrologic and 3 sediment scenarios based on historic conditions; (2) estimation of the likelihood of the scenarios under climate change; and (3) analysis of the impacts of alternatives under all hydrologic and sediment scenarios. The approach analyzed how robust the alternatives would be to climate change-driven hydrologic and

[39] CO_2e is a measure used to compare the emissions from various GHGs on the basis of their global warming potential, defined as the ratio of heat trapped by one unit mass of the GHG to that of one unit mass of CO_2 over a specific time period (usually 100 years).

sediment inputs. For the climate-change analysis, the 21 hydrologic traces used in the LTEMP analysis were weighted according to their frequency of occurrence (based on mean annual inflow to Lake Powell) in the Basin Study's 112 simulations. Figure 4.16-1 shows the weights assigned to each hydrologic trace. As shown in Figure 4.16-2, the 21 hydrologic traces were not representative of the full range of expected inflow variation under a climate-change scenario and did not include the driest traces expected under climate change. About 30% of the forecast distribution was not captured by the historic traces.

Modeling results for downstream resource effects were generated for the 21 historic hydrology traces and 3 historic sediment traces. For the analyses presented in Sections 4.2 through 4.10, the hydrology traces were weighted equally to represent their equal probability of occurrence in the absence of climate change. The climate-change weights shown in Figure 4.16-1 were applied to the modeled results for each trace to represent their probability of occurrence under climate change.

4.16.2 Summary of Impacts

4.16.2.1 Effects of LTEMP Alternatives on Climate Change

Table 4.16-1 presents total estimated GHG emissions within the system for each alternative. These emissions are an indication of the potential relative impact of the alternatives on climate change.

For estimating GHG emissions attributable to Glen Canyon Dam operations, projected power generation at the dam was averaged over the 20-year LTEMP period (Figure 4.15-1). Little difference exists among the alternatives, which range from 4,178 to 4,255 GWh per year, amounting to 1.8%. Power generation from other powerplants in the system and in the Western Interconnection region also would be similar among alternatives. For Alternative A (no action alternative), total GHG emissions in the system averaged over the 20-year LTEMP period are estimated to be about 55,177,668 MT/yr, which amounts to about 4.5% and 0.81% of total GHG emissions over the Western Interconnection region and the United States, respectively (Table 3.15-3, Section 3.15.3). Thus, GHG emissions from power generation are relatively small contributors to total GHG emissions, both in the region (11 Western Interconnection states) and in the United States.

Changes in total GHG emissions (i.e., emissions from system generation, and spot market sales and purchases) under other LTEMP alternatives relative to Alternative A would range from an increase of 5,900 MT/yr (Alternative B) to 44,522 MT/yr (Alternative F). On a percentage basis, differences from Alternative A would range from 0.011% (Alternative B) to 0.081% (Alternative F). The system includes 35 power generation facilities analyzed individually. The spot market reflects the effects of Glen Canyon Dam operations on the larger Western Interconnection region and represents an offset of about 1% of system emissions (Table 4.16-1).

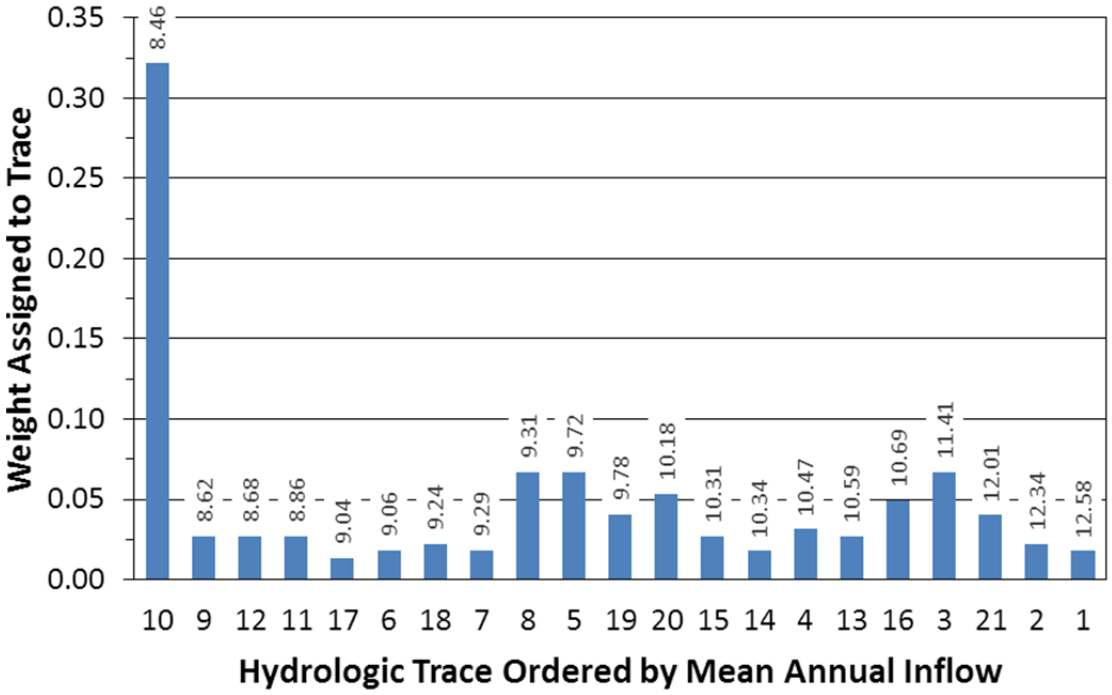

FIGURE 4.16-1 Weights Used To Reflect the Expected Frequency of Hydrologic Conditions under Climate Change (Numbers at top of bars are mean annual inflow of each trace in million acre-feet.)

In light of the 1.8% range in Glen Canyon Dam hydropower generation under the alternatives, and assuming that reduction in hydropower generation at Glen Canyon Dam is made up by fossil fuel generation facilities in the system, the smaller range in GHG emissions of only 0.081% suggests that reduced hydropower energy from, for example, Alternatives F and G does not result in a corresponding increase in GHG emissions from compensating generation at other thermal powerplants in the system. This result may be explained by examining the effects of powerplant mix and capacity expansion on emissions under the various alternatives. With respect to powerplant mix, the Glen Canyon Dam powerplant under the steady-flow Alternatives F and G does not serve peak loads, but does so under the fluctuating-flow Alternatives A through E, offsetting GHG emissions from other peaking facilities in the system, mainly gas turbines. Conversely, steady-flow alternatives can provide a higher level of baseload power, which can offset emissions from other baseload facilities in the system, mainly coal-fired facilities with relatively high GHG emissions compared to gas turbines. More detailed discussion of these factors is presented in Section 4.15.2.

Reviewing projected GHG emissions at specific powerplants within the system, the steady-flow Alternatives F and G, although they result in the highest overall GHG emissions, are expected to result in lower GHG emissions from baseload coal-fired plants (categorized as steam turbine technologies) and higher GHG emissions from gas turbine plants as compared to the fluctuating-flow Alternatives A through E. This comparison supports the conclusion that

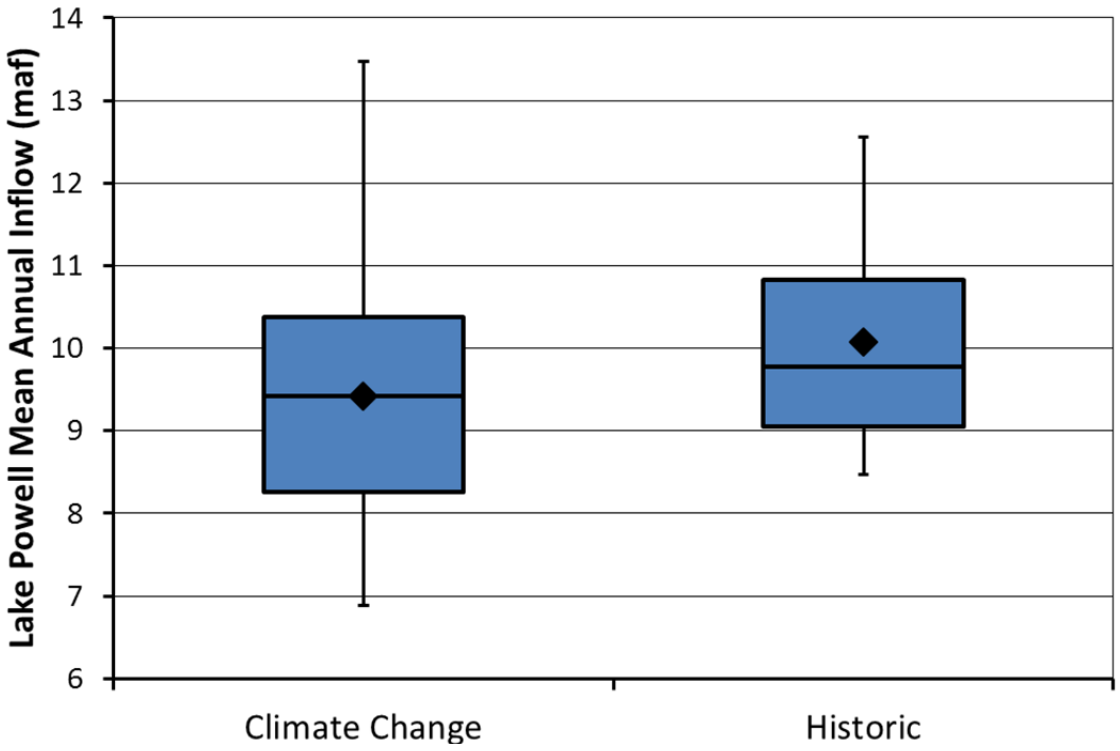

FIGURE 4.16-2 Mean Annual Inflow Showing the Mean, Median, 75th Percentile, 25th Percentile, Minimum, and Maximum Values for 112 Climate-Change Inflow Traces and 21 Historic Inflow Traces (Means were calculated as the average for all years within each of the traces. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

Alternatives F and G tend to offset a relatively greater amount of baseload power at combustion facilities in the system than do Alternatives A through E, while the latter alternatives offset relatively more emissions from gas turbines that provide peaking power.

GHG emissions under the alternatives can also be compared to both total 11-state GHG emissions at 1,226.3 million MT CO_2e in 2010 (see Table 3.15-3) and total U.S. GHG emissions at 6,810.3 million MT CO_2e in 2010 (EPA 2013d) (Table 4.16-1). Differences in emissions from Alternative A range from 0.0005% (Alternative B) to 0.0036% (Alternative F) relative to total 11-state GHG emissions, and from 0.00009% (Alternative B) to 0.00065% (Alternative F) relative to total U.S. GHG emissions.

CO_2, CH_4, and N_2O are emitted from the reservoirs associated with the Glen Canyon Dam, Lake Powell, and Lake Mead. For example, CH_4 from large dams accounted for about 4% of human-caused climate change (Lima et al. 2008). GHG emissions from biomass decay, including CH_4, in such reservoirs, have been a subject of recent debate (Pacca and Horvath 2002). Through consumption of atmospheric CO_2 by photosynthesis in plankton and aquatic plants in reservoirs, net CO_2 emissions from dam operations may be small, and uptake by reservoirs can occasionally exceed emissions. Emissions of CH_4 are possible from turbines and

TABLE 4.16-1 Summary of Impacts of LTEMP Alternatives on GHG Emissions

	GHG Emissions by Alternative (MT/yr)[a,b]						
GHG Emissions Source	A (No Action Alternative)	B	C	D (Preferred Alternative)	E	F	G

[a] GHG emissions are expressed in CO_2e.

[b] GHG emissions (metric tons) from combustion-related powerplants in the system or in the region averaged over the 20-year LTEMP period. To convert from metric ton to ton, multiply by 1.1023.

[c] Unspecified generation type.

[d] "Sales" refers to sales of power by system utilities to non-system utilities within the Western Interconnection. Sales result in a net credit to total Western Interconnection emissions, because the sales result in a reduction in emissions from those non-system utilities that are purchasing the power. "Purchases" refers to purchases by system utilities from non-system utilities within the Western Interconnection. Emissions related to these purchases are added to the total emissions in the Western Interconnection.

[e] Using an online tool from the EPA (https://www.epa.gov/energy/greenhouse-gas-equivalencies-calculator), one can express a given amount of GHG emissions in metric tons in everyday terms. For example, 1 million MT/yr is estimated to be equivalent to the amount of CO_2 that is emitted as a result of the electricity use of 148,000 households. However, because the EPA cautions that these estimates are approximate and should not be used for emission inventory or formal carbon footprinting exercises.

[f] Total 11-state GHG emissions at 1,226.4 million MT/yr CO_2e in 2010 (see Table 3.15-3).

[g] Total U.S. GHG emissions at 6,810.3 million MT/yr CO_2e in 2010 (EPA 2013d).

spillways and downstream of dams. Reservoirs such as Lake Powell and Lake Mead would be expected to produce some amount of GHG emissions consistent with levels reported for reservoirs in the semiarid western United States (Tremblay et al. 2004), but the GHG emissions from these reservoirs are not anticipated to be different among the alternatives.

As discussed in this section, increases in GHG emissions among alternatives compared to Alternative A would be small, ranging from 5,900 MT/yr for Alternative B to 44,522 MT/yr for Alternative F, which corresponds to a 0.011% to 0.081% relative change from Alternative A. However, the totality of climate change impacts is not attributable to any single action. Albeit a small contribution, this project-related emission in combination with a variety of GHG emission sources around the world could exacerbate climate-related impacts, some of which are presented in Section 3.16. In contrast, climate change would be anticipated to have an impact on the proposed action and any alternative actions, such as hydrology and downstream resources, which are discussed in Section 4.16.2.2.

4.16.2.2 Effects of Climate Change on Hydrology and Downstream Resources

As discussed in Section 4.16.1.2, the climate-change analysis approach used the historic hydrology as its basis, but gave greater weight to drier years to represent their expected increased frequency of occurrence under a climate-change scenario. As shown in Figure 4.16-2, this approach underestimated the occurrence of the driest years, but it allows a determination of the robustness of the alternatives to climate-change uncertainty.

Figure 4.16-3 presents the differences between historic and climate-change-weighted values of mean daily flow and mean daily change in flow for the LTEMP alternatives as a percentage of the historic values for the 25th percentile and mean of the two variables. Negative values indicate a decrease in the value under the climate-change scenario, while positive values indicate an increase under the climate-change scenario. Of the values examined (minimum, maximum, 25th percentile, 50th percentile, 75th percentile, and mean), the 25th percentile (representing flow under drier conditions) was the most affected. There was no difference between historic and climate-change-weighted minimum and maximum values, but this is an artifact of the weighting approach used. Because mean monthly volume equals the mean daily flow times the number of days in each month, the percentage differences in that variable are identical to those shown for mean daily flow in Figure 4.16-3. The following conclusions can be drawn from the patterns observed in Figure 4.16-3:

- The 25th percentile values of mean daily flow (and mean monthly volume values) would be very similar from October through March under climate-change and historic scenarios for all alternatives. The differences for all alternatives between historic and climate-change scenarios would increase month-by-month through August. The trend is toward lower mean daily flows under climate change, which reaches a maximum difference of about 10% to 18% (decrease from historic values) in August. In general, the differences among alternatives with respect to the effects of climate change on mean daily flow would be similar.

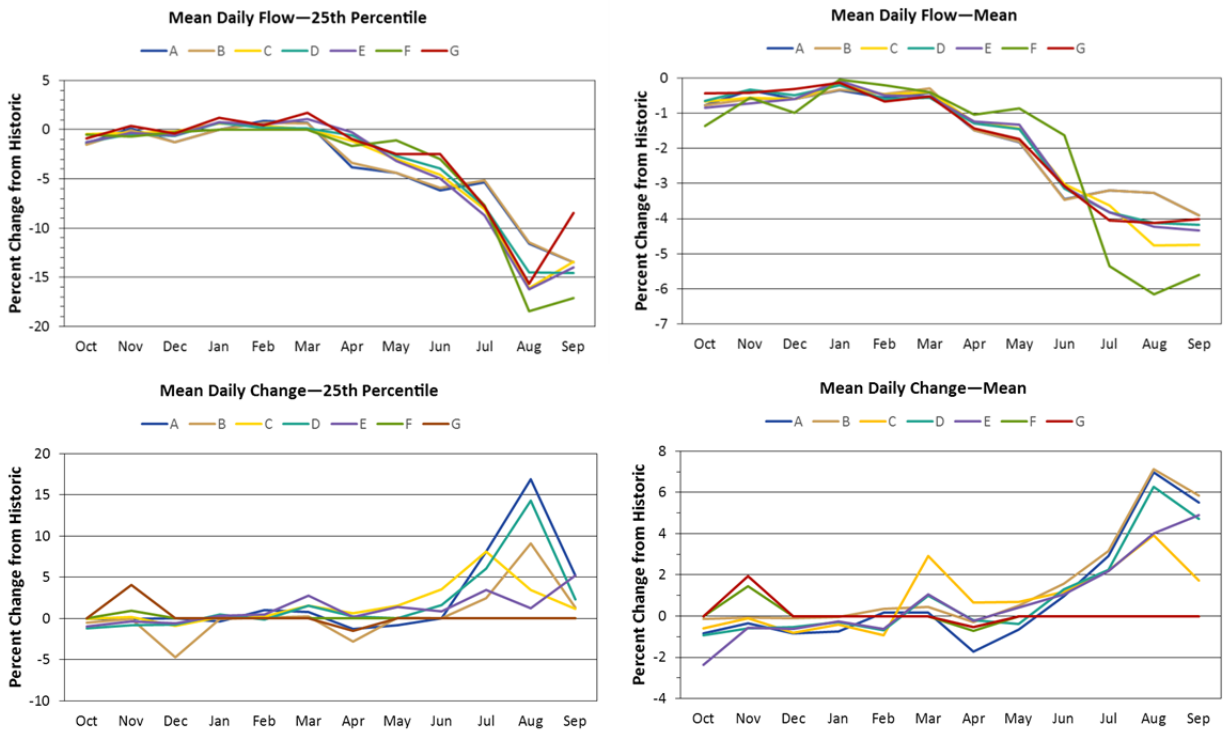

FIGURE 4.16-3 Differences between Historic and Climate-Change-Weighted Values of Mean Daily Flow and Mean Daily Change in Flow by Month for LTEMP Alternatives

- Mean values of mean daily flow (and values of mean monthly volume) would follow a pattern similar to that of the 25th percentile values of mean daily flow, but the differences between historic and climate-change scenarios would not be as great. The differences would be greatest under Alternative F in July and August, when flow would be even lower with climate change than under other alternatives.

The 25th percentile values of mean daily change under the climate-change scenario would be very similar to historic values from October through June for all alternatives, but would be higher than historic for July, August, and September for all alternatives except for the steady-flow Alternatives F and G. Under the drier conditions of climate change and lower mean daily flows, there is more flexibility to provide a wider range of flows within a day and still meet other operational constraints. It should be noted that the differences in mean daily change would be less than 1,000 cfs.

- Mean values of mean daily change would follow a pattern similar to that of the 25th percentile values of mean daily change, but the differences between historic and climate-change scenarios would not be as great. The differences would be greatest under Alternatives A, B, and D in August, when daily change would be even higher with climate change than under other alternatives.

The monthly increase in climate-change effects in mean daily flow and mean monthly volume results from operation of the dam based on the inflow forecast for the water year. Typically, operations in October, November, and December use volumes for an 8.23-maf year, with adjustments made in later months as forecasts indicate a drier or wetter year (Figure 4.2-1). Early forecasts (e.g., January) are subject to considerable uncertainty, and it is usually not until the April forecast that a reasonable identification of the annual volume can be made. Using this operational strategy under climate change would result in less water needing to be released after April, and therefore an increasing deviation from the historic pattern.

These differences in hydrology would influence the relative effect of LTEMP alternatives on resources, but, in general, the analysis conducted for this EIS indicates the differences would be relatively small (<5%) and not differ greatly among alternatives. Table 4.16-2 provides an overview of the expected effects on downstream resources. Under climate change, the impacts of most or all LTEMP alternatives would be less on sediment resources, humpback chub, trout, riparian vegetation, Grand Canyon cultural resources, Tribal values, and most recreation metrics, but there would be a reduction in the value of hydropower generation and capacity and an increase in impacts on Glen Canyon cultural resources.

4.16.3 Alternative-Specific Impacts

There are expected to be some differences in the emissions of GHGs among the LTEMP alternatives, as presented in this section. Detailed information on alternatives and hydropower assumptions and modeling can be found in Sections 2.3 and 4.13, respectively. The effects of climate change on hydrology and downstream resources are also presented.

4.16.3.1 Alternative A (No Action Alternative)

Under Alternative A (no action alternative), annual power generation would range from 2,781 to 7,677 GWh, with an average of 4,255 GWh over the 20-year (2014–2033) period. Total annual GHG emissions in the system related to power generation at the Glen Canyon Dam would range from 52,014,751 to 59,909,459 MT (from 57,336,449 to 66,038,875 tons), with an average of 55,177,668 MT (60,822,967 tons). These annual average GHG emissions would be about 4.5% and 0.81%, respectively, of the total GHG emissions over the Western Interconnection region and in the United States (see Table 3.15-3 and Section 3.15.3).

Based on the modeling performed and climate change weights applied to account for the greater likelihood of drier conditions under climate change, the following conclusions can be made. Temperature suitability for native and nonnative fish would be improved and impacts on humpback chub lessened. The overall number of trout is expected to decline, but the number of large trout would be higher than under historic hydrology. The impacts on native vegetation would be less. There would be a greater potential for impacts on cultural resources in both Glen Canyon and Grand Canyon, but an improvement in Tribal values for all metrics evaluated. Most

TABLE 4.16-2 Expected Impact of LTEMP Alternatives on Downstream Resources under Climate Change Compared to Those under Historic Conditions

Resource and Impact Indicator	Expected Impact of Climate Change on Impact Indicator Relative to Historic Conditions[a]
Hydrology	
Mean monthly volume and mean daily flow	Decrease in spring and summer, especially for Alternative F, with August being the month with the greatest departure from historic (11–19% reduction in 25th percentile values)
Mean daily change	Increase in July and August, especially for Alternatives A, B, and D (1–17% increase in fluctuating flow alternatives)
Sediment	
Sand load index (bar-building potential; higher is better)	Increase (2–4%) under Alternatives C–G; decrease (–2 to –3%) for Alternatives A and B
Sand mass balance index (higher is better)	Increase (4–9%) under all alternatives
Aquatic ecology	
Temperature suitability index—humpback chub (higher is better)	Increase under all alternatives (but especially Alternative F) in upstream reaches (RM 30–119); decrease at RM 157 under Alternatives A, B, and D, and all alternatives (except for Alternative F) at RM 213
Temperature suitability index—other native fish (higher is better)	Similar pattern as temperature suitability for humpback chub, but decrease at RM 157 only under Alternatives A and B; all alternatives would have decrease at RM 213
Temperature suitability index—coldwater nonnative fish (higher is better)	Increase under all alternatives at RM 0; decrease in all other downstream reaches
Temperature suitability index—warmwater nonnative fish (higher is better)	Increase under all alternatives at RM 0, with decreasing differences at increasing distance from the dam; decrease at RM 225 under all alternatives
Temperature suitability index—aquatic parasites (higher is better)	Increase under all alternatives at RM 0, with decreasing differences at increasing distance from the dam; decrease at RM 225 under all alternatives
Minimum number of adult humpback chub (higher is better)	Increase (0.2–2%) under all alternatives
Trout catch rate (age 2+, no./hr; higher is better)	Increase (1–4%) under Alternatives C, D, E, and G; decrease (–1 to –3%) under Alternatives A, B, and F
Number of trout outmigrants (lower is better)	Increase (0.2–4%) under Alternatives C, D, E, and G; decrease (–1 to –4%) under Alternatives A, B, and F
Trout abundance (age 1+; higher or lower is better dependent on receptor)	Increase (1–4%) under Alternatives C, D, E, and G; decrease (–1 to –3%) under Alternatives A, B, and F
Number of trout >16 in. total length (higher is better)	Increase (0.4–2%) under Alternatives A, B, C, and F; decrease (–0.1 to –1%) under Alternatives D, E, and G

TABLE 4.16-2 (Cont.)

Resource and Impact Indicator	Expected Impact of Climate Change on Impact Indicator Relative to Historic Conditions[a]
Riparian vegetation	
Native species diversity and cover (index, higher is better)	Increase (1%) under Alternatives A, B, D, and E; decrease (–0.2 to –1%) under Alternatives C, F, and G
Cultural resources	
Effect of flows on Glen Canyon resources (index, higher is better)	Decrease under all alternatives (–10 to –17%)
Wind transport of sand to protect resources (index, higher is better)	Increase (3–5%) under Alternatives C, D, E, F, and G; decrease under Alternatives A and B (–1 to –2%)
Tribal values	
Riparian vegetation diversity	Increase (0.2–2%) under all alternatives, but Alternative F (–0.2%)
Marsh index (higher is better)	Increase (1–34%) under all alternatives
Mechanical removal of trout (lower is better)	Increase (2%) under Alternative G; decrease (–6 to –16%) under Alternatives A, B, and D; no removal under Alternatives C, E, and F
TMFs (lower is better)	Decrease (–7 to –17%) under Alternatives B, C, D, E, and G; no TMFs under Alternatives A and F
Recreation	
Camping area index (higher is better)	Increase (4–5%) under Alternatives C, D, E, F, and G; decrease under Alternatives A and B (–0.02 to –2%)
Fluctuation index (higher is better)	Decrease (–0.1 to –4%) under Alternatives A–E; no change in steady flow Alternatives F and G
Glen Canyon rafting use (number of passenger days lost due to HFEs)	Increase (0.1%) under Alternative F; decrease (–0.2 to –8%) under Alternatives A–E and G
Glen Canyon inundation index (higher is better)	Increase (0.5–0.8%) under all alternatives
Hydropower	
Annual net present value of generation	Decrease (–3%) under all alternatives
Net present value of capacity	Decrease (–2 to –4%) under all alternatives

[a] These results were obtained by applying the climate weights for each trace shown in Figure 4.16-1 to the modeling results presented in the various resource sections of Chapter 4 (Sections 4.2–4.13).

recreation metrics would reflect greater impacts under climate change compared to historic hydrology. There would be a reduction in the value of hydropower generation and capacity.

4.16.3.2 Alternative B

Under Alternative B, total annual average GHG emissions are 55,183,567 MT (60,829,471 tons), which is about 0.011% higher than those under Alternative A. Annual average power generation at Glen Canyon Dam under this alternative is estimated to be about 99.7% of that under Alternative A. However, total annual emissions are slightly higher than those under Alternative A, due to the factors discussed in Section 4.16.2.1. This is caused by the power generation mix for Alternative B being different from that of Alternative A.

Under Alternative B, the impacts of climate change on sediment resources, humpback chub, trout, native vegetation, cultural resources, Tribal values, recreation, and hydropower would be very similar to those under Alternative A.

4.16.3.3 Alternative C

Under Alternative C, total annual average GHG emissions are 55,195,829 MT (60,842,987 tons), which is about 0.033% higher than those under Alternative A. Annual average power generation at Glen Canyon Dam under this alternative is estimated to be about 99.3% of that under Alternative A. However, total annual emissions are slightly higher than those under Alternative A, due to the factors discussed in Section 4.16.2.1. This is caused by the power generation mix for Alternative C being different from that of Alternative A.

Under Alternative C, the impacts of climate change on sediment resources would be reduced by climate change resulting in higher sand load index values and an improved sand mass balance. Temperature suitability would be improved, and impacts on humpback chub lessened. The overall number of trout and the number of large trout are expected to be higher than under historic hydrology. The impacts on native vegetation would be slightly greater. There would be a greater potential for impacts on cultural resources in Glen Canyon, but a lower potential in the Grand Canyon. There would be an improvement in Tribal values for all metrics evaluated. Most recreation metrics would show improvement under climate change compared to historic hydrology. There would be a reduction in the value of hydropower generation and capacity.

4.16.3.4 Alternative D (Preferred Alternative)[40]

Under Alternative D, total annual average GHG emissions are 55,200,576 MT (60,848,219 tons), which are about 0.042% higher than those under Alternative A. Annual average power generation at Glen Canyon Dam under this alternative is estimated to be about

[40] Adjustments made to Alternative D after modeling was completed (see Section 2.2.4) are not expected to result in a change in Alternative D's impacts on climate change or the impacts of climate change on Alternative D.

98.9% of that under Alternative A. Thus, total annual emissions are slightly lower than those under Alternative A, due to the factors discussed in Section 4.16.2.1. This is caused by the power generation mix for Alternative D being different from that of Alternative A.

Under Alternative D, the impacts of climate change on sediment resources would be reduced by climate change resulting in higher sand load index values and an improved sand mass balance. Temperature suitability would be improved and impacts on humpback chub lessened. The overall number of trout is expected to be higher than under historic hydrology, but the number of large trout would be lower. The impacts on native vegetation would be slightly lower. There would be a greater potential for impacts on cultural resources in Glen Canyon, but a lower potential in the Grand Canyon. There would be an improvement in Tribal values for all metrics evaluated. Most recreation metrics would show improvement under climate change compared to historic hydrology. There would be a reduction in the value of hydropower generation and capacity.

4.16.3.5 Alternative E

Under Alternative E, total annual average GHG emissions are 55,194,171 MT (60,841,159 tons), which are about 0.030% higher than those under Alternative A. Annual average power generation at Glen Canyon Dam under this alternative is estimated to be about 99.3% of that under Alternative A. Thus, total annual emissions are slightly lower than those under Alternative A, due to the factors discussed in Section 4.16.2.1. This is caused by the power generation mix for Alternative E being different from that of Alternative A.

Under Alternative E, the impacts of climate change on sediment resources, humpback chub, trout, native vegetation, cultural resources, Tribal values, recreation, and hydropower would be very similar to those under Alternative D.

4.16.3.6 Alternative F

Under Alternative F, total annual average GHG emissions are 55,222,189 MT (60,872,044 tons), which are about 0.081% higher than those under Alternative A. Annual average power generation at Glen Canyon Dam under this alternative is estimated to be about 98.3% of that under Alternative A. Thus, total annual emissions are slightly lower than those under Alternative A, due to the factors discussed in Section 4.16.2.1. This is caused by the power generation mix for Alternative F being different from that of Alternative A.

Under Alternative F, the impacts of climate change on sediment resources would be reduced by climate change, resulting in higher sand load index values and an improved sand mass balance. Temperature suitability would be improved and impacts on humpback chub lessened. The overall number of trout is expected to be lower than under historic hydrology, but the number of large trout would be higher. The impacts on native vegetation would be slightly greater. There would be a greater potential for impacts on cultural resources in Glen Canyon, but a lower potential in the Grand Canyon. There would be an improvement in Tribal values related

to marsh vegetation, but a decrease in those related to overall riparian diversity. Most recreation metrics would show improvement under climate change compared to historic hydrology. There would be a reduction in the value of hydropower generation and capacity.

4.16.3.7 Alternative G

Under Alternative G, total annual average GHG emissions are 55,218,627 MT (60,868,117 tons), which are about 0.074% higher than those under Alternative A. Annual average power generation at Glen Canyon Dam under this alternative is estimated to be about 98.2% of that under Alternative A. Thus, total annual emissions are slightly lower than those under Alternative A, due to the factors discussed in Section 4.16.2.1.

Under Alternative G, the impacts of climate change on sediment resources would be reduced by climate change, resulting in higher sand load index values and an improved sand mass balance. Temperature suitability would be improved and impacts on humpback chub lessened. The overall number of trout, including the number of large trout, is expected to be higher than under historic hydrology. The impacts on native vegetation would be slightly greater. There would be a greater potential for impacts on cultural resources in Glen Canyon, but a lower potential in the Grand Canyon. There would be an improvement in Tribal values for all metrics evaluated. Most recreation metrics would show improvement under climate change compared to historic hydrology. There would be a reduction in the value of hydropower generation and capacity.

4.17 CUMULATIVE IMPACTS

The CEQ defines a cumulative impact as "the impact on the environment that results from the incremental impact of [an] action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or nonfederal) or person undertakes such other actions" (40 CFR 1508.7). The assessments summarized in this section place the direct and indirect impacts of the alternatives, presented in the preceding sections of Chapter 4, into a broader context that takes into account the range of impacts of all actions within the Colorado River corridor, from Lake Powell and the Glen Canyon Dam downstream and west to Lake Mead, and the broader Colorado River Basin region (e.g., in the case of climate change).

4.17.1 Past, Present, and Reasonably Foreseeable Future Actions Affecting Cumulative Impacts

Past and present (ongoing) actions in the project area have been accounted for in the baseline conditions described for each resource in Chapter 3. Ongoing and reasonably foreseeable future actions considered in the cumulative impact analysis include the projects, programs, and plans of various federal agencies and other entities as described in the following sections. Many of these projects, programs, and plans reflect shared management objectives and cooperation among federal and state agencies, American Indian Tribes, and stakeholders groups

that are intended to facilitate more effective and efficient management of the resources in the LTEMP project area. Past, present, and reasonably foreseeable future actions are described in the following sections and summarized in Table 4.17-1.

As described in resource-specific sections in this chapter, the LTEMP alternatives are expected to differ in the types and magnitude of impacts on specific resources. Against the backdrop of past, present, and reasonably foreseeable future actions, however, the incremental effects of the LTEMP alternatives, as described in the following sections, are expected to be relatively minor contributions to cumulative impacts along the Colorado River corridor or within the basin at large.

4.17.1.1 Past and Present (Ongoing) Actions

There are numerous actions documented in decisions, plans, policies, and initiatives that relate directly or indirectly to the operation of Glen Canyon Dam and management of the Colorado River ecosystem (see Section 1.10). These actions are listed below, and establish the current conditions or baseline for the LTEMP.

Glen Canyon Dam 1996 Record of Decision

In 1995, Reclamation published an EIS on the impacts of Glen Canyon Dam operations (Reclamation 1995). The ROD for that EIS (Reclamation 1996) selected the MLFF alternative as the operational regime to be implemented, and in 1996, Reclamation began implementing MLFF. The goal of selecting the preferred alternative was not to maximize benefits for the most resources, but rather to find an alternative dam operating plan that would permit recovery and long-term sustainability of downstream resources while limiting hydropower capability and flexibility only to the extent necessary to achieve recovery and long-term sustainability. The ROD also specified a number of environmental and monitoring commitments—including adaptive management, monitoring/protection of cultural resources, flood frequency reduction measures, beach/habitat-building flows, a new population of humpback chub, further study of selective withdrawal, and emergency exception criteria—to avoid or minimize environmental impacts from the preferred alternative. The new operating regime was selected to create conditions that promote the protection and improvement of downstream resources while maintaining some flexibility in hydropower production. The ROD estimated that there would be a loss of hydropower benefits (between $15.1 and $44.2 million annually) resulting from selection of MLFF as the future operating regime (Reclamation 1996).

Flaming Gorge Dam Record of Decision

Since 2006, Reclamation has modified its operation of the Flaming Gorge Dam on the Green River, a major tributary of the Colorado River upstream of Lake Powell, to the extent possible, to achieve the flows and temperatures recommended by participants of the Upper

TABLE 4.17-1 Impacting Factors Associated with Past, Present, and Reasonably Foreseeable Future Actions and Basin-Wide Trends in the LTEMP Project Area

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Past and Present (Ongoing) Actions		
Glen Canyon Dam 1996 ROD (Reclamation 1996)	MLFF to reduce daily flow fluctuations and provide high steady releases of short duration at Glen Canyon Dam	In 1995, Reclamation published an EIS on the impacts of Glen Canyon Dam operations (Reclamation 1995). The ROD for that EIS (Reclamation 1996) selected the MLFF alternative as the operational regime to be implemented, and, in 1996, Reclamation began implementing operating criteria under the MLFF alternative. The goal of selecting the preferred alternative was not to maximize benefits for the most resources, but rather to find an alternative dam operating plan that would permit recovery and long-term sustainability of downstream resources while limiting hydropower capability and flexibility only to the extent necessary to achieve recovery and long-term sustainability.
Flaming Gorge Dam ROD (Reclamation 2006a)	Flow modifications to achieve more natural flows and temperatures (to preserve and protect fish species) in the Green River, a major tributary of the Colorado River	Since 2006, Reclamation has modified its operation of the Flaming Gorge Dam on the Green River, a major tributary of the Colorado River, to the extent possible, to achieve the flows and temperatures recommended by participants of the Upper Colorado River Endangered Fish Recovery Program to protect and assist in recovery of the populations and designated critical habitat of four endangered fishes, while maintaining all authorized purposes of the Flaming Gorge Unit of the CRSP, including those related to the development of water resources in accordance with the Colorado River Compact. The selected alternative (Action Alternative) was anticipated to result in minimal negative impacts to land use, recreation, mosquito control, and hydropower generation.
Aspinall Unit ROD (Reclamation 2012f)	Flow modifications to simulate more natural spring flows and moderate base flows in the lower Gunnison River, a tributary to the Colorado River	The Aspinall Unit consists of Blue Mesa, Morrow Point, and Crystal Dams, Reservoirs, and Powerplants on the Gunnison River, a tributary of the Colorado River. Reclamation published a ROD in 2012 detailing its decision to modify reservoir operations (beginning in 2012) to avoid jeopardizing endangered fish species and their designated critical habitat by allowing higher and more natural downstream spring flows and moderate base flows in the lower Gunnison River. Under the ROD, the Aspinall Unit is operated to meet specific downstream spring peak flow, duration flow, and base flow targets (at the USGS Whitewater gage), as outlined in the project's FEIS preferred alternative. Base flow is maintained to provide adequate fish passage at the Relands Fish Ladder on the Gunnison River near its confluence with the Colorado River. The selected alternative (Alternative B) ensures that operations at the Aspinall Unit will continue to honor its existing water and power contracts while minimizing environmental impacts; however, minor impacts on hydropower, and on recreation and sport fisheries, as well as a minor reduction in water stored in Blue Mesa Reservoir are anticipated.

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Past and Present (Ongoing) Actions (Cont.)		
Navajo Generating Station (NGS) (TWG 2013; EPA 2014c)	Reductions in air emissions and generation capacity	The NGS is a 2,250-MW coal-fired powerplant located on the Navajo Reservation near Page, Arizona. The powerplant is operated by SRP and serves electric customers in Arizona, Nevada, and California; it also supplies energy to the Central Arizona Project. In 2014, the EPA took final action to require an 80% reduction in NO_X emissions from NGS to reduce its impact on visibility at 11 national parks and wilderness areas. Appendix B of the NGS technical working group agreement proposes several alternatives to help the NGS achieve this goal through a reduction in generation output or other operating strategies. The reduction of generation output at the NGS will reduce levels of NO_X pollutants in the region.
Interim Guidelines (Reclamation 2007a,b)	Determines the annual volume for release from Glen Canyon Dam	Adopted in 2007, these Interim Guidelines would be used each year (through 2025 for water supply determinations and through 2026 for reservoir operating decisions) in implementing the LROC for the Colorado River reservoirs pursuant to the 1968 Colorado River Basin Project Act. The Interim Guidelines also proposed a coordinated operation plan for Lake Powell and Lake Mead, basing releases and conserved amounts on predetermined levels in both reservoirs, which would minimize shortages in the Lower Basin and decrease the risk of curtailments in the Upper Basin. In addition, the Interim Guidelines established a mechanism for storing and delivering conserved water from Lake Mead, referred to as Intentionally Created Surplus, intended to minimize the severity and likelihood of potential future shortages. Annual volumes may impact recreation economics and water quality in Lake Mead and Lake Powell and water temperatures in the Colorado River; equalization years may increase trout populations below Glen Canyon Dam and increase sandbar erosion. Effects are expected to be independent of the LTEMP alternatives.
Tamarisk Management and Tributary Restoration (GCNP) (NPS 2002a,b, 2014g)	Reduction of tamarisk trees in the project area Increased diversity of native plant species	The NPS continues its efforts to eradicate tamarisk in the GCNP with the goal of restoring more natural conditions inside the canyons along the Colorado River in the GCNP. Over the past 10 years, the NPS has completed work in 130 project areas, removing more than 275,000 tamarisk trees from over 6,000 ac. Although control methods have been effective, overall return of native diversity has been slow. NPS anticipates overall beneficial effects on native vegetation, soil characteristics, water quality, wetlands, wildlife, wilderness, and visitor experience (NPS 2002b). Adverse impacts are expected to be negligible to minor and short in duration (with the exception of microbiotic soil crusts). No significant adverse effects on threatened, endangered, and sensitive species or ethnographic resources are expected. NPS monitors and mitigates the impacts of tamarisk management on an ongoing basis.

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Past and Present (Ongoing) Actions (Cont.)		
Colorado River Management Plan (NPS 2006b,d)	Established visitor capacity based on size and distribution of campsites Established 6.5-month no-motor season Year-round use provides opportunities for a variety of visitor experiences including motorized and non-motorized trips that range from 6 to 25 days	The goal of the CRMP is to protect resources and visitor experience while enhancing recreational opportunities on the Colorado River through the GCNP by establishing visitor capacity based on size and distribution of campsites, overall resource conditions, and visitor experience variables. Recreational use patterns are based on daily, weekly, and seasonal launch limits and seasonal differences in commercial and noncommercial levels. The actions would have beneficial effects on cultural resource sites, traditional cultural properties, ethnobotanical resources, and other elements important to Tribal assessments of canyon environmental health. Beneficial impacts on commercial operators (revenues and profits) and adjacent lands were also anticipated. Impacts on visitors' use and experience were determined to be negligible to moderate and adverse to beneficial, depending on perspective and desired experience. Adverse impacts on natural resources (biological soil crusts, aquatic resources at attraction sites, special status species, and the soundscape) would range from negligible to major.
Backcountry Management Plan (for GCNP) (NPS 1988[a])	Allocates and distributes backcountry and wilderness overnight use in campsites along the Colorado River	The goal of the BCMP is to protect and preserve the park's natural and cultural resources and values and integrity of wilderness character by providing a framework for consistent decision making in managing the park's backcountry, providing a variety of visitor opportunities and experiences for public enjoyment in a manner consistent with park purposes and preservation of park resources and values and providing for public understanding and support of preserving fundamental resources and values for which Grand Canyon was established. Proposed actions would address both beneficial and adverse effects to: wildlife populations and habitat by minimizing human-caused disturbances and habitat alteration, minimizing impacts to native vegetation, reducing exotic plant species spread, and preserving fundamental biological and physical processes; enhancing wilderness character and values; developing and implementing an adaptive management process that includes monitoring natural, cultural, and experiential resource conditions and responding when resource degradation has resulted from use levels; preserving and protecting natural soil conditions by minimizing impacts to soils from backcountry recreational activities; minimizing adverse chemical, physical, and biological changes to water quality in tributaries, seeps, and springs; and preserving cultural resource integrity and condition.

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Past and Present (Ongoing) Actions (Cont.)		
Abandoned Mine Lands Closure Plan (NPS 2010b)	Closure of mine openings	The NPS will address health and safety hazards (vertical holes, unstable and falling rock, pooling water, and unsuitable air) at 16 AMLs in GCNP. Closure of mine openings[b] would have a long-term beneficial impact on historic structures by protecting mine features from vandalism; however, impacts associated with closure construction activities (installing gates, grates, or cupolas or moving earth, rocks, or tailings piles), while localized, would range from negligible to mostly minor, with some possible moderate adverse (i.e., measurable and perceptible) effects. Beneficial impacts would also be expected on bats and other wildlife by providing protection from disturbance, although NPS notes that closure construction could have minor long-term adverse effects, especially to other wildlife that use the openings for nesting, denning, or shade (effects would be partially mitigated by avoiding closing mine features that are used by a listed species). Because several AML sites are located near trails and river access points in GCNP, they are easily accessible by visitors (although no safety incidents have been documented). Impacts of AML closure, therefore, are expected to be beneficial overall because they would reduce the likelihood of injury from visitor access. Visitors wishing to experience bats and other wildlife, however, may incur localized short-term negligible to minor adverse effects (especially during closure construction when small areas would be closed to visitors). NPS notes that other sites would remain open to visitors, thus affording other opportunities to experience bats and wildlife and mitigating these impacts.
Fire Management Plan (GCNP) (NPS 2012f)	Reduction of wildfire risk in GCNP Ecosystem Restoration	The NPS manages wildland fire risk in GCNP using an adaptive management process to address the areas of firefighting, rehabilitation, hazardous fuels reduction, community assistance, and accountability. Implementation of the plan meets the park goals and objectives for managing park resources and visitor experiences, as identified in the General Management Plan (NPS 1995). It also supports the objects of the Resource Management Plan (NPS 1997). This plan may have beneficial or adverse impacts related to fire reduction, such as decreased runoff of sediments, decreased flooding, maintaining or restoring habitat in uplands.

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Past and Present (Ongoing) Actions (Cont.)		
Uranium Mining and Public Lands Withdrawal (DOI 2012b)	Withdrawal of federal lands in the Grand Canyon region from location and entry Continued exploration and mining on state and private lands	In January 2012, the Secretary of Interior withdrew from location and entry under the Mining Law of 1872 approximately 1,006,545 ac of federal land in northern Arizona for a 20-year period. The purpose of the land withdrawal is to protect the natural, cultural, and social resources in the Grand Canyon watershed from adverse effects related to locatable mineral exploration and development (i.e., uranium mining). It would have no effect on the exploration and development of any non-federal lands within its exterior boundaries; the withdrawal area would remain available for the development of federal leasable and salable minerals. Active exploration for uranium on state and private lands in the region would not be affected by the withdrawal. Potential impacts of uranium mining are currently difficult to quantify because of the uncertainties of subsurface water movement, radionuclide migration, and biological exposure pathways. Based on its study of groundwater near historic uranium mining sites in northern Arizona, the USGS concluded the likelihood of adverse impacts on water resources (from water use and degradation or impairment) is likely to be low, but if water resources were affected, the risk to the greater ecosystem, Tribes, and tourists could be significant (Bills et al. 2010; DOI 2012b). Other potential (but localized) impacts include impacts on aquatic and other biota and habitats associated with drainages in the event of accidental releases of hazardous materials into local drainages.
Comprehensive Fisheries Management Plan (below Glen Canyon Dam) (NPS 2013e)	Potential stocking of sterile rainbow trout in Lees Ferry Translocation of native fish species Removal of high-risk nonnative fish from areas important for native fish Beneficial use of all nonnative fish removed Implementation of an experimental adaptive strategy for evaluating the suitability of razorback sucker in western portions of the Grand Canyon	The main purpose of the plan is to maintain a thriving native fish community within GCNP while also maintaining a highly valued recreational trout fishery community in the Glen Canyon reach. The actions would have a beneficial effect on native and endangered fish populations, as well as visitor experience (by avoiding quality decline of the rainbow trout fishery), and no significant adverse effect on public health, public safety, or threatened or endangered species. They would, however, contribute to long-term ethnographic resource cumulative impacts resulting from fish management (specifically euthanizing fish), which constitutes an adverse effect under Section 106 of the NHPA. This effect would be mitigated to the extent possible through an MOA between the NPS, SHPO, and Tribes (NPS 2013h).

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Past and Present (Ongoing) Actions (Cont.)		
Lower Colorado River Multi-Species Conservation Program (DOI 2005)	Management of take permits (while conserving critical habitat and protecting threatened and endangered species)	The program is a cooperative species conservation effort between federal and non-federal entities within the states of Arizona, California, and Nevada. Its goal is to accommodate water diversions and power production while optimizing opportunities for future water and power development and to provide the basis for incidental take permits while conserving critical habitat and working toward the recovery of threatened and endangered species. Potential beneficial impacts to special status species in Lower Basin.
Reasonably Foreseeable Future Actions		
Special Flight Rules in the Vicinity of GCNP, AZ (14 CFR Part 93, Subpart U)	Reduction of noise in GCNP	Rules to be established to substantially restore natural quiet at GCNP in accordance with the National Parks Overflights Act of 1987 (PL 100-91). Would establish a system of routes, altitudes, flight allocations and flight free zones in the air space in and around GCNP.
Lake Powell Pipeline Project (UBWR 2015)	Construction/operation of pipeline and penstock Construction/operation of hydropower stations Construction/operation of transmission lines Increased water withdrawal from Lake Powell (adjacent to Glen Canyon Dam)	The Utah State legislature has authorized the UBWR to build a pipeline to transfer water from Lake Powell to the Sand Hollow Reservoir near St. George, Utah, to meet water demand in southwestern Utah. The proposed pipeline is currently being evaluated for potential effects on water storage in Lake Powell and related resources, the availability of water for downstream users, habitat conditions, and aquatic species and resources, including sport fisheries (UBWR 2011a,b).

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Reasonably Foreseeable Future Actions (Cont.)		
Grand Canyon Escalade (Confluence Partners, LLC 2012a)	Construction/operation of multiple elements (tramway, riverwalk, road, parking lots, and buildings) Increased visitation up to 10,000 people per day Trespass into GCNP Increased jobs and gross revenues (to the Navajo Nation)	A developer, Confluence Partners, LLC, working with the Navajo Nation has proposed the 420-ac development project on the Grand Canyon's eastern rim, on the western edge of the Navajo reservation at the confluence of the Little Colorado and Colorado Rivers. The development would include retail shops, restaurants, a museum, a cultural/visitor center, a hotel, multiple motels, a lodge with patio, roads, and parking lots. It would also include a restaurant, gift shops, an amphitheater, and a riverwalk along the canyon floor. Analysis for this project has not been conducted, so impacts have not been fully determined; however, the construction and operation of the Escalade project could result in adverse impacts on natural resources (e.g., impacts on Little Colorado River and other humpback chub habitats; wildlife disturbance due to noise and loss of habitat) and cultural resources in the areas of the Little Colorado River confluence, wilderness, visual resources, and resources of importance to multiple Tribes. It could also result in impacts on the local economy through increased tourism and job creation.
Red Gap Ranch Pipeline (City of Flagstaff City Council 2013)	Increased groundwater withdrawal from the C-aquifer on the Coconino Plateau Construction/operation of multiple elements (wells, roads, pipelines, and a treatment facility)	In anticipation of a future water supply shortfall, the City of Flagstaff has purchased property on the Red Gap Ranch on which it plans to develop new municipal wells to augment its current supply. The wells would withdraw up to 8,000 ac-ft of groundwater each year from the C-aquifer on the Coconino Plateau. A NEPA review, currently underway, is evaluating the impacts of groundwater withdrawal from the aquifer on base flow feeding the Little Colorado River, Clear Creek, and Chevelon Creek, which ultimately flow into the Colorado River. These withdrawals could affect habitats of humpback chub and other native fish, especially in the Little Colorado River. The NEPA review is also evaluating the impacts of groundwater conveyance on biological and cultural resources on the Red Gap Ranch property.
Page-LeChee Water Supply Project (NPS 2009b)	Construction/operation of water intakes and pumping station Construction/operation of a conveyance pipeline	The Page-LeChee would improve the existing water supply system for the city of Page and the LeChee Chapter of the Navajo Nation. It would increase the capacity of water already drawn from Lake Powell; it would include water intakes, a pumping station, and a conveyance pipeline located on the GCNRA. While the proposal would allow higher diversions of water from Lake Powell, actual consumptive use would continue to be subject to the city's contract with the Bureau of Reclamation.

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Reasonably Foreseeable Future Actions (Cont.)		
Four Corners Power Plant (FCPP) and Navajo Mine Energy Project (OSMRE 2015a, b)	Reduced NO_x and PM pollutants emissions Coal-mining activities and associated land disturbance and air emissions	The FCPP, located just north Fruitland, New Mexico (about 160 mi east of Glen Canyon Dam), historically consisted of five pulverized coal-burning steam electric generating units with a total generating capability of 2,100 MW and other ancillary facilities. The proposed lease amendment would extend the life of the powerplant to 2041. Under the proposed alternatives, air emissions would not exceed NAAQS and deposition impacts with 50 km (31 mi) of the FCPP are expected to be negligible. The Arizona Public Service Company closed three of the five generation units (Units 1, 2, and 3) at the end of 2013, and over the next couple of years is scheduled to install SCR controls on the remaining two units (Units 4 and 5) to reduce NO_x and PM pollutants that contribute to regional haze and visibility issues (to benefit the 16 Class 1 Federal Areas, including the GCNP, within 300-km (186-mi) radius of the facility (OSMRE 2015b). Development of a new coal mine would result in land disturbance and air emissions.
Clean Power Plan Proposed Rule (EPA 2014b)	Reduced CO_2 emissions	The Clean Power Plan Proposed Rule would reduce atmospheric carbon by limiting the CO_2 emissions from existing fossil-fuel fired powerplants in the United States. The draft plan would establish state-by-state carbon emissions rate reduction targets with the aim of reducing emissions from the power sector to about 30% below 2005 levels by 2030 (EPA 2014b). The EIA (2015) estimates the proposed rule would result in a reduction of U.S. power sector CO_2 emissions to about 1,500 million MT/yr by 2025 (levels not seen since the early 1980s). The U.S. Supreme Court granted a stay in February 2016, halting implementation of the plan.
Human Activities Affecting Climate		
	Increased temperatures (air and surface water) Increased variability in precipitation and stream flows Drought conditions and water loss (through evaporation and evapotranspiration) Increased risk of wildfires Decreased snowpack and stream flows (due to less late winter precipitation and snowpack sublimation)	The southwest is already experiencing the effects of climate change, with the decade from 2001 to 2010 being the warmest on record (Garfin et al. 2014; World Meteorological Organization 2014; NAS 2007). Precipitation trends are more variable across the region, but drought-induced water shortages in the Colorado River Basin are a growing concern. Changes in temperature and precipitation patterns could take a toll on the diversity of plant and animal species (e.g., widespread loss of trees due to wildfires). Other possible effects include forest insect outbreaks, reduced crop yields, and an increased risk of heat stress and disruption to electric power generation. The recreational economy could also be affected by a shorter snow season and reduced streamflow (Garfin et al. 2014).

TABLE 4.17-1 (Cont.)

Actions	Impacting Factors	Description of the Action and Its Effect(s)
Human Activities Affecting Climate (Cont.)		
	Seasonal shifts in snowmelt and high stream flows (to earlier in the year)	
	Increased flooding potential (due to earlier snowmelt)	
	Decreased spring and summer runoff (due to decreased snowpack)	
	Lowered reservoir levels (Lakes Powell and Mead)	
	Increased agricultural water demand (due to increased temperatures)	
	Reduced agricultural yields Insect outbreaks	
	Increased production rates of algae and invertebrates	
	Spread of nonnative species adapted to warmer temperatures	
	Increased wildfires	
	Reduced plant and animal diversity (widespread tree mortality)	
	Heat threats to human health	

[a] New BCMP expected to be implemented with ROD in 2016.

[b] NPS notes that except for backfilling, most closure types would be reversible, thereby reducing the impacts of closure on those sites eligible for the *National Register* (NPS 2010b).

Colorado River Endangered Fish Recovery Program to protect and assist in recovery of the populations and designated critical habitat of four endangered fishes, while maintaining all authorized purposes of the Flaming Gorge Unit of the CRSP, including those related to the development of water resources in accordance with the Colorado River Compact. The selected alternative (Action Alternative) was anticipated to result in minimal negative impacts to land use, recreation, mosquito control, and hydropower generation (Reclamation 2006a).

Aspinall Unit Record of Decision

The Aspinall Unit, managed and operated by Reclamation (in cooperation with various other federal agencies), consists of Blue Mesa, Morrow Point, and Crystal Dams, Reservoirs, and Powerplants on the Gunnison River, a tributary of the Colorado River upstream of Lake Powell. It was originally authorized by the Colorado River Storage Project Act of 1956. In 2012, Reclamation published a ROD that details the decision to modify reservoir operations (beginning in 2012) to avoid jeopardizing endangered fish species and their designated critical habitat by allowing higher and more natural downstream spring flows and moderate base flows in the lower Gunnison River (Reclamation 2012f). The selected alternative (Alternative B) ensures that operations at the Aspinall Unit will continue to honor its existing water and power contracts while minimizing environmental impacts; however, minor impacts on hydropower, and on recreation and sport fisheries, as well as a minor reduction in water stored in Blue Mesa Reservoir are anticipated (Reclamation 2012f).

Navajo Generating Station

The Navajo Generating Station (NGS) is a 2,250-MW coal-fired powerplant located on the Navajo Reservation near Page, Arizona. The powerplant is operated by SRP and serves electric customers in Arizona, Nevada, and California. It also supplies energy to the Central Arizona Project, which diverts water from the Colorado River at Lake Havasu near Parker to agricultural land Indian Tribes in southern Arizona (SRP 2016; Reclamation 2016). In 2014, the EPA took final action to require an 80% reduction in NO_X emissions from NGS to reduce its impact on visibility at 11 Class I federal areas (national parks and wilderness areas) (EPA 2014c). Appendix B of the NGS technical working group (NGSTWG 2013) proposes several alternatives to help the NGS achieve this goal through a reduction in generation output (e.g., ceasing generation on one NGS unit) or other operating strategies. The reduction of generation output at the NGS will reduce levels of NOx pollutants in the region.

Interim Guidelines for Coordinated Operation of Lake Powell and Lake Mead

In 2005, spurred by a multi-year drought, decreasing system storage, and growing demands for Colorado River water, the Secretary directed Reclamation to work with the Basin States to develop additional strategies for addressing the coordinated management of the reservoirs of the Colorado River system. In response, Reclamation began to develop and adopt interim operational guidelines that would address the operation of Lake Powell and Lake Mead

during drought and low-reservoir conditions. Adopted in 2007, these Interim Guidelines would be used each year (through 2025 for water supply determinations and through 2026 for reservoir operating decisions) in implementing the LROC for the Colorado River reservoirs pursuant to the 1968 Colorado River Basin Project Act. The ROD (2007b) did not modify the authority of the Secretary to determine monthly, daily, hourly, or instantaneous releases from Glen Canyon Dam.

The completed Interim Guidelines determine the availability of Colorado River water for use in the Lower Basin, on the basis of Lake Mead's water surface elevation, as a way to conserve reservoir storage and provide water users and managers with greater certainty regarding the reduction of water deliveries during drought and other low-reservoir conditions. The Interim Guidelines also proposed a coordinated operation plan for Lake Powell and Lake Mead, basing releases and conserved amounts on predetermined levels in both reservoirs, which would minimize shortages in the Lower Basin and decrease the risk of curtailments in the Upper Basin. In addition, the Interim Guidelines established a mechanism for storing and delivering conserved water from Lake Mead, referred to as "intentionally created surplus," intended to minimize the severity and likelihood of potential future shortages. Nothing in this LTEMP EIS is intended to affect or will affect future decisions that may be made regarding the implementation of the LROC after the Interim Guidelines expire in 2026.

Drought conditions in the Colorado River Basin between 2000 and 2007, coupled with increased demands for Colorado River water supplies, resulted in decreased reservoir storage in the basin from 55.8 million ac-ft in 1999 (94% of capacity) to 32.1 million ac-ft in 2007 (54% of capacity). The interim guidelines incorporate three main elements: (1) shortages to conserve reservoir storage; (2) coordinated operation of Lakes Powell and Mead on the basis of specified reservoir conditions to minimize shortages in the Lower Basin and avoid the risk of curtailments of use in the Upper Basin; and (3) water conservation in the Lower Basin to increase retention of water in Lake Mead. The interim guidelines presented in Section XI of the ROD (Reclamation 2007b) define "normal conditions" in Lake Mead as reservoir levels above elevation 1,075 ft AMSL and below elevation 1,145 ft AMSL. They quantify surplus and shortage conditions against these levels and define apportionments to Lower Basin states on this basis.

Tamarisk Management and Tributary Restoration Project at Grand Canyon National Park

The NPS continues its efforts to eradicate tamarisk in side canyons, tributaries, developed areas, and springs above the pre-dam water level in GCNP (NPS 2002a,b, 2014g). Tamarisk is a nonnative shrub that was introduced to the United States in the 19th century as an erosion control agent. Since its introduction, the plant has spread throughout the west and has caused major changes to natural ecosystems. The shrub reached the GCNP in the 1920s and by the time Glen Canyon Dam was completed in 1963, it had become a dominant riparian zone species along the Colorado River. The NPS's ongoing goal is to restore more natural conditions inside canyons along the river in GCNP and to prevent further loss or degradation of existing native biota. To this end, restoration biologists use an adaptive strategy to manage and control tamarisk in the

GCNP. Control measures involve a combination of mechanical and chemical methods tailored to site-specific conditions and plant size. These include pulling, cutting to stump level, applying herbicide, and girdling (leaving the dead tree in place for wildlife habitat) (NPS 2014g).

The tamarisk leaf beetle (*Diorhabda* spp.) was not intentionally introduced in GCNRA or GCNP, but was discovered in 2009 near Navajo Bridge and at RM 12, and at several locations, including Lees Ferry, in 2010. It is currently found throughout Glen and Grand Canyons (Section 3.6.2). The beetle causes early and repeated defoliation of tamarisk, eventually resulting in mortality. Although the beetle has been associated with widespread defoliation of some tamarisk communities along the river, its long-term effects on tamarisk abundance and distribution in Glen and Grand Canyons is not currently known.

Colorado River Management

The CRMP specifies the actions that NPS follows to protect resources and visitor experience while enhancing recreational opportunities on the Colorado River through GCNP (NPS 2006a,b). The CRMP describes management goals for two geographic sections of the Colorado River: (1) Lees Ferry to Diamond Creek, and (2) Diamond Creek to Lake Mead. The selected action for the Lees Ferry to Diamond Creek section (RM 0 to 226) defines mixed motor/no motor seasons and reduces the maximum group size for commercial groups. It establishes use patterns based on daily, weekly, and seasonal launch limits, provides year-round noncommercial use and a 6.5 month non-motorized use period during the shoulder and winter seasons. Management of the Lower Gorges section from Diamond Creek to Lake Mead (RM 226 to 277) involves cooperation between the NPS and the Hualapai Tribe, and provides opportunities for shorter whitewater and smoothwater trips (NPS 2006b).

Backcountry Management Plan

The Backcountry Management Plan defines the concepts, policies, and operational guidelines NPS follows to manage visitor use and protect natural resources in the backcountry and wilderness areas of the GCNP (NPS 1988). The objectives of the Backcountry Management Plan are to provide a variety of backcountry recreational visitor opportunities that are compatible with resource protection and visitor safety. The plan supports the objectives of the CRMP and is currently undergoing revision. A Draft EIS on the proposed plan was issued in late 2015 (NPS 2015b).

Abandoned Mine Lands Closure Plan

In 2010, the NPS finalized an EA that evaluated methods to correct health and safety hazards (vertical holes, unstable and falling rock, pooling water, and unsuitable air) at 16 abandoned mine lands (AMLs) in GCNP (NPS 2010b). The resources affected by AML closure are historic structures (mine features such as adits, shafts, and cairns, among others) and

districts, bats and other wildlife (including federally listed species and species of management concern), visitor experience (including health and safety), and wilderness.

Fire Management at Grand Canyon National Park

The NPS manages wildland fire risk in GCNP through its Fire Management Program, as detailed in its Fire Management Plan (NPS 2012d). The Fire Management Plan employs an adaptive management process to address the areas of firefighting, rehabilitation, hazardous fuels reduction, community assistance, and accountability. Implementation of the plan meets the park goals and objectives for managing park resources and visitor experiences, as identified in the General Management Plan (NPS 1995). The Fire Management Plan also supports the objectives of the Resource Management Plan (NPS 1997). These include protecting human health and safety and private and public property; restoring and maintaining park ecosystems in a natural and resilient condition; interpreting and educating Tribes, stakeholders, and the public about the importance of the natural fire regime; and promoting a science-based program that relies on current and best-available information, as described in Table 3.2 of NPS (1995).

Uranium Mining and the Northern Arizona Withdrawal of Public Lands

Uranium mineralization in the Grand Canyon region is associated with geologic features called breccia pipes. A breccia pipe is a cylindrical, vertical mass of broken rock (breccia) that typically measures tens of meters across and hundreds of meters vertically. There are 1,300 known or suspected breccia pipes in the Grand Canyon region (Spencer and Wenrich 2011). Development of uranium minerals associated with breccia pipes dates back to the 1940s. By the late 1980s, more than 71 breccia pipes had been found to contain ore-grade rock (DOI 2012b). As of 2010, over 23 million lb of uranium (U_3O_8) had been produced from nine breccia pipes (Spencer and Wenrich 2011); the estimated mean undiscovered uranium endowment for the region is about 933.6 million lb (Otton and Van Gosen 2010)

In January 2012, the Secretary of Interior withdrew from location and entry under the Mining Law of 1872 approximately 1,006,545 ac of federal land in northern Arizona for a 20-year period (DOI 2012b). The withdrawal includes 684,449 ac of federal land administered by BLM north of GCNP (North and East Parcels) and 322,096 ac of federal land administered by the USFS south of GCNP (South Parcel). The purpose of the land withdrawal is to protect the natural, cultural, and social resources in the Grand Canyon watershed from adverse effects related to locatable mineral exploration and development (i.e., uranium mining). The withdrawal would have no effect on the exploration and development of any non-federal lands within its exterior boundaries (with the exception of about 23,993 ac of split estate lands where locatable minerals are owned by the federal government), and the withdrawal area would remain available for the development of federal leasable and salable minerals (e.g., oil and gas leases and sand and gravel permits). The public land laws would still apply (DOI 2012b).

Although 3,156 mining claims predate BLM's notice of withdrawal in 2009, most of these did not have valid existing rights at the time of the notice and, therefore, cannot be

developed during the withdrawal period. The BLM estimates that 11 mines, including four existing uranium mines, could still be developed under the full withdrawal, a level similar to that in the 1980s when the high price of uranium spurred interest in mining (DOI 2012b). Arizona State land parcels and private lands in the region could also be developed (NPS 2013k). Thus, uranium mining, while reduced, will continue throughout the withdrawal period.

Active exploration for uranium in the region is currently focused on state and private lands located within the Cataract Canyon/Havasu Creek surface and groundwater basins, to the south of GCNP. These lands are adjacent to the Havasupai Reservation, Hualapai Reservation, and the Kaibab National Forest, and are operated near the Boquillas Ranch and other private lands owned by the Navajo Nation (NPS 2013k).

Comprehensive Fisheries Management below Glen Canyon Dam

The NPS is implementing its Comprehensive Fisheries Management Plan for all fish-bearing waters in GCNP and GCNRA below Glen Canyon Dam. The plan was developed in coordination with the Arizona Game and Fish Department, the FWS, Reclamation, and the USGS GCMRC; its purpose is to maintain a thriving native fish community within GCNP, while also maintaining a highly valued recreational trout fishery in the Glen Canyon reach, defined as the 16.5 mi of river downstream from Glen Canyon Dam on the Colorado River in the GCNRA, including Lees Ferry and the mouth of the Paria River (NPS 2013e, 2013h).

The plan's management goals for the Colorado River and its tributaries in GCNP are as follows:

1. Meet or exceed population and demographic goals for the appropriate GCNP recovery unit for existing ESA-listed fish species, maintain self-sustaining populations, and restore distribution of those species to the extent practicable;

2. Maintain or enhance viable populations of existing native fish and restore native fish communities and native fish habitat in GCNP to the extent practicable;

3. Restore self-sustaining populations of extirpated fish species, including Colorado pikeminnow, razorback sucker, bonytail, and roundtail chub, as appropriate and to the extent feasible (if feasibility studies determine each species can be reasonably restored without impacting existing ESA-listed species);

4. Foster meaningful Tribal relations and integrate Tribal knowledge and perspectives into park management decisions and practice; and

5. Prevent further introductions of nonnative (exotic) aquatic species, and remove when possible, or otherwise contain, individuals or populations of nonnative species already established in GCNP.

The plan's management goals for the Colorado River and Paria River in GCNRA are as follows:

1. Maintain a highly valued recreational rainbow trout fishery with minimal emigration of rainbow trout downstream to GCNP;

2. Restore and maintain healthy, self-sustaining native fish communities; native fish habitat; and the important ecological role of native fish to the extent possible;

3. Foster meaningful Tribal relations and integrate Tribal knowledge and perspectives into park management decisions and practices; and

4. Prevent further introductions of nonnative (exotic) species.

Lower Colorado River Multi-Species Conservation Program

The Lower Colorado River Multi-Species Conservation Program (LCRMSCP) implements and coordinates the Secretary of the Interior's statutory responsibilities under the ESA (DOI 2005). The program is a cooperative species conservation effort between six federal agencies (Reclamation, BIA, NPS, BLM, WAPA, and the FWS) and numerous non-federal entities within the states of Arizona, California, and Nevada. Its goal is to accommodate water diversions and power production while optimizing opportunities for future water and power development (lead agency: Reclamation) and to provide the basis for incidental take permits (lead agency FWS) while conserving critical habitat and working toward the recovery of threatened and endangered species as well as reducing the likelihood of additional species being listed. Measures to mitigate the impacts of the incidental take of species covered under the Program are contained in its Habitat Conservation Plan (LCRMSCP 2004). The Habitat Conservation Plan and other program information are available at http://www.lcrmscp.gov/index.html.

4.17.1.2 Reasonably Foreseeable Future Actions

Special Flight Rules in the Vicinity of Grand Canyon National Park

The NPS will establish new rules to substantially restore natural quiet at GCNP in accordance with the National Parks Overflights Act of 1987 (P.L. 100-91). The rules would create a system of routes, altitudes, flight allocations, and flight-free zones in the air space in and around GCNP.

Lake Powell Pipeline Project

In 2006, the Utah State legislature passed the Lake Powell Pipeline Development Act to authorize the Utah Board of Water Resources (UBWR) to build a pipeline to transfer water from Lake Powell to the Sand Hollow Reservoir near St. George, Utah, to meet water demand in southwestern Utah. At full development, the pipeline is expected to annually deliver up to 82,000 ac-ft to Washington County Water Conservancy District and 4,000 ac-ft to Kane County Water Conservancy District. The proposed project would consist of (1) building and operating 139 mi of 69-in. diameter pipeline and penstock, 35 mi of 30-in. to 48-in. diameter pipeline, and 6 mi of 24-in. diameter pipeline; (2) a combined conventional peaking and pumped storage hydropower station; (3) five conventional in-pipeline (booster) hydropower stations; and (4) transmission lines. The booster pumping stations along the length of the pipeline would provide the 2,000-ft lift needed to move the water over the high point within the Grand Staircase-Escalante National Monument. From the high point, water would flow through a series of hydroelectric turbines to make use of the 2,900-ft drop in elevation from the high point to the end of the pipeline in St. George (UBWR 2015; FERC 2011). The Lake Powell intake would be located near the south end of the reservoir adjacent to Glen Canyon Dam (UBWR 2011a). UBWR plans to have its licenses, permits, and ROD issued sometime in 2015 so construction can begin in 2020 (water delivery would not begin until 2025) (UBWR 2015).

Grand Canyon Escalade

Private developers have proposed to the Navajo Nation, a 420-ac development project, known as the Grand Canyon Escalade, on the Grand Canyon's eastern rim on the western edge of the Navajo reservation at the confluence of the Little Colorado and Colorado Rivers. The development would include a 1.4-mi-long, eight-person tramway (gondola) to transport visitors 3,200 ft from the rim to the canyon floor. On the rim, the development would include retail shops, restaurants, a museum, a cultural/visitor center, a hotel, multiple motels, a lodge with patio, roads, and parking for cars and RVs. It would also include a restaurant, gift shops, an amphitheater, and a riverwalk (with an elevated walkway) along the canyon floor. Analysis for this project has not been conducted, so impacts have not been fully determined; however, the construction and operation of the Escalade project could result in adverse impacts on natural and cultural resources in the areas of the Little Colorado River confluence, wilderness, visual resources, and resources of importance to multiple Tribes. It could also result in beneficial impacts to the local economy through increased tourism and job creation.

Red Gap Ranch Pipeline

In 2006, Reclamation completed a study that projected a water supply shortfall of about 3,370 ac-ft/yr for the City of Flagstaff (and other towns in Coconino County) by the year 2050 (Reclamation 2006b). To address its shortfall, the City of Flagstaff has purchased property on the Red Gap Ranch (about 34 mi to the east), on which it plans to develop new municipal wells to augment its current supply. The wells would withdraw up to 8,000 ac-ft of groundwater each year from the C-aquifer (on the Coconino Plateau) and send it via pipeline to the City (City of

Flagstaff City Council 2013). Because the pipeline crosses federal land and is partially funded with federal dollars, the proposed project is currently undergoing a NEPA review (EA). The scope of the EA is to evaluate the impacts of groundwater withdrawal on the base flow that feeds the Little Colorado River, Clear Creek, and Chevelon Creek (which ultimately feed the Colorado River), as well as the impacts the conveyance of groundwater (including the construction of pipelines, roads, and a treatment facility) could have on biological and cultural resources on the Red Gap Ranch property.

Page-LeChee Water Supply Project

The Page-LeChee water supply project is a water supply facility providing domestic water supply for the city of Page and the LeChee Chapter of the Navajo Nation (NPS 2009b). The proposed project would improve the existing system (consisting of three pumps operating at 3,050 gpm) and increase the capacity of water already drawn from Lake Powell; it would include water intakes, a pumping station, and a conveyance pipeline located on the GCNRA (from Lake Powell to a tie-in point on the existing system near U.S. 89 between the Glen Canyon rim and the water treatment plant in Page). Although the proposal would allow higher diversions of water from Lake Powell, actual consumptive use would continue to be subject to the city's contract with Reclamation.

Four Corners Power Plant and Navajo Mine Energy Project

The Office of Surface Mining Reclamation and Enforcement (OSMRE) has completed a final EIS for the lease amendment with the Navajo Nation that would extend the life of the Four Corners Power Plant (FCPP) to 2041 (OSMRE 2015a, b). The FCPP, located just north of Fruitland, New Mexico (about 160 mi east of Glen Canyon Dam), historically consisted of five pulverized coal-burning steam electric generating units with a total generating capability of 2,100 MW and other ancillary facilities, including Morgan Lake and Morgan Lake Dam, fly ash storage silos and bottom ash dewatering bins, three switchyards, an intake canal, and access road (OSMRE 2015b). The Arizona Public Service Company closed three of the five generation units (Units 1, 2, and 3) at the end of 2013, and over the next couple of years is scheduled to install selective catalytic reduction (SCR) controls on the remaining two units (Units 4 and 5) to reduce NO_X and particulate matter (PM) pollutants that contribute to regional haze and visibility issues (to benefit the 16 Class 1 Federal Areas, including the GCNP, within 300-km (186-mi) radius of the facility (OSMRE 2015b). The proposed action would also include the renewal of the transmission line right-of-way that connects the powerplant to the power grids in Arizona and New Mexico and the development of a new 5,600-ac mine area, the Pinabete Mine Permit area, to supply coal to the powerplant for up to 25 years (beginning July, 2016). The Pinabete Mine area is a surface coal mining and reclamation operation located near the existing Navajo Mine in San Juan County, New Mexico (OSMRE 2015c), and would result in land disturbance and air emissions in the project area.

EPA's Clean Power Plan Proposed Rule for Existing Power Plants

The Clean Power Plan Proposed Rule is being developed by the U.S. Environmental Protection Agency (EPA) under Section 111(d) of the Clean Air Act (CAA) to reduce atmospheric carbon by limiting the CO_2 emissions from existing fossil-fuel fired powerplants in the United States. The final plan, released in October 2015, establishes state-by-state carbon emissions rate reduction targets with the aim of reducing emissions from the power sector to about 30% below 2005 levels by 2030 (EPA 2014b, 2015c). The EIA (2015) estimates the proposed rule would result in a reduction of power sector CO_2 emissions to about 1,500 million MT/yr by 2025, levels not seen since the early 1980s. The U.S. Supreme Court stayed implementation of the Clean Power Plan on February 9, 2016, pending judicial rule (EPA 2016).

4.17.2 Climate-Related Changes

The southwest is already experiencing the effects of climate change (Garfin et al. 2014). The decade from 2001 to 2010 was the warmest on record, with temperatures almost 1.1°C higher than historic averages (Garfin et al. 2014; World Meteorological Organization 2014). Precipitation trends are more variable across the region, but drought-induced water shortages in the Colorado River Basin are a growing concern, prompting federal and state agencies, Tribes, and other stakeholders to develop adaptation and mitigation strategies to address imbalances between water supply and demand in the coming years (Garfin et al. 2014; NAS 2007; Reclamation 2007b, 2012c). Section 4.16 provides a discussion of climate change as related to the LTEMP.

Higher temperatures in the Colorado River Basin have resulted in less precipitation falling and being stored as snow at high elevations in the Upper Basin (the main source of runoff to the river), increased evaporative losses, and a shift in the timing of peak spring snowmelt (and high streamflow) to earlier in the year (NAS 2007; Christensen et al. 2004; Jacobs 2011). These effects in turn have exacerbated competition among users (farmers, energy producers, urban dwellers), as well as effects on ecological systems, during a time when due to a rapidly rising population water demand has never been higher (Garfin et al. 2014).

As discussed in the *Colorado River Basin Water Supply and Demand Study* (Reclamation 2012e), the general picture for climate change, as it relates to Colorado River Basin hydrology, includes decreased inflow to the reservoir system (due to lower precipitation), greater evaporation and evapotranspiration losses (due to higher temperatures), and increased demand (due to increased population size). Combined, these factors increase the probability and likely duration of delivery shortages in coming decades. It has been estimated that the shortfall created by future supply and demand imbalances could range from 2.3 to 4.1 maf per year, during any given deficit period (Reclamation 2012e). When climate change considerations are taken into account, this value increases to around 7.4 maf per year during the deficit period (Reclamation 2012e). In 2007, DOI adopted interim guidelines (Reclamation 2007b) to allocate shortages and specify modifications to the apportionments to the Lower Basin states in the event of water shortage conditions at Lake Mead (see section above).

Changes in temperature and precipitation patterns attributed to climate change could also take a toll on the region's rich diversity of plant and animal species (e.g., widespread loss of trees due to wildfires). Other possible effects include forest insect outbreaks, reduced crop yields, and an increased risk of heat stress and disruption to electric power generation (during summer heat waves). The recreational economy could also be affected by a shorter snow season and reduced streamflow (Garfin et al. 2014). Such effects are likely to continue well into the foreseeable future (NAS 2007). These changes would be the same under all LTEMP alternatives and would be unaffected by the alternatives.

4.17.3 Cumulative Impacts Summary by Resource[41]

The following sections discuss the past, present, and reasonably foreseeable future actions, including the LTEMP alternatives, that could contribute to cumulative impacts on resources within the project area. Table 4.17-2 provides a summary of these contributions by resource area.

The physical presence and design constraints of Glen Canyon Dam have created a new baseline condition for resources within the Colorado River corridor, from Lake Powell and the dam downstream and west to Lake Mead. Current safety and design requirements limit flow through the dam to no more than 45,000 cfs, about 53% of its historical maximum flow. Management of water flow within the river system is also constrained by the various treaties, decrees, statutes, regulations, contracts, and agreements that are collectively known as the Law of the River. Recent drought conditions in the Colorado River Basin have necessitated further regulation (i.e., the 2007 Interim Guidelines) to allocate shortages and reduce apportionments to the Lower Basin states during periods of declining reservoir storage at Lake Mead. The water supply and demand equation is further stressed by the challenges of increasing demand in the seven Basin States (due to a rising population) and the temperature variability and drought attributed to climate change, which are projected to reduce flows into the foreseeable future.

As described in resource-specific sections in this chapter, the LTEMP alternatives are expected to differ in the types and magnitude of impacts on specific resources. Against the backdrop of past, present, and reasonably foreseeable future actions, however, the incremental effects of the LTEMP alternatives, as described in the following sections, are expected to be relatively minor contributions to cumulative impacts along the Colorado River corridor or within the basin at large.

4.17.3.1 Water Resources

Although LTEMP alternatives differ in monthly, daily, and hourly flows, all alternatives must be consistent with and subject to the Law of the River as identified in GCPA

41 Adjustments made to Alternative D after modeling was completed (see Section 2.2.4) are not expected to result in a change in Alternative D's cumulative impact.

TABLE 4.17-2 Summary of Cumulative Impacts and Incremental Contributions under LTEMP Alternatives

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Water Resources	Colorado River between Glen Canyon Dam and Lake Mead; Lakes Powell and Mead	Projected future changes in flow due to increased water demand (as a result of population growth and development), and decreased water supply, drought, and increased water temperature attributed to climate change could be the greatest contributors to adverse impacts on Colorado River flows, storage in Lakes Powell and Mead, and water quality (temperature and salinity). The 2007 Interim Guidelines and related water conservation efforts, should provide more predictability in water supply to users in the Basin States (especially the Lower Basin) through 2026, and may also benefit water temperature and water quality in Lakes Powell and Mead. Future water depletions from Lake Powell including those from the proposed Lake Powell Pipeline Project and Page-LeChee Project could affect availability of water for release from Glen Canyon Dam.	The proposed action is consistent with the 2007 Interim Guidelines for annual water deliveries. The contribution of the proposed action to cumulative impacts would be negligible compared to the effects of past, present, and reasonably foreseeable future actions. With the exception of Alternative B, the LTEMP alternatives would result in slightly greater summer warming and a slightly increased potential for bacteria and pathogens along shorelines.
Sediment Resources	Colorado River between Glen Canyon Dam and Lake Mead; inflow deltas in Lake Mead	Potential future hydrology in the Colorado River (as determined by the 2007 Interim Guidelines), including the effects of climate change, could affect tributary sediment delivery (supply), fine sediment transport, sandbar formation, and lake delta formation over the long term. Glen Canyon Dam and Lake Powell trap most of the mainstem Colorado River sediment supply (post-dam sediment supplies less than 10% of the pre-dam supply). Implementation of HFEs could result in an improvement in sandbar building.	LTEMP alternatives are expected to improve sediment conditions to varying degrees by conserving sediment and building sandbars at higher elevations. Alternatives with the most HFEs (Alternatives C, D, E, F, and G) have the highest sandbar building potential. Alternative A has the lowest sandbar building potential. The proposed action's contribution to cumulative impacts would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Natural Processes	Colorado River ecosystem in Glen, Marble, and Grand Canyons	Projected future changes in flow due to increased water demand (as a result of population growth and development) and decreased water supply (and sediment supply), drought, and increased water temperature attributed to climate change would contribute to adverse impacts on natural processes through changes in Colorado River flows, sediment supply, and temperature. Implementation of HFEs could result in an improvement in sandbar building. Tamarisk control and fisheries management actions could improve natural processes by restoring native species.	Compared to Alternative A, Alternatives C, D, F, and G are expected to increase sediment conservation, increase the stability of nearshore habitats, and provide slightly warmer water temperatures. The proposed action's contribution to cumulative impacts would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Aquatic Ecology	Colorado River between Glen Canyon Dam and Lake Mead	Aquatic resources would be affected by changes in flow due to increased water demand (as a result of population growth and development); decreased water supply, drought, and increased water temperature attributed to climate change; and other foreseeable actions (related to fish management and uranium mining). The potential for urban and agricultural runoff also increases with population growth, producing adverse effects on water quality, which could ultimately affect aquatic biota and habitat. Drought conditions (and actions such as the Lake Powell pipeline project) would result in lower reservoir elevations and benefits to aquatic resources associated with warmer release temperatures. Warmer water temperatures, however, could also result in adverse effects if they increase the distribution of nonnative species adapted to warm water (e.g., fish parasites). 2007 Interim Guidelines determine annual volume and equalization years may increase trout production and river temperature both of which may impact humpback chub populations. Uranium mining could also have adverse (though local) effects on aquatic biota and habitats associated with ephemeral drainages (in the event of an accidental release of hazardous materials). Translocation of native fish species (humpback chub) from the Little Colorado River to other tributaries within the Grand Canyon would have a beneficial (protective) impact on aquatic resources.	Compared to Alternative A, Alternative D would have lower trout numbers, slightly higher humpback chub numbers, and increased food base productivity. Alternatives with higher fluctuation levels (Alternatives B and E) have lower trout numbers and slightly higher humpback chub numbers than Alternative A, but less nearshore habitat stability and aquatic productivity. The proposed action's contribution to cumulative impacts, however, would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Vegetation	Riparian zone along the Colorado River between Glen Canyon Dam and Lake Mead	Lower regional precipitation with climate change would result in a shift to more drought-tolerant species in the New High Water Zone; those in the Old High Water Zone would continue to decline. Drought conditions would favor nonnative tamarisk (which is tolerant of drought stress). However, tamarisk control efforts by the NPS and possibly the effects of the tamarisk leaf beetle and splendid tamarisk weevil would increase tamarisk mortality and improve conditions for native shrubs over time. Feral burros contribute to impacts on riparian vegetation in the Old High Water Zone (by reducing vegetation and decreasing species diversity); recreational visitors may also contribute to vegetation loss and the introduction of exotic plant species.	Most alternatives, including Alternative A, result in a decrease in native community cover and wetlands. Alternative D is the only alternative that results in an overall improvement in vegetation. The program's contribution to cumulative impacts, however, would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.
Wildlife	Colorado River corridor between Glen Canyon Dam and Lake Mead	Cumulative impacts on aquatic resources and riparian vegetation (as described in the above entries) affect riparian and terrestrial wildlife. Wildlife may also be affected by other future actions and basin-wide trends. Increased water demand and lower flows downstream of Glen Canyon Dam could stress riparian and wetland vegetation, affecting both wildlife habitats and the wildlife prey base. Warmer discharges (attributed to climate change) would likely increase algae and invertebrates, increasing the prey base for some species. Vegetation management could adversely affect birds in the short term, but are expected to provide benefits in the long term. Wildlife disturbance could result from various actions, including uranium mining, the Grand Canyon Escalade Project, and recreational activities (hiking, rafting, fishing, and camping). Habitat loss is a concern for those projects involving the construction of roads, effluent ponds (mining), and buildings.	Most alternatives would have little effect on most wildlife species. Alternatives with more fluctuations, and less-even monthly release volumes (Alternatives A and B), would have greater impact on species that use nearshore habitats or feed on insects with both terrestrial and aquatic life stages. The proposed action's contribution to cumulative impacts, however, would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Cultural resources	Cultural sites within Glen and Grand Canyons	Cultural resources (primarily archaeological sites) are in an ongoing state of deterioration due to natural erosive processes or, in some cases, human causes related to the presence and operation of Glen Canyon Dam or park visitation. Visitor traffic along the Colorado River can result in deterioration of sites as artifacts exposed by erosion are moved or removed from the site. These effects are somewhat mitigated through enforcement of NPS's Colorado River Management Plan and Backcountry Management Plan in GCNP (with similar enforcement in GCNRA). The effects of climate change on landscape features containing archaeological remains are unclear. Ongoing dam operations may affect sediment availability for site stabilization in GCNP and lowered reservoir levels may affect archaeological sites along shorelines in GCNRA and LMNRA.	Alternatives with extended-duration HFEs (Alternatives D and G) could adversely impact terraces that support cultural resources in Glen Canyon. Alternatives with more HFEs (e.g., Alternatives C, D, E, F, and G) could provide for greater protection of sites by providing more sand for wind transport to these sites. The proposed action's contribution to cumulative impacts, however, would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.
Tribal resources	Glen, Marble, and Grand Canyons	Many Tribes regard the Canyons as sacred space, the home of their ancestors, the residence of the spirits of their dead, and the source of many culturally important resources. Development related to projects like the Lake Powell Pipeline and uranium mining in the region, as well as fish/vegetation management practices, have ongoing adverse impacts on Tribe members. Actions and basin-wide trends affecting aquatic life, vegetation, and wildlife (as described above) would also affect resources of value to Tribes.	All alternatives except Alternative F include either mechanical removal of trout or TMFs and may have an adverse impact to Tribes. Alternatives that include vegetation treatments (all action alternatives), and alternatives that improve vegetation conditions (Alternatives B and D), could lead to a more natural riparian ecosystem and provide a benefit. No alternative would affect Tribal water rights. The proposed action's contribution to cumulative impacts, however, would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Recreation, visitor use and experience	Colorado River and associated recreational sites between Glen Canyon Dam and Lake Mead	The HFE protocol has had a beneficial effect on camping and beach access (and therefore visitor use and experience) because it has a direct effect on sediment transport and deposition. Other actions taken by the NPS, as described in various management plans (tamarisk management, GCNP backcountry, noise and special flight rules, fire), also benefit visitor use and experience. The CRMP (which regulates boating and rafting) and the Comprehensive Fisheries Management Plan and Non-Native Fish Control Program are protective of natural/cultural resources and also have long-term beneficial effects on recreation and visitor experience. Warming water temperatures (and reduced flows below Glen Canyon dam) attributed to climate change could affect the health of the trout fishery below the dam, thus contributing to adverse cumulative impacts on recreation related to the trout fishery.	Most alternatives would result in a reduction in navigation concerns (with the exception of Alternative B), lower catch rates, and increased camping area (with the greatest potential increase in camping area under Alternative G and higher catch rates under Alternatives F and G). The proposed action's contribution to cumulative impacts, however, would be negligible compared to the effects of past, present, and reasonably foreseeable future actions.
Wilderness	Colorado River and associated recreational and wilderness sites between Glen Canyon Dam and Lake Mead	The HFE protocol and other actions taken by the NPS, as described in various management plans (the CRMP, tamarisk management, GCNP backcountry, noise and special flight rules, fire) would benefit wilderness values and experience (although noise and visual effects associated with some actions diminish these values over the short term). The Grand Canyon Escalade would contribute to adverse impacts on visitors seeking solitude or a wilderness experience due to its visual and noise effects and the presence of infrastructure, all of which are incompatible with the character of GCNP. Basin-wide effects related to climate change (e.g., reduced water availability) could diminish wilderness values and experience by reducing opportunities for solitude.	Disturbance from non-flow actions would occur under all alternatives; the most crowding at rapids would occur under Alternative E; alternatives with greater fluctuations (e.g., Alternatives A, B, and E) could affect wilderness character. The program's contribution to cumulative impacts, however, would be negligible compared to the effects of past, present, and reasonably foreseeable future actions

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Visual resources	Shorelines and waters of the Colorado River between Glen Canyon Dam and Lake Mead; shorelines of Lakes Powell and Mead; and the general landscape in the project area	Projected future declines in reservoir levels due to increased water demand, decreased water supply, the planned Lake Powell Pipeline project, and drought attributed to climate change could increase the likelihood of exposure of calcium carbonate rings and sediment deltas in Lakes Powell and Mead. Infrastructure associated with the Lake Powell Pipeline project (pipeline, facilities, viewing platforms, and transmission lines), uranium mining, vegetation changes, and elements of the Grand Canyon Escalade development would also add to visual contrast and noticeable changes in the existing landscape.	LTEMP alternatives do not vary with respect to their impacts on visual resources. the proposed action's contribution to cumulative impacts would be negligible compared to the effects of past, present, and reasonably foreseeable future actions

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Hydropower	Utilities and their customers who purchase power generated by Glen Canyon Dam WAPA, Upper Colorado Basin Fund, environmental programs funded by CRSP power revenues; Upper Basin State apportionment-funded projects	Operating criteria imposed by the 1996 ROD for Glen Canyon Dam to comply with the Grand Canyon Protection Act have placed multiple restrictions on the variability of water released from the dam, thus restricting dam operational flexibility. Under the current operating regime (MLFF), fluctuations in release rates, ramp rates, and maximum hourly increases/decreases are restricted and the maximum release rate for power generation is limited to 25,000 cfs. Maximum releases above 25,000 cfs occur through bypass tubes to achieve a constant release rate. Bypassing water around generators produces no energy, which can result in additional purchases of replacement power. Increased demand for electricity in the service territories of the eight largest WAPA customer utilities and planned retirement of existing powerplant generating capacity would require an estimated 4,820 MW of new capacity to be built over the next 20 years. Changes in operations due to environmental concerns at other generating stations (the Aspinall Unit and Flaming Gorge Dam) have also resulted in reductions in generating capacity at these facilities, necessitating the purchase of replacement capacity from other sources and increasing wholesale power rates. Changes at NGS to meet air emissions requirements may result in a reduction in generation output at the facility and its contribution to power in the Western Interconnection. This could result in excess transmission capacity within the Western Interconnection.	LTEMP alternatives vary with respect to hydropower production, hydropower capacity, and retail rates, and therefore cumulative impacts. Alternatives with higher fluctuation levels (Alternatives A, B, D, and E) achieve higher values of generation and capacity and lower impacts on retail rates than do alternatives with steadier flows (Alternatives C, F, and G), especially if more water is released in the high-demand months of July and August. Alternatives A and B would have the least effect on the value of generation, the value of capacity, and retail rates, while Alternatives F and G would have the highest. However, the proposed action's contribution to cumulative impacts would be small compared to the effects of past, present, and reasonably foreseeable future actions.

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Socioeconomics and environmental justice	Six-county region in the vicinity of the Colorado River between Lakes Powell and Mead; recreational resources, including Lake Powell, Lake Mead, and the Grand Canyon (Colorado River)	Projected future changes in reservoir levels and river flow due to increased water demand, decreased water supply, and drought attributed to climate change could be the greatest contributors to adverse impacts on the recreational use values associated with fishing, day rafting, and whitewater boating. The Grand Canyon Escalade would likely increase recreational visitation and expenditure rates along the Colorado River. The annual release volume from Glen Canyon Dam, as determined by the 2007 Interim Guidelines, also affects recreation economics. NPS regulates the number of boating trips (specified in the CRMP and the Comprehensive Fisheries Management Plan). Therefore, regional economics of these activities are not expected to change in the foreseeable future.	LTEMP alternatives result in relatively minor changes in use value and economic activity associated with reservoir and river recreation, and in residential retail rates. Environmental justice issues are associated with alternatives that incorporate frequent trout control actions (Alternatives C, D, and G), or result in increased economic impacts on Tribes associated with the cost of electricity (Alternatives F and G). The proposed action's contribution to cumulative impacts would be negligible compared to the effects of past, present, and reasonably foreseeable future actions

TABLE 4.17-2 (Cont.)

Resource/System	Region of Influence	Contributors to Cumulative Impacts	Contributions of LTEMP Alternatives to Cumulative Impacts
Air quality and climate change	GCNP and the 11-state Western Interconnectionion region	The construction of new (and the renewal of existing) fossil fuel-fired powerplants to meet increased energy demands from population and industrial growth in the region, coupled with drought conditions brought on by climate change (which increase the potential for wildfires and dust storms), could increase visibility degradation in the foreseeable future. The natural scattering of light would continue to be the main contributor to visibility degradation (haze) in the region, including GCNP. Other significant contributors would include wildfires, controlled burns, windblown dust, and emissions from metropolitan areas (manufacturing, coal-fired powerplants, and combustion sources like diesel engines). Hydropower generation at Glen Canyon Dam does not generate air emissions; however, dam operations can affect ambient air quality by causing a loss of generation that is offset by generation from coal, natural gas, or oil units. Under baseline operations (Alternative A), emissions of SO_2 and NO_x generated by powerplants affected by Glen Canyon Dam operations would be about 9.9% and 3.0% of the total emissions over the Western Interconnectionion region, respectively. Air quality impacts due to emissions under the other alternatives would be negligible because they would be only slightly increased or decreased relative to the baseline. Increases in GHG emissions associated with changes in operations under LTEMP alternatives would be negligible. The EPA's Clean Power Plan Proposed Rule (currently stayed by the U.S. Supreme Court) would have a beneficial impact on the air quality in the region by mandating reductions in CO_2 emissions from fossil fuel-fired powerplants. The closure of three coal-burning units at the FCPP would reduce levels of NO_x and PM pollutants that contribute to regional haze and visibility issues in the GCNP. The reduction of generation output at the NGS to meet air emissions requirements will reduce levels of NO_x in the region.	LTEMP alternatives are expected to have negligible differences with respect to their impacts on air emissions including GHGs. The contribution of the proposed action to cumulative impacts would be negligible compared to the effects of past, present, and reasonably foreseeable future actions

Section 1802(b). As a consequence, the impacts of alternatives do not vary in their contribution to cumulative impacts on water supply and delivery.

Current water quality conditions and characteristics of Lake Powell (Section 3.2.2.1), Colorado River below Glen Canyon Dam (Section 3.2.2.2), and Lake Mead (Section 3.2.2.3) reflect the effects of past and present (ongoing) actions. Before Glen Canyon Dam was constructed, the river was characterized by wide natural fluctuations in water quality characteristics (e.g., temperature, salinity, turbidity, and nutrients). In the post-dam era, these variations are moderated and the river has seen an overall improvement in water quality. Future water quality would likely be affected most by increased water demand and climate change. Although most alternatives would likely result in a slightly increased potential for bacteria and pathogens along shorelines, the contribution of continued operations under the LTEMP to cumulative impacts on water quality is expected to be negligible regardless of which alternative is selected.

As the population in the Basin States grows and expands, municipal, industrial, and agricultural water demand continues to increase. In its 2013 study, Reclamation concluded that the total consumptive use and loss (i.e., surface water and groundwater depletions and evaporative losses) for the Arizona portion of the Upper Colorado River Basin (covering about 6,900 mi^2) was 35,037 ac-ft, more than half of which is water pumped directly from Lake Powell and used by the Navajo Generating Station (Reclamation 2014e).

Urban runoff, industrial releases, and municipal discharges are considered some of the leading nonpoint sources of contaminants to surface waters (EPA 2004). Areas of intensive agriculture can have an adverse effect on the water quality as a result of the salinity, nutrients, pesticides, selenium, and other trace elements that are common constituents in agricultural runoff. As a result, water management and efficient water use become important variables in the Colorado River supply and demand equation (Beckwith 2011). The 2007 Interim Guidelines, and related water conservation efforts, should provide more predictability in water supply to users (especially in the Lower Basin) through 2026.

The general picture for climate change, as it relates to Colorado River Basin hydrology, includes decreased inflow to the reservoir system (e.g., lower precipitation) and greater losses (e.g., evapotranspiration associated with higher temperatures and increased demand from the growing population). Climate change is expected to result in more frequent and severe drought conditions in the Southwest. Meeting increasing water needs (e.g., the Lake Powell Pipeline project and the Page-LeChee water supply project) will likely lead to lower reservoir levels in Lake Powell, which may already be affected by increased evaporation associated with higher air temperatures. As discussed in Section 4.2.2, decreasing the elevation of Lake Powell can lead to warmer water discharges from Glen Canyon Dam and increased water temperatures downstream.

4.17.3.2 Sediment Resources

The construction and presence of Glen Canyon Dam has affected Glen, Marble and Grand Canyons by (1) reducing the sediment supply, and by (2) reducing the annual peak flows.

Among the actions considered under LTEMP, HFE releases (which are highest under Alternatives C, D, E, F, and G) have the greatest impact on sediment resources (and sandbar building potential), although variability in hydrology or sediment supply from tributary inputs has a greater impact than HFEs. Cumulative impacts that affect this variability in hydrology and sediment supply (such as climate change) have the potential to affect sediment resources in the future.

It has been estimated that the post-dam sand supply to Marble Canyon is less than 10% of the pre-dam supply (Topping et al. 2000a; Topping, Rubin, Nelson et al. 2000; Wright, Schmide et al. 2008), with the majority of the sediment evacuation between the dam and Phantom Ranch (RM 87) occurring during the three decades following dam construction. The reduced sediment supply would move downstream at different rates in the various LTEMP alternatives, but sediment supply to Marble and Grand Canyons would not differ among the alternatives. The 1996 ROD modifications to the flow regime resulted in benefits for the building and retention of sandbars.

Future climate change implications on sediment resources are highly variable and cannot be accurately quantified. Conceptually, climate change can affect the sediment resource in two ways: by changing the hydrology in the drainage area upstream of Glen Canyon Dam, and by changing the hydrology in the drainage area downstream of Glen Canyon Dam, especially in the drainage area of primary sediment contributors such as the Paria River and the Little Colorado River. A drier future hydrology in these drainage areas could decrease the availability of sand in Marble and Grand Canyons.

4.17.3.3 Natural Processes

Cumulative impacts on natural processes (water flow, water temperature, and sediment supply) reflect those discussed under water resources (Section 4.17.3.1) and sediment resources (Section 4.17.3.2). Although some of the LTEMP alternatives could affect these resources (e.g., potential sandbar growth through implementation of HFE releases, which is greatest under Alternatives C, D, E, F, and G), the incremental effects of the alternatives are not anticipated to contribute significantly to cumulative impacts on natural processes along the Colorado River corridor or within the basin at large. Implementation of HFEs could result in an improvement in sandbar building over the long term. Tamarisk control and fisheries management actions could improve natural processes by restoring native species. Climate change (and its effects on water flow, water temperature, and sediment supply), however, would likely have a greater effect on natural processes than any of the LTEMP alternatives.

4.17.3.4 Aquatic Ecology

Section 3.5.1 describes the current conditions of the aquatic food base in the Colorado River downstream of Glen Canyon Dam. The current state of the aquatic food base reflects the effects of past and present (ongoing) actions; Section 4.5.3 discusses potential impacts of the various LTEMP alternatives. The aquatic food base may also be affected by other reasonably

foreseeable actions, particularly climate change, dam modification, water use, introduction of nonnative species, and uranium mining.

Population growth, industrial development, and the warming associated with climate change will act in concert to increase demand for water (Schindler 2001). The potential for urban and agricultural runoff also increases with population growth, producing adverse effects on water quality, which could ultimately affect aquatic biota and habitat. Climate change is also expected to result in more frequent and severe drought conditions in the Southwest, which will continue to tax water supplies. Combined with increased evaporation associated with higher temperatures, meeting water needs would lead to lower reservoir levels in Lake Powell. The Lake Powell Pipeline Project would also contribute to lower Lake Powell reservoir elevations (FWS 2011c). Lowering of Lake Powell elevations can lead to warmer water discharges from Glen Canyon Dam. The Red Gap Ranch Pipeline, which would withdraw groundwater contributing to the base flow of the Little Colorado River, could reduce habitat availability and suitability in the Little Colorado River with subsequent adverse effects on humpback chub and designated critical habitat, although the magnitude of these impacts have not been quantified.

Warmer water temperatures would likely increase production rates of algae and invertebrates (Woodward et al. 2010; FWS 2011c). Lower levels of Lake Powell may also result in increases in the composition and density of zooplankton downstream of Glen Canyon Dam, because waters would be withdrawn closer to the surface (Reclamation 1995). However, warmer temperatures, particularly in winter, may allow many invertebrate species to complete their life cycles more quickly (Schindler 2001). For example, if stream temperatures are raised by only a few degrees in winter, many aquatic insects that normally emerge in May or June may emerge in February or March and face death by freezing or be prevented from mating because of being inactivated by low air temperatures. In addition, increases in stream temperatures may cause an exaggeration in the separation of the emergence of males and females (e.g., males may emerge and die before females emerge) (Nebeker 1971). Temperatures above the optimum can lead to the production of small adults and lower fecundity (Vannote and Sweeney 1980).

Warmer water temperatures can expand the distribution of nonnative species adapted to warmer temperatures. This includes fish parasites such as the Asian tapeworm, anchor worm, and nonnative crayfish. Increased zooplankton due to climate change may increase abundance of cyclopoid copepods. All cyclopoid copepod species appear to be susceptible to infection by, and therefore serve as intermediate hosts for, the Asian tapeworm (Marcogliese and Esch 1989). Crayfish can prey on fish eggs and larvae and can diminish the abundance and structure of aquatic vegetation such as filamentous algae through grazing (FWS 2011c). Nonnative crayfish are present in Lake Powell (northern or virile crayfish [*Orconectes virilis*]) and Lake Mead (red swamp crayfish [*Procambarus clarkii*]). Warmer temperatures may allow the crayfish to expand into the mainstem of the Colorado River either downstream of Lake Powell or upstream of Lake Mead.

As discussed in Section 3.5.1, some nonnative species introductions occurred in order to supplement the aquatic food base (e.g., *Gammarus*, snails, and midges); while accidental introductions have occurred via fish stocking and recreational fishing, often with detrimental effects on both lower trophic levels or fish species (e.g., the New Zealand mud snail and parasitic

trout nematode [*Truttaedacnitis truttae*]). The quagga mussel (*Dreissena bugensis*), which is established in Lake Powell, may develop viable populations in the mainstem of the Colorado River, at least within the Glen Canyon reach.

Concern has been raised about the diatom *Didymosphenia geminata* ("didymo") becoming established in the Colorado River. High-density blooms of didymo are frequent in rivers directly below impoundments. In these river reaches, stable flows and fairly constant temperatures favor development of large masses of didymo (see Spaulding and Elwell 2007). Didymo can form nuisance benthic growths that extend for more than 1 km and persist for several months (Spaulding and Elwell 2007). Mayflies, stoneflies, caddisflies, and dragonflies have an inverse relationship with didymo coverage, while midges and aquatic worms dominate didymo-covered areas (Larson and Carreiro 2008). Nevertheless, the presence of didymo has been associated with increased periphyton biomass and increased invertebrate densities and richness (Kilroy et al. 2009; Gillis and Chalifour 2010). Given the large amounts of non-nutritious stalk material present on stream substrates in affected areas, didymo is predicted to have deleterious effects on native fish, especially those that inhabit benthic habitats, consume benthic prey, and nest beneath or between cobbles (see Spaulding and Elwell 2007). Didymo is present in waters from 4 to 27°C (39 to 81°F) (Spaulding and Elwell 2007), so warming would not be a factor in its occurrence in the Colorado River. However, development of didymo blooms likely requires both low mean discharge and variation in discharge. Scouring events usually remove didymo stalk material from substrates (Kirkwood et al. 2007).

Uranium mining peaked in the 1980s in the Grand Canyon region, but there is now a renewed interest due to increases in uranium prices. Increased uranium mining (on state and private lands) could increase the amount of uranium, arsenic, and other trace elements in local surface water and groundwater flowing into the Colorado River (Alpine 2010). Uranium, other radionuclides, and metals associated with uranium mines can affect the survival, growth, and reproduction of aquatic biota.

Aquatic biota and habitats most likely to be affected during mine development and operation are those associated with small, ephemeral, or intermittent drainages. Impacts on aquatic biota and habitats from the accidental release of regulated or hazardous materials into ephemeral drainages would be localized and small, especially if a rapid response to a release is undertaken. The accidental spill of uranium ore into a permanent stream or river such as Kanab Creek would potentially pose a localized short-term impact on the aquatic resources. However, the potential for such an event is extremely low. Most ore solids would settle in the waterbody within a short distance from a spill site (Edge Environmental, Inc. 2009). It is expected that expedient and comprehensive cleanup actions would be required under U.S. Department of Transportation regulations and that an emergency response plan would be in place for responding to accidents and cargo spills (Edge Environmental, Inc. 2009). Overall, the potential for impacts on aquatic biota from an accidental spill would be small to negligible. Spencer and Wenrich (2011) estimated that if an ore load is washed into the Colorado River and is pulverized and dissolved (a scenario that is extremely unlikely to impossible), the uranium concentration in the river would increase from the current 4.0 ppb to only 4.02 ppb (undetectable against natural variations). Predicted no chemical effect concentrations for aquatic vascular plants, aquatic invertebrates, and fish are ≥5.0 ppb; the lowest chronic concentrations are well above that

concentration (see Hinck et al. 2010). For these reasons, the impacts from uranium mining on aquatic biota in the Colorado River or its major tributaries would be expected to be localized and would not be expected to reduce the viability of affected resources.

The incremental effects of the LTEMP alternatives on fish are not expected to contribute significantly to cumulative impacts along the Colorado River corridor or within the basin at large. Examination of the various hydrologic traces used to model effects of alternatives on aquatic resources indicated that hydrology (i.e., whether a 20-year trace was drier or wetter on average) had a greater influence on the model results than the operational differences among alternatives. Similarly, climate change has the potential to have greater effects on fish resources than any of the alternatives because of its direct influences on hydrologic patterns. For example, more frequent droughts and warmer atmospheric temperatures have the potential to result in greater increases in the temperature of water being released from the dam than the operational actions being considered, and this in turn may improve thermal suitability for humpback chub, humpback chub aggregations, and native fish. However, any subsequent benefits may be offset by increased abundance and expansion of nonnative fish and aquatic fish parasites. There are a number of other actions being taken within the Colorado River Basin that could also contribute to significant cumulative effects on fish populations or fish communities. For example, actions to increase the number of self-sustaining populations of humpback chub within the basin (e.g., translocation of humpback chub from the Little Colorado River to other tributaries within the Grand Canyon) have the potential to increase overall numbers of humpback chub and could provide some level of protection against catastrophic events in the Little Colorado River that could greatly reduce or eliminate the population of humpback chub in the Grand Canyon.

4.17.3.5 Vegetation

In addition to effects of releases from Glen Canyon Dam and NPS's experimental vegetation treatment program, factors that would impact riparian plant communities include the tamarisk leaf beetle (*Diorhabda* spp.) and splendid tamarisk weevil (*Coniatus* spp.), which occur along much of the Colorado River below Glen Canyon Dam. By late 2012, the tamarisk leaf beetle had been found in many locations in the Grand Canyon, with an estimated 70% defoliation at some sites (Johnson et al. 2012). Tamarisk leaf beetle is not expected to have impacts on populations of other plant species, such as native shrubs (Dudley and Kazmer 2005). Fire management policies for GCNP include fuel reduction by removal of dead woody material as well as fire suppression; however, riparian areas are generally avoided (NPS 2012d).

The replacement of tamarisk by other species and the timing of replacement would be affected by flow characteristics as well as site-specific factors. The potential reduction in the dominance of tamarisk in many areas and the decrease in total area of tamarisk-dominated communities along the Colorado River could result in an increase in native species or, more likely, other nonnative species, especially where soils have high nitrogen levels (Hultine et al. 2010; Shafroth et al. 2005, Shaforth, Brown et al. 2010; Belote et al. 2010; Reynolds and Cooper 2011; Uselman et al. 2011; Johnson et al. 2012; Bateman et al. 2013). Many nonnative species are already present along portions of the Colorado River and Lake Mead (Table 4.6-5). Short-term changes in nutrient dynamics in the riparian ecosystem could also occur with increased activity of tamarisk leaf beetles, with subsequent effects on the future

development of native or nonnative communities (Uselman et al. 2011). Soil seed banks may contain a high diversity of species and would potentially influence subsequent plant community composition; however, the regrowth of native species may be slow (Reynolds and Cooper 2011; Belote et al. 2010).

As discussed in Section 4.6, hydrologic conditions have a greater effect on native community types in the Fluctuation Zone and New High Water Zone than do the operational characteristics of the LTEMP alternatives. Within each alternative, the occurrence of flows with significant effects on riparian vegetation, such as extended high flows and extended low flows, are determined in large part by the inflow to Lake Powell as a result of hydrologic variation (Section and 4.2). Other events, such as spill flows (flows >45,000 cfs that would necessitate use of the spillway) could have pronounced effects on riparian vegetation, but these too result from hydrologic variation and not characteristics of the alternatives. However, with forecasting capabilities currently used by the Bureau of Reclamation, it is unlikely that spill flows would occur in the future. Within a year, under any alternative, monthly operations may be increased or decreased based on changing annual runoff forecasts, and application of the Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (Reclamation 2007a).

Feral burros contribute to cumulative impacts on riparian vegetation, especially vegetation in the Old High Water Zone. Researchers documented vegetation impacts from feral burros as early as 1974, noting vegetation destruction and decreases in species diversity. These impacts, along with impacts on soils, remain visible on the landscape today with very little vegetation recovery (Leslie 2004).

Visitation from commercial and private river trips, as well as backcountry hikers and anglers, also can affect vegetation. Visitors have created trails and added to the loss of vegetation in upland and Old High Water Zone areas. Administrative actions such as tamarisk eradication projects and archaeological site monitoring programs can also contribute to vegetation impacts. The intentional or unintentional spread of exotic plant species by humans coming into the area of effect contributes to the current levels of impacts along the Colorado River corridor. This can have localized, adverse, short- or long-term, year-round effects on vegetation by visitors in the riparian zone, and has effects in camping areas, trails, and in popular visitation areas (NPS 2006b).

Riparian ecosystems are expected to be affected by long-term changes in the climate across the Colorado River watershed. Under a climatic trend of lower precipitation, there would likely be fewer years with extended high flows and an increase in the number of years with extended low flows under any of the alternatives. It is also possible that, with lower regional precipitation, there could be fewer sediment-triggered HFEs if the Paria River delivers less sediment. Riparian plants in the Old High Water Zone are expected to continue to decline. The New High Water Zone would tend to experience a shift toward more drought-tolerant species, such as arrowweed and mesquite. Tamarisk is tolerant of drought stress, and has an advantage over native species that require access to groundwater, such as cottonwood and willow, in areas where water tables are lowered. Thus, tamarisk may be maintained under drier climate conditions, although recruitment events may be limited and, as noted above, effects of

defoliation may greatly affect tamarisk-dominated communities. Communities that require a shallow water table or relatively frequent inundation, such as marsh, shrub wetland, and cottonwood-willow woodland, would likely decline.

Natural events, such as floods inside canyons and rockfalls, scour vegetation; this can add to the loss of diverse and intact native vegetation and contribute to the spread of invasive, exotic plant species. In addition, as noted in Section 3.6.2, years with unusually high inflow into Lake Powell, such as 1983, may result in emergency dam releases greater than 45,000 cfs that would have major and lasting effects on vegetation (Mortenson et al. 2011; Ralston 2012).

The effects of the LTEMP alternatives on riparian vegetation communities are relatively small compared to the effects of other factors, especially future hydrology. For this reason, the incremental effects of the alternatives on native and nonnative plant species are not expected to contribute significantly to cumulative impacts along the Colorado River corridor or within the basin at large. Most alternatives, including Alternative A, are expected to result in a decrease in native community cover and wetlands. Alternative D is the only alternative that is expected to result in an overall improvement in vegetation.

4.17.3.6 Wildlife

Section 3.7 describes the current condition of wildlife in the Grand Canyon, which reflects the effects of past and present cumulative impacts; Section 4.7 discusses the potential impacts the various LTEMP alternatives may have on wildlife. Because the assessment of impacts on wildlife is based partly on an evaluation of impacts on the aquatic food base, fish (Section 4.5.2), and riparian vegetation (Section 4.6), cumulative impacts on those resources will also result in cumulative impacts on wildlife. Wildlife may also be affected by other reasonably foreseeable future actions and basin-wide trends contributing to cumulative impacts (Sections 4.17.1.2 and 4.17.2), particularly water use, climate change, vegetation management, AML closure, fire, trout management, introduction or spread of nonnative species, human-associated noise and visual disturbance (e.g., from recreation), and uranium mining.

Population and industrial growth, coupled with climate change, will act in concert to increase water demand in the region (Schindler 2001) and lower flows downstream of Glen Canyon Dam. This could stress existing riparian and wetland vegetation, leading to plant community alterations that would affect both wildlife habitats and the wildlife prey base. Climate change would not affect all wildlife species uniformly. Some species would experience distribution contractions and likely shrinking populations while other species would increase in suitable areas and thus possibly experience increases in population numbers. Generally, the warmer the current range is for a species, the greater the projected distributional increase (or lower the projected loss) will be for that species due to climate change (van Riper et al. 2014).

Lowering of Lake Powell elevations can lead to warmer water discharges from Glen Canyon Dam. Warmer water temperatures would likely increase production rates of algae and invertebrates (Woodward et al. 2010; also see FWS 2011c) leading to increases in the prey base

for some wildlife species such as amphibians, lizards, waterfowl, insectivorous songbirds, and bats.

Riparian vegetation management activities (e.g., removal of nonnative plants and planting of native plants) would modify the cover, stratification, and distribution of plant communities along the Colorado River. Eradication of tamarisk could affect birds by altering prey availability, increasing nest abandonment and predation, and reducing the quantity of riparian habitat available to breeding birds (Paxton et al. 2011). In the long term, riparian vegetation management may diversify riparian habitats and establish a more productive wildlife community. Additional factors that could affect riparian wildlife habitat include the tamarisk leaf beetle and splendid tamarisk weevil, which occur along much of the Colorado River below Glen Canyon Dam and result in defoliation and mortality of tamarisk (Section 4.17.3.4). Widespread tamarisk mortality would likely result in a net loss in riparian habitat for at least a decade or more (Paxton et al. 2011). It seems unlikely that the effects of large-scale defoliation in areas dominated by tamarisk will be compensated for by use of tamarisk beetles as a food resource by birds (Puckett and van Riper 2014).

The highly flammable tamarisk has created a fire hazard previously absent along the river. This threatens breeding bird populations, as well as other wildlife. In addition, if native or mixed habitat stands burn, monotypic tamarisk will likely recolonize, eliminating the crucial structure necessary for southwestern willow flycatchers and other nesting birds (e.g., thermal buffering through shading becomes insufficient and will be further exacerbated by warming climate trends) (Schell 2005).

The quagga mussel (*Dreissena rostriformis bugensis*), which is currently established in Lake Powell, may develop viable populations in the mainstem of the Colorado River, at least within the Glen Canyon reach. An established population of quagga mussels may increase the prey base available to diving ducks. Warmer temperatures may allow crayfish inhabiting Lake Mead and Lake Powell to expand into the mainstem of the Colorado River, providing an additional prey item for some wildlife species.

In the past, uranium mining led to localized peregrine falcon nest failures in areas such as Kanab Canyon and its multiple side canyons, where numerous mining claims existed (Payne et al. 2010). Although 684,449 ac of federal land administered by BLM north of GCNP (North and East Parcels) and 322,096 ac of federal land administered by the USFS south of GCNP (South Parcel) would be withdrawn from locatable mineral exploration and development (i.e., uranium mining), increased uranium mining on non-federal (state and private) lands remaining open to mining could locally affect wildlife habitat (e.g., habitat loss and fragmentation) and increase the amount of uranium, arsenic, and other trace elements in local surface water and groundwater flowing into the Colorado River (Alpine 2010). Edge habitat associated with uranium mines and associated access roads may provide habitat for brown-headed cowbirds (Payne et al. 2010), which are brood parasites of songbirds. Grazing and recreation, including use of commercial pack-stock, also increase brown-headed cowbird populations (Schell 2005). Habitat loss from uranium mines and associated access roads could affect the distribution and movement of big game mammals (e.g., elk, mule deer, bighorn sheep, and mountain lions), and potentially increase their mortality from vehicle collisions or poaching

(Payne et al. 2010). There could be a potential contaminant exposure issue associated with amphibians (or other wildlife) attracted to uranium mine effluent ponds (Payne et al. 2010). In general, any impacts on wildlife from uranium mining would be localized and should not affect the viability of affected resources, especially with the use of best management practices to control mine discharges and proper mine reclamation.

The Grand Canyon Escalade Project and its associated facilities near the confluence of the Little Colorado River could cause both a localized loss of wildlife habitat and source of wildlife disturbance due to human presence. Wildlife species in the Grand Canyon are currently exposed to various sources of manmade noise ranging from human conversation to aircraft flyovers. The potential effects of noise on wildlife include acute or chronic physiological damage to the auditory system, increased energy expenditures, physical injury incurred during panicked responses, interference with normal activities (e.g., feeding), and impaired communication (AMEC Americas Limited 2005). The response of wildlife to noise would vary by species; physiological or reproductive condition; distance; and the type, intensity, and duration of the disturbance. Regular or periodic noise could cause adjacent areas to be less attractive to wildlife and result in a long-term reduction in use by wildlife in those areas. Responses of wildlife to disturbance often involve activities that are energetically costly (e.g., flying or running), altering their behavior in a way that might reduce food intake, communication, and nesting (Hockin et al. 1992; Brattstrom and Bondello 1983; Cunnington and Fahrig 2010; Francis et al. 2009; Maxell 2000).

Recreational activities such as hiking, rafting, fishing, and camping can result in disturbance to wildlife. For example, hikers, rafters, anglers, and researchers can disturb bald eagles; however, southwestern willow flycatchers are not apparently sensitive to rafts or boats passing their breeding sites, but people moving through occupied habitat can disturb the birds or impact a nest (Holmes et al. 2005). Impacts on reptiles and amphibians can include occasional opportunistic collecting or harassment by recreationists. As demand for reptiles in the pet trade increases and collectors seek new sources of supply, many national parks are experiencing problems with illegal reptile collection, especially of rattlesnakes (NPS 2014h). Recreationists can affect birds and other wildlife by removing or modifying vegetation within both the new and old high-water zones (e.g., for campsites and trails) (NPS 2005a).

During winter 1990–1991, more eagles were detected in reaches with low human use compared to reaches with high to moderate human use between Glen Canyon Dam and the Little Colorado River. No eagles were found within 1 km of intensively used areas near Lees Ferry and Navajo Bridge. Repeated flushing by bank fishermen, hikers, or boats could have caused wintering eagles to avoid reaches heavily used by anglers (Brown and Stevens 1997). Winter camping, especially in important eagle activity areas, can disturb bald eagles and has the potential to seriously disrupt a wintering eagle concentration (Sogge and Tibbitts 1994).

The effects of the LTEMP alternatives on wildlife are relatively small compared to the effects of other factors, especially future hydrology, and are not expected to contribute significantly to cumulative impacts along the Colorado River corridor or within the basin at large. Most alternatives would have little effect on most wildlife species. Alternatives with more fluctuations, and less even monthly release volumes (Alternatives A and B), would have greater

impact on species that use nearshore habitats or feed on insects with both terrestrial and aquatic life stages.

4.17.3.7 Cultural Resources

The proposed action is not expected to significantly change the ongoing cumulative impacts on historic properties. Past dam operations resulted in transformations to the environment that may contribute to the nature, severity, and rate of erosive forces having the potential to act upon and influence the integrity of these historic properties. The past action primarily affecting these resources was the construction and operation of the Glen Canyon Dam and the resulting loss of sediment in the river channel below the dam.

The river immediately downstream from Glen Canyon Dam was intentionally scoured in 1965 during a series of high-pulse flows. These pulse flows, coupled with other dam operation activities, transformed the pre-dam Glen Canyon, which had plentiful sand, native species, and active natural processes, to a present-day Glen Canyon that is incised, narrowed, and armored (Grams et al. 2007). The Glen Canyon Dam has prevented sediment-laden extreme high flows that occurred periodically in the past and allowed for both deposition and erosion at higher elevations, as well as extreme low flows that exposed sandbars and allowed wind transport to higher elevation terraces.

For GCNRA, these transformations include bed incision and reduction in the base level of erosion, sediment evacuation and exposure of terrace faces, and changes in gully type and formation processes. The degree to which these transformations may contribute to impacts on historic properties remains poorly understood, and is the subject of ongoing research. For GRCA, these transformations are primarily tied to loss of low-elevation sandbars and the degradation of the pre-dam river terraces that were home to peoples for the past 10,000 years.

In addition, the effects from visitors remain a persistent issue, although not overarching. The proposed action pertains to the operation of Glen Canyon Dam and does not alter any policies concerning visitor use of the river. The concern over visitor effects is exacerbated by erosion, which continues to expose additional portions of archaeological sites. The more artifacts are exposed at a site, the more opportunities exist for a visitor to pick up an artifact and move it. Only education can make visitors aware of the need to leave the artifacts as they lie.

Historic properties in the APE remain in a continual state of deterioration. The erosive forces that created the Grand Canyon continue to operate throughout both GCNRA and GCNP and continue to destabilize the historic properties found there. The degradation of historic properties due to natural causes remains the biggest challenge faced by historic property managers. Rain events cause gullying and remove the sediment that surrounds the historic properties along the Colorado River. Little can be done to slow these climatic processes although implementing management strategies to stabilize and minimize sediment losses may be effective tools in the future.

4.17.3.8 Tribal Resources

Actions contributing to cumulative impacts on Tribal resources include the continued use or reopening of breccia pipe uranium mines adjacent to the park, the development of new mines on state land lying within the Grand Canyon watershed, continued traffic of visitors to sites sacred to the Tribes, and specific projects, including the Lake Powell Pipeline, the Grand Canyon Escalade, and the Red Gap Ranch Pipeline.

Uranium prospecting and mining in the Grand Canyon watershed could contribute to cumulative effects on Tribes. Uranium mining has the potential to contaminate water sources that supply aquifer systems that feed springs, seeps, and their associated ecosystems within the Grand Canyon National Park (GCNP 2013). Many Tribes consider drilling or mining to be wounding the earth (BLM 2011). In 2012, the decision was made to withdraw over a million acres of federal lands surrounding GCNP in northern Arizona from uranium mining for the next 20 years. However, four existing mines were grandfathered and continue to operate intermittently as the price of uranium fluctuates. In addition, the withdrawal of federal lands has resulted in the concentration of new uranium exploration on state lands, some of which are within the Grand Canyon watershed. Past mining has resulted in the contamination of springs and seeps feeding the Grand Canyon, reducing their sacred nature. Uranium mining is currently taking place at sacred sites, including the Red Butte Traditional Cultural Property south of GCNP. Tribes in the region have expressed concern that contamination in the drainage to Havasu Canyon or in other watersheds and aquifers would be devastating to the downstream resources of importance to the Havasupai (Havasupai Tribal Council 2015). However, the LTEMP alternatives do not include any action that would result in water contamination and none are expected to contribute to cumulative impacts.

Continued use of the riparian zone by visitors to the Canyons has the potential to result in damage to places of cultural importance to the Tribes. Continued disturbance over time and space could result in the loss of the function and sacredness of traditional cultural places. These potential losses can be partially mitigated by the education of canyon visitors regarding the sanctity of the Canyons.

Actions affecting aquatic life, vegetation, and wildlife would also affect resources of value to Tribes (see Sections 4.5, 4.6, and 4.7). For example, changes in the tamarisk population due to the tamarisk leaf beetle and splendid tamarisk weevil, as well as long-term changes in the climate could contribute to cumulative impacts on riparian ecosystems across the Colorado River watershed. A summary of such impacts on Tribal resources is provided in Section 4.9.3.

The Lake Powell Pipeline proposes to carry water from Lake Powell to Sand Hollow Reservoir near St. George, Utah, to help meet water demand in southwestern Utah (UBWR 2011c). Impacts on historic properties have not been assessed for this project. Impacts on other resources of Tribal importance from the pipeline could include loss of some wildlife habitat and temporary loss of vegetation and riparian communities. The Red Gap Ranch Pipeline, which would withdraw and convey groundwater to augment Flagstaff's water supply, could affect springs of importance to Tribes, although the impacts of this action have not yet been assessed.

LTEMP alternatives that include mechanical trout removal or TMFs (all Alternatives except F), may have an adverse effect that would add to the cumulative impacts on Tribal resources (see also Table 4.9-2).

4.17.3.9 Recreation, Visitor Use, and Experience

Section 3.10 presents the recreational resources and activities that could be affected by the LTEMP alternatives. Most of the LTEMP alternatives would result in fewer navigation concerns, lower catch rates, and increased camping area (with the greatest potential increase in camping area under Alternative G and higher catch rates under Alternatives F and G). Section 4.10 presents the estimated incremental effects of the alternatives on those recreational resources and activities. The following paragraphs analyze the potential cumulative effects of past, present, and future actions on recreation resources that may also incur incremental effects from the LTEMP alternatives. Other resources analyzed separately that could incur cumulative effects that might also affect recreation include sediment, water quality, and the trout fishery below Glen Canyon Dam.

Some of the past and present actions described in Section 4.17.1.1, including natural events, could have effects on recreation. The past and present actions that could affect camping and beach access are those that affect sediment transport and deposition. Among these, the 2007 Interim Guidelines affect sediment retention and deposition through required equalization flows, which tend to erode beaches, while the 2011 HFE protocol would benefit beach and campsite building through sediment deposition. Such effects are already captured in the analysis of the LTEMP alternatives, which are subject to the provisions of ongoing programs.

Among ongoing actions that could affect recreation, visitor use, and experience, is the 2006 CRMP, which sets the number of annual launches for commercial and noncommercial boating and rafting.

The Comprehensive Fisheries Management Plan and the Non-native Fish Control Program would protect and benefit recreational fishing below Glen Canyon Dam. These two management programs would limit the effects of the LTEMP alternatives on the recreational fishery. Most of the alternatives incorporate management actions consistent with these plans, including TMFs and mechanical removal of trout. These plans and actions would tend to reduce cumulative impacts on the trout fishery through active management.

Of the reasonably foreseeable future actions, the proposed Grand Canyon Escalade project, including a gondola running from the canyon rim to the canyon floor near the confluence of the Little Colorado River and the Colorado River would contribute to cumulative impacts on recreational resources. The nature of effects, positive or negative, would depend on the perspective of a particular visitor. Users of the facility would benefit from the services offered. Adverse effects on wilderness experience are discussed in Section 4.17.10. Overall, however, effects of the Escalade project on recreationists are expected to be negative, because the vast majority of visitors come to experience natural beauty and solitude, which is incompatible with development within the Grand Canyon.

Climate change could affect recreation resources in a number of ways, some of which would add significantly to effects from ongoing actions and trends discussed. Warming temperatures could reduce runoff and water supply to the Colorado River and increase water demand from municipalities and for cooling, further reducing supply. Reduced availability of water could lower the elevation of Lake Powell, leading to warming and reduced flows below the Glen Canyon Dam. Warming could reduce DO levels in tailwaters. These factors could affect the health of the trout fishery below the dam and could affect boating through lower flows and higher daily fluctuations, as discussed in the previous paragraph. The combination of climate change and increasing water demands from regional population growth could increase the cumulative effects of reduced water availability.

The LTEMP alternatives would vary with respect to recreation, but would not significantly add to cumulative effects on recreation. Most alternatives would result in a reduction in navigation concerns (with the exception of Alternative B), lower catch rates, and increased camping area (with the greatest potential increase in camping area under Alternative G and higher catch rates under Alternatives F and G).

4.17.3.10 Wilderness

Wilderness character, as used in this EIS, is defined in Section 3.11 as the wilderness values and experience that may be impacted by LTEMP alternatives. Section 4.11 analyzes potential direct impacts on wilderness values and experience of the alternatives. In this section, potential cumulative effects on wilderness experience caused by other past, present, or future actions in the region are analyzed; aspects of the analysis of cumulative effects on recreation (Section 4.17.3.10) are also relevant to this discussion.

The GCNP Backcountry and Fire Management Plan would tend to benefit visitor use and experience under all the LTEMP alternatives through the protection of wilderness and visual resources and soundscapes, while mitigating to some extent visitor effects on the same resources.

The 2006 CRMP, which regulates commercial and noncommercial boating and rafting, would also tend to enhance visitor experience while protecting natural and cultural resources. By limiting the number of rafters on the river, this plan would protect wilderness experience and solitude. The 2010 Abandoned Mine Closure Plan could also enhance wilderness experience and protect natural resources through restoration of a more natural state. Similarly, the 2012 withdrawal of approximately a million acres of federal land in the vicinity of GCNP from entry for uranium mining would enhance wilderness values regionally by limiting industrial development in areas surrounding the parks.

With respect to foreseeable actions in the study area, the proposed Noise and Flight management alternatives could have a substantial beneficial effect on wilderness values in GCNP. The proposed Grand Canyon Escalade development on 420 acres near the confluence of the Little Colorado and Colorado Rivers could have adverse effects on wilderness values and experience in that area. Visitors seeking solitude or a wilderness experience could be adversely

affected by the visual and noise effects and the presence of infrastructure, which is incompatible with the character of GCNP.

Basin-wide trends that could affect wilderness values and experience would be primarily those related to climate change. Wilderness and wilderness experience would be adversely affected to the extent that warming and reduced water availability promote the growth of invasive and nonnative species, which would alter the native character of vegetation. Low water availability could cause crowding and loss of solitude on the river due to reduced navigability and delays at rapids from periodic low flows.

The LTEMP alternatives vary with respect to their impact on wilderness experience. Disturbance from non-flow actions would occur under all alternatives; the most crowding at rapids would occur under Alternative E; alternatives with greater fluctuations (e.g., Alternatives A, B, and E) could affect wilderness character. None of the alternatives would significantly contribute to the cumulative impacts for this resource.

4.17.3.11 Visual Resources

The current condition of visual resources is described in Section 3.12; this reflects the effects of past and present cumulative impacts on resources within the project area. Section 4.12 discussed the potential impacts of the various LTEMP alternatives on visual resources within the project area. Visual resources within the shorelines and waters of the Colorado River between Glen Canyon Dam and Lake Mead, the shorelines of Lake Powell and Mead, and the general landscape of the area may also be affected by reasonably foreseeable actions and basin-wide factors contributing to cumulative impacts, including the Lake Powell Pipeline Project, uranium mining, the Grand Canyon Escalade development, water use, and climate change.

Increased water demands from population and industrial growth, coupled with conditions brought on by climate change such as severe drought and higher temperatures, could lead to lower Lake Powell reservoir levels. In addition, the Lake Powell Pipeline Project would likely result in slightly lower Lake Powell reservoir levels (UBWR 2011a,b). Additional impacts could result from the pipeline alignment, proposed facilities, and transmission lines associated with the Lake Powell Pipeline Project. No new infrastructure is proposed by any of the LTEMP alternatives; however, if water is transferred to Sand Hollow Reservoir from Lake Powell, the water level in Lake Powell could become lower, resulting in a slight increase in the height of the calcium-carbonate ring that surrounds Lake Powell and increasing the exposure of sediment deltas. These actions could also slightly increase the months of exposure of Cathedral-in-the-Desert.

Uranium mining operations have the potential to change the landscape character in the project area. The Grand Canyon Escalade development project includes a gondola, riverwalk, amphitheater, visitor center, and retail complex. The development would be visible from six of the seven eastern viewpoints in GCNP (Confluence Partners, LLC 2012b) and would cause a visual contrast with the surrounding natural environment of the Grand Canyon and Colorado

River. Impacts on the landscape under the proposed LTEMP action are negligible and are not expected to contribute to cumulative impacts affecting the landscape character.

4.17.3.12 Hydropower

Power operations and power marketing as they relate to Glen Canyon Dam and the Glen Canyon powerplant are described in Section 3.13; Section 4.13 presented the potential impacts that change in dam operations under the LTEMP alternatives would have on the economic value of hydropower resources and on electricity capacity expansion necessary for the eight largest WAPA customer utilities to replace lost hydropower generation, as well as the resulting impacts on retail electricity rates charged by the eight largest customer utilities. Increased demand for electricity in the service territories of the eight largest WAPA customer utilities and planned retirement of existing powerplant generating capacity would require an estimated 4,820 MW of new capacity to be built over the next 20 years (Section 4.13).

The incremental impact of the LTEMP alternatives generating capacity over the 20-year period would be relatively small (<1% of baseline) and variable. Changes in operations at Glen Canyon Dam (relative to current baseline conditions under Alternative A) would reduce available generating capacity at Glen Canyon Dam under all LTEMP alternatives except Alternative B. This reduction in capacity would be replaced by purchases from other sources or construction of new capacity.

The LTEMP alternatives vary with respect to hydropower production, hydropower capacity, and retail rates, and therefore cumulative impacts. Alternatives with higher fluctuation levels (Alternatives A, B, D, and E) achieve higher values of generation and capacity and lower impacts on retail rates than do alternatives with steadier flows (Alternatives C, F, and G), especially if more water is released in the high-demand months of July and August. Alternatives A and B would have the least effect on the value of generation, the value of capacity, and retail rates, while Alternatives F and G would have the highest.

Changes in operations under LTEMP alternatives could reduce available generating capacity, necessitating the purchase of replacement capacity from other sources and potentially increasing the wholesale power rates to entities allocated preference power. The average change in the retail rate (residential and commercial utility bills) varies from a decrease of 0.27% in Alternative B to an increase of 1.21% in Alternative F. The average change in the monthly residential electricity bill varies from a decrease of $0.27 in Alternative B to an increase of $1.02 in Alternative F.

Since the implementation of MLFF, between 1997 and 2005, multiple restrictions have been placed on the variability of water released from the dam, thus restricting dam operational flexibility. Under the current operating regime, described in more detail in Section 3.13.1.3, fluctuations in release rates, ramp rates, and maximum hourly increases/decreases are restricted and the maximum release rate for power generation is limited to 25,000 cfs. Maximum releases above 25,000 cfs occur through bypass tubes to achieve a constant release rate. Bypassing water around generators produces no energy, which can result in additional purchases of replacement

power. The average annual costs associated with reductions in electricity generation over this time period have ranged from $38 million to $50 million (in 2009 dollars) (Veselka et al. 2010).

Changes in operations at the Flaming Gorge Dam and the Aspinall Unit are expected to result in a reduction of generating capacity 529,800 and 9,914 MWh (on an average annual basis), respectively (Reclamation 2005b, 2012i). These reductions in capacity will necessitate replacement by purchases from other sources or construction of new capacity over the 20-year period.

Changes at NGS to meet air emissions requirements may result in a reduction in generation output at the facility and its contribution to power in the Western Interconnection. This could result in excess transmission capacity within the Western Interconnection.

4.17.3.13 Socioeconomics and Environmental Justice

Actions and basin-wide trends contributing to cumulative impacts in the project area (including Lake Powell, Lake Mead, and the stretch of the Colorado River between them) are those that affect the economic valuation of its recreation resources and its recreational visitation and expenditure rates. Those actions and trends having a high, adverse, and disproportionate impact on minority and low-income populations are also of concern. The most significant trends affecting recreation are those related to climate change (decreased water supply and drought), because they have a direct effect on reservoir levels (exposed beaches and mudflats) and the seasonal timing of fluctuations in river flow. Regional economics (i.e., expenditures by visitors) for various types of recreational activities, including angling, rafting, and boating, as well as expenditures on gasoline (for vehicles and boats), camping fees or motel expenses, guide services, and fishing license fees are somewhat controlled by NPS regulations; the number of boating trips are controlled as specified in the CRMP and the Comprehensive Fisheries Management Plan cited in Table 4.17-1. These are not expected to change significantly under any of the LTEMP alternatives.

The impact analysis determined on the basis of the 2010 Census that minority or low-income populations exist in some block groups within San Juan (Utah) and Coconino (Arizona) counties (Section 4.14.2.4). Impacts on Tribes are associated with alternatives that incorporate frequent trout control actions (Alternatives C, D, and G), which affect Tribal values, or result in increased economic impacts on Tribes associated with the cost of electricity (especially Alternatives F and G).

4.17.3.14 Air Quality and Climate Change

The current condition of local and regional air quality is described in Section 3.15; Section 4.15 presented the potential impacts of the LTEMP alternatives on visibility within the project area (GCNP and the six-state area). Air quality is affected by air emissions from both natural (e.g., wildfires and windblown dust) and manmade (e.g., power generation from fossil fuel-fired plants) sources. The primary cause of visibility degradation in the region is the

scattering and absorption of light by fine particles. Other important contributors to visibility degradation include combustion-related sources, fugitive dust sources, and particulate organic matter. Emissions of SO_2 and NO_x from fossil fuel combustion are the major manmade causes of visibility impairment; these emissions have been substantially reduced in the six-state area in the past decade in response to state and federal requirements (Section 3.15.2).

The construction of new powerplants (and the renewal of existing coal-fired plants permits) to meet energy demands from population and industrial growth in the region, coupled with drought conditions brought on by climate change that could increase the potential for wildfires and dust storms, could increase visibility impacts in the foreseeable future. The natural scattering of light would continue to be the main contributor to visibility impairment (haze) in the region, including GCNP. Other significant contributors to visibility degradation include wildfires, windblown dust, and emissions from metropolitan areas (automobiles, manufacturing, coal-fired powerplants, and combustion sources like diesel engines).

Although hydropower generation at Glen Canyon Dam does not generate air emissions, dam operations can affect ambient air quality by causing a loss of generation that is offset by generation from coal, natural gas, or oil units (Section 4.15.1). Under baseline operations (Alternative A), emissions of SO_2 and NO_x would be about 10% and 3.0% of the total emissions over the Western Interconnection region, respectively. Air quality impacts due to emissions under the other alternatives would be negligible because they would be only slightly increased or decreased relative to the baseline.

The EPA's Clean Power Plan Proposed Rule (currently stayed by the U.S. Supreme Court) would have a beneficial impact on the air quality in the region by mandating reductions in CO_2 emissions from fossil fuel-fired powerplants (to 30% below 2005 levels by 2030). The closure of three coal-burning units at the FCPP may also have a beneficial impact by reducing levels of NO_x and PM pollutants that may contribute to regional haze and visibility issues in the GCNP. The change to control technology or reduction of generation output at the NGS to meet air emissions requirements will also reduce levels of NO_x pollutants in the region.

The incremental impact of the LTEMP alternatives on air quality over the 20-year period is based on the emissions associated with power generation needed from other powerplants to meet uninterrupted power demand of customers in the region. There is negligible difference in the additional power generation needed among the alternatives (4,172 to 4,250 GWh per year); the differences in SO_2 and NO_x precursor emissions are also negligible (Table 4.15-1).

GHG emissions under all the LTEMP alternatives can be compared to total U.S. GHG emissions at 6,810.3 MMt CO_2e in 2010 (EPA 2013d) (Table 4.16-1). Differences in emissions relative to total U.S. GHG emissions are less than 1%, and range from 0.8089% (Alternative A) to 0.8094% (Alternatives F and G). Therefore, potential impacts of dam operations on climate change under the various alternatives are expected to be very small.

4.18 UNAVOIDABLE ADVERSE IMPACTS

On the basis of the assessments presented in Sections 4.1–4.17, each of the alternatives is expected to result in some unavoidable adverse impacts on resources. These adverse impacts result from the flow and non-flow actions included in each alternative and could be minimized through adaptive management and implementation of mitigation measures.

All of the alternatives, including Alternative A, would result in continued reductions (for continued compliance with the Grand Canyon Protection Act) in hydropower production relative to pre-1996 ROD operations that more closely matched generation with electrical demand, due to restrictions on maximum and minimum flow, within-day fluctuation levels, and ramping rates. Steady flow alternatives (Alternatives F and G) would result in the greatest adverse impacts on hydropower value. Alternative B would result in an increase in hydropower energy and capacity compared to Alternative A; Alternatives D and E would produce less energy and capacity than Alternative A; Alternative C would produce less than Alternatives D and E, but more than Alternatives F and G. Alternative F would produce less energy and capacity than any of the alternatives.

Under all of the alternatives, sediment availability in the river channel below the dam would continue to be limited due to the presence of the dam. No operational alternative can reverse the reduction in sediment availability. Because of this sediment-depleted condition, all of the alternatives would continue to produce a net loss of sand from the Colorado River ecosystem. Alternatives C, D, E, F, and G retain more sandbars than Alternative A or Alternative B.

Implementation of mechanical removal of trout and TMFs would represent an unavoidable adverse impact on certain Tribes if these actions are needed to manage the trout fishery and mitigate trout impacts on humpback chub, because these actions are not in keeping with important Tribal values. The adverse impacts of mechanical removal could be mitigated with the provision of beneficial use (e.g., making euthanized fish available for human consumption). Any other mitigation to avoid adverse impacts would need to be identified in discussion with the Tribes.

The remaining unavoidable adverse impacts on certain resources are those associated not with the alternatives themselves; instead, they are consequences of existing operational rules (i.e., requirements of the Law of the River and the 2007 Interim Guidelines; Reclamation 2007a), 1996 Glen Canyon Dam ROD (Reclamation 1996), and the presence of Glen Canyon Dam and current dam infrastructure. For example, temperature and sediment impacts of all alternatives are related to the inability of operations themselves to provide for warmer temperatures or restore sediment supplies. Infrastructure changes, which are not within the scope of the LTEMP EIS, could mitigate those impacts; however, without that infrastructure, these adverse impacts are unavoidable.

4.19 RELATIONSHIP BETWEEN SHORT-TERM USE AND LONG-TERM PRODUCTIVITY

Under all alternatives, different restrictions on flow fluctuations result in tradeoffs between peak hydropower production and productivity of the environment, which is largely related to increased nearshore habitat stability, aquatic food base productivity, and sandbar building downstream from the dam. For example, alternatives that have increased flow fluctuations or uneven monthly release volumes, such as Alternatives A and B, benefit peak hydropower energy and capacity and other resources (such as humpback chub) but result in less habitat stability and sandbar building. Alternatives with steady flows, such as Alternatives F and G, have the greatest reduction in peak hydropower energy and capacity, but result in more habitat stability and sandbar building downstream from the dam, and corresponding benefits for other resources such as recreation, aquatic food base, and trout. As a result, each of the alternatives presents a different balance between impacts on resources that appear to benefit from increased fluctuations and those that benefit from reduced fluctuations. Alternatives C, D, and E represent alternatives with more even monthly release volumes, and in the case of Alternatives C and D, fluctuation levels that are comparable to or lower than those under Alternative A. These alternatives were designed to strike a more even balance among resource impacts. However, regardless of the alternative, experimental flow and non-flow actions associated with alternatives (e.g., HFEs, TMFs, mechanical trout removal) would be tested in an attempt to maintain a balance that improves long-term productivity of the environment downstream of Glen Canyon Dam. Similarly, experimental elements of the alternatives are designed to improve our understanding of how resources respond to operations and how management actions can be best used to avoid, minimize, or mitigate impacts on resources and the long-term productivity of resources analyzed in the LTEMP EIS.

4.20 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

Any experiment or operation that bypasses Glen Canyon Dam generators (e.g., HFEs that exceed powerplant capacity through generator bypass) would cause an irretrievable loss of hydropower production. Hydropower production forgone on a given day due to flows that reduce flexibility (e.g., lower summer flow or reduced fluctuations under certain alternatives) would create an irretrievable loss (see Section 4.13.2.1).

There could be some small differences among alternatives in total air emissions (<0.1% difference in emissions of SO_2, NO_x, or GHGs) that are related to differences among alternatives in the amount of energy and capacity that would be provided by Glen Canyon Dam. As part of an integrated electric grid, any loss of generation or capacity from Glen Canyon Dam must be offset by generation from a mix of other sources, including renewable energy sources and fossil-fuel-fired powerplants. The portion of the energy that comes from fossil-fuel-fired powerplants would produce these small differences in emissions; see sections 4.15 and 4.16.

Archeological sites by their nature are non-renewable, therefore any loss due to dam operations would be irretrievable. See Section 4.8.3 for the relative performance in comparison to Alternative A.

No other instances of irreversible or irretrievable commitments of resources are expected under any of the alternatives. Although operations, flow actions, non-flow actions, and experiments could result in unexpected impacts on natural and cultural resources, a long-term monitoring program implemented as part of the ongoing Glen Canyon Dam Adaptive Management Program would be used to inform the need for changes in operations and actions to minimize impacts and improve downstream resources in accordance with the objectives of this EIS. Safeguards have been incorporated into alternatives, including implementation considerations that would preclude taking specific actions if implementation would result in unacceptable adverse impacts, and off-ramps that would be used to alter operations or stop actions to prevent irreversible losses.

5 CONSULTATION AND COORDINATION

One intent of the National Environmental Policy Act of 1969, as amended (NEPA), is to encourage the participation of federal and state agencies and affected citizens in the assessment procedure, as appropriate. Consultation, coordination, and public involvement are integral to identifying relevant issues and concerns and ensuring that these issues are addressed. For this Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS), this was accomplished primarily through public meetings and workshops, informal and formal agency meetings, webinars, individual contacts, website updates, news releases, and *Federal Register* notices.

Acting as joint-lead agencies, the Bureau of Reclamation (Reclamation) and the National Park Service (NPS) have prepared this EIS in close coordination with several federal and state agencies (see Section 1.3). Development of this EIS also included input from Tribal governments, local agencies, programs, nongovernmental organizations, and the general public. This chapter summarizes the formal consultation and coordination that have occurred during the preparation of this EIS.

5.1 CONSULTATION AND COORDINATION WITH OTHER AGENCIES AND PROGRAMS

5.1.1 U.S. Department of the Interior

The U.S. Department of the Interior (DOI), through Reclamation and NPS, has prepared this EIS, with assistance from Argonne National Laboratory (Argonne) and the U.S. Geological Survey (including staff from the Patuxent Wildlife Research Center, Grand Canyon Monitoring and Research Center, and Southwest Biological Science Center). Reclamation has the primary responsibility for operating Glen Canyon Dam. NPS has the primary responsibility for managing downstream resources and visitors for the Grand Canyon National Park, Glen Canyon National Recreation Area, and Lake Mead National Recreation Area. As joint leads, both agencies have been equally involved in all aspects of the development of the LTEMP and EIS.

5.1.2 Cooperating Agencies

On December 8, 2011, in accordance with Title 40 *Code of Federal Regulations,* Part 1501.6 (40 CFR 1501.6) of the Council on Environmental Quality (CEQ) regulations for implementing NEPA and 43 CFR 46.225 of the DOI's regulations for implementing NEPA, Reclamation and NPS invited 25 federal, Tribal, state, and local government agencies to participate in the development of the EIS as Cooperating Agencies. Fifteen of these agencies expressed interest in participating as Cooperating Agencies. The Cooperating Agencies, which include three federal entities, five state agencies, and six Tribes, are listed in Table 5.1-1, along with descriptions of their participation.

All Cooperating Agencies have had the opportunity to participate in regular meetings and workshops and webinars related to the development of this EIS, participate in monthly meetings with the joint leads, and review and comment on the Draft EIS. Beginning in February 2012, the Cooperating Agencies met every month during the preparation of the EIS. In addition, more than 30 meetings, workshops, and webinars were conducted with stakeholders and Cooperating Agencies to assist in the development of alternatives and performance measures, conduct the Structured Decision Analysis (SDA), and provide general status updates. Federal Cooperating Agencies (i.e., Bureau of Indian Affairs [BIA], U.S. Fish and Wildlife Service [FWS], and Western Area Power Administration [WAPA]) also participated in the process of alternative development for the EIS.

5.1.3 American Indian Tribes

As part of the government's Treaty and Trust responsibilities, the Federal Government works on a government-to-government basis with American Indian Tribes. The government-to-government relationship and the process for developing open and transparent communication, effective collaboration, and informed federal decision-making with Indian Tribes was identified in Executive Order (E.O.) 13175, "Consultation and Coordination with Indian Tribal Governments" (U.S. President 2000); E.O. 13007, "Indian Sacred Sites" (U.S. President 1996); Secretarial Order (S.O.) 3206, "American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act" (DOI 1997); S.O. 3317, "Department of the Interior Policy on Consultation with Indian Tribes" (DOI 2011a); and the President's "Memorandum on Government-to-Government Relations with Native American Tribal Governments" (U.S. President 1994a). In addition, Section 106 of the National Historic Preservation Act (NHPA) requires federal agencies to consult with Indian Tribes on undertakings on Tribal lands and on historic properties of significance to the Tribes that may be affected by an undertaking (36 CFR 800.2 (c)(2)). Both Reclamation and NPS coordinate and consult with all Tribal governments, Native American communities and organizations, and Tribal individuals whose interests might be directly and substantially affected by activities within their jurisdiction.

Government-to-government consultation was conducted throughout development of this EIS, in accordance with provisions of the Executive Orders and Secretarial Orders listed above as well as Section 106 of the NHPA, and any additional applicable natural and cultural resource laws (e.g., NEPA, the Endangered Species Act [ESA], NHPA, and Migratory Bird Treaty Act), as well as agency-specific guidance, such as:

- DOI, Departmental Manual, *Departmental Responsibilities for Indian Trust Resources*, 512 DM 2 (1995).

- DOI, Departmental Manual, *Departmental Responsibilities for Protecting/ Accommodating Access to Indian Sacred Sites*, 512 DM 3 (1998).

TABLE 5.1-1 Summary of Cooperating Agency Involvement

Cooperating Agency	Type	Summary of Involvement
Arizona Game and Fish Department (AZGFD)	State	AZGFD is a Cooperating Agency in recognition of its role in conserving, enhancing, and restoring Arizona's diverse wildlife resources and habitats. AZGFD is also a member of the Glen Canyon Dam Adaptive Management Work Group (AMWG). AZGFD participated in several stakeholder meetings, and representatives offered expertise during development of resource goals, performance metrics, and the aquatic modeling approach.
Bureau of Indian Affairs (BIA)	Federal	BIA is a Cooperating Agency in recognition of its administration of federal trust responsibility to Indian Tribes. BIA assisted in government-to-government consultations and served in an advisory capacity to Reclamation and the Indian Tribes.
Colorado River Board of California (CRBC)	State	CRBC is a Cooperating Agency in recognition of its responsibility for maintaining or increasing the quantity of California's Colorado River water resources. CRBC is also a member of the Glen Canyon Dam AMWG and represents California as part of the group of seven Basin States that have interests in the Colorado River. CRBC contributed to the development of the Resource Targeted Condition Dependent Alternative, which served as the basis of Alternative E, and, as part of the Basin States group, provided comments on performance metrics and modeling results.
Colorado River Commission of Nevada (CRCN)	State	CRCN is a Cooperating Agency in recognition of its responsibility for acquiring and managing water and hydropower resources from the Colorado River. CRCN is also a member of the Glen Canyon Dam AMWG and represents Nevada as part of the group of seven Basin States that have interests in the Colorado River. CRCN contributed to the development of the Resource Targeted Condition Dependent Alternative, which served as the basis of Alternative E, and, as part of the Basin States group, provided comments on performance metrics and modeling results.
The Havasupai Tribe	Tribe	The Havasupai Tribe is a Cooperating Agency in recognition of its relationship with the Colorado River and the Canyons. The Tribe has interests in aspects of the operation of Glen Canyon Dam and Colorado River resources below the dam. Havasupai representatives have participated in Cooperating Agency meetings and meetings and webinars pertaining to Tribal values, and have contributed written portions to the EIS.
The Hopi Tribe	Tribe	The Hopi Tribe is a Cooperating Agency in recognition of its relationship with the Colorado River and the Canyons. The Tribe has interests in aspects of the operation of Glen Canyon Dam and Colorado River resources below the dam. The Tribe is also a member of the Glen Canyon Dam AMWG and Technical Working Group (TWG). Hopi representatives have participated in Cooperating Agency meetings and meetings and webinars pertaining to Tribal values, provided comments on performance metrics and resource goals, and have contributed written portions to the EIS.

TABLE 5.1-1 (Cont.)

Cooperating Agency	Type	Summary of Involvement
The Hualapai Tribe	Tribe	The Hualapai Tribe is a Cooperating Agency in recognition of its relationship with the Colorado River and the Canyons. The Tribe has interests in aspects of the operation of Glen Canyon Dam and Colorado River resources below the dam. The Tribe is also a member of the Glen Canyon Dam AMWG and TWG. Hualapai representatives have participated in Cooperating Agency meetings and meetings and webinars pertaining to Tribal values, provided comments on performance metrics and resource goals, and have contributed written portions to the EIS.
The Kaibab Band of Paiute Indians	Tribe	The Kaibab Band of Paiute Indians is a Cooperating Agency in recognition of its relationship with the Colorado River and the Canyons. The Tribe has interests in aspects of the operation of Glen Canyon Dam and Colorado River resources below the dam. The Tribe is also a member of the Glen Canyon Dam AMWG and TWG. Kaibab representatives have participated in Cooperating Agency meetings and meetings and webinars pertaining to Tribal values, and provided comments on performance metrics and resource goals.
The Navajo Nation	Tribe	The Navajo Nation is a Cooperating Agency in recognition of its relationship with the Colorado River and the Canyons. The Tribe has interests in aspects of the operation of Glen Canyon Dam and Colorado River resources below the dam. The Tribe is also a member of the Glen Canyon Dam AMWG and TWG. Navajo representatives have participated in Cooperating Agency meetings and meetings and webinars pertaining to Tribal values, and provided comments on performance metrics and resource goals.
The Pueblo of Zuni	Tribe	The Pueblo of Zuni is a Cooperating Agency in recognition of its relationship with the Colorado River and the Canyons. The Tribe has interests in aspects of the operation of Glen Canyon Dam and Colorado River resources below the dam. Zuni representatives have participated in Cooperating Agency meetings and meetings and webinars pertaining to Tribal values, provided comments on performance metrics and resource goals, and have contributed written portions to the EIS.
Salt River Project (SRP)	Public Utility	SRP is a Cooperating Agency in recognition of its role as one of the primary public utility companies in Arizona. SRP participated in several Cooperating Agency and stakeholder meetings and provided comments on performance metrics and modeling results.
Upper Colorado River Commission (UCRC)	Inter-State	UCRC is a Cooperating Agency in recognition of its role as part of the group of seven Basin States that have interests in the Colorado River. UCRC is also a Glen Canyon Dam AMWG member. UCRC contributed to the development of the Resource Targeted Condition Dependent Alternative, which served as the basis of Alternative E, and, as part of the Basin States group, provided comments on performance metrics and modeling results.

TABLE 5.1-1 (Cont.)

Cooperating Agency	Type	Summary of Involvement
U.S. Fish and Wildlife Service (FWS)	Federal	FWS is a Cooperating Agency in recognition of its jurisdiction by law and special expertise with respect to the ESA and biological resources within the study area. FWS has participated in the formation and development of LTEMP resource goals and objectives, performance metrics and alternatives, as well as the development of the aquatic modeling approach. In addition, a representative from FWS serves as the Tribal Liaison and has participated in government-to-government meetings with the Tribes.
Utah Associated Municipal Power Systems (UAMPS)	Public Utility	UAMPS is a Cooperating Agency in recognition of its role as a purchaser of electricity from the Colorado River Storage Project. UAMPS is also a member of the AMWG. UAMPS participated in Cooperating Agency and stakeholder meetings and provided comments on the performance metrics.
Western Area Power Administration (WAPA)	Federal	WAPA is a Cooperating Agency in recognition of its role in marketing and transmitting electricity from the Glen Canyon Dam. WAPA representatives participated in the development of alternatives and hydropower performance metrics and provided funds for the hydropower systems analysis.

- Reclamation, *Protocol Guidelines, Consulting with Indian Tribal Governments*, 2001 (Reclamation 2012g).

- *Programmatic Agreement among the Bureau of Reclamation, the Advisory Council on Historic Preservation, the National Park Service, the Arizona State Historic Preservation Officer, Havasupai Tribe, Hopi Tribe, Hualapai Tribe, Kaibab Paiute Tribe, Navajo Nation, San Juan Southern Paiute Tribe, Shivwits Paiute Tribe, and Zuni Pueblo Regarding the Operation of Glen Canyon Dam*, 1994 (Reclamation 1994).

- NPS, *Management Policies 2006* (NPS 2006d).

On November 30, 2011, 43 Tribes, bands, and organizations were formally invited to enter into government-to-government consultation on the LTEMP EIS. The letters, sent by the joint-lead agencies, provided notification of the intent to prepare the LTEMP EIS; initiated government-to-government consultation; and invited the Tribes to identify concerns related to historic properties, including traditional cultural properties and archaeological sites, natural resources, relevant Indian Trust assets, and other issues of importance.

A total of 31 Tribes responded to the invitation. Six Tribes agreed to participate as Cooperating Agencies (see Section 5.1.2); three Tribes (the Fort Mojave Tribal Council, Pueblo of Zia, and Gila River Indian Community) agreed to participate as Consulting Tribes; eight Tribes (Pueblo of Santa Clara, Ute Indian Tribe, Ute Mountain Ute, Pueblo of Nambe, Yavapai Apache, Paiute Indian Tribe of Utah, the Pueblo of Santa Ana, and the Fort Yuma Quechan) declined participation, but asked to remain on the mailing list; and 14 Tribes (Ak Chin Indian Community, Cocopah Indian Tribe, Fort McDowell Yavapai Tribal Council, Jicarilla Apache Nation, Ohkay Owingeh, Southern Ute Tribal Council, the Pueblo of Acoma, the Pueblo of Laguna, the Pueblo of Sandia, Yavapai-Prescott Indian Tribe, Chemehuevi Tribal Council, Tohono O'odham Nation, the Pueblo of Pojoaque, and the White Mountain Apache) declined participation in the LTEMP EIS. The joint leads have yet to receive a response to the request for consultation from the remaining 12 Tribes (Colorado River Indian Tribes, Las Vegas Tribe of Paiute Indians, Moapa Band of Paiute Indians, Salt River Pima-Maricopa Indian Community, San Carlos Apache Tribe, San Juan Southern Paiute Tribe, the Pascua Yaqui Tribe, the Pueblo of Cochiti, the Pueblo of Jemez, the Pueblo of San Felipe, the Pueblo of Tesuque, and Tonto Apache).

Cooperating and consulting Tribes were invited to attend meetings, workshops, and webinars, and to review various documents related to the development of the LTEMP EIS. A series of workshops, conference calls, and webinars were held with Tribes to identify Tribal resource goals and ways to measure the relative performance of alternatives against those goals. A list of major face-to-face meetings, webinars, and conference calls involving Tribes is provided in Appendix N, Table N-2. Meeting notes and other important documents related to the LTEMP EIS development process were sent to those Tribes who wished to remain on the mailing list. Reclamation and NPS will continue to provide consultation opportunities for interested Tribes and keep all Tribal entities informed about the NEPA process for the EIS. A full summary of Tribal communication as of March 2015 is provided in Appendix M.

5.1.4 Other Consultations

5.1.4.1 National Historic Preservation Act (NHPA)

Section 106 of the NHPA of 1966, as amended, and its implementing regulations, requires federal agencies to address the effect of projects on historical properties (i.e., resources determined eligible or listed on the *National Register of Historic Places* [NRHP]) and to give the State Historic Preservation Officers (SHPOs), Advisory Council on Historic Preservation (ACHP), and Traditionally Associated American Indian Tribes, as necessary, a reasonable opportunity to comment on such effects. Reclamation has the lead for Section 106 compliance and initiated the process of consultation with the Arizona SHPO. Consultations regarding eligibility of cultural resources to the NRHP and the effect of the proposed federal action are ongoing. In addition, consultations occurred with Tribal Historic Preservation Officers and Indian Tribes with concerns under E.O. 13007, "Indian Sacred Sites" (U.S. President 1996), the Native American Graves Protection and Repatriation Act, and Section 106 of the NHPA.

On November 30, 2011, 43 Tribes, bands, and organizations were formally invited to enter into government-to-government consultation on the LTEMP EIS (see Section 5.1.3). As part of the consultation process for this EIS, Reclamation will continue to identify concerns, assess the potential for cultural resources impacts, develop appropriate mitigation measures, and seek concurrence with the determination of effect. If adverse effects are identified, Reclamation would continue consultation to seek options to avoid, minimize, or mitigate the adverse effects on historic properties. Reclamation, in consultation with interested parties, is developing a Programmatic Agreement to address any cultural resource effects and mitigation measures. Reclamation and NPS conducted a number of formal and informal consultation meetings with Tribes (Havasupai Tribe, Hopi Tribe, Hualapai Tribe, Kaibab Band of Paiute Indians, Navajo Nation, and the Pueblo of Zuni) just prior to and after the release of the DEIS.

5.1.4.2 State and Local Water and Power Agency Coordination

Reclamation and NPS have had various discussions with state and local water agencies regarding the proposed federal action. The seven Basin States in particular have been continuously engaged throughout the scoping and alternatives development processes. This engagement has consisted of conference calls, webinars, and face-to-face meetings to discuss process, resource goals, alternative characteristics, metrics to determine the relative performance of alternatives against those metrics, and the overall modeling approach used to quantify impacts.

One of the alternatives considered in the LTEMP EIS (Alternative E) was developed by the Basin States (as the Resource-Targeted Condition-Dependent Alternative) and submitted to the joint-lead agencies. The joint-lead agencies shared initial impact analysis results and insights that were ultimately used by the Basin States to further refine Alternative E.

The Colorado River Energy Distributors Association (CREDA) is an organization that represents consumer-owned electric systems that purchase federal hydropower and resources of the Colorado River Storage Project. While not a Cooperating Agency, CREDA, a member of the Glen Canyon Dam Adaptive Management Work Group (AMWG), submitted Alternative B, and Reclamation and NPS worked closely with CREDA to define and model resource effects of this alternative. CREDA has also participated in stakeholder meetings and provided comments on the performance metrics.

5.1.4.3 U.S. Fish and Wildlife Service (FWS)

FWS participated in the formation and development of LTEMP alternatives, providing expertise in several workshops and webinars. FWS also worked with the joint-lead agencies and subject matter expert groups in the development of resource goals and objectives and performance metrics to evaluate the alternatives. FWS provided expertise during the development of the aquatic modeling approach used in this EIS.

Reclamation and NPS consulted with FWS on the effects of the LTEMP on species listed under Section 7 of the ESA (The Biological Assessment is included in Appendix O of this EIS). This consultation was a continuation of ongoing consultation that has occurred since 1995. Reclamation has consulted with FWS on a total of five experimental actions. The Biological Opinion prepared for the LTEMP supersedes the 2011 opinion on the high-flow experimental protocol and nonnative fish protocols.

5.2 PUBLIC INVOLVEMENT

Public involvement in the NEPA process is intended to give the public the chance to provide input throughout the development of an EIS and the decision-making process for actions with environmental effects. An objective of public involvement is to obtain information from the public to assist the decision-maker (Secretary of the Interior) throughout the entire process, culminating in a Record of Decision and eventual implementation of the selected alternative. The primary goals of public involvement are:

1. *Credibility and transparency*: creating an open and visible decision-making process for groups with divergent viewpoints.

2. *Identifying public concerns and values*: providing a mechanism by which the involved agencies can understand the problems, issues, and possible solutions from the perspectives of the public.

3. *Developing a consensus*: providing a process for reaching a consensus on specific actions.

In order to identify issues, address public concerns, obtain public input, and keep the public informed, several opportunities were provided for public participation during the preparation of this EIS. These included an early and open public scoping process and public meetings related to development of preliminary alternatives. The public scoping process is described below in Section 5.2.1.

5.2.1 Public Scoping Process and Comments Received

The process of soliciting input from the public is called scoping. Public scoping is a phase of the NEPA analysis process and was intended to give the public the chance to comment on the LTEMP, recommend alternatives, and identify and prioritize the resources and issues to be considered in the EIS analyses. Consistent with CEQ requirements (40 CFR 1501.7) and DOI NEPA regulations at 43 CFR Part 46, an early and open public scoping process was carried out to determine the resources or issues to be evaluated in the LTEMP EIS, the alternatives to be included in the LTEMP EIS, and concerns or observations regarding Glen Canyon Dam operations and downstream resources. Reclamation and NPS have considered the public scoping comments in developing this EIS.

Reclamation and NPS published a Notice of Intent (NOI) to prepare the LTEMP EIS in the *Federal Register* (Volume 76, page 39435) on July 6, 2011 (DOI 2011b). The NOI provided initial information on the purpose and need of the LTEMP EIS, explained the decision for Reclamation and NPS to co-lead the project, and encouraged the participation of stakeholders in the development of the LTEMP EIS. The public scoping period started with the publication of the NOI and ended on January 31, 2012.

Early in the scoping process, Reclamation and NPS established a website for the LTEMP EIS (http://ltempeis.anl.gov) that provided background information about the project, information on public involvement, answers to frequently asked questions, and links to documents for review. During the public scoping process, a link to the project's online comment form was provided and made available on the NPS's Planning, Environment, and Comment website. In addition, project updates and announcements were made available via an email subscription list, press releases, and social media (e.g., Twitter and Facebook).

"A Notice to Solicit Comments and Hold Public Scoping Meetings on the Adoption of a Long-Term Experimental and Management Plan for the Operation of Glen Canyon Dam" was published in the *Federal Register* (Volume 76, page 64104) on October 17, 2011 (DOI 2011c), which provided the date, time, and place for six public meetings to be held to solicit public input on the scope of the EIS, including potential alternatives and issues to be addressed within the document. Meetings were held in the following locations:

- Phoenix, Arizona (November 7, 2011)
- Flagstaff, Arizona (November 8, 2011)
- Page, Arizona (November 9, 2011)
- Salt Lake City, Utah (November 15, 2011)
- Las Vegas, Nevada (November 16, 2011)
- Lakewood, Colorado (November 17, 2011)

The notice also indicated that there would be one web-based public meeting (November 15, 2011) for those who could not attend in person. The public was also notified of the meetings via a press release, local media outlets, and an op-ed article disseminated for publication in local and regional newspapers.

At the public meetings, the public could view exhibits about the project, discuss issues informally, and ask questions of technical experts and managers. A total of 221 people attended these meetings. For the web-based meeting, the public was able to listen to, via the Internet, a live overview presentation of the LTEMP EIS and to ask questions of technical experts and managers.

A total of 447 individuals, recreational groups, environmental groups, power customers or organizations, federal and state government agencies, and other organizations provided scoping comments on the LTEMP EIS. Although no formal campaign letters were received, some commenters chose to incorporate in their submissions entire letters or portions of letters from various other commenting organizations.

Comments received during the public scoping period covered a wide range of topics and issues and represented a variety of views and interpretations. Comments addressed various aspects of the proposed action, including the purpose and need (as stated in the July 6, 2011, NOI [DOI 2011b]); environmental issues; dam operations and hydropower; geographic and temporal scope; policy and regulatory concerns; LTEMP approach and considerations; alternatives; other issues; and stakeholder involvement. A detailed summary of comments received can be found in *Summary of Public Scoping Comments on the Glen Canyon Dam Long-Term Experimental and Management Plan Environmental Impact Statement* (Argonne 2012), available on the LTEMP website (http://ltempeis.anl.gov).

In general, the most frequent topic for comments on the LTEMP EIS was related to environmental issues. Comments and concerns frequently raised by the public included restoration of the downstream Colorado River ecosystem; reestablishment of ecosystem patterns and processes to their pre-dam range of natural variability; elimination or minimization of further beach erosion; facilitation of sediment redeposition; in situ maintenance and preservation of the integrity of cultural and archeological resources; elimination of adverse impacts on and assistance in the recovery of native species; nonnative fish management; and assistance in repropagation of native riparian plant communities.

5.2.2 Public Meetings on Alternatives

Members of the public were invited to participate in a 2-day open public meeting on preliminary alternative concepts, hosted by Reclamation and NPS. The meeting was held on April 4 and 5, 2012, at the High Country Conference Center in Flagstaff, Arizona. More than 70 people attended the meeting, including members of the public, stakeholders, and project staff from Reclamation, NPS, and Argonne.

During this meeting, alternatives being considered for inclusion in the LTEMP EIS were presented and discussed. Stakeholders and other attendees who had alternatives to propose were able to present those ideas at the meeting; four individuals representing different stakeholder groups presented their ideas. Following the presentations, meeting attendees broke into smaller groups and focused on evaluating and refining the preliminary alternative concepts. These small groups reported their discussions in an open forum during the meeting.

Reclamation and NPS evaluated the feedback received at this meeting and used it to develop the final set of alternatives considered in this EIS (discussed in detail in Chapter 2). Maintaining that all alternatives meet the purpose and need of the proposed action, this evaluation resulted in new alternative concepts, the modification of existing concepts, and the combination of some concepts into single alternatives.

Regular updates of the LTEMP EIS process were provided at public meetings of the Glen Canyon Dam AMWG. LTEMP EIS joint leads regularly presented the status of preliminary EIS-related materials (e.g., purpose and need, resource goals, and preliminary draft alternatives) and coordination activities with the Cooperating Agencies. These meetings are described in more detail in Section 5.2.3.

5.2.3 Glen Canyon Dam Adaptive Management Working Group

The Glen Canyon Dam AMWG is a federal advisory committee. As an advisory committee, the AMWG has provided a forum for discussion of key issues related to the operation of Glen Canyon Dam among the federal agencies, Indian Tribes, environmental groups, recreational interest groups, federal power purchase contractors, and other stakeholders who have interests in the resources of the Colorado River. AMWG members meet several times throughout the year to discuss competing issues on how to protect downstream resources and strike a wise balance on river operations. Their recommendations are regularly provided to the Secretary by the Secretary's Designee, who often brings these competing issues to a consensus (Reclamation 2014d).

Separate meetings regarding the LTEMP EIS have been held with the Glen Canyon AMWG because of its status as a Federal Advisory Committee. These meetings occurred on February 18–22, 2013, May 8, 2013, August 8–9, 2013, February 18–20, 2014, May 27, 2014, August 27–28, 2014, February 25–26, 2015, and May 28, 2015. These meetings were conducted to provide an explanation of alternatives, performance criteria, and SDA; conduct swing-weighting exercises; answer budget questions; and provide general status updates.

5.2.4 Public Involvement on the LTEMP DEIS

On January 8, 2016, the LTEMP DEIS was filed with Region 9 of the U.S. Environmental Protection Agency (EPA); a Notice of Availability and Notice of Public Meetings were published in the *Federal Register* (81 FR 963); and an email notification of the availability of the DEIS for download from the project website (www.ltempeis.gov) was sent to approximately 600 members of the public who had signed up for notification during the scoping period. Prior to this date, the DEIS was sent to each of the Governors, Senators, and Representatives from relevant congressional districts of the seven Colorado River Basin States (Arizona, California, Colorado, Utah, Nevada, New Mexico, and Wyoming).

In addition to making the DEIS available on the public website, 84 compact disc copies of the DEIS were mailed to individuals at their request; 46 copies were picked up at public meetings held for the DEIS; and copies were made available for public review after the DEIS was published at the following locations:

- J. Willard Marriott Library, University of Utah, 295 South 1500 East, Salt Lake City, Utah 84112.

- Cline Library, Northern Arizona University, 1001 S. Knoles Drive, Flagstaff, Arizona 86011-6022.

- Burton Barr Central Library, 1221 North Central Avenue, Phoenix, Arizona 85004.

- Page Public Library, 479 South Lake Powell Boulevard, Page, Arizona 86040.

- Grand County Library, Moab Branch, 257 East Center Street, Moab, Utah 84532.

- Sunrise Library, 5400 East Harris Avenue, Las Vegas, Nevada 89110.

- Denver Public Library, 10 West 14th Avenue Parkway, Denver, Colorado 80204.

- Natural Resources Library, U.S. Department of the Interior, 1849 C Street NW, Main Interior Building, Washington, D.C. 20240-0001.

The original 90-day public comment period was extended an additional 32 days (122-day total) to May 9, 2016, after several requests were received from the public and Cooperating Agencies. During the comment period, two in-person meetings and two Internet-based webinars were held to provide the public with information about the content and findings of the DEIS and to receive written comments on the DEIS. The meetings and webinars were held on the following dates:

- Webinar—Tuesday, February 16, 2016, at 6:30 p.m. Mountain Standard Time (MST);

- Meeting—Monday, February 22, 2016, at 6:00 p.m. MST, Flagstaff, Arizona;

- Meeting—Thursday, February 25, 2016, at 6:00 p.m. MST, Phoenix, Arizona; and

- Webinar—Tuesday, March 1, 2016, at 1:00 p.m. MST.

At these meetings, LTEMP staff were available to take comments and answer questions before and after presentations were made on the DEIS.

During the public comment period, the public was encouraged to submit comments electronically through the NPS Public, Environment, and Public Comment (PEPC) website. Comments were also received, however, through the mail or using a public comment form provided at the public meetings. More than 3,000 individual comment documents were received on the DEIS. Substantive comments within these documents were used to make changes to the DEIS when deemed appropriate and justified. Responses to comments are provided in Appendix Q of the EIS.

In addition to the public meetings described above, meetings were held with Cooperating Agencies, Tribes, and AMWG stakeholders after the comment review period ended to discuss potential revisions to the EIS.

7 LIST OF PREPARERS

This chapter presents information on the preparers of the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS). The list of preparers is organized by agency or organization, and information is provided on education, experience, and contribution to the LTEMP EIS.

Name	Education/Experience	Contribution
Bureau of Reclamation		
Mary Barger	B.A., Anthropology; 36 years of federal archaeology and Section 106 experience. Upper Colorado Region/Archaeologist.	Reclamation lead for cultural and Tribal resources
Alan Butler	B.S./M.S., Civil Engineering; 6 years experience in civil engineering. Lower Colorado Region, Hydrologic Engineer.	Technical analyst and subject matter expert, reservoir operations and hydrology; reservoir modeling
Rick Clayton	B.S., Civil Engineering; B.S., Environmental Economics; 14 years experience in reservoir operations; 3 years experience in powerplant operations. Upper Colorado Region General Engineer.	Reclamation lead for power resource analysis; hydrology and reservoir modeling
Todd Gaston	M.S. Resource Economics; B.S. Environmental Science; 7 years experience in natural resources management and economics. Technical Service Center, Economics and Resource Planning Team.	Technical analyst and subject matter expert, socioeconomics, recreational economics
Katrina Grantz	Ph.D., Civil Engineering; 14 years experience in water resources research, hydrology, and decision support systems; 8 years experience in reservoir operations. Upper Colorado Region/Hydraulic Engineer.	Co-lead EIS project manager. Lead author of Section 4.2 (water resources) and Appendix D, technical lead for reservoir operations and hydrology; reservoir modeling
Dave Harpman	Ph.D., Natural Resource Economics; MSc., Agricultural Economics; BSc., Fisheries Management; 24 years experience. Technical Service Center Natural Resource Economist.	Technical lead for recreational economics; subject matter expert, socioeconomics
Beverley Heffernan	B.A., History; 30 years experience in NEPA compliance. Upper Colorado Region/Manager, Environmental Resources Division.	Project management and review

Name	Education/Experience	Contribution
Jianchun "Victor" Huang	Ph.D., Civil Engineering; 14 years experience in hydraulics and sediment transport. Technical Service Center, Sedimentation and River Hydraulics Group, Hydraulic Engineer.	Technical analyst and subject matter expert, sediment resources; sediment modeling
Glen Knowles	M.S., Zoology; 20 years experience in aquatic ecology, fisheries biology, and conservation biology. Upper Colorado Region/Chief, Adaptive Management Group, Biologist.	Project management and review
Jim Prairie	Ph.D., Civil Engineering; 15 years experience in water resources research, hydrology, and salinity modeling, and decision support systems. Upper Colorado Region/Hydrologic Engineer.	Technical analyst and subject matter expert, reservoir operations and hydrology, climate change; reservoir modeling, water quality modeling
Kendra Russell	M.S., Geography and Environmental Engineering; B.S. Civil and Environmental Engineering; 6 years experience in water resources engineering. Technical Service Center, Sedimentation and River Hydraulics; Hydraulic Engineer.	Project management and review; subject matter expert, sediment resources and modeling
David Varyu	M.S., Civil Engineering; 9 years experience in hydraulic engineering and sediment transport. Technical Service Center, Sedimentation and River Hydraulics Group; Hydraulic Engineer.	Lead author of sediment resources sections (Section 4.3, Appendix E); technical lead, sediment resources; sediment modeling
Nick Williams	B.S., Civil and Environmental Engineering; M.S., Civil and Environmental Engineering; 5 years as an environmental engineer; 5 years as a water quality specialist. Upper Colorado Region/Water Quality Specialist.	Technical analyst and lead for temperature and water quality modeling
National Park Service		
Jan Balsom	M.A., Anthropology; 32 years experience in southwestern archaeology, Tribal relations, and Park Management. Grand Canyon National Park Deputy Chief for Science and Resource Management.	Project management and review; lead author of park operations and management section (Appendix O); subject matter expert for Grand Canyon cultural and Tribal resources, park management, and wilderness, natural processes, and hydropower

Name	Education/Experience	Contribution
Robert Billerbeck	M.S., Conservation Biology; 18 years experience in Natural Resource Management and Environmental Compliance. Intermountain Region Colorado River Coordinator.	Co-lead EIS project manager
Martha Hahn	M.S., Recreation Behavior; 38 years experience in resources and public land management. Grand Canyon National Park/Chief, Science and Resource Management.	Project management and review; subject matter expert for ecological resources
Jennifer Rebenack	M.S., Fisheries Biology; 8 years experience in fisheries and wildlife ecology and environmental compliance. Intermountain Region Colorado River Program Biologist.	Project management assistant
Argonne National Laboratory		
Jennifer Abplanalp	M.A., Anthropology; 13 years experience in cultural resources and 2 years experience in visual impact assessments.	Contributing author of Tribal and visual resources sections (Sections 3.9, 3.12, 4.9, 4.12; Appendix I); subject matter expert, Tribal resources, cultural resources, and visual resources; records management
Timothy Allison	M.S., Mineral and Energy Resource Economics; M.A., Geography; 24 years experience in regional analysis and economic impact analysis.	Lead author of hydropower and socioeconomics sections (Sections 3.13, 3.14, 4.14; Appendix L); technical analyst and lead for socioeconomic and environmental justice
Georgia Anast	B.A., Mathematics/Biology; over 20 years experience in environmental assessment.	Comment processing; administrative record
Kevin J. Beckman	B.S., Mathematics and Computer Science; 5 years experience in Web programming and visual impact analysis.	Public website development
Ron Black	B.S., Electronics Engineering; 20 years experience in programming.	Technical analyst vegetation modeling
Edward Bodmer	M.B.A., Econometrics; B.S., Finance; 30 years experience in utility ratemaking and financial analysis.	Contributing author of retail rate sections (Section 4.13, Appendix K.3); technical lead for retail rate impact analysis

Name	Education/Experience	Contribution
Young Soo Chang	Ph.D., Chemical Engineering; 24 years experience in air quality and noise impact analysis.	Lead author of air quality and climate change sections (Sections 3.15, 3.16, 4.15, 4.16; Appendix M); technical lead for air quality
Vic Comello	M.S., Physics; 38 years writing and editing experience.	Contributing editor
Mary Finster	Ph.D., Civil and Environmental Engineering; 8 years experience in health risk assessment.	Lead author of water and sediment resource sections (Sections 3.2, 3.3), and water quality section (Section 4.2); technical lead for water quality; public comment processing, scoping
Jessica Griffin	M.S., Historical Archaeology; 3 years experience in cultural resources assessments.	Project management assistant
John Hayse	Ph.D., Zoology; 27 years experience in ecological research and environmental assessment.	Lead author of aquatic resource sections (Sections 3.5, 4.5; Appendix F); technical lead for aquatic ecology; lead technical analyst temperature suitability modeling
Ihor Hlohowskyj	Ph.D., Zoology; 37 years experience in ecological research; 35 years in environmental assessment.	Lead author of natural processes sections (Sections 3.4, 4.4); contributing author of aquatic resource sections (Sections 3.5, 4.5; Appendix F); technical lead for natural processes subject matter expert, native and nonnative fish
Pat Hollopeter	B.A., Religion; M.A., Philosophy; 30 years experience editing technical communication products.	Contributing editor
Mark Jusko	M.S., Computer Science; 34 years experience in software engineering.	Hydropower and power systems modeling and graphics
Kirk E. LaGory	Ph.D., Zoology; M.S., Environmental Science; 38 years experience in ecological research; 28 years in environmental assessment.	Argonne EIS project manager; lead author of introduction and alternatives sections (Chapters 1 and 2) and Appendices A and B; contributing author of water resources and wildlife sections (Sections 4.2, 4.7)

Name	Education/Experience	Contribution
James E. May	M.S., Water Resources Management; B.A., Zoology; 32 years experience in natural resources management; 11 years of consulting experience in land use planning and NEPA compliance.	Contributing author of recreation sections (Sections 3.10, 4.10); subject matter expert recreation, visitor use and experience
Michele Nelson	Graphic designer; 36 years experience in graphic design and technical illustration.	Graphics
Daniel O'Rourke	M.S., Industrial Archeology; B.A. History and Anthropology; 19 years experience in archaeology.	Lead author of cultural resources sections (Sections 3.8, 4.8; Appendix H); technical lead for cultural resources; subject matter expert, Tribal resources
Terri Patton	M.S., Geology; 26 years experience in environmental research and assessment.	Lead author of cumulative impacts section (Section 4.17); subject matter expert geology, soil, sediment resources, and cumulative impacts
Kurt Picel	Ph.D., Environmental Health Sciences; 35 years experience in environmental health analysis and 20 years in environmental assessment.	Argonne EIS project management; lead author of recreation and wilderness sections (Sections 3.10, 4.10; Appendix J); contributing author of air quality and climate change sections (Sections 4.15, 4.16; Appendix M); subject matter expert for recreation, visitor use and experience, and wilderness
Leslie Poch	M.S., Nuclear Engineering; 30 years experience in power systems analysis and hydropower modeling.	Lead author of hydropower sections (Section 4.13, Appendix K.1); technical lead, hydropower modeling and power systems analysis
Carolyn M. Steele	B.A., English; B.A., Rhetoric; 9 years experience in technical writing and editing.	Lead editor
Robert Sullivan	M.L.A., Landscape Architecture; 25 years experience in visual impact analysis and simulation; 13 years in website development.	Lead author of visual resources sections (Sections 3.12, 4.12); technical lead for visual resources
Jack C. Van Kuiken	M.S., Systems Science; 39 years experience in electrical power systems modeling, optimization, and analysis.	Technical analyst and subject matter expert, hydropower modeling and power systems analysis

Name	Education/Experience	Contribution
Robert Van Lonkhuyzen	B.A., Biology; 24 years experience in ecological research and environmental assessment.	Lead author of vegetation sections (Sections 3.6, 4.6; Appendix G); technical lead for vegetation
Bruce Verhaaren	M.A., Anthropology; Ph.D., Near Eastern Languages and Civilizations; 34 years experience in archaeological analysis; 24 years in environmental assessment and Tribal resources.	Lead author of Tribal resources sections (Sections 3.9, 4.9; Appendix I); technical lead for Tribal resources; subject matter expert, cultural resources; records management
Tom Veselka	M.S., Meteorology; 34 years experience in energy, power, and environmental systems modeling/optimization.	Contributing author of hydropower sections (Section 4.13; Appendix K.1); subject matter expert, hydropower modeling and power systems analysis
William S. Vinikour	M.S., Biology with environmental emphasis; 38 years experience in ecological research and environmental assessment.	Lead author food base (Sections 3.5, 4.5; Appendix F) and wildlife sections (Sections 3.7, 4.7); subject matter expert, aquatic food base and wildlife
Cory Weber	M.S., Operations Management and Information Systems; 9 years experience in research software and visualization development.	Technical analyst hydropower modeling
Kelsey Wuthrich	B.S., Civil and Environmental Engineering; 2 years experience in environmental science.	Technical analyst sediment, cultural, recreation, and water use modeling
Emily Zvolanek	B.A., Environmental Science; 6 years experience in GIS mapping.	GIS mapping and analysis
U.S. Geological Survey		
Barbara Ralston	Ph.D., Botany; 28 years experience in floristics and 20 years experience in southwestern riparian ecology.	Lead technical analyst vegetation modeling
Michael C. Runge	Ph.D., Wildlife Science; 16 years experience in decision analysis, wildlife population modeling, statistical analysis, and ESA consulting; 5 years experience in NEPA assessment.	Lead author structured decision analysis (Appendix C); project management and review; technical lead, structured decision analysis
Charles Yackulic	Ph.D., Ecology and Evolution; Research Statistician.	Lead technical analyst humpback-chub trout modeling; subject matter expert, aquatic ecology, aquatic modeling

Name	Education/Experience	Contribution
U.S. Fish and Wildlife Service		
Sarah Rinkevich	Ecological Services/Federal Tribal Liaison.	Federal Tribal Liaison
Western Area Power Administration		
S. Clayton Palmer	M.A., Economics; 30 years experience in hydropower generation analysis, environmental economics, and economic and financial analysis.	Contributing author of environmental justice section (Section 4.14) and lead author of electrical wholesale rate section (Appendix K.2); technical analyst and subject matter expert, hydropower modeling and power systems analysis
Thomas Hackett	B.S., Management/Computer Information Systems; 9 years experience in electricity rates and budget analyses.	Contributing author of electrical wholesale rate section (Appendix K.2); technical analyst hydropower modeling and power systems analysis

8 GLOSSARY

A

Abiotic: Absence of living organisms, includes chemical and physical environments and processes.

Aboriginal: The first or earliest known of its kind present in a region.

Above mean sea level (AMSL): Elevation or altitude of any object relative to the average sea level.

Acre-foot: Volume of water, 43,560 cubic feet (ft^3) (1,233 cubic meters [m^3], 325,851 gallons), that would cover 1 acre to a depth of 1 foot.

Active capacity: Reservoir capacity normally available to store and regulate reservoir inflows to meet established reservoir operating requirements. For Lake Powell, this reservoir storage capacity is nearly 21 million acre-feet (maf).

Active conservation capacity: Reservoir capacity assigned to regulate reservoir inflow for irrigation, power generation, municipal and industrial use, fish and wildlife, navigation, recreation water quality, and other purposes. Also referred to as active storage. For Lake Powell, this is the reservoir storage above the penstock openings at an elevation of 3,490 feet (ft) (1,064 meters [m]).

Active storage: See *active conservation capacity*.

Adaptive management: Method or system for examining alternative strategies for meeting measurable goals and objectives and then, if necessary and in response to new information and/or changing circumstances, adjusting actions according to what is learned.

Adaptive Management Work Group (AMWG): Federal advisory committee to the Secretary of the Interior. Incorporates those stakeholders with interest in the operation of Glen Canyon Dam and downstream resources and continues public involvement in the decision-making process.

Advection: The typically horizontal movement of a mass of fluid, such as water.

Adverse impact: Abnormal, harmful, or undesirable effect that results from taking a particular action.

Aeolian processes: Erosion, transport, and deposition of sediment by the wind. Commonly occurs in areas with sparse or nonexistent vegetation, a supply of fine sediment, and strong winds.

Aerate: To supply or impregnate with gas, usually air.

Affected environment: Existing biological, physical, social, and economic conditions of an area subject to change, both directly and indirectly, as the result of a proposed human action. Also, the chapter in an environmental impact statement (EIS) describing current environmental conditions. A description of the affected environment must include information necessary to assess or understand impacts, must contain enough detail to support the impact analyses, and must highlight environmentally sensitive resources.

Aggradation: Process of filling and raising the level of a streambed, floodplain, or sandbar by deposition of sediment. The opposite of degradation.

Aggregation: A consistent and disjunct group of fish that has no significant exchange of individuals with other aggregations, as indicated by recapture of tagged juveniles and adults and movement of radio-tagged adults.

Air quality: Measure of the condition, including health-related and visual characteristics, of the air. Often derived from quantitative measurements of the concentrations of specific injurious or contaminating substances (i.e., air pollutants).

Air Quality Control Region (AQCR): An interstate or intrastate area designated by the U.S. Environmental Protection Agency for the attainment and maintenance of National Ambient Air Quality Standards.

Albedo (effects): The fraction of solar radiation reflected by a surface or object, often expressed as a percentage. Snow-covered surfaces have a high albedo; the albedo of soils ranges from high to low; vegetation-covered surfaces and oceans have a low albedo. The Earth's albedo varies mainly through varying cloudiness, snow, ice, leaf area, and land-cover changes.

Algae: Simple plants containing chlorophyll; most live submerged in water.

Algal bloom: Rapid and flourishing growth of algae.

Allocation, allotment: Refers to a distribution of water through which specific persons or legal entities are assigned individual rights to consume pro-rata shares of a specific quantity of water under legal entitlements. For example, a specific quantity of Colorado River water is distributed for use within each Lower Division state through an apportionment. Water available for consumptive use in that state is further distributed among water users in that state through the allocation. An allocation does not establish an entitlement; the entitlement is normally established by a written contract with the U.S. government.

Alluvial: Formed by the action of running water, such as that related to river and stream deposits.

Alluvium: Sedimentary material (e.g., clay, silt, sand, gravel, or other particulates) transported and deposited by the action of flowing water.

Alternatives: Courses of action that may meet the specific goals and objectives of a proposed action, often by different means and at varying levels of accomplishment, including the most likely future conditions without the project (i.e., no action).

Ambient: Surrounding environment or natural conditions in a given place and time.

American Indian: The indigenous peoples in North America within the boundaries of the present-day continental United States, Alaska, and the island state of Hawaii.

American Indian Tribe: Any extant or historical clan, Tribe, band, nation, or other group or community of indigenous peoples in the United States.

American Indian Religious Freedom Act (P.L. 95-341) (AIRFA): Act requiring federal agencies to consult with Tribal officials to ensure protection of religious cultural rights and practices.

Amphibian: Cold-blooded, smooth-skinned vertebrate animal that has a life stage in water (e.g., hatches as an aquatic larva with gills) and a life stage on land (e.g., transforms into an adult with air-breathing lungs). Includes salamanders, frogs, and toads.

Amphipod: An order of crustacean that is found in almost all aquatic environments.

AMSL: See *above mean sea level*.

AMWG: See *Adaptive Management Work Group*.

Anaerobic bacteria: Bacteria that survive and grow in environments with little or no oxygen.

Ancillary services: Those services necessary to support the transmission of electric power from seller to purchaser given the obligations of control areas and transmitting utilities within those control areas to maintain reliable operations of the interconnected transmission system. See *regulation* and *spinning reserves*.

Anions: Ions that carry a negative charge (e.g., chloride, nitrate, sulfate, and phosphate).

Anoxic: Areas of water that are depleted of dissolved oxygen.

Antecedent: Prior or preceding event, condition, or cause.

Anthropogenic: Created, caused, or produced by humans.

Apportionment: Refers to the distribution of Colorado River water available to each Lower Division state in normal, surplus, or shortage condition years, as set forth, respectively, in Articles II(B)(1), II(B)(2), and II(B)(3) of the 1964 Supreme Court Decree in the case of Arizona v. California.

Appropriation: Amount of water legally set apart or assigned to a particular purpose or use.

Aquatic: Living or growing in or on the water.

Aquatic biota: Collective term describing the organisms living in or depending on the aquatic environment.

Aquatic habitat: Bodies of water that provide food, cover, and other elements critical to the completion of an organism's life cycle (e.g., streams, rivers, and lakes).

Aquifer: Permeable water-bearing underground rock formation that readily yields usable amounts of water to a well or spring. The formation could be sand, gravel, limestone, and/or sandstone.

Archaeological and Historic Preservation Act (AHPA): Legislation that amended the Reservoir Salvage Act of 1960, requiring federal agencies to provide for the preservation of historical and archeological data that might otherwise be lost or destroyed as the result of any federally licensed activity or program causing an alteration of terrain.

Archaeological resource: Any material remains or physical evidence of past human life or activities that are of archeological interest, including the record of the effects of human activities on the environment. An archeological resource is capable of revealing scientific or humanistic information through archeological research.

Archaeological Resources Protection Act of 1979 (ARPA): Legislation establishing requirements to protect archaeological resources and sites on public lands and Indian lands and to foster increased cooperation and exchange of information between governmental authorities, the professional archaeological community, and private individuals.

Archaeological site: A place (or group of physical sites) in which evidence of past activity is preserved (either prehistoric, historic, or contemporary); that has been, or may be, investigated using the discipline of archaeology; and that represents a part of the archaeological record.

Archaic: In American archeology, a cultural stage following the earliest known human occupation in the Americas (about 5500 BC to AD 100). This stage was characterized by a hunting and gathering lifestyle and seasonal movement to take advantage of a variety of resources.

Archaeology: Study of human cultures through the recovery and analysis of their material remains.

Arid: A region that receives too little water to support agriculture without irrigation. Less than 10 in. of rainfall a year in a region is typically considered arid.

Arroyo: Gully or channel cut by an ephemeral stream.

Arthropod: Any of the invertebrate animals (such as insects, spiders, or crustaceans) having an exoskeleton, a segmented body, and jointed limbs.

Artifact: Object produced or shaped by human beings and of archaeological or historical interest.

Aspect: The direction in which a feature faces.

Assemblage: A collection or community of plants or animals characteristically associated with a particular environment, which can be used as an indicator of that environment.

Attainment Area: An area considered to have air quality as good as or better than the National Ambient Air Quality Standards for a given pollutant. An area may be in attainment for one pollutant and in nonattainment for others.

Attenuation: Gradual loss of strength or intensity.

Authorization: Act by the Congress of the United States that sanctions the use of public funds to carry out a prescribed action.

Automatic generation control (AGC): Computerized power system regulation to maintain scheduled generation within a prescribed area in response to changes in transmission system operational characteristics.

Available hydropower (AHP): The monthly capacity and energy that is actually available based on prevailing water release conditions.

Average peak annual discharge: Found by generating a list of the single highest value of discharge from each year and calculating the mean.

B

Backwater: A relatively small, generally shallow area of a river with little or no current. See *return-current channel*.

Bald and Golden Eagle Protection Act: Law passed in 1940 that prohibits anyone without a permit issued by the Secretary of the Interior from taking bald or golden eagles, including their parts, nests, or eggs.

Bank storage: Water absorbed and stored in the banks of a stream, lake, or reservoir, and returned in whole or in part as the level of the water body surface falls.

Base flow: Portion of stream or river discharge that is derived from a natural storage source (i.e., groundwater recharge).

Baseline: Information identified or found at the beginning of a study or experiment that serves as a basis against which subsequent findings are measured or compared.

Baseload: Minimum load in a power system over a given period of time.

Baseload plant: Energy plant or powerplant normally operated to produce the minimum amount of power required to meet some or all of a given region's continuous energy demands. Consequently, it operates essentially at a constant load.

Basin: Area of land that drains to a particular stream, river, pond, or lake.

Basin States: In accordance with the Colorado River Compact of 1922, the Colorado River Basin is comprised of those parts of Arizona, California, Colorado, Nevada, New Mexico, Utah, and Wyoming within and from which waters drain naturally into the Colorado River. These seven states are referred to as the Basin States. See *Colorado River Compact of 1922*.

Bathymetric: Pertains to the study of the underwater depth of a lake, ocean, or reservoir floor.

Beach: Sandbar that generally is considered to have recreational value. See *sandbar*.

Bed elevation: Height of streambed above a specified level. Change in bed elevation in pools of the Colorado River commonly is used as a measure of change in the amount of sediment stored on the riverbed.

Bedload: Sediment moving on or near the streambed and frequently in contact with it.

Bed material: Unconsolidated material of which a streambed is composed.

Bedrock: Native consolidated, solid rock foundation underlying the surface. Above it is usually an area of loose, broken, and weathered unconsolidated deposits of soil, sand, clay, or gravel.

Benthic: Living in or occurring at the bottom of a body of water.

Biodiversity: Number and kinds of organisms per unit area or volume; the composition of species in a given area at a given time.

Biological Assessment: Document prepared for the Endangered Species Act of 1973 (ESA) Section 7 process to determine whether a proposed major construction activity under the authority of a federal action agency is likely to adversely affect listed species, proposed species, or designated critical habitat.

Biological control: The use of living organisms, such as predators, parasitoids, and pathogens, to control pest insects, weeds, or diseases. Typically involves some human activity.

Biological Opinion (BO): Document stating opinion of the U.S. Fish and Wildlife Service (FWS) and the National Marine Fisheries Service (NMFS) as to whether a federal action is likely to jeopardize the continued existence of a threatened or endangered species or result in the destruction or adverse modification of critical habitat.

Biological response: Reactions or changes in cells, tissues, organs, and/or entire organisms resulting from chemical, physical, or environmental agents and stressors.

Biomass: Total amount of combustible solid, liquid, or gas derived from biological processes (e.g., living organisms) in a particular area or environment.

Biota: Living organisms (e.g., plants and animals) in a given region.

Blue-ribbon fishery: Designation made by the U.S. government and other authorities to identify recreational fisheries of extremely high quality. The designation is typically based on water quality, quantity, and accessibility; natural reproduction capacity; angling pressure; and the specific species present.

Bryophytes: Group of non-vascular, seedless plants including mosses, liverworts, and hornworts.

Bypass tube: Conduits that are used to release water in addition to the releases made through the powerplant. See *jet tube*.

C

Campable area: Areas suitable for recreational camping.

Candidate species: Plant or animal species about which sufficient information on biological status and threats is known to propose them as endangered or threatened. Undergoing status review by the FWS, but not yet officially listed as threatened or endangered under the ESA.

Capacity: In power terminology, the load for which a generator, transmission line, or system is rated; expressed in kilowatts. In this document, also refers to powerplant generation capability under specific operating conditions and the amount of marketable resource under such conditions.

Carbon dioxide (CO_2): A colorless, odorless, nonpoisonous gas that is a normal part of the Earth's atmosphere. Carbon dioxide is a product of fossil fuel combustion, but is also exhaled by humans and animals and absorbed by green growing things and by the sea. It is the most prominent greenhouse gas that traps heat radiated into the atmosphere.

Carbon monoxide (CO): Colorless, odorless gas that is toxic if breathed in high concentrations over an extended period. Listed as a criteria air pollutant under Title I of the Clean Air Act (CAA).

Carnivore: Any flesh-eating or predatory organism.

Carrying capacity: Maximum density of wildlife or population of a specific species that a particular region can sustain without deterioration of the habitat or hindering future generations' ability to maintain the same population.

Catch and release: Practice within recreational fishing intended as a conservation measure in which captured fish are unhooked and returned to the water before experiencing serious exhaustion or injury.

Cations: Ions that carry a positive charge (e.g., sodium, magnesium, calcium, iron, and aluminum).

Cenozoic age: Era extending from about 65 million years ago to the present.

Census block group: Geographic entities consisting of groups of individual census blocks. Census blocks are grouped together so that they contain between 250 and 550 housing units.

Channel: Natural or artificial watercourse with a definite bed and banks to confine and conduct continuously or periodically flowing water.

Channel margin bar: Narrow sand deposits that continuously or discontinuously line the riverbank.

Chemocline: Boundary or gradient between water masses of different chemical composition (e.g., salinity).

Chironomid: Group of two-winged flying insects that live their larval stage underwater and emerge to fly about as adults.

Cladocera: An order of small crustaceans commonly called water fleas.

Cladophora: Filamentous green alga that is very important to the food chain in the Colorado River below Glen Canyon Dam.

Class I scenic resource: Classification of areas within Glen Canyon that have outstanding scenic quality such as intricately carved landscapes, unique canyons, and unique geological features.

Class II scenic resource: Classification of an area within Glen Canyon that has superior quality or a diversity of form and color.

Clay: Fine-grained soil, rock, or mineral fragment that has a diameter of less than 0.002 millimeters (mm). Clay is often made up of one or more minerals (e.g., hydrous aluminum phyllosilicates, sometimes with iron, magnesium, alkali metals, alkaline earths, and other cations) with traces of metal oxides and organic matter.

Clean Air Act (CAA): Comprehensive federal law that regulates air emissions. This act establishes national ambient air quality standards (NAAQS) that protect public health and the environment. Under this act, construction and operating permits, as well as reviews of new stationary emissions sources and major modifications to existing sources, are required. It further requires facilities to comply with emission limits or reduction limits stipulated in State Implementation Plans (SIPs) and prohibits the federal government from approving actions that do not conform to SIPs. Originally passed in 1963, the national air pollution control program is actually based on the 1970 version of the law. The 1990 CAA amendments, in large part, were intended to deal with previously unaddressed or under-addressed problems such as acid rain, ground level ozone, ozone depletion, and air toxics.

Clean Water Act (CWA): Establishes the basic structure for regulating discharges of pollutants into the waters of the United States and regulating quality standards for surface waters. Under the CWA, the U.S. Environmental Protection Agency (EPA) has implemented several pollution control programs, such as setting wastewater standards for industry and requiring National Pollutant Discharge Elimination System (NPDES) permits for discharges of effluents to surface waters. The basis of the CWA was enacted in 1948 and was called the Federal Water Pollution Control Act, but the Act was significantly reorganized and expanded in 1972. "Clean Water Act" became the Act's common name with amendments in 1972.

Climate change: Significant and lasting change in the statistical distribution of weather conditions and patterns over periods of years, ranging from decades to millions of years.

Clovis technological complex: A widespread, distinctive early Paleoindian culture defined by a distinct form of fluted stone projectile points named for Clovis, New Mexico, the city near which they were found. Clovis technology dates to around 13,500 years ago.

Cobble: Loose particles of rock or mineral (sediment) that range in size from 64 to 256 mm in diameter. Cobbles are larger than gravel, but smaller than boulders.

Code of Federal Regulations (CFR): Codification and compilation of the general and permanent rules published in the *Federal Register* by the departments and agencies of the United States Federal Government. It is divided into 50 subject matter titles that represent broad areas subject to federal regulation. Each title contains one or more individual volumes, which are updated once each calendar year, on a staggered basis.

Cohort: A group of fish that were generated in the same spawning season and are born at the same time.

Coldwater fish: Species of fish that require relatively cold water (50–60°F, or 10–15°C) to survive. Cold water can hold more dissolved oxygen than warm water, so these species generally inhabit deeper lakes and ponds in northern regions, spring-fed streams and lakes with a constant cold water supply, or lakes in high altitudes that are cold. Rainbow trout is an example of a coldwater species.

Colorado River Basin: All areas that drain to the Colorado River and its tributaries.

Colorado River Basin Project Act of 1968 (CRBPA): Act that authorized construction of a number of water development projects, including the Central Arizona Project (CAP), and required the Secretary of Interior to develop the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs, or Long-Range Operating Criteria (LROC).

Colorado River Basin Salinity Control Act: Law enacted by Congress in 1974 that directed the Secretary of the Interior to proceed with a program to enhance and protect the quality of water available in the Colorado River for use in the United States and Republic of Mexico.

Colorado River Compact of 1922: Provides for the equitable division and apportionment of the use of the waters of the Colorado River System between the Upper Basin and Lower Basin states.

Colorado River Ecosystem: Community of aquatic, riparian, and terrestrial fauna and flora of the Colorado River mainstream corridor and its tributaries, along with that system's processes and environments. In general, the CRE encompasses the Colorado River primarily from the forebay of Glen Canyon Dam to the western boundary of Grand Canyon National Park and includes the area where the Glen Canyon Dam operations impact physical, biological, recreational, cultural, and other resources.

Colorado River Simulation System (CRSS): Operational model of the Colorado River Basin based on a monthly time step.

Colorado River Storage Project Act (CRSPA) of 1956: Authorized comprehensive development of the water resources of the Upper Basin states (Colorado, New Mexico, Utah, and Wyoming) by providing for long-term regulatory storage of water, including construction of Glen Canyon Dam, to meet the entitlements of the Lower Basin states (Arizona, California, and Nevada).

Commercial river trip: Trip organized by a boating company that conducts tours and recreational outings for paying passengers.

Community: All members of a specified group of species present in a specific area at a specific time; a group of people who see themselves as a unit.

Compact: Agreement between states apportioning the water of a river basin to each of the signatory states.

Compact point: Lee Ferry, Arizona, the reference point designated by the Colorado River Compact dividing the Colorado River into two sub-basins, the Upper Basin and the Lower Basin.

Concentration: Amount of a chemical in a particular volume or weight of air, water, soil, or other medium.

Concrete-arch dam: Dam design often used in a narrow, steep-sided rock canyon with curvatures in both horizontal and vertical directions. The safety of an arch dam is dependent on the strength of the side wall abutments and the strength and elasticity of the concrete used in its construction.

Conductivity: Measure of the ability of water to pass an electrical current. Conductivity is an indicator of the amount of dissolved salts in a stream, and is often used to estimate the amount of total dissolved solids (TDS) rather than measuring each dissolved constituent separately. Conductivity in water is also affected by temperature.

Confluence: Meeting point of two or more rivers.

Consolidated Decree: Entered by the United States Supreme Court on March 27, 2006, in the case of Arizona v. California, 547 U.S. 150 (2006). In 1963, the Supreme Court reached a Decision in the case of Arizona v. California. The 1964 Supreme Court Decree in the case of Arizona v. California implemented the 1963 Decision. This 1964 Supreme Court Decree was supplemented over time after its adoption and the Supreme Court entered a Consolidated Decree in 2006 incorporating all applicable provisions of the earlier-issued Decisions and Decrees.

Consumptive water use: Total amount of water used by vegetation, human activities, and natural cycling processes (e.g., evaporation, transpiration, incorporation) that is not available for other uses within the system.

Continental climate: A climate lacking marine influence and characterized by more extreme temperatures than marine climates; therefore, it has a relatively high annual temperature range for its latitude.

Continental Divide: Drainage divide that separates the Atlantic and Pacific watersheds of North America.

Contingent valuation: Survey method asking for the maximum values that users would pay for access to a particular activity.

Control area: Part of a power system, or a combination of systems, to which a common electrical generation control scheme is applied.

Convection: Motions in a fluid that result in the transport and mixing of the fluid's properties.

Cooperating Agency: With respect to the National Environmental Policy Act of 1969, as amended (NEPA), process, an agency that has jurisdiction by law or special expertise concerning an aspect of a proposed federal action, and that is requested by the lead agency to participate in the preparation of an Environmental Impact Statement.

Coordinated operation: Generally, the operation of two or more interconnected electrical systems to achieve greater reliability and economy. As applied to hydropower resources, the operation of a group of hydropower plants to obtain optimal power benefits with due consideration for all other uses.

Copepods: Small crustaceans that live in virtually all marine and freshwater habitats.

Cosmology: Set of beliefs regarding the origin and structure of the universe.

Council on Environmental Quality (CEQ): Established by NEPA, CEQ regulations (40 CFR Parts 1500–1508) describe the process for implementing NEPA, including preparation of Environmental Assessments and EISs, and the timing and extent of public participation.

Cover: Vegetation, rocks, or other materials used by wildlife for protection from predators or weather.

Creel census: Angler survey to collect data on the harvest, size, and distribution of various species of fish.

Criteria air pollutants: Six common air pollutants for which NAAQS have been established by the EPA under Title I of the CAA. Included are sulfur dioxide (SO_2), nitrogen oxides (NO_x), carbon monoxide (CO), ozone (O_3), particulate matter ($PM_{2.5}$ and PM_{10}), and lead (Pb). Standards were developed for these pollutants on the basis of scientific knowledge about their health effects.

Critical habitat: Specific areas within the geographical area occupied by the species that have physical or biological features essential to the conservation of a listed endangered or threatened species and may require special management considerations or protection. These areas are legally designated via *Federal Register* notices.

Cross-sectional area: Area of a stream, channel, or waterway, usually measured perpendicular to the flow.

Crustacean: Aquatic animals with hard external skeletons and segmented limbs, belonging to the class Crustacea; includes cladocerans, shrimp, crayfish, fairy shrimp, isopods, amphipods, lobsters, and crabs.

Cubic foot per second (cfs): As a rate of streamflow, a cubic foot of water passing a reference section in 1 second. A measure of a moving volume of water (1 cfs = 0.0283 m^3/s).

Cultural modification: Any human-caused change in the land form, water form, or vegetation, or the addition of a structure that creates a visual contrast in the basic elements (e.g., form, line, color, or texture) of the naturalistic character of a landscape.

Cultural property: The tangible evidence or expression of cultural heritage such as works of art, buildings, or their ruins.

Cultural resource: Any sites, districts, buildings, structures, objects, or features significant in history, architecture, archeology, culture, or science. Also, Native American sacred sites or special use areas that provide evidence of the prehistory and history of a community.

Cumulative impact: Impact assessed in an EIS that results from the incremental impacts of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or nonfederal), private industry, or individual undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

Cyanobacteria: Blue-green algae, prokaryotic, photosynthetic organisms that generally have a blue-green tint and lack chloroplasts.

Cyprinids: Largest family of freshwater fish, commonly called the carp family or minnow family.

D

Daily fluctuation: Difference between daily maximum and minimum releases from the dam. These scheduled fluctuations are used to maximize efficiency of power generation.

Dead capacity: Reservoir capacity from which stored water cannot be evacuated by gravity. At Glen Canyon Dam, this is the Lake Powell storage below the river outlet works openings at an elevation of 3,374 ft (1,028 m).

Debris fan: Sloping mass of water and debris, including boulders, cobbles, gravel, sand, silt, clay, and organic material (e.g., tree limbs), formed by debris flows at the mouth of a tributary.

Debris flow: Mixture of rocks, sediment, and organic material containing less than 40% water by volume that flows downslope under the force of gravity (e.g., flash flood).

Defoliation: Process by which a plant, shrub, or tree loses its leaves. Possible causes include insect activity, disease, chemicals, or the coming of autumn.

Degradation: Process wherein elevation of streambeds, floodplains, and sandbars is lowered by erosion. The opposite of aggradation.

Delivery: The amount of water delivered to the point of use.

Delta: Flat alluvial area formed at the mouth of some rivers and streams (e.g., Colorado River) where the mainstream flows into a body of standing water, such as a sea or lake (e.g., Lake Powell or Lake Mead), and deposits large quantities of sediment.

Depletion: Loss of water from a stream, river, or basin resulting from consumptive use.

Deposition: Settlement of material out of the water column and on to the streambed or flooded areas. Occurs when the energy of flowing water is unable to support the load of suspended sediment.

Desiccation: Process of drying out.

Desired future condition (DFC): Measurable target or value, established for any resource area that is of interest to managers; provides a reference point for evaluating treatment effectiveness and the need to implement additional treatments or management actions.

Detritivore: An organism that feeds on dead and decomposing matter.

Detritus: Loose natural materials, such as rock fragments or organic particles, that result directly from disintegration of rocks or organisms.

Diatom: Microscopic, single-celled, or colonial algae having cell walls of silica.

Diel fluctuations: Changes or fluctuations that occur in a 24-hour period that usually includes a day and the adjoining night.

Diptera: Order of insects that includes all true flies.

Direct effect (impact): Effect on the environment caused by an action; occurs at the same time and place as the initial action.

Direct impact: See *direct effect*.

Discharge (flow): Volume of water that is released from the dam at any given time or that passes a given point within a given period of time. Usually expressed in cubic feet per second (cfs).

Dispatch: The operating control of an integrated electric system whose job it is to (1) assign generation to specific generating plants and other sources of electric supply to effect the most reliable and economical supply as the total of the significant area loads rises or falls; (2) control operations and maintenance of high-voltage lines, substations, and equipment, including administration of safety procedures; (3) operate the interconnection; and (4) schedule energy transactions with other interconnected electric utilities.

Dissolved oxygen (DO): Amount of free oxygen found in water expressed as a concentration, milligrams per liter (mg/L), or as percent saturation (the amount of oxygen the water holds compared to the maximum amount it could absorb at that temperature). Low DO levels adversely affect fish and other aquatic life. The ideal dissolved oxygen for fish life is between 7 and 9 mg/L; most fish cannot survive when DO falls below 3 mg/L.

Dissolved solids: See *total dissolved solids (TDS)*.

Divert: To direct a flow away from its natural course.

Downstream: Situated or moving in the direction of a stream or river's current.

Drainage: Process of removing surface or subsurface water from a soil or area.

Drawdown: Lowering of a reservoir's water level; process of depleting reservoir or groundwater storage.

Drift: Food organisms dislodged and moved by river current. Can include algae, plankton, invertebrates, and larval fish.

Driftwood: Remains of trees that have been washed onto a shoreline by the action of winds, tides, or waves.

Drought: Period of unusually persistent dry weather that persists long enough to cause serious problems such as crop damage and/or water supply shortages.

Dune: Wind-deposited sand body, usually a rounded hill, ridge, or mound.

E

Ecological resource: Animals, plants, and the habitats in which they live, which may be land, air, or water.

Ecological restoration: Process of assisting in the recovery of an ecosystem that has been degraded, damaged, or destroyed.

Ecology: The relationship between living organisms and their environments.

Ecoregion: A geographically distinct area of land that is characterized by a distinctive climate, ecological features, and plant and animal communities.

Ecosystem: Complex system composed of a community of fauna and flora and that system's chemical and physical processes and environment.

Ecosystem management: Approach to natural resource management that seeks an understanding of the interrelationships among important physical, chemical, biological, cultural, political, and social processes in order to conserve resources and sustain ecosystems to meet both ecological and human needs of current and future generations.

Ectoparasitic: Living on the exterior of another organism, the host, obtaining nourishment from the latter.

Eddy: Current of water moving against the main current in a circular pattern. See *recirculation zone*.

Effect: Environmental consequences (the scientific and analytical basis for comparison of alternatives) that occur as a result of a proposed action. See *direct effect* and *indirect effect*.

Efficiency: Ratio of useful energy output to total energy input, usually expressed as a percentage.

Electric power system: Physically connected electric power generating, transmission, and distribution facilities operated as a unit under one control.

Electrical demand: Energy requirement placed upon a utility's generation at a given instant or averaged over any designated period of time.

Electrofishing: Application of a direct electric current to attract and temporarily immobilize fish for easy capture. See *mechanical removal*.

Embayment: a recess or an indentation in a shore line that forms an area with low flow.

Emergent marsh plants: Plants that are rooted in soil with basal portions that typically grow beneath the surface of the water but whose leaves, stems, and reproductive organs are above the water.

Emissions: Substances that are discharged into the air from industrial processes, vehicles, and living organisms.

Empirical: Based on experimental data rather than theory.

Encroachment: Act of advancing, intruding, or extending beyond established, usual, or proper limits.

Endangered species: Species or subspecies (plant or animal) whose survival is at risk of extinction throughout all or a significant portion of its range because it is either few in numbers or threatened by changing environmental or predation parameters. Requirements for declaring a species endangered are found in the ESA.

Endangered Species Act of 1973 (ESA): Provides a federal program for the conservation of threatened and endangered plants and animals and the habitats in which they are found. Requires consultation with the FWS and/or the National Oceanic and Atmospheric Administration (NOAA) Fisheries Service to determine whether endangered or threatened species or their habitats will be affected by a proposed activity and what, if any, mitigation measures are needed to address the impacts.

Endemic: Native to and restricted to a particular geographic region.

Energy: Electric capacity generated and/or delivered over time; usually measured in kilowatt-hours.

Environmental Assessment (EA): Concise public document that a federal agency prepares under NEPA to provide sufficient evidence and analysis to determine whether a proposed action, or its alternatives, may have significant environmental effects on the human environment. In general, an EA must include brief discussions on the need for the proposal, the alternatives, the environmental impacts of the proposed action and alternatives, and a list of agencies and persons consulted. If significant effects may occur, an EIS is prepared instead of an EA.

Environmental Impact Statement (EIS): Detailed document required of federal agencies under NEPA for major proposals or legislation that will or could significantly affect the environment. An EIS is prepared with public participation and must disclose significant issues and impacts on the human environment that may result from the proposed action or its alternatives. An EIS includes the following: the environmental impact of the proposed action; any adverse impacts that cannot be avoided by the proposed action; alternative courses of action; relationships between local short-term use of the human environment and the maintenance and enhancement of long-term productivity; and a description of the irreversible and irretrievable commitment of resources that would occur if the action were accomplished.

Environmental justice: Fair treatment of people of all races, cultures, incomes, and educational levels with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies.

Ephemeral stream: Stream that flows briefly only in direct response to precipitation and whose channel is, at all times, above the water table.

Epilimnion: Top layer of a thermally stratified lake or reservoir that exhibits essentially uniform warmer temperature. See *stratification*.

Epiphyte: A plant that derives its moisture and nutrients from the air and rain and grows on another plant for support.

Equalization flow: Dam releases made to balance water storage between Lake Powell and Lake Mead. Pursuant to the Interim Guidelines, these flow events are carried out if (1) the end of the water year storage forecast for Lake Powell is greater than that of Lake Mead; and (2) the storage forecast for the end of the water year in the Upper Basin reservoirs is greater than the quantity of storage required by Section 602(a) of the CRBPA (602[a] storage) for that same date.

Equalization tier: Operation elevation that applies when Lake Powell's projected January 1 elevation is above the elevation in the equalization table of the Interim Guidelines. The tier provides for Lake Powell releases of more than 8.23 maf during the water year until the content of the lakes equalizes or certain elevations are attained.

Erosion: Gradual destruction or wearing away of a material (e.g., rock or sand) or object (e.g., beach) by water, wind, or other natural agents.

Ethnobotany (ethnobotanical): The plant lore and agricultural customs of a people; the study of such lore and customs.

Ethnohistory: The use of both historical and ethnographic data such as maps, music, paintings, photography, folklore, and oral tradition to understand a culture on its own terms and according to its own cultural code.

Euphotic zone: The superficial layer of a water body within the range of effective light penetration for photosynthesis.

Eutrophication: Enrichment of a body of water as a result of high concentrations of minerals and organic nutrients (especially nitrogen and phosphorus) that stimulate and promote the proliferation of aquatic plant life, thus reducing the dissolved oxygen content of the water.

Evaporation: Water vapor losses to the atmosphere from land areas, bodies of water, and all other moist surfaces.

Evapotranspiration: Sum of water transpired or used by plants and evaporated from surfaces (e.g., water bodies and soils) in a specific time period; usually expressed in depth of water per unit area.

Exceedance: Measured level of an air pollutant that is higher than the national or state ambient air quality standards. Also applies to water volume, flow, or energy generation that is above a particular percentage (exceedance level).

Excess capacity: Power generation capacity available on a short-term basis in excess of the firm capacity available through long-term contracts.

Executive Order (EO): President's or governor's directive or declaration that implements or interprets a federal statute, a constitutional provision, or a treaty. It has the force of law and is usually based on existing statutory powers; requires no action by Congress or a state legislature.

Existence value: Value people place on simply knowing an area or feature continues to exist in a particular condition.

Exotic species: Nonnative plant or animal deliberately or accidentally introduced into a new habitat where it is able to reproduce and survive.

Experimental flow: Investigational releases (e.g., high-flow experiments) that are designed to explore, test, and assess the relationships between dam operations and downstream resources in and along the Colorado River within the Grand Canyon National Park (GCNP) and Glen Canyon National Recreation Area (GCNRA).

Experimental population: Specific reintroduced populations of listed species under the ESA. The FWS determines whether an experimental population is "essential" or "nonessential" to the continued existence of the species.

Exposure: Contact of an organism with a chemical, radiological, or physical agent.

Extinct species: Species having no living members, such that it is no longer in existence.

Extirpated species: Species that no longer exists in a given region or area.

Extirpation: Elimination of a species or subspecies from a particular area, but not from its entire range.

F

Fan-eddy complex: An assemblage of geomorphic features created by a debris fan that projects into a stream or river and creates an area of recirculation (eddy) just downstream of the debris fan.

Fauna: Animals in a specific region or habitat, considered as a group.

Feature: Large, complex artifact, or part of a site, such as a hearth, cairn, housepit, rock alignment, or activity area.

Fecal coliform bacteria: Group of organisms common to the intestinal tracts of humans and animals. The presence of fecal coliform bacteria in water is an indicator of pollution and of potentially dangerous bacterial contamination.

Fecundity: Number of produced eggs or offspring; reproductive capability.

Federal Register: Official daily publication for rules, proposed rules, and notices of federal agencies and organizations, as well as executive orders and other presidential documents; published by the Office of the Federal Register, National Archives and Records Administration (NARA).

Filamentous algae: Plant that forms a greenish mat on the water surface.

Finding of No Significant Impact (FONSI): NEPA document issued by a federal agency briefly presenting the reasons why an action, not otherwise excluded, will not have a significant effect on the human environment if implemented. This finding is based on the results of an EA and other factors in the public planning record for a proposed action.

Fine sediment: Soil particles, typically defined as less than 1–2 mm in diameter (e.g., clay and silt), that are naturally filtered from coarser fractions and carried by water.

Firm energy or power: Uninterruptible energy and power guaranteed by the supplier to be available at all times except for reasons of uncontrollable forces or continuity of service provisions.

Fishery: Specified waters or area where fish or other aquatic animals are reared and caught.

Flash flood: Sudden high-flow event through a valley, canyon, or wash, following a short-duration, high-intensity rainfall.

Flatwater boating: Form of low-speed boating (e.g., canoeing or kayaking) that relies on flat waters (e.g., lakes, gorges, or slow-moving rivers), as opposed to rapids or white water.

Flood: Relatively high flow or inundation of water, as measured by either gage height or discharge quantity, that overtops the natural or artificial banks in any reach of a river and threatens or causes damage.

Flood Control Act of 1944: Act authorizing the construction of certain public works on rivers and harbors for flood control and other purposes.

Flood control capacity: Reservoir capacity assigned for the sole purpose of regulating flood inflows to reduce flood damage downstream.

Flood control pool: Reservoir volume above the active conservation and joint-use pool that is reserved for flood runoff and then evacuated as soon as possible to keep that space in readiness for the next flood. See *reservoir capacity*.

Flood flows: In this report, water releases from Glen Canyon Dam in excess of powerplant capacity (i.e., 31,500 cfs).

Floodplain: Mostly level, low-lying land adjacent to a water body that is subjected to inundation and submersion during high flow or rainfall events. The relative elevations of floodplain areas determine their frequency of flooding, which ranges from rare, severe, storm events to flows experienced several times a year.

Flora: Community of plants in a specific region or habitat, considered as a group.

Flow: Volume of water passing a given point per unit of time. See *instream flow requirements*, *minimum flow*, *peak flow*, *ponding flow*, *spike flow*, and *steady flow*.

Flow regime: Flow variation through time resulting from operations of the Glen Canyon Dam.

Fluctuating flows: Water released from Glen Canyon Dam that varies in volume, usually within a given range (e.g., 1,000 to 31,500 cfs), over a 24-hour period.

Fluctuation zone: Area of a sandbar or vegetation zone that is within the range of fluctuating flow.

Fluvial: Pertaining to a river or stream; indicates the presence or interaction of a river within an area or landform.

Fluvial geomorphology: Study and examination of stream and river channels, both in their natural setting and their response to human-induced changes in a watershed. Includes the processes that operate in river systems and the landforms they create or have created.

Folsom technological complex: A widespread, distinctive early Paleoindian culture defined by a distinct form of fluted stone projectile points named for Folsom, New Mexico, the city near which they were found. Folsom technology dates to between 11,500 and 10,000 years ago.

FONSI: See *Finding of No Significant Impact*.

Food chain: Succession of organisms in a community in which food energy is transferred from one organism to another as each consumes a lower member and in turn is consumed by a higher member.

Food web: Complex system or network of interrelated and interdependent food chains that describes how food energy is passed throughout an ecological community.

Food base: Substances or materials that provide living things with the nutrients they need to provide energy, grow, and sustain overall life.

Forage fish: Generally, small fish that produce prolifically and are consumed by predators.

Forced outage: Nonscheduled shutting down of a generating unit or other facility for emergency or other unforeseen reasons.

Forebay: Impoundment immediately above a dam or hydroelectric powerplant intake structure.

Fossil fuel: An energy source formed in the Earth's crust from decayed organic material. Common fossil fuels are petroleum, coal, and natural gas.

Fragmentation: Process by which habitats are increasingly subdivided into smaller units, resulting in their increased insularity as well as losses of total habitat area.

Fry: Life stage of fish between the egg and fingerling stages.

Fugitive dust: The dust released from any source other than a definable point source such as a stack, chimney, or vent. Sources include construction activities, storage piles, and roadways.

Full pool: Volume of water in a reservoir at maximum design elevation. At Lake Powell this is at an elevation of 3,700 ft (1,130 m). Total volume is 27 maf; this volume is decreasing as the lake fills with sediment.

G

Gage: Device or instrument used for measuring or testing.

Gated spillway: Overflow section of dam restricted by use of gates that can be operated to control releases from the reservoir to ensure the safety of the dam.

Gaging station: Specific location on a river or stream where systematic observations and measurements of hydrologic data are obtained through mechanical or electrical means.

Generation (power): Process of producing electrical energy by transforming other forms of energy. Also, the amount of electric energy produced.

Generator: Machine that converts mechanical energy into electrical energy.

Geology: Science that deals with the study of the materials, processes, environments, and history of the Earth, including rocks and their formation and structure.

Geomorphology: Geological study of the configuration and evolution of landforms and earth features.

Gigawatt-hour (GWh): One billion watt-hours of electrical energy.

Glen Canyon Dam: Second highest concrete arch dam in the United States. Constructed to harness the power of the Colorado River to provide for the water and power needs for people in the western United States.

Glen Canyon Dam Adaptive Management Program (GCDAMP): Provides an organization and process for cooperative integration of dam operations, downstream resource protection and management, and monitoring and research information, as well as to improve the values for which the GCNP and GCNRA were established.

Glen Canyon Environmental Studies (GCES): Program started by the Bureau of Reclamation in 1982 to collect scientific evidence on the positive and negative impacts on downstream environmental and cultural resources as a result of daily fluctuating releases from the dam.

Glen Canyon National Recreation Area (GCNRA): Area that encompasses hundreds of square miles from Lees Ferry in Arizona to the Orange Cliffs of southern Utah for water-based and backcountry recreation.

Global warming: Increase in the near-surface temperature of the Earth. Global warming has occurred in the distant past as the result of natural influences, but the term is today most often used to refer to the warming that many scientists predict will occur as a result of increased anthropogenic emissions of greenhouse gases.

Gradient: See *slope*.

Grand Canyon Monitoring and Research Center (GCMRC): Science provider for the GCDAMP. Operated by the U.S. Geological Survey, the GCMRC provides relevant scientific information about the status and trends of natural, cultural, and recreational resources found in those portions of the GCNP and GCNRA affected by Glen Canyon Dam operations.

Grand Canyon National Park (GCNP): A National Park since 1919, the area contains unique combinations of erosional forms. It is 277 river miles long and up to 18 miles wide. The area encompasses 1,218,375 acres and lies on the Colorado Plateau in northwestern Arizona, with land that is semiarid and consists of raised plateaus and structural basins.

Grand Canyon National Park Enlargement Act: An act of Congress enacted in 1975 to further protect the Grand Canyon by enlarging the park in the state of Arizona.

Grand Canyon Protection Act of 1992 (GCPA): Directs the operation of Glen Canyon Dam in compliance with existing law to protect, mitigate adverse impacts on, and improve the values for which the GCNP and GCNRA were established, including, but not limited to, natural and cultural resources and visitor use.

Green algae: Members of the plant phylum Chlorophyta, which possess the green pigment chlorophyll that they use to capture light energy to fuel the manufacture of sugars. This diverse group of algae consists primarily of freshwater eukaryotic organisms, which serve as food and oxygen sources for other aquatic organisms.

Greenhouse effect: Increasing mean global surface temperature of the Earth caused by gases in the atmosphere (including carbon dioxide, methane, nitrous oxide, ozone, and chlorofluorocarbon). The greenhouse effect allows solar radiation to penetrate, but also absorbs infrared radiation returning to space.

Greenhouse gases (GHGs): Heat-trapping gases in the atmosphere that contribute to global warming and temperature gain near the Earth's surface. Natural and human-made GHGs include water vapor, carbon dioxide, methane, nitrogen oxides, ozone, and fluorinated gases (e.g., chlorofluorocarbons).

Gross generation: Total amount of electrical energy produced by a generating station or stations, measured at generator terminals.

Groundwater: Supply of water found beneath the Earth's surface, usually in porous rock formations (i.e., aquifers), which may supply wells and springs.

Gully: Landform that erodes sharply into soil, typically on a hillside; caused by running water. Gullies are similar to ditches or small valleys, but they are typically only 3 to 30 ft (0.9 to 9 m) wide and deep.

H

Habitat: Area or place, including physical and biotic conditions, where a plant or animal lives.

Hanging garden: Unique biological feature formed when spring water flows through cracks in the sandstone and seeps out through the canyon walls, allowing plants to grow vertically.

Harvest: In a recreational fishery, refers to numbers of fish that are caught and kept.

Head: Height of water above a specified point.

Headwater: Source and upper part of a stream or lake inflow.

Heavy metal: Metallic elements with high atomic weights (e.g., lead, mercury, cadmium, chromium, and arsenic) that are generally toxic in relatively low concentrations to plant and animal life.

Herbaceous: The plant strata that contain soft, not woody, stemmed plants that die to the ground in winter.

Herbivore: Animal that feeds on plants.

Herpetofauna: General grouping for reptiles and amphibians.

High flow: Pulses or temporary influxes of water that typically occur after periods of precipitation and are contained within the natural banks of the river (i.e., do not cause flooding). In a river, these events can lead to a temporary reduction in downstream temperature and increases in salinity, dissolved oxygen, and turbidity. High flows suspend and deliver large amounts of sediment and organic matter downstream, which can redeposit on sandbars and beaches. They can also restore and enhance riparian vegetation and can prevent undesirable vegetation from invading river channels. In addition, high-flow events can work to reshape and maintain native fish habitats, stimulate food base production, and suppress numbers of nonnative fish.

High-flow experiment (HFE): High-volume test releases (31,500 to 45,000 cfs) from the Glen Canyon Dam that are performed under sediment-enriched conditions. HFEs are specifically designed to benefit downstream resources; this includes maintaining and rebuilding sandbars and beaches in downstream reaches. Also referred to as a high-flow test.

High-flow test: See *high-flow experiment*.

Historic: The time period after the appearance of written records. In the New World, this generally refers to the time period after the beginning of European settlement at approximately 1600 AD.

Historic property: Any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the *National Register of Historic Places* maintained by the Secretary of the Interior. They include artifacts, records, and remains that are related to and located within such properties.

Historic resource: In the United States, material remains and the landscape alterations that have occurred since the arrival of Europeans.

Human environment: Natural and physical environment and the relationship of people with that environment including all combinations of physical, biological, cultural, social, and economic factors in a given area.

Hydraulic: Powered by water.

Hydroelectric plant: Electric powerplant using falling water as its motive force.

Hydroelectric power: Electricity produced by water.

Hydrogen sulfide (H_2S): A colorless, flammable, and extremely hazardous gas that occurs naturally in crude petroleum, natural gas, and hot springs.

Hydrograph: Graph showing, for a given point in a stream, the discharge, stage, velocity, or other property of water with respect to time.

Hydrologic budget: An accounting of the inflow to, outflow from, and storage change in a hydrologic unit such as an aquifer or drainage basin.

Hydrologic cycle: Continuous circulation of water in all of its phases (gas, liquid, solid) from the atmosphere to Earth by precipitation, and from Earth to the atmosphere by evaporation and transpiration. The land phase includes infiltration, runoff, and exchange between surface water and groundwater.

Hydrology: Science dealing with the occurrence, properties, distribution, circulation, and transport of water, including groundwater, surface water, rain, and snow.

Hydropower: See *hydroelectric power*.

Hypolimnetic: Pertaining to the lower, colder portion of a lake or reservoir, which is separated from the upper, warmer portion (epilimnion) by the thermocline.

Hypolimnion: Non-circulating bottom layer of a thermally stratified lake or reservoir that exhibits essentially uniform colder temperature and low dissolved oxygen.

Hypoxia: depressed levels of dissolved oxygen in water, usually resulting in decreased metabolism.

I

Igneous rock: A crystalline rock formed by the cooling and solidification of molten or partly molten material (magma). Igneous rock includes volcanic rock (rock solidified above the Earth's surface) and plutonic rock (rock solidified at considerable depth).

Impact: Effect, influence, alteration, or imprint caused by an action. See *adverse impact*, *cumulative impact*, *direct impact*, and *indirect impact*.

Impoundment: Body of water created by a dam, dike, floodgate, or other barrier.

Inactive capacity: Reservoir capacity that can be released from the dam but is normally not available (i.e., for power generation) because of operating agreements or physical restrictions. At Glen Canyon Dam, this is the reservoir storage above the river outlet works openings at elevation 3,374 ft (1,038 m) and below the penstock openings at elevation 3,490 ft (1,064 m), which is about 3.9 maf.

Indian trust assets: Lands, natural resources, or other assets held in trust or restricted against alienation by the United States for Native American Tribes or individual Native Americans.

Indian trust resource: Those natural resources, either on or off Indian lands, retained by or reserved by or for Indian Tribes through treaties, statutes, judicial decisions, and Executive Orders, which are protected by a fiduciary obligation on the part of the United States.

Indigenous: Native to an area.

Indirect effect (impact): Effect that occurs away from the place of action with effects that are related to, but removed from, a proposed action by an intermediate step or process. An example would be changes in surface-water quality resulting from soil erosion at construction sites.

Indirect impact: See *indirect effect*.

Inflow: Amount or rate of water flowing into a body of water. In this report, the water flowing into Lake Powell from the Colorado River and/or its tributaries; or water entering the Colorado River from tributaries between Glen Canyon Dam and Lake Mead; or water flowing into Lake Mead, mainly from the Colorado River.

Infrastructure: Basic facilities, utilities, services, and transportation framework needed to meet public and administrative needs for the functioning of an organization, system, or community.

In-situ: In its natural position or place; unmoved, unexcavated, remaining at the site or subsurface.

Insolation: Solar energy that is received on a given surface area during a given time.

Instream flow requirements: Amount of water flowing through a stream course needed to sustain instream values.

Intake: Structure in a dam, reservoir, or river through which water can be drawn into an outlet pipe or waterway.

Interconnected systems: System consisting of two or more individual power systems normally operating with connecting tie lines.

Interflow: Lateral movement of water in the upper layer of soil.

Interim shortage criteria/interim guidelines: Operational guidelines and coordinated reservoir management strategies (established in 2007) to address operations of Lake Powell and Lake Mead, particularly under drought and other low reservoir conditions. These criteria also provide a greater degree of certainty to U.S. Colorado River water users and managers of the Colorado River Basin by detailing information on when, and by how much, water deliveries will be reduced under specified reservoir conditions.

Intermittent stream: Stream that flows only at certain times of the year when the ground-water table is high; occasionally is dry or reduced to a pool stage when losses from evaporation or seepage exceed the amount of inflow.

Inundate: To cover with impounded waters or floodwaters.

Invasive species: Nonnative plant or animal, including noxious and exotic species, that is an aggressive colonizer and can out-compete other species. Their introduction causes or is likely to cause economic or environmental harm or harm to human health.

Invertebrate: Animal without a spinal cord, usually replaced by a hard exoskeleton or shell. Examples include insects, spiders, crayfish, snails, or clams.

Ion: Atom or molecule that carries either a positive or negative electrical charge.

Irretrievable commitments of resources: Those resources that are lost or lose value for a period of time and cannot be restored as a result of an action, such as temporary loss of power productivity due to of modified operations.

Irreversible commitments of resources: Those resources that cannot be regained, restored, or returned to their original condition within a reasonable time frame, such as the extinction of a species.

Irrigation district: A cooperative, self-governing public corporation set up as a subdivision of the state government, with definite geographic boundaries; organized and having taxing power to obtain and distribute water for irrigation of lands within the district; created under the authority of a state legislature with the consent of a designated fraction of the landowners or citizens.

J

Jeopardy opinion: FWS or NMFS opinion that an action is likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat.

Jet tube: A Glen Canyon Dam outlet that releases water below the level of penstocks. Four jet tubes with a combined release capacity of 15,000 cfs are not equipped with generation capability, but allow for a total release of about 45,000 cfs when used in combination with maximum releases from each of the eight penstocks.

Juvenile: Young organism older than 1 year but not having reached reproductive age.

K

Kaibab formation: The rock that makes the canyon rims and is the youngest of the Grand Canyon's geologic layers.

Kilovolt (kV): 1,000 volts (V).

Kilowatt (kW): Unit of electric power capacity equal to 1,000 watts (W), or about 1.34 horsepower (HP).

Kilowatt-hour (kWh): Basic unit of electric energy equaling an average of 1 kW of power applied over 1 hour.

L

Lake Mead National Recreation Area (LMNRA): American's first national recreation area; encompasses Lake Mead and Lake Mohave.

Lake Powell: Reservoir created by the completion of the Glen Canyon Dam on the Colorado River in 1963.

Landform: Any feature of the Earth's surface having a distinct shape and origin. Landforms include major features (such as continents, ocean basins, plains, plateaus, and mountain ranges) and minor features (such as hills, valleys, slopes, drumlins, and dunes).

Landmark (historic): Significant historic places designated by the Secretary of the Interior because they possess exceptional value or quality in illustrating or interpreting the heritage of the United States.

Landmark (visual): Type of reference point external to the observer. Usually a simply defined physical object that can be seen from many angles and distances over the tops of smaller elements and used as a radial reference.

Landscape: Traits, patterns, and structure of a specific geographic area including its biological composition, its physical environment, and its anthropogenic or social patterns.

Larva, larvae (pl.): The immature stage between the egg and pupa of insects having complete metamorphosis where the immature differs radically from the adult (e.g., caterpillars, grubs).

Larval fish: First life stage of fish after hatching. Larvae are not able to feed themselves, and carry a yolk-sac that provides their nutrition.

Latitude: Angular distance north or south of the equator, measured in degrees.

Law of the River: As applied to the Colorado River, the collective set of documents that apportions the Colorado River waters and regulates the use and management of the Colorado River among the seven Basin States and Mexico. It is comprised of numerous operating criteria, regulations, and administrative decisions included in federal and state statutes, interstate compacts, court decisions and decrees, an international treaty, and contracts with the Secretary of the Interior.

Lead (Pb): A gray-white metal that is listed as a criteria air pollutant. Health effects from exposure to lead include brain and kidney damage and learning disabilities. Sources include leaded gasoline and metal refineries.

Lead agency (or agencies): Federal agency (or agencies) either preparing or taking primary responsibility for preparing the NEPA compliance documents.

Lee Ferry: Reference point marking division between the Upper and Lower Colorado River basins. The point is located in the mainstream of the Colorado River 1 mi below the mouth of the Paria River in Arizona.

Lees Ferry: The historic location of Colorado River ferry crossings (1873 to 1928) and the current site of the U.S. Geological Survey stream gage above the Paria River confluence.

Limnology: Scientific study of the physical, chemical, meteorological, and biological aspects of freshwater bodies.

Listed species: Species, subspecies, or distinct population segments that have been added to the federal list of endangered and threatened wildlife and plants and receive legal protection under the ESA.

Load: Amount of electrical power or energy delivered or required at a given point.

Load-following: A pattern of hydropower generation that reacts instantaneously to change in demand for power.

Loam: Soil consisting of an easily crumbled mixture of clay, silt, and sand.

Low flow: Flow releases from the dam at a rate of 8,000 cfs or less.

Lower Basin: Those parts of the states of Arizona, California, Nevada, New Mexico, and Utah, within and from which waters drain naturally into the Colorado River below Lee Ferry, Arizona; defined by the Colorado River Compact of 1922.

Lower Colorado River Multi-Species Conservation Plan (MSCP): 50-year multi-stakeholder federal and non-federal partnership set up to protect the lower Colorado River environment while ensuring the certainty of existing river water rights and power operations; address the needs of threatened and endangered native species and their habitats in compliance with state and federal endangered species laws; and reduce the likelihood of listing additional species along the lower Colorado River.

Lower Division: Division of the Colorado River system that includes the states of Arizona, Nevada, and California; area defined by Article II of the Colorado River Compact of 1922.

Lower-elevation balancing tier: Operation elevation that applies when Lake Powell's projected January 1 elevation is below 3,525 ft (1,074 m) AMSL. The tier provides for attempting to balance the contents of Lake Mead and Lake Powell, if possible, within the constraint that the release from Lake Powell would be not more than 9.5 maf and no less than 7.0 maf.

M

Macroinvertebrate: Animal without vertebrae, usually with a hard exoskeleton or shell, of a size large enough to be seen by the unaided eye.

Macrophyte (aquatic): Aquatic plant that is large enough to be observed with the naked eye. Grows in or near water.

Main channel: Deepest or central part of the bed of a stream or river, containing the main current.

Mainstem: Main course of a stream or river.

Mainstream: Principal or largest stream or river of a given area or drainage basin; in this document, the Colorado River.

Major federal action: Proposed federal undertaking entirely or partly financed, assisted, conducted, regulated, or approved by federal agencies that has the potential for significant impacts on the human environment and is thus subject to federal control and responsibility.

Mammal: Air-breathing animal whose skin is more or less covered with hair or fur and has mammary glands. Young are born alive (except for the platypus and echidna) and are nourished with milk. Mammals include humans, dogs, cats, deer, mice, squirrels, raccoons, bats, opossums, whales, seals, and others.

Management action: Decision-making response carried out to achieve a specific purpose.

Meander: Bends and loops in a river channel as the river snakes through a flat land area.

Mechanical removal (fish): Use of electrofishing, nets, and other gear types to physically remove fish from an ecosystem. See *electrofishing*.

Median: Middle value in a distribution, above and below which lie an equal number of values.

Megawatt (MW): One million watts of electrical power.

Megawatt-hour (MWh): One million watt-hours of electrical energy.

Memorandum of Understanding (MOU): Document structuring the collaboration among federal agencies and other stakeholders (e.g., Tribes, local governments) and describing an intended common line of action.

Mesa: A broad, flat-topped elevation with one or more steeply sloping to vertical sides.

Mesozoic age: An era of geologic time between the Paleozoic and the Cenozoic eras, spanning the time between 251 and 65 million years ago. The word Mesozoic is from Greek and means "middle life."

Metalimnion: Middle layer of a thermally stratified lake or reservoir where there exists a rapid decrease in temperature with depth. Also called thermocline.

Meteorology: Study of the Earth's atmosphere, particularly its patterns of climate and weather.

Metric ton: Unit of mass equal to 1,000 kilograms.

Microclimate: The climate of a small area, particularly that of the living space of a certain species, group, or community.

Mid-elevation tier: Operation elevation that applies when Lake Powell's projected January 1 elevation is below 3,575 ft (1,090 m) AMSL and at or above 3,525 ft (1,074 m) AMSL. The annual releases in this tier are either 7.48 maf or 8.23 maf, depending upon the projected elevation of Lake Mead being above or below 1,025 ft (312 m) AMSL, respectively.

Midge: A very small, non-biting, two-winged insect, related to deer flies, mosquitos, and craneflies.

Mill: Monetary cost and billing unit used by utilities; equal to 1/1,000 of a U.S. dollar (equivalent to 1/10 of one cent).

Milligram per liter: Equivalent to one part per million.

Million acre-feet (maf): Unit of volume; the volume of water that would cover 1 million acres to a depth of 1 foot.

Mineral: Naturally occurring inorganic element or compound having an orderly internal structure and characteristic chemical composition, crystal morphology, and physical properties such as density and hardness. Minerals are the fundamental units from which most rocks are made.

Minimum flow: The lowest flow that occurs during the day, month, or year.

Mitigation: Action implemented to eliminate, avoid, minimize, or reduce the severity of an adverse impact on a particular resource resulting from the proposed action or its alternatives. Mitigation can include one or more of the following: (1) avoiding impacts; (2) minimizing impacts by limiting the degree or magnitude of an action; (3) rectifying impacts by restoration, rehabilitation, or repair of the affected environment; (4) reducing or eliminating impacts over time; and (5) compensating for the impact by replacing or providing substitute resources or environments to offset the loss.

Modified low fluctuating flow (MLFF): Current operating flow regime for the Glen Canyon Dam. The MLFF regime was established as the preferred alternative in the 1995 EIS and subsequent 1996 Record of Decision (ROD). In general, MLFF combines reduced daily flow fluctuations below the historic pattern of releases with high steady releases of short duration, intended to protect or enhance downstream resources while allowing limited flexibility for power operations. Established flows included minimum flows of no less than 8,000 cfs between 7 a.m. and 7 p.m., and 5,000 cfs at night; maximum rate of release limited to 25,000 cfs during fluctuating hourly releases; and releases of greater than 25,000 cfs (other than for emergencies) made steady on a daily basis in response to high inflow and storage conditions.

Monoculture: the cultivation or growth of a single crop or organism, especially on agricultural or forest land.

Monsoon: Rain event caused by a change in atmospheric circulation (e.g., wind direction) that results in stormy conditions, including excessive rainfall.

Morphology: Form and structure of an object (e.g., biological organism or rock formation) or any of its parts.

Mortality: Relative incidence or prevalence of death in a population.

Mouth (river): Natural opening, as the part of a stream or river, that empties into a larger body of water (e.g., another river, lake, bay, or ocean).

Myxozoa: Group of small parasitic animals that live in aquatic environments; one species in this group, *Myxobolus cerebralis*, is the parasite that causes whirling disease in rainbow trout.

N

National Ambient Air Quality Standards (NAAQS): Air quality standards established by the CAA, as amended. The primary NAAQS specify maximum outdoor air concentrations of criteria pollutants that would protect the public health within an adequate margin of safety. The secondary NAAQS specify maximum concentrations that would protect the public welfare from any known or anticipated adverse effects of a pollutant.

National Environmental Policy Act of 1969 (NEPA): Act passed by Congress in 1969 that sets national policy, procedures, tools, and compliance measures to support environmental protection, including encouraging productive harmony between people and their environment; promoting efforts that will prevent or eliminate damage to the environment and the biosphere and simulate the health and welfare of people; enriching the understanding of the ecological systems and natural resources important to the nation; and establishing a Council on Environmental Quality. It requires federal agencies to integrate environmental values into their decision-making processes by considering the environmental impacts of their proposed actions and reasonable alternatives to those actions. To meet this requirement, federal agencies prepare one of the following: a categorical exclusion, an EA, or an EIS.

National Historic Preservation Act (NHPA): Federal law providing that property resources with significant national historic value be placed on the *National Register of Historic Places*. It does not require permits; rather, it mandates consultation with the proper agencies whenever it is determined that a proposed action might affect a historic property.

National Register of Historic Places (NRHP): Official list of the nation's cultural resources worthy of preservation. Authorized under the NHPA, the NRHP is part of a national program to coordinate and support public and private efforts to identify, evaluate, and protect historic and archeological resources. Properties listed in the NRHP include districts, sites, buildings, structures, and objects that are significant in American history, architecture, archeology, engineering, and culture.

Native: Species of plants or wildlife that originated in the particular area or region in which they are growing or living.

Native American: See *American Indian*.

Native American Graves Protection and Repatriation Act (NAGPRA): Act that established the priority for ownership or control of Native American cultural items excavated or discovered on federal or Tribal land after 1990 and the procedures for repatriation of items in federal possession. The act allows for the intentional removal or excavation of Native American cultural items from federal or Tribal lands only with a permit or upon consultation with the appropriate Tribe.

Natural condition: State or status of resources that would occur (to the extent practicable) in the absence of human activities and/or dominance over the landscape.

Natural flow: The flow of any stream or river as it would be if unaltered by upstream diversion, storage, import, export, or change in upstream consumptive use caused by human activities.

Natural resource: Features and values that are inherently supplied by nature and considered to have value, including plants and animals, water, air, soils, topographic features, geologic features, and paleontological resources.

Natural Zone: An area managed for the conservation of natural resources and ecological processes while providing for their use by the public, as established by the National Park Service.

Nearshore: Area located between the boundary of the mainstem current and the shoreline. These regions are typically characterized by low water velocities (compared to the mainstem) and reduced turbulent mixing.

Nematode: An elongated, cylindrical worm parasitic in animals, insects, or plants, or free-living in soil or water.

Neotropical migratory bird: Bird that breeds in North America (i.e., Canada and the United States) during the spring and summer months and spends the winter months in Mexico, Central America, South America, or the Caribbean islands.

New High Water Zone (NHWZ): The area located next to the river, corresponding to river flows of 25,000 to 40,500 cfs, colonized with vegetation since the construction of Glen Canyon Dam; typically composed of riparian species, both native and nonnative.

Nitrate (NO_3): Naturally occurring plant nutrient that is essential to all life. It commonly enters water supply sources from decaying plants, manures, fertilizers, or other organic residues.

Nitrogen dioxide (NO_2): Toxic reddish brown gas that is a strong oxidizing agent, produced by combustion (as of fossil fuels). It is the most abundant of the oxides of nitrogen in the atmosphere and plays a major role in the formation of ozone. NO_2 is one of the six criteria air pollutants specified under Title I of the CAA. See *nitrogen oxides*.

Nitrogen oxides (NO_x): Includes various nitrogen compounds, primarily nitrogen dioxide and nitric oxide. They form when fossil fuels are burned at high temperatures and react with volatile organic compounds to form ozone, the main component of urban smog. They are also precursor pollutants that contribute to the formation of acid rain.

No action alternative: An alternative required by CEQ to be included in all EAs and EISs, representing conditions that would occur if the agency did not take the proposed action being considered. The environmental effects resulting from taking no action are compared to the effects of permitting the proposed action or any other action alternative to go forward.

Nonattainment area: The EPA's designation for an air quality control region (or portion thereof) in which ambient air concentrations of one or more criteria pollutants exceed NAAQS.

Non-firm power: Power that is not available continuously and may be interruptible; may be marketed on a short-term basis.

Nonnative: Species of plants or wildlife that did not originate in the particular area in which they are growing or living and that often interfere with natural biological systems.

Non-use valuation: The process of assigning a non-use value to a resource.

Non-use value: The economic benefit that arises from the knowledge that a resource exists (existence value), has been preserved for potential use in the future (option value), and will be available for use by one's heirs (bequest value). Non-use value is theoretically and conceptually distinct from use value. Contingent valuation is the only technique currently available for estimating non-use value.

Normal condition: As it relates to the Colorado River, when the Secretary of the Interior has determined that there is available water for annual releases totaling 7.5 maf to satisfy consumptive use in the Lower Division states pursuant to Article II(B)(1) of the Consolidated Decree.

Notice of Intent (NOI): Announcement published in the *Federal Register* that an EIS will be prepared and considered. Includes description of the proposed action and alternatives; provides time, place, and descriptive details of the proposed scoping process; and identifies the lead agency (or agencies) contact person.

NPS-28, Cultural Resource Management Guidelines: National Park Service guidelines that elaborate on policies and standards and offer guidance in applying them to establish, maintain, and refine park cultural resource programs.

Nutrients: Chemical elements or compounds that are essential to plant and animal growth and development, such as nitrogen and phosphorus. Nutrients are measured in milligrams per liter (mg/L).

O

Obligate species: Restricted to a particular condition of life; for example, dependent on a particular habitat to be able to breed.

Off-peak energy: Electric energy supplied during periods of relatively low system demand.

Old High Water Zone (OHWZ): Area of vegetation above the level corresponding to flood flows of about 120,000 to 125,000 cfs; typically composed of native tree species.

On-peak energy: Electric energy supplied during periods of relatively high system demand.

Operating tier: Pursuant to the Interim Guidelines established in 2007, coordinated operations of Lake Powell and Lake Mead defined four operation tiers: (1) Equalization Tier, (2) Upper Elevation Balancing Tier, (3) Mid-Elevation Tier, and (4) Lower Elevation Balancing Tier. See specific tiers for additional information.

Organic matter: Material derived from living plant or animal organisms.

Organochlorine pesticide: Pesticide containing a compound of carbon, chlorine, and hydrogen that does not break down easily and is stored in fatty tissues of any animal ingesting it. Accumulates in animals in higher trophic levels.

Oscillatoria: Genus of benthic (bottom-dwelling) cyanobacteria or plankton (blue-green algae) occurring in blooms in fresh water.

Ostracod: Group of small crustaceans with a bivalved carapace that can be closed to completely cover the body; important planktonic fish food.

Outage (power): Period during which a generating unit, transmission line, or other facility is out of service and power is not available.

Outflow (hydrology): Amount or rate of water flowing out of or from a body of water. In this report it refers to water leaving Lake Powell by way of Glen Canyon Dam.

Outlet works: Device, usually consisting of one or more bypass pipes or tunnels through the embankment of the dam, used to release and regulate water flow from a dam. These structures are similar in purpose to spillways, but outlet works can provide a lower volume and more controlled release. See *jet tube*.

Ozone (O_3): Strong-smelling, reactive, toxic gas consisting of three oxygen atoms chemically attached to each other. Ozone is formed in the atmosphere by chemical reactions involving NO_X and volatile organic compounds (VOCs) in the presence of sunlight. Ozone is one of the six criteria air pollutants under the CAA and is a major constituent of smog.

P

Paleoclimate: a climate prevalent at a particular time in the geologic past.

Paleoindian period: A late Pleistocene stage of cultural evolution in the Americas at the end of the last ice age, when the first traces of human activity begin to appear in the archaeological record characterized by big-game hunting and the use of fluted projectile points.

Paleozoic: An era of geologic time, from the end of the Precambrian to the beginning of the Mesozoic, or from about 542 to 251 million years ago; also, the rocks deposited during this time.

Parasite: Organism that lives on or in an organism of another species (i.e., host) in a way that harms or is of no advantage to the host. Parasites rarely kill their hosts, instead, they obtain nutriment from the host body to live, grow, and multiply.

Particulate matter (PM): Fine solid or liquid particles such as dust, smoke, mist, fumes, or smog, found in air or emissions that stick to lung tissue when inhaled. The size of the particulates is measured in micrometers (μm), which is 1 millionth of a meter (0.000039 in.). Particle size is important because the EPA has set standards for $PM_{2.5}$ and PM_{10} particulates, both of which are criteria air pollutants under the CAA. See *$PM_{2.5}$* and *PM_{10}*.

Pathogen: Bacterium, virus, or other microorganism that can cause disease in other living microorganisms or in humans, animals, and plants.

Peak demand: See *peak load*.

Peak flow: Maximum instantaneous flow in a specified period of time.

Peak load: Maximum electrical demand in a stated period of time.

Peak load plant: Powerplant that normally is operated to provide power during maximum load periods.

Peaking power: Powerplant capacity typically used to meet the highest levels of demand in a utility's load or demand profile.

Penstock: Conduit pipe used to convey water under pressure from a storage reservoir to the turbines of a hydroelectric powerplant.

Per capita income: The average income per person in a given group.

Perennial stream: Stream that flows continuously throughout the year because it lies at or below the groundwater table, which constantly replenishes it.

Periphyton: Complex mixture of algae, cyanobacteria, other microbes, and detritus that is attached to submerged surfaces in most aquatic ecosystems. It serves as an important food source for invertebrates, tadpoles, and some fish.

pH: A measure of the relative acidity or alkalinity of a solution, expressed in a scale of 0 to 14, with a neutral point at 7. Acid solutions have pH values lower than 7, and basic (i.e., alkaline) solutions have pH values higher than 7.

Phantom Ranch: Constructed in 1922, the Phantom Ranch is the only accommodation for hikers in the inner Grand Canyon. It consists of a cluster of guest houses and a canteen lying between Bright Angel Creek and the Colorado River in GCNP.

Phosphorous: Essential chemical food element that can contribute to the eutrophication of lakes and other water bodies. Increased phosphorus levels result from discharge of phosphorus-containing materials into surface waters.

Photosynthesis: Process in which chlorophyll-containing cells convert light into chemical energy, forming organic compounds from inorganic compounds.

Phreatophyte: Any plant, typically living in the desert, that obtains its water from long taproots that reach the water table.

Physiography: The physical geography of an area or the description of its physical features.

Phytoplankton: Microscopic, single-celled photosynthetic organisms that live suspended in water.

Piscivorous: Habitually feeding on fish.

Plankton: Tiny plant (phytoplankton) and animal (zooplankton) organisms with limited powers of locomotion usually living free in the water away from substrates.

Plano technological complex: Distinctive early Paleoindian culture defined by a range of unfluted stone projectile points. Plano technology dates to 11,000 to 8,000 years ago.

PM_{10}: Particulate matter with a mean aerodynamic diameter of 10 μm (0.0004 in.) or less. Particles with diameters smaller than this can be inhaled and accumulate in the respiratory system. PM_{10} is one of the six criteria pollutants specified under Title I of the CAA.

$PM_{2.5}$: Particulate matter with a mean aerodynamic diameter of 2.5 μm (0.0001 in.) or less. Particles with diameters smaller than this can lodge deeply in the lungs. $PM_{2.5}$ is one of the six criteria pollutants specified under Title I of the CAA.

Pollinator: Agent, such as an insect or bird, that moves pollen from the male anthers of a flower to the female stigma of a flower to accomplish fertilization.

Pollutant: Any material entering the environment that has undesired effects.

Ponding flow: Relatively high flows that produce warm low-velocity slackwater areas at tributary mouths that provide thermal refuges for drifting larvae and young warmwater fish (e.g., humpback chub).

Pool: Deep area of a stream or river between rapids or where the current is slow.

Post-dam: Period of time after the completion of Glen Canyon Dam in 1963.

Power demand: Rate at which electric energy is required and delivered to or by a system over any designated period of time.

Power marketing: Process by which Western Area Power Administration sells power generated at Glen Canyon Dam and other Colorado River Storage Project facilities. Subject to a number of requirements established under statutory criteria.

Power operations: Physical operations of a large electrical power system, including hydropower generation, control (operational flexibility, scheduling, load following, and reserves), and transmission.

Power pool: Two or more interconnected electric systems that operate on a coordinated basis to achieve economy and reliability in supplying their combined loads.

Powerplant: Structure that houses turbines, generators, and associated control equipment related to the generation of electrical power.

Powerplant capacity: For Glen Canyon Dam, maximum flow that can pass through the turbines when Lake Powell is full (33,200 cfs). Also refers to the electrical capacity of the generators; total nameplate generating capacity for the powerplant is 1,021,248 kilowatts.

Pre-dam: Period of time before the completion of the Glen Canyon Dam in 1963.

Predation: Act of preying or plundering, specifically the interaction between species when one animal (predator) captures and eats another animal (prey).

Predatory: Relating to or characteristic of organisms that survive by preying on other organisms for food.

Preference customer: In accordance with congressional directives, publicly owned systems, and nonprofit cooperatives that have preference over investor-owned systems for purchase of power from federal projects.

Preferred alternative: Alternative the lead agency (or agencies) believes would fulfill its statutory mission and responsibilities under NEPA, giving consideration to economic, environmental, technical, and other factors.

Prescribed fires: Application of fire (by planned or unplanned ignitions) to fuels in either their natural or modified states, under specified conditions, to allow the fire to burn in a predetermined area while producing the fire behavior required to achieve certain management objectives.

Prevention of significant deterioration (PSD): A federal air pollution permitting program intended to ensure that air quality does not diminish in attainment areas that meet NAAQS.

Primitive: Belonging to or characteristic of an early age of development.

Productivity (ecology): Rate of biomass generation by an individual, population, or community within an ecosystem. Also, the fertility or capacity of a given habitat or area.

Programmatic Agreement (PA): Document that records the terms and conditions agreed upon to resolve the potential adverse effects of a federal agency program, complex undertaking, or other situations in accordance with Section 800.14(b), "Programmatic Agreements," of 36 CFR Part 800, "Protection of Historic Properties."

Project area: Area in which a proposed action would occur and directly affect the environment. The project area for the LTEMP EIS is Lake Powell, Lake Mead, and the Colorado River and its corridor in between.

Proliferation: Rapid growth or increase in production of new parts or offspring.

Proposed action: An action proposed by an agency, subject to a NEPA analysis.

Proterozoic era: Final era of the Precambrian, spanning the time between 2.5 billion and 544 million years ago. Fossils of both primitive single-celled and more advanced multicellular organisms begin to appear in abundance in rocks from this era. Its name means "early life."

Protohistoric: Period between prehistory and history, during which a culture or civilization has not yet developed writing but other cultures have already noted its existence in their own writings. The protohistoric culture may also be in the process of developing its own writing techniques and creating its own written record.

Public involvement: Process of obtaining public input into each stage of development of planning documents. Required as a major input into any EIS.

R

Radionuclide: Unstable nuclide that undergoes radioactive decay.

Ramp rate: Rate of change (cfs/hr) in instantaneous dam releases. The ramp rate is established to prevent undesirable effects due to rapid changes in loading or, in the case of hydroelectric powerplants, discharge.

Range: Geographic region in which a given plant or animal normally lives or grows.

Rapid: Turbulent section of a river. Fast-flowing current typically is caused by a relatively steep descent in the riverbed or a constriction of the main channel.

Reach: Any specified length of a stream or river.

Rearing: Bringing up from the early stages of life, through maturity, until fully grown.

Reattachment bar: Sandbar located where downstream flow meets the riverbank at the downstream end of a recirculation zone. An element of a fan-eddy complex.

Recirculation zone: Area of flow composed of one or more eddies immediately downstream from a constriction in the channel, such as a debris fan or rock outcrop. An element of a fan-eddy complex.

Reclamation Project Act of 1939: This act provides a comprehensive plan for the variable payment of construction charges on U.S. reclamation projects.

Record of Decision (ROD): Document separate from but associated with an EIS that publicly and officially discloses the responsible agency's decision on the EIS alternative to be implemented.

Recovery: Return to or regaining of any former and better state or condition. As it relates to ESA, recovery is the process by which the decline of an endangered or threatened species is arrested or reversed, and threats to its survival (including the ecosystem upon which they depend) are neutralized, so that its long-term survival in nature can be ensured.

Recruitment: Survival of young plants and animals from birth to reproductive age or a life stage less vulnerable to environmental change.

Redd: Depression, or spawning nest, dug by fish (especially trout or salmon) in river- or lakebed for the deposition of eggs.

Redeposition: Formation into a new accumulation, such as the settlement of sedimentary material that has been picked up and moved (reworked) from the place of its original deposition.

Refuge: Protection or shelter, as from something dangerous, threatening, harmful, or unpleasant.

Refugia: Locations or areas where conditions remain suitable to allow a species or a community of species to survive following extinction in surrounding areas. Plural of refugium.

Region of influence (ROI): Area occupied by affected resources and the distances at which impacts associated with a proposed action may occur.

Regulation: Capacity devoted to providing the minute-by-minute change in generation above and below a generator's operating set point. It is needed to maintain a constant voltage within a power control area given variation in generator units. Regulation results in instantaneous deviations above and below the mean hourly flow within each hour that do not affect the mean hourly flow over a full hour. In the United States, regulating capacity is controlled by computers (via automatic generation control).

Reptile: Cold-blooded vertebrate of the class Reptilia whose skin is usually covered in scales or scutes. Reptiles include snakes, lizards, turtles, crocodiles, and alligators.

Reserve generating capacity: Extra generating capacity available to meet unanticipated capacity demand for power in the event of generation loss due to scheduled or unscheduled outages of regularly used generating capacity.

Reservoir: Natural or artificially impounded body of water, commonly created by the building of a dam, that is used for the storage, regulation, and control of water.

Reservoir capacity: Total or gross storage capacity of the reservoir at full supply level.

Restoration: Manipulation of the physical, chemical, or biological characteristics of a resource or site with the goal of improving or returning its natural/historic functions to any former and better state or condition.

Return-current channel: Channel excavated by upstream eddy flow that forms behind a reattachment bar. See *backwater*.

Riffle: Stretch of choppy water caused by an underlying rock shoal or sandbar.

Riparian: Along a river, pond, lake, or tidewater.

Riparian zone: Area encompassing the alluvial sediment deposits where river and alluvial groundwater supplement that available from local precipitation.

Risk: Likelihood of suffering a detrimental effect as a result of exposure to a hazard.

River basin: Land area surrounding one river from its headwaters to its mouth. The area drained by a river and its tributaries.

River corridor: River and the area of land adjacent to it, including the talus slopes at the bases of cliffs, but not the cliffs themselves.

River mile (RM): Unit of measurement (in miles) that quantifies distance (or length) in miles along a river from its mouth or other reference point. On the Colorado River, River Mile 0 is located at the U.S. Geological Survey gage at Lees Ferry, Arizona; points downstream are positive values while those upstream are negative.

River runner: Individual who recreationally navigates a moving body of water, typically a whitewater river, using a raft, kayak, or other type of boat. See *whitewater rafting*.

River stage: Water surface elevation of a river above a reference datum.

Riverine: Of, resembling, relating to, or situated on a river or riverbank.

RiverWare: Commercial river system simulation computer program that was configured to simulate operation of the Colorado River for this EIS.

Rotifer: Microscopic, multicellular invertebrates from the class Rotifera; common in freshwater.

Runoff: Portion of the precipitation, melted snow, or irrigation water that flows across ground surface and eventually is returned to surface water sources. Runoff can pick up pollutants from the air or land and carry them to the receiving waters.

S

Sacred landscape: Natural places recognized by a cultural group as having spiritual or religious significance.

Sacred site: Any specific, discrete, narrowly delineated location on federal land that is identified by an Indian Tribe, or Indian individual determined to be an appropriately authoritative representative of an Indian religion, as sacred by virtue of its established religious significance to, or ceremonial use by, an Indian religion; provided that the Tribe or appropriate authoritative representative of an Indian religion has informed the agency of the existence of such a site.

Salinity: Degree of dissolved minerals (e.g., salts) in water. Also commonly referred to as total dissolved solids (TDS). See *total dissolved solids*.

Salmonid: Of, belonging to, or characteristic of fish belonging to the Salmonidae family, which includes salmon, trout, and whitefish.

Salt Lake City Area Integrated Projects (SLCA/IP): Part of an interconnected generation and transmission system that includes federal, public, and private power-generating facilities.

Sand: Rock or mineral fragment of any composition that has a diameter ranging from 0.5 to 2.0 mm. Sand has a gritty feel.

Sand budget: Management tool used to analyze and describe the various sand and sediment inputs (sources) and outputs (sinks) within a defined system; can be used to predict morphological change over time.

Sand load: See *sediment load*.

Sand mass balance: Difference between the mass of sand being transported into an area and the mass of sand being transported out of the area. A positive sand mass balance indicates that sand is accumulating in the area, whereas a negative sand mass balance indicates that the mass of sand is decreasing in the area.

Sandbar: Any of the fine-grained alluvial deposits that intermittently form the riverbank. These fine-grained deposits are in contrast to the rocky surfaces predominately found throughout the Grand Canyon. See *beach*.

Sandstone: Sedimentary rock composed primarily of sand-sized (0.0025 to 0.08 in.) grains.

Scheduled outage: Shutdown of a generating unit or other facility for inspection or maintenance, in accordance with an advance schedule.

Scheduling: Matching of daily system energy and capacity needs with available generation.

Schist: Metamorphic rock formed from many types of rocks. Minerals in the rocks include micas, chlorite, talc, hornblende, and garnets. The minerals are characteristically platey and foliated (layered), indicating they were subjected to intense compression.

Scope: Range of actions, alternatives (including no action), and impacts to be considered in an EIS.

Scoping: Process required by NEPA to solicit input, issues, and information from within the agency, other agencies, and the public related to the proposed action prior to preparation of an EIS. Scoping assists the preparers of an EIS in defining the proposed action, identifying alternatives, and developing preliminary issues to be addressed in an EIS.

Scour: Erosion in or along a stream bed caused by high flow velocities.

Secretary: Secretary of the Department of the Interior (DOI) and duly appointed successors, representatives, and others with properly delegated authority.

Sediment: Unconsolidated solid material that is washed from land (e.g., from weathering of rock) and is carried by, suspended in, or deposited by water or wind. Sediment varies in size and includes clay, silt, sand, gravel, and cobble.

Sediment augmentation: Adding sand-, silt-, or clay-size sediments to the Colorado River to increase turbidity or sediment supply.

Sediment load: Mass of sediment passing through a stream cross-section in a specified period of time.

Sediment transport: Movement of sediment in a downstream direction caused by flowing water.

Sedimentary rock: Rock formed at or near the Earth's surface from the consolidation of loose sediment that has accumulated in layers through deposition by water, wind, or ice, or organisms. Examples are sandstone and limestone.

Sedimentation: Removal, transport, and deposition of sediment particles by wind or water.

Seep: Moist or wet place where groundwater slowly exits through soil or rock.

Seepage: Relatively slow movement of water through a medium such as sand.

Semi-arid: Moderately dry region or climate where moisture is normally greater than under arid conditions but still limits the production of vegetation.

Sensitive species: Plant or animal species listed by the state or federal government as threatened, endangered, or a species of special concern. The list of sensitive species typically varies from state to state, and the same species can be considered sensitive in one state but not in another. Also, a species that is adversely affected by disturbance or altered environmental conditions. See also *special status species*.

Separation bar: Sandbar located at the upstream end of a recirculation zone, where downstream flow becomes separated from the riverbank, creating an eddy.

Shoal: Shallow area in a body of water.

Shortage condition: When the Secretary has determined that there is available for annual release less than 7.5 maf to satisfy consumptive use in the Lower Division states pursuant to Article II(B)(3) of the Consolidated Decree.

Silt: Fine rock fragments or mineral particles of any composition between sand and clay in size that have diameters ranging from 0.002 to 0.05 mm.

Simulid: Group of two-winged flying insects who live their larval stage underwater and emerge to fly about as adults.

Sinuous: Ratio of the length of a river's thalweg to the length of the valley proper. A measure of a river's meandering.

Site: In archeology, any location of past human activity.

Slope: Change in elevation per unit of horizontal distance.

Socioeconomic: Social and economic conditions in the study area.

Solar radiation: Electromagnetic radiation emitted by the sun.

Soundscapes: Sound or combination of sounds that forms or arises from an immersive environment.

Spawn: To lay eggs, especially fish.

Spawning beds: Places where eggs of aquatic animals lodge or are placed during or after fertilization.

Special status species: Any plant or animal species that is listed or proposed for listing as threatened or endangered by the FWS or NMFS under the provisions of the ESA. Also any species designated by the FWS as "candidate," "sensitive," or a "species of concern"; or a species listed by a state in a category implying potential endangerment or extinction (e.g., sensitive or rare).

Species of special concern: Species that may have a declining population, a limited occurrence, or low numbers for any of a variety of reasons.

Spike flow: Natural or experimental increase in the flow of water for a short duration.

Spills: Water releases from Glen Canyon Dam that do not pass through the turbines for the generation of electricity.

Spillway: Overflow channel of a dam to provide a controlled release.

Spinning reserves: Extra generating capacity that is available for immediate use in response to system problems or sudden load changes by increasing the power output of generators that are already connected to the power system. Within minutes or less, reserves allow for increases in the water release rates at Glen Canyon Dam to increase power generation, up to a limit known as the spinning reserve requirement, to compensate for the loss in generation elsewhere in the grid.

Spring: Point at which groundwater meets the Earth's surface, causing water to flow from the ground.

Stage: See *water-surface elevation*.

Stakeholder: Person, group, or organization that has direct or indirect investment, share, or interest in an organization or project because it can affect or be affected by related actions, objectives, and/or policies.

State Historic Preservation Office(r) (SHPO): The state officer charged with the identification and protection of prehistoric and historic resources in accordance with the NHPA.

Steady flow: Flow released from the dam at any volume that does not vary beyond a small percentage over a 24-hour period.

Stewardship: Conducting, supervising, managing, or protecting something considered of value or worth caring for and preserving. The concept of stewardship has been applied in diverse areas, including the environment, economics, health, property, information, and religion.

Strata: Single, distinct layers of sediment or sedimentary rock.

Stratification: Thermal layering of water in lakes and streams. Lakes usually have three zones of varying temperature: epilimnion—top layer with essentially uniform warmer temperature; metalimnion—middle layer of rapid temperature decrease with depth; and hypolimnion—bottom layer with essentially uniform colder temperatures.

Stratigraphy: Layers of sediments and rocks that reflect the geologic history of an area. With respect to cultural resources and archaeological sites, the relative stratigraphic locations of human artifacts help determine the sequence in which past human activities took place.

Stream: Natural water course. See *ephemeral stream*, *intermittent stream*, and *perennial stream*.

Stream flow: Volume or rate, expressed in cubic feet per second (cfs), of water moving in a stream or river, at any given time.

Stream gage: Active, continuously functioning field measuring device for which stream flow is computed or estimated.

Subadult: Fish that are less than 3 years of age.

Subsistence: The practices by which a group or individual acquires food, such as through hunting and gathering, fishing, and agriculture.

Substrate: Surface on which a plant or animal grows or is attached.

Sulfur dioxide (SO_2): Colorless gas released from many sources, especially burning fossil fuels. Sulfur dioxide is one of the six criteria air pollutants specified under Title I of the CAA.

Sulfur oxides (SO_x): Compounds containing sulfur and oxygen, such as sulfur dioxide (SO_2) and sulfur trioxide (SO_3). Pungent, colorless gases that are formed primarily by fossil fuel combustion, notably from coal-fired powerplants. Sulfur oxides may damage the respiratory tract, as well as plants and trees.

Surface water: Water on the Earth's surface that is directly exposed to the atmosphere, as distinguished from water in the ground (groundwater).

Surplus condition: When the Secretary has determined that there is available for annual release more than 7.5 maf to satisfy consumptive use in the Lower Division states pursuant to Article II(B)(2) of the Consolidated Decree.

Surplus energy: Energy greater than that of contracted firm load that may be available for a short-term period to serve additional load; usually attributed to favorable, but unanticipated, hydrologic conditions.

Suspended solids: Small particles of sand, silt, clay, and organic material moving with the water or along the bed of the stream that are not in true solution (i.e., can be removed by filtration or settling).

Suspension: Heterogeneous mixture of fine solid particles in a liquid or gas, such as sand in water. The suspended particles will settle over time, if left undisturbed, or can be removable by filtration.

Sustainable hydropower (SHP): Fixed level of long-term capacity and energy available from SLCA/IP facilities during summer and winter seasons; this amount is the minimum commitment level for capacity that Western will provide to all SLCA/IP customers.

Sweat lodge: In Native American culture, a ceremonial event of traditional prayers and songs that are held in a lodge constructed of a wood frame covered with blankets, with hot stones that release steam when water is poured on them.

T

Tailwater: Reach of river immediately downstream of a dam, where the water is more similar to that in the reservoir than farther downstream.

Talus: Sloping accumulation of rock debris; also, rock fragments at the base of a cliff as the result of sliding or falling.

Taxa: Taxonomic unit or category within the biological system of classification to which organisms are assigned, including species, genus, family, order, class, and phylum.

Technical Work Group (TWG): Subcommittee comprised of technical representatives of the Adaptive Management Work Group (AMWG) to develop criteria and standards for monitoring and research programs.

Temperate: Moderate climate that lacks extremes in temperature.

Temperature control device (TCD): Apparatus used to modify the dam's penstocks to allow for selective withdrawal from the reservoir, as to influence the temperature of the release water (e.g., warm surface water versus cold deep water).

Temporal: Of, relating to, or limited by time.

Temporary structure: Any structure that can be readily and completely dismantled and removed from the site between periods of actual use. It may or may not be authorized at the same site from season to season or from year to year.

Terrace: Surface form of a high sediment deposit having a relatively flat surface and steep slope facing the river.

Terrain: Topographic layout and features of a tract of land or ground.

Terrestrial: Pertaining to plants or animals living on land rather than in water.

Texture: Visual manifestations of light and shadow created by the variations in the surface of an object or landscape.

Thalweg: Line connecting the deepest points along the length of a valley or riverbed.

Thermal: Of, relating to, affected by, or producing heat.

Thermocline: Zone of maximum change in temperature in a water body, separating upper (epilimnetic) from lower (hypolimnetic) zones.

Threatened species: Any species or subspecies that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. Requirements for declaring a species threatened are contained in the ESA of 1973.

Toe: Point at which the bottom of a slope or embankment intersects the natural ground, such as the upstream or downstream toe of the dam or the downstream toe of a landslide or debris fan.

Topography: Physical shape of the ground surface; the relative position and elevations of natural and human-made features of an area.

Total dissolved solids (TDS): Dissolved materials in the water including ions such as potassium, sodium, chloride, carbonate, sulfate, calcium, and magnesium. In many instances, the term TDS is used to reflect salinity, since these ions are typically in the form of salts. See *salinity*.

Toxicity: Harmful effects on an organism caused by exposure to a hazardous substance. Environmental exposures are primarily through inhalation, ingestion, or contact with the skin.

Trace (hydrology): Sequence of flows over a specified period of time.

Traditional Cultural Property (TCP): Site or resource that is eligible for inclusion in the NRHP because of its association with cultural practices or beliefs of a living community that are (1) rooted in that community's history, and (2) important in maintaining the continuing cultural identity of the community.

Traditional use area: Broad landscapes over which contemporary people and their ancestors have hunted, fished, and gathered.

Translocation: Intentional capture, movement, and release of individuals of a species from one location or area to another. This type of transfer is typically done to prevent harm to the individuals or to establish additional populations elsewhere.

Transmission line: Facility for transmitting electrical energy at high voltage from one point to another point.

Travertine: Sedimentary rock formed by the precipitation of carbonate minerals from solution in ground and surface waters, and/or geothermal hot springs.

Tribal land: In the NAGPRA, tribal land is defined as: (1) all lands within the exterior boundaries of any Indian reservation; (2) all dependent Indian communities; and (3) any lands administered for the benefit of Native Hawaiians pursuant to the Hawaiian Homes Commission Act, 1920, and section 4 of Public Law 86-3. In the NHPA, Tribal land is defined as (1) all lands within the exterior boundaries of any Indian reservation, and (2) all dependent Indian communities.

Tribe: Term used to designate a federally recognized group of American Indians and their governing body. Tribes may be comprised of more than one band.

Tributary: River or stream that flows into another stream, river, or lake.

Trigger: Condition-dependent or environmental cues that determine management actions.

Trophic: Of, relating to, or pertaining to nutrition, food, or feeding. For example, the feeding habits or food relationship of different organisms in a food chain.

Trout: Prized game fish native to the Northern Hemisphere, that has been widely introduced (i.e., it is nonnative) across the globe, including the Colorado River below Glen Canyon Dam (with exception of the native cutthroat trout). These fishes feature a streamlined, speckled body with small scales and soft fins, although their individual coloring and appearance can change depending on the specific surroundings and environment in which they live. Typically smaller than the related salmon, trout are usually found in cool (50–60°F, 10–16°C), clear freshwater streams and lakes. Trout are an important food source for humans and wildlife including brown bears, birds of prey (e.g., eagles), and other animals. However, their existence threatens many native fish species and their habitats owing to competition, displacement, and predation.

Trout management flow (TMF): Special type of fluctuating flow designed to reduce the recruitment of trout by disadvantaging young-of-the-year (YOY) trout.

Turbidity: Measure of the water clarity or the ability of light to pass through water. Affected by the amount of suspended particles, dissolved solids, and colloidal materials that are suspended in water.

Turbine: Device or machine for generating rotary mechanical power from the energy of a stream of fluid (such as water, steam, hot gas, or wind). Turbines convert the kinetic energy of fluids to mechanical energy through the principles of impulse and reaction, or a mixture of the two. Turbines are considered the most economical means of turning large electrical generators.

Turbulent: Marked or characterized by disturbances, changes, and unrest, such as unsteady motion and agitation of water.

U

Upper Basin: Those parts of the states of Arizona, Colorado, New Mexico, Utah, and Wyoming, within and from which waters drain naturally into the Colorado River above Lee Ferry, Arizona; defined by the Colorado River Compact of 1922.

Upper Colorado River Commission: Commission established by the Upper Colorado River Basin Compact with five appointed members, one from each of the Upper Division States (Colorado, New Mexico, Utah, Wyoming) and one representing the United States of America. Its purpose is to administer the Upper Colorado River Basin Compact.

Upper Division: Division of the Colorado River system that includes the states of Colorado, New Mexico, Utah, and Wyoming; area defined by Article II of the Colorado River Compact of 1922.

Upper-elevation balancing tier: Operation elevation that applies when Lake Powell's projected January 1 elevation is below the elevation in the equalization table of the Interim Guidelines, but above 3,575 ft (1,090 m) AMSL. The tier defines several different operations for attempting to balance the contents of Lake Mead and Lake Powell, if possible, that may occur based on the projected elevations of each lake, within the constraint that the release from Lake Powell would be not more than 9.0 maf and no less than 7.0 maf.

Upstream: Toward the source of a stream or river, against the normal direction of water flow.

Use value: Economic benefit associated with the physical use of a resource, usually measured by the consumer surplus or net economic value associated with such use. The contingent value method is one technique used to estimate use value.

V

Varial zone: Portion of the river bottom that is alternately flooded and dewatered.

Velocity: Rate of flow of water or water-sediment mixture.

Vertebrate: Animal species with a backbone. Includes fish, amphibians, reptiles, birds, and mammals.

Visibility degradation: Scattering and absorption of light by fine particles with a secondary contribution by gases; cumulative emissions of air pollutants from a myriad of sources.

Visitor day: Use of a site or area for 12 visitor hours, which may be aggregated by one or more persons for a single continuous or intermittent use (e.g., multiple visits).

Visitor use: Usage of recreation and wilderness resources by people for inspiration, stimulation, solitude, relaxation, education, pleasure, or satisfaction.

Visual contrast: Opposition or unlikeness of different forms, lines, colors, or textures in a landscape.

Visual impact: Any modification in land forms, water bodies, or vegetation, or any introduction of structures that negatively or positively affect the visual character or quality of a landscape through the introduction of visual contrasts in the basic elements of form, line, color, and texture.

Visual resource: Refers to all objects (manmade and natural, moving and stationary) and features such as landforms and water bodies that are visible on a landscape.

Volatile organic compound (VOC): Broad range of organic compounds that readily evaporate at normal temperatures and pressures. Sources include certain solvents (e.g., acetone), degreasers (e.g., benzene), and fuels (e.g., gasoline). VOCs also react with other substances (primarily nitrogen oxides) to form ozone. They contribute significantly to photochemical smog production and certain health problems.

W

Warmwater fish: Species of fish that grow best in water at least 80°F (27°). Warm water holds less DO than cool or cold water, so warmwater species, such as largemouth bass, catfish, and bluegill, require less oxygen to survive.

Wash: Normally dry streambed that occasionally conveys flowing water.

Water column: Hypothetical “cylinder” of water from the surface of a water body to the bottom, within which physical and chemical properties can be measured.

Water quality: Term used to describe the chemical, physical, and biological characteristics of water, usually with respect to its suitability for a particular purpose.

Water right: Legal entitlement of an individual or entity to extract water from a water source (surface water or groundwater) for a beneficial use (e.g., potable water supply, irrigation, mining, livestock).

Water table: Upper level of groundwater below which soil and rock are saturated with water.

Water year: Period of time beginning October 1 of one year and ending September 30 of the following year and designated by the calendar year in which it ends.

Waterfowl: Water birds, usually referring to ducks, geese, and swans.

Watershed: Region or area from which all water entering a particular water body drains. Also known as a basin.

Water-surface elevation (stage): Height, or elevation, of a water surface above or below an established reference level, such as sea level.

Weed: Plant considered undesirable, unattractive, or troublesome, usually introduced and growing without intentional cultivation.

Western Area Power Administration (WAPA): One of four power marketing administrations of the U.S. Department of Energy that markets and delivers reliable, renewable, cost-based hydroelectric power and related services within a 15-state region of the central and western United States.

Western Electricity Coordinating Council (WECC): Regional entity responsible for coordinating and promoting bulk electric system reliability in the Western Interconnection.

Wetlands: Federally protected areas that are saturated or flooded by surface or groundwater frequently enough or long enough to support plants, birds, and animals adapted to live in wet environments. Generally include swamps, marshes, bogs, estuaries, wet meadows, river overflows, mud flats, natural ponds, and other inland and coastal areas.

Wheeling: Occurs when two indirectly connected utilities agree to purchase or sell power to each other.

Whirling disease: Disease caused by a parasite; results in neurological damage to young fish, causing them to swim in a corkscrew pattern. Affected fish are unable to feed properly and are vulnerable to predators.

Whirlpool: Water moving rapidly in a circle so as to produce a depression.

Whitewater boating: See *whitewater rafting*.

Whitewater rafting: Recreational navigation of a moving body of water (e.g., river) characterized by fast-flowing rough water or rapids, using a raft, kayak, or other type of boat.

Wild and Scenic Rivers Act: Primary river conservation law enacted in 1968. The Act was specifically intended by Congress to balance the existing policy of building dams on rivers for water supply, power, and other benefits with a new policy of protecting the free-flowing character and outstanding values of other rivers.

Wilderness: Undeveloped land retaining its primeval character without permanent improvements or human habitation, and that generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable.

Wilderness Act of 1964: Legislation enacted in 1964 to designate wilderness areas, with Congressional approval, to ensure that these lands are preserved and protected in their natural condition.

Wilderness areas: Areas and lands designated by Congress and defined by the Wilderness Act of 1964 as places "where the earth and its community are untrammeled by man, where man himself is a visitor who does not remain." Designation is aimed at ensuring that these lands are preserved and protected in their natural condition.

Wilderness characteristics: Wilderness characteristics include (1) naturalness: the area generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) outstanding opportunities: the area has either outstanding opportunities for solitude, or outstanding opportunities for primitive and unconfined types of recreation; (3) size: the area is at least 5,000 acres (20 km^2) of land, or is of sufficient size to make practicable its preservation and use in an unimpaired condition; and (4) values: the area may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

Willingness to pay: Method of estimating the value of activities, services, or other goods, where value is defined as the maximum amount a consumer would be willing to pay for the opportunity rather than do without. The total willingness to pay, minus the user's costs of participating in the opportunity, defines the consumer surplus and benefits.

Wind rose: Circular diagram, for a given locality or area, showing the frequency and strength of the wind from various directions over a specified period of record.

World Heritage Site: Area identified by the World Heritage Committee of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) as having outstanding universal value for cultural and natural heritage.

X

Xeric: Low in moisture. Dry environmental conditions. Habitats or sites characterized by their limited water availability.

Y

Young-of-year (YOY): Young (usually fish) produced in the current calendar year. Also referred to as age 0.

Z

Zooplankton: Small, usually microscopic animals (such as protozoans), found in lakes and reservoirs. Zooplankton can be permanent (i.e., rotifers or cladocerans) or temporary, as with the early life stages (i.e., eggs, larvae, juveniles, and adults) of many fish and invertebrate species.

ABSTRACT

The U.S. Department of the Interior (DOI), through the Bureau of Reclamation and National Park Service (NPS), proposes to develop and implement a Long-Term Experimental and Management Plan (LTEMP) for operations of Glen Canyon Dam. The LTEMP would provide a framework for adaptively managing Glen Canyon Dam operations over the next 20 years, consistent with the Grand Canyon Protection Act of 1992 (GCPA) and other provisions of applicable federal law. The LTEMP would determine specific options for dam operations, non-flow actions, and appropriate experimental and management actions that will meet the GCPA's requirements and minimize impacts on resources within the area impacted by dam operations, including those of importance to American Indian Tribes.

The Final Environmental Impact Statement (FEIS) was developed in accordance with the National Environmental Policy Act of 1969, as amended (NEPA), and followed the implementing regulations developed by the President's Council on Environmental Quality in Title 40 *Code of Federal Regulations* (CFR) Parts 1500 to 1508 and DOI regulations implementing NEPA in 43 CFR Part 46. The FEIS analysis draws on the scientific information that has been collected under the Glen Canyon Dam Adaptive Management Program over the last 20 years to identify the potential environmental effects associated with taking no action, as well as a reasonable range of alternatives to no action for implementing the proposed federal action. Seven alternatives were considered and analyzed for the LTEMP EIS—a no action alternative (Alternative A), a hydropower-focused alternative (Alternative B), three condition-dependent alternatives (Alternatives C, D, and E), and two steady flow alternatives (Alternatives F and G). These alternatives incorporated a broad range of operations and experimental actions that together allowed for a full evaluation of possible impacts of the

proposed action. Based on the impact analyses conducted, DOI has chosen Alternative D as both the preferred and the environmentally preferred alternative. Alternative D is expected to result in an improvement in conditions for humpback chub, trout, and the aquatic food base; have the least impact on vegetation, wetlands, and terrestrial wildlife; improve sandbar building potential and conserve sediment; sustain or improve conditions for reservoir and river recreation; improve preservation of cultural resources; respect and enhance Tribal resources and values; and have limited impacts on hydropower resources.

2.3.4 Grand Canyon First! Alternative 2-86
2.3.5 Species Community and Habitat-Based Alternative 2-86
2.3.6 Stewardship Alternative 2-86
2.3.7 Twelve-Year Experiment of Two Steady-Flow Alternatives 2-87
2.3.8 Decommission Glen Canyon Dam Alternative 2-87
2.3.9 Fill Lake Mead First Alternative 2-88
2.3.10 Full-Powerplant Capacity Operations Alternative 2-88
2.3.11 Run-of-the-River Alternative 2-88
2.4 Alternative Elements Eliminated from Detailed Study 2-89
2.4.1 New Infrastructure 2-89
2.4.2 Flow and Non-Flow Actions 2-90
2.5 Summary Comparison of Alternatives 2-91

3 AFFECTED ENVIRONMENT 3-1

3.1 Project Area 3-1
3.1.1 Colorado River Setting 3-1
3.1.2 Geologic Setting 3-3
3.1.2.1 Tribal Perspectives on Geologic Setting 3-3
3.1.3 Climatic Setting 3-4
3.1.4 Glen Canyon Dam Releases and Flow 3-5
3.1.5 Colorado River Ecosystem Resource Linkages 3-6
3.2 Water Resources 3-6
3.2.1 Hydrology 3-7
3.2.1.1 Lake Powell Hydrology 3-8
3.2.1.2 Hydrology of the Colorado River Downstream of Glen Canyon Dam 3-11
3.2.1.3 Lake Mead Hydrology 3-13
3.2.1.4 Seeps and Springs 3-14
3.2.2 Water Quality 3-16
3.2.2.1 Lake Powell Water Quality 3-16
3.2.2.2 Colorado River Water Quality 3-19
3.2.2.3 Lake Mead Water Quality 3-27
3.2.3 Tribal Perspectives on Water Resources 3-29
3.2.4 Hydrology and Climate Change 3-32
3.2.4.1 Basis for Runoff Estimates 3-32
3.2.4.2 Water Variability and Availability 3-33
3.2.4.3 Seasonal Timing Shifts 3-34
3.2.4.4 Water Quality 3-35
3.3 Sediment Resources 3-35
3.3.1 Background: Geomorphology of the Colorado River 3-35

CONTENTS (Cont.)

3.3.1.1 Geomorphic Features of the Colorado River 3-37
3.3.1.2 Glen Canyon Geomorphology 3-40
3.3.1.3 Marble and Grand Canyon Geomorphology 3-41
3.3.2 Sediment Characteristics and Transport Mechanisms 3-43
3.3.2.1 Particle Size and Sediment Supply 3-45
3.3.2.2 Sediment Transport Capacity 3-46
3.3.2.3 River Stage 3-46
3.3.3 Sediment Sources 3-46
3.3.3.1 Gaged Tributaries 3-48
3.3.3.2 Ungaged Tributaries 3-48
3.3.4 Sediment Transport and Storage 3-50
3.3.4.1 Sediment Transport 3-50
3.3.4.2 Sediment Storage 3-51
3.3.4.3 High-Flow Experiments 3-51
3.3.4.4 Sediment Supply Limitation 3-53
3.3.4.5 Sandbar Deposition and Retention 3-53
3.3.5 Lake Deltas 3-56
3.4 Natural Processes 3-57
3.5 Aquatic Ecology 3-59
3.5.1 Aquatic Food Base 3-59
3.5.1.1 Periphyton and Rooted Aquatic Plants 3-61
3.5.1.2 Plankton 3-63
3.5.1.3 Macroinvertebrates 3-63
3.5.1.4 Nonnative Invasive Species 3-66
3.5.1.5 Food Web Dynamics 3-69
3.5.2 Native Fish 3-70
3.5.2.1 Special Status Fish Species 3-72
3.5.2.2 Other Native Species 3-86
3.5.3 Nonnative Fish 3-90
3.5.3.1 Coldwater Nonnative Species 3-94
3.5.3.2 Warmwater Nonnative Species 3-100
3.5.3.3 Interactions with Native Species 3-101
3.5.3.4 Nonnative Fish Control Activities and Effects of Flow Conditions 3-104
3.6 Vegetation 3-109
3.6.1 Historic and Remnant Riparian Plant Communities 3-110
3.6.2 Existing Riparian Vegetation Downstream from Glen Canyon Dam 3-111
3.6.2.1 Tribal Perspectives on Vegetation 3-119
3.6.3 Special Status Plant Species 3-121
3.7 Wildlife 3-124
3.7.1 Invertebrates 3-125
3.7.2 Amphibians and Reptiles 3-126
3.7.3 Birds 3-127

CONTENTS (Cont.)

3.7.4 Mammals ... 3-129
3.7.5 Special Status Wildlife Species ... 3-131
3.7.5.1 Invertebrates ... 3-132
3.7.5.2 Amphibians and Reptiles ... 3-136
3.7.5.3 Birds ... 3-136
3.7.5.4 Mammals ... 3-142
3.7.6 Tribal Perspectives on Wildlife ... 3-142
3.8 Cultural Resources ... 3-144
3.8.1 Area of Potential Effect ... 3-146
3.8.2 Description of Cultural Resources and Site Types ... 3-149
3.8.2.1 Archaeological Resources ... 3-149
3.8.2.2 Historic Resources ... 3-153
3.8.2.3 Cultural Landscapes ... 3-155
3.8.2.4 Traditional Cultural Properties and Ethnographic Resources ... 3-156
3.9 Tribal Resources ... 3-156
3.9.1 Fort Mojave Indian Tribe ... 3-157
3.9.2 Havasupai ... 3-158
3.9.3 Hopi ... 3-158
3.9.4 Hualapai ... 3-159
3.9.5 Navajo Nation ... 3-162
3.9.6 Pueblo of Zuni ... 3-164
3.9.7 Southern Paiute Tribes ... 3-167
3.9.8 Indian Trust Assets and Trust Responsibility ... 3-168
3.10 Recreation, Visitor Use, and Experience ... 3-168
3.10.1 Glen Canyon Reach of the Colorado River in Glen Canyon National Recreation Area ... 3-169
3.10.1.1 Lees Ferry Recreational Fishery ... 3-169
3.10.1.2 Day-Rafting, Boating, and Camping in the Glen Canyon Reach ... 3-174
3.10.2 The Colorado River in Grand Canyon National Park ... 3-178
3.10.2.1 Campsites in Grand Canyon National Park ... 3-179
3.10.2.2 River Flow and Fluctuation ... 3-183
3.10.2.3 Hualapai Tribe Recreation Program ... 3-186
3.10.3 Recreation Use on Lake Mead and Lake Powell ... 3-187
3.10.3.1 Lake Mead National Recreation Area ... 3-187
3.10.3.2 Lake Powell, Glen Canyon National Recreation Area ... 3-187
3.10.4 Park Operations and Management ... 3-187
3.11 Wilderness ... 3-188
3.11.1 Law and Policy ... 3-189
3.11.2 Defining Wilderness Character ... 3-190
3.12 Visual Resources ... 3-192
3.12.1 Glen Canyon National Recreation Area ... 3-193

CONTENTS (Cont.)

3.12.2 Grand Canyon and the Colorado River 3-195
3.12.3 Lake Mead National Recreation Area 3-198
3.13 Hydropower 3-198
3.13.1 Power Operations 3-199
3.13.1.1 Hydropower Generation 3-199
3.13.1.2 Basin Fund 3-200
3.13.1.3 Operational Flexibility 3-201
3.13.1.4 Scheduling 3-202
3.13.1.5 Load/Generation Following and Regulation 3-203
3.13.1.6 Capacity Reserves 3-205
3.13.1.7 Disturbances and Emergencies and Outage Assistance 3-205
3.13.1.8 Transmission System 3-206
3.13.2 Power Marketing 3-206
3.13.2.1 Wholesale Rates 3-209
3.13.2.2 Retail Rates 3-209
3.14 Socioeconomics and Environmental Justice 3-209
3.14.1 The Six-County Region of Influence 3-210
3.14.1.1 Population 3-210
3.14.1.2 Income 3-211
3.14.1.3 Employment 3-211
3.14.1.4 Unemployment 3-213
3.14.1.5 Environmental Justice 3-213
3.14.2 The Seven-State Region of Influence 3-221
3.14.2.1 Population 3-221
3.14.2.2 Income 3-222
3.14.2.3 Employment 3-224
3.14.2.4 Unemployment 3-226
3.14.2.5 Environmental Justice 3-226
3.14.3 Non-Use Value 3-228
3.15 Air Quality 3-229
3.15.1 Local Air Quality 3-229
3.15.2 Regional Air Quality 3-231
3.15.3 Regional Air Emissions 3-234
3.16 Climate Change 3-236

4 ENVIRONMENTAL CONSEQUENCES 4-1

4.1 Overall Analysis and Assessment Approach 4-1
4.2 Water Resources 4-9
4.2.1 Analysis Methods 4-10
4.2.1.1 Hydrology 4-10
4.2.1.2 Water Quality 4-13
4.2.2 Summary of Impacts 4-14

CONTENTS (Cont.)

4.2.2.1 Hydrology 4-14
4.2.2.2 Water Quality 4-37
4.2.3 Alternative-Specific Impacts 4-47
4.2.3.1 Alternative A (No Action Alternative) 4-48

APPENDIX K: Hydropower Systems Technical Information and Analysis K-1

K.1 Economic Value of Glen Canyon Dam Powerplant Capacity and Energy Production K-3
K.1.1 Power Systems Background K-3
K.1.2 Glen Canyon Dam, Reservoir, and Powerplant Background K-5
K.1.3 Power Systems Geographic Scope K-8
K.1.3.1 Top Tier: General Western Interconnection Perspective Modeling K-9
K.1.3.2 Middle Tier: LTF Customer Utility Systems K-11
K.1.3.3 Bottom Tier: WAPA SLCA/IP Hydropower Resources K-15
K.1.4 Overview of Power Systems Methods K-16
K.1.5 Description of Individual Power System Models K-20
K.1.5.1 Colorado River Simulation System Model K-20
K.1.5.2 Representative Trace Tool K-21
K.1.5.3 Hydropower Outage Model K-21
K.1.5.4 Generation and Transmission Maximization-Lite K-21
K.1.5.5 Sand Budget Model K-29
K.1.5.6 Large SLCA/IP Powerplant Spreadsheets K-29
K.1.5.7 Small SLCA/IP Powerplant Spreadsheet K-30
K.1.5.8 Loads Shaping Algorithm K-30
K.1.5.9 AURORA K-31
K.1.5.10 LMP Calibration Spreadsheet K-34
K.1.5.11 Firm Capacity Spreadsheet K-35
K.1.6 SLCA/IP Market System, Data Sources, and Model K-38
K.1.6.1 Historical Data Sources K-38
K.1.6.2 AURORA Model Dispatch Results for 2013 ..... K-42
K.1.6.3 SLCA/IP Market System Projections K-43
K.1.7 Glen Canyon Dam Powerplant Capacity Cost and Benefit Methodology K-59
K.1.7.1 Treatment of Glen Canyon Dam Capital and Fixed O&M Costs K-61
K.1.7.2 WAPA's SLCA/IP LTF Obligations and Glen Canyon Dam Replacement Capacity K-61
K.1.7.3 WAPA SLCA/IP Firm Hydropower Capacity K-62
K.1.7.4 Firm Capacity Curves for LTEMP Power Systems Analyses for the Peak Month of August K-79
K.1.7.5 AURORA Capacity Expansion Reserve Margin Targets and Capacity Additions K-82
K.1.7.6 Dispatch Performed by AURORA Model Capacity Expansion Runs K-86
K.1.7.7 Rationale for the Selection of Hydrology Conditions Used for Capacity Expansion Runs K-90

CONTENTS (Cont.)

K.1.8 Glen Canyon Dam Energy Economic Benefits Methodology K-90
K.1.9 Net Present Value Calculations and Study Period Adjustments K-94
K.1.10 Power Systems Results K-96
K.1.10.1 Main Drivers of Differences among Alternatives K-97
K.1.10.2 Capacity Expansion Modeling K-101
K.1.10.3 Economic Impacts K-108
K.1.10.4 Sensitivity of Results to Exceedance Level K-116
K.1.10.5 Sensitivity of Results to Discount Rate K-121
K.1.10.6 Sensitivity of Results to the Base Capacity Expansion Path K-121
K.1.10.7 Sensitivity of Results to the Assumed Future Hydrological Conditions K-123
K.1.10.8 Sensitivity of Results to Changes in Ancillary Services K-125
K.1.10.9 Sensitivity of Results to Customer Capacity Expansion Assumptions K-129
K.1.10.10 Summary of Economic Ranking K-131
K.2 WAPA's SLCA/IP Firm Electric Service Rate Impacts K-131
K.2.1 Relationship between the Economic Impacts of LTEMP Alternatives and Impacts on SLCA/IP FES Rates K-133
K.2.2 Temporal Scope of the Analysis and Input Data K-133
K.2.3 SLCA/IP Rate Setting K-134
K.2.4 Calculation of Net Electrical Energy Expense K-135
K.2.4.1 SLCA/IP Electrical Production K-135
K.2.4.2 Sustainable Hydropower and Available Hydropower Capacity and Energy K-135
K.2.5 Calculation of Capacity Expenses and Total Net Costs K-139
K.2.6 WAPA Replacement Resources K-143
K.2.7 Post-2024 Marketing Period K-144
K.2.8 Power Repayment Studies to Determine Rate Impacts K-146
K.2.8.1 PRS Expenses K-146
K.2.8.2 PRS Revenue Distribution K-149
K.2.8.3 The SLCA/IP PRS K-149
K.2.8.4 Standard PRS Rate-Setting Method Versus the Method Used in This Analysis K-150
K.2.9 Results K-150
K.2.9.1 Pinch-Point Year K-152
K.2.10 Definitions Used in Section K.2 ..... K-153
K.3 Impacts on Retail Electricity Rates K-154
K.3.1 Analysis Approach K-154
K.3.1.1 Database of Sales, Rates, and SLCA/IP Allocation for Retail Utility Systems K-156
K.3.1.2 Incorporation of Power Systems Analysis and Capital Recovery Factors K-158

CONTENTS (Cont.)

K.3.1.3 Inflation Rates, Sales Growth, and Interest Rates from EIA K-161
K.3.1.4 Calculation Process for Computing Rate and Bill Impacts K-162
K.3.2 Results K-167
K.3.2.1 Grid Cost Changes Relative to WAPA Wholesale Revenues K-168
K.3.2.2 Retail Rate Changes for Individual Systems and SLCA/IP Power Relative to Total Resources K-169
K.3.2.3 Using Regression Equations to Approximate Retail Rate Changes for Systems Not Included in the Database K-171
K.3.3 Summary of Impacts K-172
K.3.3.1 Average Rate Impacts under LTEMP Alternatives over the 20-Year LTEMP Period K-172
K.3.3.2 Average Year-by-Year Rate Impacts K-174
K.3.3.3 Individual System Impacts and Summary Descriptions of LTEMP Alternatives K-179
K.3.4 Impacts on Small Systems K-185
K.3.5 Alternative-Specific Impacts K-187
K.3.5.1 Alternative A K-187
K.3.5.2 Alternative B K-187
K.3.5.3 Alternative C K-188

APPENDIX Q: Responses to Public Comments on the Glen Canyon Dam Long-Term Experimental and Management Plan Draft Environmental Impact Statement Q-1

FIGURES

1-1 Generalized Locations of Glen Canyon Dam, Lake Powell, the Colorado River between Lake Powell and Lake Mead, and Adjacent Lands 1-5

1-2 Glen Canyon Dam..... 1-6

1-3 Map of the Colorado River between Lake Powell and Lake Mead 1-20

1-4 Indian Reservations within or Adjacent to the LTEMP EIS Project Area..... 1-25

2-1 Mean, Minimum, and Maximum Daily Flows under Alternative A in an 8.23-maf Year Based on Values Presented in Table 2-3 2-18

2-2 Simulated Hourly Flows under Alternative A in an 8.23-maf Year 2-18

2-3 Simulated Hourly Flows under Alternative A for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-19

2-4 Mean, Minimum, and Maximum Daily Flows under Alternative B in an 8.23-maf Year Based on Values Presented in Table 2-4 2-21

2-5 Simulated Hourly Flows under Alternative B in an 8.23-maf Year 2-22

2-6 Simulated Hourly Flows under Alternative B for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-22

2-7 Example Mean, Minimum, and Maximum Daily Flows for a Hydropower Improvement Experiment under Alternative B in an 8.23-maf Year 2-24

2-8 Simulated Hourly Flows for a Hydropower Improvement Experiment under Alternative B in an 8.23-maf Year..... 2-24

2-9 Simulated Hourly Flows for a Hydropower Improvement Experiment under Alternative B for a Week in July in an 8.23-maf Year 2-25

2-10 Mean, Minimum, and Maximum Daily Flows under Base Operations of Alternative C in an 8.23-maf Year Based on the Values Presented in Table 2-5.... 2-26

2-11 Simulated Hourly Flows under Alternative C in an 8.23-maf Year 2-28

2-12 Simulated Hourly Flows under Alternative C for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-28

2-13 Decision Tree for Sediment-Related Actions under Alternative C..... 2-29

FIGURES (Cont.)

2-14 Decision Tree for Humpback Chub-Related Actions under Alternative C 2-30

2-15 Example Implementation of a Two-Cycle TMF in June and July with Resumption of Normal Fluctuations between Cycles and Afterward 2-40

2-16 Mean, Minimum, and Maximum Daily Flows under Triggered Low Summer Flows of Alternative C in an 8.23-maf Year Based on the Values Presented in Table 2-6 2-42

2-17 Mean, Minimum, and Maximum Daily Flows under Alternative D in an 8.23-maf Year Based on Values Presented in Table 2-8 2-45

2-18 Simulated Hourly Flows under Alternative D in an 8.23-maf Year 2-47

2-19 Simulated Hourly Flows under Alternative D for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-47

2-20 Decision Tree for Implementation of Sediment-Related Experimental Treatments under Alternative D..... 2-55

2-21 Decision Tree for Implementation of Aquatic Resource-Related Experimental Treatments under Alternative D..... 2-56

2-22 Mean, Minimum, and Maximum Daily Flows under Triggered Low Summer Flows of Alternative D in an 8.23-maf Year Based on the Values Presented in Table 2-10 2-69

2-23 Mean, Minimum, and Maximum Daily Flows under Alternative E in an 8.23-maf Year Based on the Values Presented in Table 2-11 2-74

2-24 Simulated Hourly Flows under Alternative E in an 8.23-maf Year..... 2-74

2-25 Simulated Hourly Flows under Alternative E for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-75

2-26 Decision Tree for Sediment-Related Actions under Alternative E 2-76

2-27 Decision Tree for Trout-Related Actions under Alternative E..... 2-77

2-28 Mean, Minimum, and Maximum Daily Flows under Base Operations of Alternative F in an 8.23-maf Year Based on the Values Presented in Table 2-12 2-82

FIGURES (Cont.)

2-29 Mean, Minimum, and Maximum Daily Flows under Alternative G in an 8.23-maf Year Based on Values Presented in Table 2-13 2-83

3.1-1 LTEMP Project Area and Surrounding Lands 3-2

3.2-1 Map of Lake Powell and Associated Major Tributaries 3-8

3.2-2 Pattern of Annual Historic Flows at Lees Ferry 3-12

3.2-3 Map of Lake Mead and Associated Major Tributaries 3-13

3.2-4 Profile of Lake Powell from Glen Canyon Dam to the Inflow of the Colorado River 3-16

3.2-5 Water Temperature at Lees Ferry 3-18

3.2-6 Water Temperatures at Four Stations along the Colorado River from Lees Ferry to Diamond Creek, 1995–2014 3-21

3.2-7 Mid-June Warming above Release Temperatures Measured at Diamond Creek, 1994–2004, as a Function of Mean Weekly Discharge 3-22

3.3-1 Geomorphic Features of the Colorado River 3-36

3.3-2 Schematic Diagram of the Fan-Eddy Complex on the Colorado River 3-38

3.3-3 River Cross Section Depicting Sediment Entrapment and Sandbar Building 3-38

3.3-4 Aeolian and Fluvial Sand Deposits along the Colorado River 3-40

3.3-5 Debris Fans and Variation in Water-Surface Elevation and Channel Width for Colorado River Flows below Glen Canyon Dam 3-42

3.3-6 Comparison of Sandbars Used as Campsites, based on Inventories Conducted in 1973, 1983, and 1991 3-42

3.3-7 Repeated Photography Illustrating Sediment Losses and Sandbar Changes along the Colorado River 3-44

3.3-8 Annual Sediment Contributions from the Paria and Little Colorado Rivers 3-49

3.3-9 Matched Photographs of RM 172 Illustrating Positive Depositional Response to the 2008 HFE 3-52

FIGURES (Cont.)

3.3-10 Conceptual Diagram of the Dependency between Net Sandbar Size, Duration and Frequency of HFEs, and Post-HFE Erosion Rates 3-54

3.3-11 Average Campsite Area above the References Stage: before, after, and 6 Months following the 2008 HFE 3-55

3.3-12 Longitudinal Profiles of the Mainstem Colorado Riverbed Upstream of the Hoover Dam in 1935, 1948, 1963, and 2001 3-57

3.5-1 Temperature Ranges for Spawning, Egg Incubation, and Growth by Native and Nonnative Fishes of the Colorado River System below Glen Canyon Dam 3-71

3.5-2 Humpback Chub Aggregation Areas along the Colorado River between Glen Canyon Dam and Lake Mead 3-74

3.5-3 Estimated Adult Humpback Chub Abundance from Age-Structured Mark-Recapture Model Incorporating Uncertainty in Assignment of Age 3-75

3.5-4 Estimated Total Adult Abundance of Humpback Chub in the Lower 8 mi of the Little Colorado River and a 2-mi Portion of the Colorado River Just Downriver of the Confluence of the Little Colorado and Colorado Rivers, for September, 2009 through 2012 3-76

3.5-5 Water Temperatures at Lees Ferry and the Little Colorado River Confluence, 1995 to Present 3-81

3.5-6 Mean Electrofishing Catch Rates of Rainbow Trout in the Glen Canyon Reach, 1991–2013 3-96

3.5-7 Mean Electrofishing Catch Rates of Brown Trout in the Colorado River between Lees Ferry and Lake Mead, 2000–2009 3-99

3.6-1 Riparian Vegetation Zones along the Colorado River below Glen Canyon Dam ... 3-114

3.7-1 Riparian Zones Used by Nesting Birds 3-124

3.7-2 Threatened, Endangered, and Sensitive Species Observed along the Colorado River Corridor 3-135

ADAPTIVE MANAGEMENT WORKING GROUP DESIRED FUTURE CONDITIONS

This page intentionally left blank

APPENDIX A:

ADAPTIVE MANAGEMENT WORKING GROUP DESIRED FUTURE CONDITIONS

The Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS) joint lead agencies have used the 2012 Glen Canyon Dam Adaptive Management Program (GCDAMP) Desired Future Conditions (DFCs) as a basis for the resource goals and objectives of the EIS as presented in Section 1.4 of the EIS. The resource goals and objectives are based on and consistent with the DFCs, but are more concise and direct relative to the LTEMP purpose and need of the proposed action. The following text is based on the document *Desired Future Conditions for the Colorado River Ecosystem in Relation to Glen Canyon Dam* (DFC Ad Hoc Committee 2012).

The DFCs were intended to be used within the GCDAMP to help guide the development of recommendations concerning management of Glen Canyon Dam operations and related activities and dam impacts on Grand Canyon National Park (GCNP) and Glen Canyon National Recreation Area (GCNRA). The DFCs focus on those conditions that can be accomplished through dam operations and also identify those conditions that might be achieved through non-operational measures.

The Secretary of the Interior (the Secretary) is authorized to consider and implement both operational and non-operational measures to address downstream effects of Glen Canyon Dam if those measures meet the Grand Canyon Protection Act's (GCPA's) goal of protecting, mitigating adverse impacts on, and improving the resources downstream of the dam. Section 1802 of the GCPA provides the following:

a. *In General*—The Secretary shall operate Glen Canyon Dam in accordance with the additional criteria and operating plans specified in Section 1804 and exercise other authorities under existing law in such a manner as to protect, mitigate adverse impacts on, and improve the values for which GCNP and GCNRA were established, including, but not limited to, natural and cultural resources and visitor use.

b. *Compliance with Existing Law*—The Secretary shall implement this section in a manner fully consistent with and subject to the Colorado River Compact, the Upper Colorado River Basin Compact, the Water Treaty of 1944 with Mexico, the decree of the Supreme Court in Arizona v. California, and the provisions of the Colorado River Storage Project Act of 1956 and the Colorado River Basin Project Act of 1968 that govern allocation, appropriation, development, and exportation of the waters of the Colorado River basin.

c. *Rule of Construction*—Nothing in this title alters the purposes for which the GCNP or the GCNRA were established or affects the authority and

> responsibility of the Secretary with respect to the management and administration of the GCNP and GCNRA, including natural and cultural resources and visitor use, under laws applicable to those areas, including, but not limited to, the Act of August 25, 1916 (39 Stat. 535), as amended and supplemented.

The Bureau of Reclamation (Reclamation) is charged with balancing a complex set of interests in operating the dam. Those interests include not only the endangered species below the dam, but also Tribes in the region, the seven Colorado River basin states, large municipalities that depend on water and power from Glen Canyon Dam, agricultural interests, GCNP, GCNRA, and national energy needs at a time when clean energy production is becoming increasingly important. The DFCs will assist the Glen Canyon Dam Adaptive Management Work Group (AMWG) in providing recommendations to the Secretary of the Interior for future decision-making. The DFCs have evolved from discussions during the entire 16-year history of the AMWG, and were generated in the following form from the concerted work of the DFC Ad Hoc Group and the federal agency regional leadership during 2010 and 2011.

The vision and mission of the AMWG (adopted on July 21, 1999) was developed to guide adaptive management of Glen Canyon Dam, and helps explain how and why definition of desired conditions is important:

> *The Grand Canyon is a homeland for some, sacred to many, and a national treasure for all. In honor of past generations, and on behalf of those of the present and future, we envision an ecosystem where the resources and natural processes are in harmony under a stewardship worthy of the Grand Canyon.*
>
> *We advise the Secretary of the Interior on how best to protect, mitigate adverse impacts to, and improve the integrity of the Colorado River ecosystem affected by Glen Canyon Dam, including natural biological diversity (emphasizing native biodiversity), traditional cultural properties, spiritual values, and cultural, physical, and recreational resources through the operation of Glen Canyon Dam and other means.*
>
> *We do so in keeping with the federal trust responsibilities to Indian Tribes, in compliance with applicable federal, state, and Tribal laws, including the water delivery obligations of the Law of the River, and with due consideration to the economic value of power resources.*
>
> *This will be accomplished through our long-term partnership utilizing the best available scientific and other information through an adaptive ecosystem management process.*

The DFCs are intended to be statements of qualitative goals and objectives for the GCDAMP, realistic and achievable through the operation of Glen Canyon Dam and related activities, subject to the Law of the River and other laws and authorities and consistent with the GCPA. These DFCs may not be entirely or collectively achievable; there will be tradeoffs and

inherent limitations. This fact does not diminish their value. These DFCs of the affected resources have been identified by the stakeholders as appropriate goals for the GCDAMP and are based on information available at this time. As new information develops, the DFCs may need further revision and refinement. Therefore, these DFCs are neither fixed nor final. This is intended to be a "living document" that reflects advances in learning and understanding. This is consistent with the process—and application—of adaptive management.

The Colorado River Ecosystem (CRE) is defined as the Colorado River mainstream corridor and interacting resources in associated riparian and terrace zones, located primarily from the fore bay of Glen Canyon Dam to the western boundary of GCNP. It includes the area where the dam operations impact physical, biological, recreational, cultural, and other resources. The scope of GCDAMP activities may include limited investigations into some tributaries (e.g., the Little Colorado and Paria Rivers).

The majority of the CRE exists within the boundaries of two national parks and proposed wilderness areas. Despite these protections, the CRE could be considered "a human-dominated ecosystem, one whose aesthetic appeal, goods and services, and spiritual services are widely used and appreciated and needed by a broad cross-section of society. Adaptive management of the CRE has been adopted to ensure the sustainability of the natural environment with the least impact on the goods and services the CRE provides to society. As such, and as information about the CRE has increased, its stewardship is moving toward an ecosystem perspective, fully recognizing the role of humans, and this approach is reflected in the structure of this document" (DFC Ad Hoc Committee 2012).

The DFCs are divided into four categories, including the CRE, Power, Cultural Resources, and Recreation. There are many direct, indirect, short-term, and long-term ecosystem responses to dam existence and operations. The DFCs are directly or indirectly linked to each other on short- and long-term bases through dam-related flows, sediment retention and distribution, hydropower production, fish and wildlife populations, recreation, and visitor experience. The following sections are excerpted from the 2012 DFC document.

A.1 DESIRED FUTURE CONDITIONS: COLORADO RIVER ECOSYSTEM

A.1.1 DFC Description

The term "ecosystem" refers to the combined physical and biological components of an environment. An ecosystem is generally an area within the natural environment in which physical (abiotic) factors and processes of the environment, such as geology, climate, and soil development, function along with interdependent (biotic) organisms, such as plants and animals, in the same habitat and create a dynamic and interconnected system. Ecosystems usually encompass a number of food webs. An ecosystem is a functional unit within a given area consisting of living things and the nonliving chemical and physical factors of their environment, linked together through nutrient cycle and energy flow.

A.1.2 DFC Background and Legislation

Glen Canyon Dam has had a profound impact on the aquatic and terrestrial domains of the CRE from lower Lake Powell downstream to Lake Mead. The CRE DFCs are designed to be consistent with the GCPA, Law of the River, and other appropriate laws and mandates. The CRE DFCs apply the requirements of the GCPA, and are the goals that AMWG members will consider when making recommendations to the Secretary.

A.1.3 Why the Colorado River Ecosystem DFCs Are Important

These CRE DFCs address the natural resource values for which the GCNP and the GCNRA were established. The DFCs aim to comply with the GCPA and describe the individual resource objectives sought with the realization that they may not be achievable in the process of finding the most desirable mix of resources in the CRE and the natural habitats, and natural ecosystem processes. Native and nonnative species are to be managed in accord with federal regulations, policies, and guidelines. The CRE described herein includes most of the native natural resources found in the Colorado River. Those resources are managed, consistent with the Law of the River, described in part in Section 1802(b) of the GCPA, under the National Park Service (NPS) Organic Act, the Redwoods Amendment, NPS 2006 Management Policies, the Wilderness Act, the Antiquities Act, the Endangered Species Act (ESA), the GCPA, the Fish and Wildlife Coordination Act, and other federal legislation. The health of the river ecosystem and the protection of the resource values of GCNP and GCNRA are important to the nation, many Native American Tribes, the economy of the Southwest, and the millions of visitors to the parks and the region.

The CRE DFCs will provide a foundation for and help define the components of the Core Monitoring Program under development by the Grand Canyon Monitoring and Research Center (GCMRC). The Core Monitoring Program ultimately will be essential to quantifying, measuring, and reporting the status of the natural resources, allowing the Secretary and the GCDAMP to track progress toward desired outcomes. DFCs will also provide foundation support in the development of other planning and management assignments associated with the GCDAMP.

A.1.4 Colorado River Ecosystem DFCs

A.1.4.1 Sediment-Related Resources DFCs

High-elevation open riparian sediment deposits along the Colorado River in sufficient volume, area, and distribution so as to provide habitat to sustain native biota and desired ecosystem processes include the following:

- Nearshore habitats for native fish,
- Marsh and riparian habitat for fish (food chain maintenance),

- Cultural resource preservation, and
- Maintenance of camping beaches.

A.1.4.2 Water Quality DFCs

Water quality with regard to dissolved oxygen, nutrient concentrations and cycling, turbidity, temperature, and so forth, is sufficient to support natural ecosystem functions, visitor safety, and visitor experience to the extent feasible and consistent with the life history requirements of focal aquatic species including the following:

- Ecosystem-sustaining nutrient distribution, flux, and cycling.
- Hydro-physical conditions and characteristics of the CRE necessary to sustain aquatic biota.
- Acceptable water quality for human health and visitor experience.

A.1.4.3 Colorado River Ecosystem Aquatic Resource DFCs

Aquatic Food Base DFCs

- The aquatic food base will sustainably support viable populations of desired species at all trophic levels.
- Assure that an adequate, diverse, productive aquatic food base exists for fish and other aquatic and terrestrial species that depend on those food resources.

Native Species DFCs

- Native fish species and their habitats (including critical habitats) sustainably maintained throughout in each species' natural ranges in the CRE.
- Healthy, self-sustaining populations of other remaining native fish with appropriate distribution (flannelmouth sucker, bluehead sucker, speckled dace) so that listing under the ESA is not needed.

Humpback Chub DFCs

- Achieve humpback chub recovery in accord with the ESA and the humpback chub comprehensive management plan, and with the assistance of collaborators within and external to the GCDAMP.

- A self-sustaining humpback chub population in its natural range in the CRE.

- An ecologically appropriate habitat for the humpback chub in the mainstem.

- Spawning habitat for humpback chub in the Lower Little Colorado.

- Establish additional humpback chub spawning habitat and spawning aggregations within the CRE, where feasible.

- Adequate survival of young-of-year or juvenile humpback chub that enter the mainstem to maintain reproductive potential of the population and achieve population sizes consistent with recovery goals.

Rainbow Trout DFCs

A high-quality trout fishery in GCNRA, as further described in the Recreation DFC that does not adversely affect the native aquatic community in GCNP:

- Minimize emigration of nonnative fish from the Lees Ferry reach in GCNRA to downstream locations.

- Minimize emigration of nonnative warm water fish to the mainstem Colorado River.

Extirpated Species DFC

Re-establish fishes extirpated from Grand Canyon, where feasible and consistent with recovery goals for humpback chub and the recovery goals of those extirpated fishes. See the linkages that follow for further information.

Nonfish Biotic Communities DFCs

Native non-fish aquatic biota and their habitats are sustainably maintained with ecologically appropriate distributions:

- Populations of native non-fish species (invertebrates and vertebrates, including northern leopard frog).

- GCDAMP support, actions, and funding are limited to incorporation of dam operations that are conducive to restoration of extirpated species.

- Minimize the abundance and distribution of nonnative species in the CRE.

- Sustainable dam-influenced aquatic, wetland, and springs plant communities and associated biological processes, including those supporting threatened and endangered species and their habitats.

A.1.4.4 Colorado River Ecosystem Riparian Resource DFCs

Native riparian systems in various stages of maturity are diverse, healthy, productive, self-sustaining, and ecologically appropriate, as indicated by the following:

- Native, self-sustaining riverine wetlands, and riparian vegetation and habitat, with appropriate mixture of age classes.

- Healthy, self-sustaining populations of native riparian fauna (both resident and migratory).

- Habitat for sensitive species within the CRE.

- Encourage the resolution of the taxonomic status of the Kanab ambersnail (e.g., completely describe the taxa and subspecies).

- Habitat for neotropical migratory birds, waterfowl, and other appropriate native bird species.

- Ecological functions of tributary mouths and riverside springs, including habitat for native species.

A.1.5 Colorado River Ecosystem DFCs Additional Information

A.1.5.1 Colorado River Ecosystem Linkages

Physical characteristics, including climate, site-specific geomorphology, dam-related discharge and flow, and tributary flows, generally predominate over biological processes. The aquatic and riparian components of the CRE are linked to fluvial habitat distribution and the collection, composition, structure, and population dynamics of living organisms. “Lateral” bio-ecological processes, such as competition, and “top-down” processes, such as predation, parasitism, and decomposition, can influence some elements of these linkages over time.

In addition to physical and biological interactions, the CRE is linked to Native American cultural resources such as archeological and cultural properties. Recreation benefits have resulted from both dam operations and healthy ecosystem conditions.

A.1.5.2 Colorado River Ecosystem Metrics

These DFCs are intended to guide the gathering and analysis of data pertinent to the CRE in GCNP and GCNRA. The CRE DFCs and the related documents will be used to provide direction toward development of the core monitoring program under development by the GCMRC. Through diligent and consistent monitoring, GCMRC may inform the Secretary as to whether as to what degree these DFCs are being achieved. Such monitoring may include the following:

- Percentage of critical habitat lost or gained;
- Condition of species variability (native population, abundance, distribution);
- Carrying capacity thresholds; and
- Population estimates.

A.2 POWER DESIRED FUTURE CONDITIONS

A.2.1 Power DFC Description

Hydroelectric power is generated by the release of stored water through Glen Canyon Dam. The dam's eight generators can produce up to 1,320 megawatts: enough electricity to serve 1.3 million residential customers. The integration of hydropower and other resources provides an efficient and flexible operation of this region's electrical resources. Releases of water from Glen Canyon Dam are adjusted in part to follow customer loads.

A.2.2 Power DFC Background and Legislation

Glen Canyon Dam is an important component of the Colorado River Storage Project (CRSP), which stores water, the Western United States' most vital resource, during wet years for use in times of drought, much like a bank account. As part of the nation's critical infrastructure, the water stored by Glen Canyon Dam is vital to the growing water needs of the Western United States. More than 30 million people depend on the water stored behind the dam for drinking, irrigation, and other municipal and industrial uses.

Revenues from the sale of hydropower generation from Glen Canyon Dam and other CRSP facilities are used to repay reimbursable costs and interest on the interest-bearing costs of

the federal investment in the CRSP, and are also used to repay over 85% of the irrigation costs of CRSP federal irrigation projects. These revenues are also used, instead of annual federal appropriations, to pay for the yearly operation, maintenance, and replacement costs of Glen Canyon Dam and other CRSP facilities.

The Reclamation Project Act of 1939 provides that hydropower produced by Glen Canyon Dam and other CRSP facilities be offered for sale first to municipalities, other public corporations and cooperatives, and other nonprofit organizations financed in whole or in part by loans made pursuant to the Rural Electrification Act of 1936. Customers include rural electric associations, federal facilities, state agencies, universities, and 57 Native American entities.

A.2.3 Why the Power DFC Is Important

- Hydropower is an authorized purpose of Glen Canyon Dam.
- Hydropower produced by Glen Canyon Dam is under long-term contract to not-for-profit entities and 57 Tribal entities.
- Power revenues are a significant funding source (providing an estimated $20 million/year) for the GCDAMP, Upper Colorado River and San Juan River Endangered Fish Recovery Programs, and the Colorado River Salinity Control Program.
- Hydropower is a renewable resource that is an important component in the Western Electricity Coordinating Council (WECC). Hydropower production is a national objective to help meet the nation's needs for reliable, affordable, and environmentally sustainable electricity.
- Glen Canyon generation has the ability to "ramp up" to meet system reliability obligations that are important when regional power shortages or power/transmission system disruptions occur.

A.2.4 Power DFCs

- Glen Canyon Dam capacity and energy generation is maintained and increased, so as to produce the greatest practicable amount of power and energy, consistent with the other DFCs.
- Ensure continued delivery of Glen Canyon Dam hydropower to the existing customers who have entered into long-term firm power contracts with the Western Area Power Association (WAPA).
- Ensure sufficient and efficient production of Glen Canyon Dam hydropower in order to provide the revenues to support the CRSP facilities and purposes.

- Maintain the operational flexibility (including but not limited to load following capability, ramp rates, and emergency operations allowances) that enable Reclamation and WAPA to meet the system operating and other regulatory requirements of WECC, North American Electric Reliability Corporation, and the Federal Energy Regulatory Commission, as well as emergency operating criteria for safety and human health situations.

- Maximize the environmental benefits of hydropower generation at Glen Canyon Dam.

- Minimize carbon emissions through hydropower generation at Glen Canyon Dam.

A.2.5 Power DFC Additional Information

A.2.5.1 Power Linkages

- Operational changes, including experimentation and management actions, which include changes to volumes; release limitations (minimum and maximum); ramp rates; and hourly, daily, monthly, and seasonal variability, all potentially impact this resource.

- The above-identified parameters could have impacts to the CRE resources as well as recreational and cultural resources, depending on the operational design.

A.2.5.2 Power Metrics

- Valuation (measurement characterization for an average year):
  - Electric generating capacity (MW);
  - Electric generating energy (MWH);
  - Load following capability (MW/hr);
  - Ramp rate capability (MW/hr);
  - CO_2, SO_2, and NO_X emissions (tons);
  - Power plant water consumption (acre-feet); and
  - Costs ($ millions).

A.3 CULTURAL RESOURCES DESIRED FUTURE CONDITIONS

A.3.1 Cultural Resources DFC Description

Preservation and appropriate management of cultural resources are vital at many levels. At the most basic level, cultural resources are our history; they define and reaffirm us, and provide a tangible record of who we are and where we have been. Their importance may be to the nation as a whole, to a local community, or to a group traditionally associated with the area. This includes resources within the Grand Canyon region, such as resources along the river corridor in Glen and Grand Canyons.

A.3.2 DFC Background and Legislation

Recognition of the importance of cultural resources is codified through numerous statutes and executive orders that mandate protection, consideration, and preservation of cultural resources. Because of the structure of federal law, particularly the National Historic Preservation Act of 1966 (NHPA), cultural resources will be considered below in two broad groupings: (1) those that fall within the purview of the NHPA (*National Register of Historic Places* [NRHP] eligible historic properties); and (2) all other resources of traditional cultural importance. This is done for purely pragmatic reasons; there are specific legal requirements for cultural resources that fall under the NHPA umbrella that do not apply to the second class of cultural resources. The Cultural Resources DFCs apply the requirements of the Grand Canyon Protection Act to "protect, mitigate adverse impacts to, and improve the values for which GCNP and Grand Canyon National Recreation Area (GCNRA) were established," including cultural resources, and are the goals that AMWG members will consider when making recommendations to the Secretary.

A.3.3 Why the Cultural Resources DFCs Are Important

The cultural resources of the Grand Canyon provide a record of human history in the area. They also encompass the traditional cultural use and significance of the Grand Canyon. Maintaining these resources is important to the nation as a whole so we can better understand the long history of the people who came before us and to the traditional groups that consider this area to have traditional significance to them. A number of Native American groups believe the Grand Canyon is their place of origin. These DFCs will help to maintain compliance with relevant cultural resource laws, maintain traditional cultural linkage with the Grand Canyon, and maintain traditional cultural access to and use of resources in the Grand Canyon in accordance with applicable law.

A.3.4 NRHP Eligible (or Potentially Eligible) Historic Properties DFCs

These resources are historic properties that are eligible or potentially eligible for inclusion in the NRHP. The criteria for inclusion are defined in the NHPA, and are described in more detail in *National Register* Bulletins 15 and 38. Resources in the Grand Canyon include the following:

- Prehistoric archaeological sites (including trails, petroglyphs, and pictographs);

- Historic sites (boats, mining, European exploration, river running); and

- Traditional Cultural Properties—for the Grand Canyon, these include:
  - Archaeological sites,
  - Traditional resource use areas,
  - Sacred sites,
  - Landmarks/geographic features,
  - Springs,
  - The Colorado River,
  - Ethno-ecological resources,
  - Significant event locations, and
  - The Grand Canyon itself.

A.3.4.1 Prehistoric Archaeological Sites and Historic Sites

To the extent feasible, maintain significance and integrity through preservation in place:

- If preservation in place is not feasible or reasonable, then implementation of appropriate preservation treatments will be implemented to ensure reduction or elimination of threats consistent with NPS management policies, Tribal traditional values, and historic preservation law.

- Public access to historic properties on Tribal lands is managed by the respective Tribes. On lands administered by the NPS, access to some sites for users of the river corridor is maintained as long as integrity of the sites is not compromised.

A.3.4.2 Traditional Cultural Properties (TCPs)

- Attributes are maintained; for example, NRHP eligibility is not compromised. These attributes will be specific to traditionally associated peoples and will need to be identified by the federal agencies in consultation with those groups. Attributes may include aspects of location or physical integrity, and may be

intangible elements that link the resource to ongoing traditional cultural practices.

- The ability of traditionally associated people to maintain access to and use of the resources is preserved, in accordance with applicable law.

- Culturally appropriate conditions of resources are maintained based on traditional ecological knowledge; integration of the desired condition is included in relevant monitoring and management programs.

- Maintain ongoing consultation with the groups for whom the resource has traditional value. Because the desired condition of a TCP needs to be determined by the group for whom it has the traditional value, ongoing consultation is necessary to assess the condition of the resource.

- Mitigate impacts that affect the integrity of the TCPs. How and if effects can be mitigated will need to be determined in conjunction with the traditionally associated peoples for whom the resource holds value.

A.3.5 NRHP Eligible (or Potentially Eligible) Historic Properties DFC Additional Information

A.3.5.1 NRHP Eligible (or Potentially Eligible) Historic Properties Linkages

The goals for the following all have the potential to directly or indirectly affect the condition of the NRHP eligible properties (including some examples of effects):

- Flow
  - Direct inundation
  - Levels of sediment deposition
  - Fluctuation frequency and range

- Sediment
  - Distribution (laterally and vertically)

- Vegetation
  - Species composition
  - Density

- Recreation
  - Camping locations
  - Recreational visitation
  - Trailing

In addition, management and research actions have the potential to directly or indirectly impact these resources.

A.3.5.2 NRHP Eligible (or Potentially Eligible) Historic Properties Metrics

- Erosion (or deposition) rates of substrates in which the sites are contained, and
- Impacts at sites that will affect eligibility.

A.3.6 Resources of Traditional Cultural Significance but Not NRHP Eligible

These are resources of cultural significance to traditional peoples, often Native American Tribes, that do not meet some aspect for eligibility for inclusion in the NRHP. A common reason that a resource does not meet NRHP eligibility requirements is that the resource lacks a clearly defined boundary or does not remain in a fixed location.

Resources that have the potential to be considered of traditional cultural significance in the Grand Canyon include the following:

- Animal resources,
- Geologic materials,
- Landscapes,
- Plant resources,
- Soundscapes,
- Viewscapes, and
- Water.

A.3.7 Resources of Traditional Cultural Significance DFCs

- Maintain the ability of traditionally associated peoples to access and use the resource in accordance with applicable law.
- Maintain culturally appropriate resource conditions based on traditional ecological knowledge and integrate this desired condition into monitoring and management programs.

- Maintain effective consultation with the groups for whom the resource has traditional cultural significance.

A.3.8 Resources of Traditional Cultural Significance Linkages

The goals for the following resources all directly or indirectly affect the condition of resources with traditional cultural significance:

- Flow,
- Sediment,
- Vegetation, and
- Recreation.

In addition, management and research actions have the potential to directly impact these resources.

A.3.9 Resources of Traditional Cultural Significance Metrics

Because culture defines the roles resources play in that culture, only members of that culture can assess the status or health of the resources. Therefore, measures for resource status or health and appropriate management will need to be determined individually by federal agencies in consultation with the traditionally associated peoples.

A.4 RECREATION DESIRED FUTURE CONDITIONS

A.4.1 Recreation DFC Description

The Recreation DFCs are meant to describe goals and objectives for human use of the CRE through GCNRA and the GCNP. They are intended to include not only traditional recreational activities such as whitewater rafting, camping, and fishing, but also such things as educational activities, spiritual engagement, and other appropriate activities and values. Grand Canyon and Glen Canyon offer many ways for people to experience, appreciate, and learn from them, even to those who never visit in person.

A.4.2 DFC Background and Legislation

Recreational use on the Colorado River began before there were any dams there, although its exact beginnings are unknown. Recreational and other activities and values in the Grand

Canyon and Glen Canyon have increased greatly since the construction of Glen Canyon Dam. The Recreation DFC applies the requirements of the GCPA to "protect, mitigate adverse impacts to, and improve the values for which GCNP and Grand Canyon National Recreation Area (GCNRA) were established," including visitor use/recreation, and the goals that AMWG members will consider when making recommendations to the Secretary.

A.4.3 Why the Recreation DFC Is Important

A.4.3.1 Grand Canyon National Park

The Grand Canyon is a unique place in the world. Its natural beauty, challenging environment, fascinating history, wilderness character, biodiversity, and sheer size offer a rare and valuable experience. The river corridor is at the heart of the Grand Canyon. The river corridor and the canyon are worthy of the greatest possible respect, treatment, and protection that can be afforded them. They must be kept vital and intact for future generations.

A.4.3.2 Glen Canyon National Recreation Area

The river corridor through the GCNRA provides opportunity to enjoy outdoor beauty with relatively easy access. It supports a valuable and high-quality trout fishery and offers excellent outdoor opportunities that are more accessible and less demanding than those of the Grand Canyon. It is deserving of respect and protection, while also providing the recreational opportunities for which it was established.

A.4.4 Recreation DFCs

The recreation DFCs have been divided in to four subcategories, each corresponding to a different section of the overall ecosystem or type of use.

A.4.4.1 River Recreation in Grand Canyon National Park

- Stewardship worthy of the Grand Canyon so that it can be passed from generation to generation in as natural a condition as possible.

- Provide maximum opportunity to experience the wilderness character of the canyon.

- Wilderness experiences and benefits available in the canyon include solitude, connection to nature, personal contemplation, joy, excitement, the natural sounds and quiet of the desert and river, and extended time periods in a unique environment outside the trappings of civilization.

- A river corridor landscape that matches natural conditions as closely as possible, including extensive beaches and abundant driftwood.

- A river corridor ecosystem that matches the natural conditions as closely as possible, including a biotic community dominated in most instances by native species.

- A dynamic river ecosystem characterized by ecological patterns and processes within their range of natural variability.

- Numerous campable sandbars distributed throughout the canyon.

- Recreational and wilderness experiences minimally affected by research and management activities.

- River flows that continue to be within a range that is reasonably safe, given the inherent risks involved in river recreation.

A.4.4.2 River Recreation in Glen Canyon National Recreation Area

- A quality recreation experience in Glen Canyon.

- Camping beaches suitable for recreational use.

- A setting and ecosystem that is as close to natural conditions as possible.

- Quality river running and angling recreation opportunities.

A.4.4.3 Blue Ribbon Trout Fishery in Glen Canyon National Recreation Area

- A high-quality sustainable recreational trout fishery in the river corridor in GCNRA, while minimizing emigration of nonnative fishes.

- Operate Glen Canyon Dam to achieve the greatest benefit to the trout fishery in GCNRA without causing excessive detriment to other resources.

A.4.4.4 River Corridor Stewardship

- Management of Glen Canyon Dam that is significantly driven by concern for the cultural values and ecological integrity of the river corridor through the Grand Canyon, with preservation and protection considered over the long term (multiple generations).

- A well-informed public, confident that high-quality scientific information is being used for best stewardship practices in the CRE.

A.4.5 Recreation DFC Additional Information

A.4.6 Recreation Linkages

- A natural, healthy, and protected ecosystem is a fundamentally key element to the recreation experience and wilderness character of the river corridor.

- Cultural resources within and near the river corridor:
  - The history of human habitation and use is an important part of the recreation experience. Individual sites are valuable whether they are open for visitation or designated off-limits.
  - Outfitters and guiding opportunities.
  - Local businesses.

A.4.7 Recreation Metrics

- Socioeconomic value of river recreation in GCNP.

- Socioeconomic value of the river corridor visitation and the Grand Canyon itself, as a whole.

- Economic effects of Grand Canyon tourism.

- Factors that make up the "wilderness character" of the river corridor.

- Number and size of campable beaches, safe flows for an optimal recreation experience.

- Socioeconomic value of river recreation in GCNRA.

- Socioeconomic value of the river corridor itself in GCNRA.

- Socioeconomic value of the fishery in GCNRA.

- Effect of the trout on the ecosystem in GCNP and the social and economic costs of mitigation.

- Characteristics most valued for the fishery; for example, the number, condition, and size of fish, and the ease or challenge of catching them.

- River running visitation metrics.
- Water quality variables that influence river recreation.
- Other river running safety issues.

PERFORMANCE METRICS USED TO EVALUATE ALTERNATIVES

This page intentionally left blank

APPENDIX B:

PERFORMANCE METRICS USED TO EVALUATE ALTERNATIVES

This appendix describes a set of scientifically based performance metrics that were used by the Environmental Impact Statement (EIS) team to evaluate the impacts of alternatives on key resources in the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) EIS. The metrics were also used in a structured decision analysis process to objectively evaluate how alternatives perform relative to stakeholder values and in the face of critical uncertainties (Appendix C). The metrics were developed in a series of workshops among subject matter experts working on the LTEMP EIS and were revised to incorporate feedback from Cooperating Agencies and other stakeholders. The performance metrics are intended to be objective measures of the performance of alternatives relative to goals for each affected resource evaluated in the EIS.

Evaluation of these metrics represents only a component of the impact analysis performed for the EIS. Other sources of both quantitative and qualitative information, in addition to the metrics described below, were used to assess the overall and relative performance of alternatives and their constituent elements.

The affected resources, associated goals, and performance metrics are described below.

B.1 AQUATIC ECOLOGY

B.1.1 Humpback Chub

Resource Goal: Meet humpback chub recovery goals, including maintaining a self-sustaining population, spawning habitat, and aggregations in its natural range in the Colorado River and its tributaries below the Glen Canyon Dam.

Performance Metrics

- **Number of Adult Humpback Chub.** This metric provides the estimated number of adult (200 mm+) humpback chub in the Little Colorado River population over the LTEMP period relative to the estimated adult population size in September 2011.

  The modeled number of humpback chub adults was calculated using a size-structured model that considers both the Little Colorado River and mainstem components of the Little Colorado River aggregation and used empirically derived estimates of growth and survival that differ for these two areas. In addition, the size structure of the modeled humpback chub population at the end of the 20-year traces was compared to evaluate possible differences

among alternatives. Growth and survival rates in the mainstem are based on inputs related to monthly water temperature for each of the Colorado River Simulation System (CRSS) traces (modeled using the Wright et al. 2008 model) and estimated annual trout abundance in the Little Colorado River reach occupied by humpback chub. Trout abundance was estimated using a trout emigration submodel that models the numbers of trout that leave the Glen Canyon reach (see description of trout fishery metrics below) and subsequently pass through Marble Canyon to the Little Colorado River reach.

- **Potential for Self-Sustaining Aggregations of Humpback Chub.** The potential for a self-sustaining aggregation of humpback chub to be supported at each of eight locations (river mile [RM] 30, 61 [Little Colorado River], 88, 108, 119, 125–128, 157, and 213) was based on the output of a temperature suitability model that considers how well water temperatures under a particular alternative meet temperature requirements for important humpback chub life history aspects (spawning, egg incubation, and growth) at each aggregation area. It was assumed that mainstem spawning and egg incubation would be required to support self-sustaining aggregations at each location except for the aggregation at the confluence of the mainstem and the Little Colorado River (RM 61), where successful tributary spawning is known to occur. At each location, the potential for successful spawning, egg incubation, and rearing for juvenile humpback chub at various temperatures was calculated using triangular probability functions based on the reported ranges of suitable temperatures and the reported optimal temperatures for each life history need as presented in Valdez and Speas (2007). A temperature suitability score for each life history need was generated for each day of the modeled LTEMP period using modeled predictions of water temperatures for the aggregation location (modeled using the Wright et al. 2008 model).

  Annual mean temperature suitability scores for each life history need were calculated by averaging daily suitability scores that occur during the appropriate portion of each water year (i.e., April–June for spawning and egg incubation and year-round for growth). The annual potential for an aggregation to be self-sustaining at a particular location was calculated as the geometric mean of the annual temperature suitability scores for each life history event within a particular water year (a value between 0 and 1), and the overall means of the annual scores for each hydrologic trace were used to statistically compare the potential for self-sustaining aggregations to be supported by the various alternatives.

  For each hydrologic trace, the number of aggregation locations where the estimated annual temperature suitability score is $\geq$0.5 was determined for each alternative. The mean number of aggregations with temperature suitability values $\geq$0.5 for all traces was used as an indicator of overall humpback chub temperature suitability for each alternative.

B.1.2 Other Native Fish

Resource Goal: Maintain self-sustaining native fish species populations and their habitats in their natural ranges on the Colorado River and its tributaries.

Performance Metrics

- **Temperature Suitability for Warmwater Native Fish.** The potential for self-sustaining populations of native warmwater fish (other than humpback chub) to be supported at each of five locations (RM 15, 0, 61, 157, and 225) was based upon the output of a temperature suitability model (similar to the modeling approach for humpback chub aggregation evaluations) that evaluates the suitability of water temperatures under a particular long-term (e.g., 20 years) operational regime for meeting identified needs for major life history aspects (spawning, egg incubation, and growth) of a group of native fish species. The model generates individual temperature suitability scores for four species of native fish (flannelmouth sucker, bluehead sucker, razorback sucker, and speckled dace) at each location. Modeled monthly temperatures at different locations under different alternatives (modeled using the Wright et al. 2008 model) were the primary input needed to generate the temperature suitability scores for this metric.

  The relative suitability of conditions under each alternative to support native fish was represented by the mean of the temperature suitability scores for these four species, calculated for each location, and also by an overall metric for each alternative that combined the temperature suitability scores for the four species at all locations.

B.1.3 Trout Fishery

Resource Goal: Achieve a healthy high-quality recreational trout fishery in Glen Canyon National Recreation Area and reduce or eliminate downstream trout migration consistent with National Park Service (NPS) fish management and Endangered Species Act (ESA) compliance.

Performance Metrics

- **Lees Ferry Trout Abundance Index.** For age 1+ fish.

- **Catch Rate Index (number/hr).** For age 2+ fish.

- **Emigration Estimate.** Number of age-0 trout moving into Marble Canyon from Glen Canyon.

- **Number of Trout >16 in. Total Length.** These metrics were estimated using a trout-humpback chub model developed specifically for the LTEMP EIS by

Lew Coggins (U.S. Fish and Wildlife Service), Josh Korman (Ecometrics), and Charles Yackulic (Grand Canyon Monitoring and Research Center [GCMRC]). The model uses inputs related to annual water volumes, water temperatures, and specifics of the release patterns (e.g., occurrence of high-flow experiments [HFEs], implementation of trout management flows, amount of daily flow fluctuation) to estimate recruitment and survival of trout within the Glen Canyon reach. Emigration of trout into Marble Canyon was based on statistical relationships to the abundance of trout in Glen Canyon. Size structure of trout within the Glen Canyon reach was modeled for age 1+ trout and the calculated number of trout that exceed 16 in. total length was calculated as an estimate of the quality of the fishery. Angling catch rate was calculated for age 2+ trout based on estimated vulnerability of different age classes.

B.1.4 Nonnative Aquatic Species

Resource Goal: Minimize or reduce presence and expansion of aquatic nonnative invasive species.

Performance Metrics

- **Potential for Establishment and Expansion of Nonnative Fish.** The potential for self-sustaining populations of nonnative warmwater and coldwater fish to be supported at each of five locations (RM –15, 0, 61, 157, and 225) was based upon the output of a temperature suitability model that considers how well water temperatures under a particular alternative meet identified needs for required life history aspects (spawning, egg incubation, and growth) of warmwater and coldwater groups of nonnative fish species. The model generates individual temperature suitability scores for four species of warmwater nonnative fish (channel catfish, green sunfish, smallmouth bass, and striped bass) and two species of coldwater fish (brown trout and rainbow trout) at each location.

  The relative suitability of temperature conditions under each alternative to support the two groups of nonnative fish was represented by the mean of the temperature suitability scores for the species within the groups, calculated for each location, and also by an overall metric composed of the temperature suitability scores for the groups at all locations. Modeled monthly temperatures at different locations under different alternatives (modeled using the Wright et al. 2008 model) were the primary input needed to generate the temperature suitability scores for this metric.

- **Potential for Establishment and Expansion of Aquatic Parasites.** A similar temperature suitability model was used to evaluate temperature suitability for the selected fish parasite species (Asian tapeworm, anchor worm, trout

nematode, and whirling disease) based on the suitability of specific temperatures to meet the requirements for host species activity and the development of infestations at each of five locations (RM 15, 0, 61, 157, and 225). As with the nonnative fish modeling, temperature suitability for the parasite species under each alternative was evaluated for the five identified locations using modeled water temperature regimes.

The relative suitability of temperature conditions under each alternative to support the parasite species was represented by the mean of the temperature suitability scores for the species group, calculated for each location, and also by an overall metric composed of the temperature suitability scores for the group at all locations.

B.2 ARCHAEOLOGICAL AND CULTURAL RESOURCES

Resource Goal: Maintain the integrity of potentially affected *National Register of Historic Places* (NRHP) eligible or listed historic properties in place, where possible, with preservation methods employed on a site-specific basis.

Performance Metrics

- **Wind Transport of Sediment Index.** This metric evaluated the availability of fine sediment for wind transport and potential deposition on historic properties at higher elevations (i.e., those properties located at stages above 45,000 cfs). Deposited sediment would serve to protect those resources from erosion. Optimal conditions for wind transport of sediment occur when (1) there is deposition of fine sediment by flows above the stage of normal operations, which represents the availability of sand at higher elevations, and (2) there are low flows which expose more sand during the windy season, which would make more dry sand available for redistribution by the wind. This criterion accounts for the two processes using the equation:

$$Wind\ Transport\ Index = FF \times SLI$$

where *FF* is the flow factor and *SLI* is the Sand Load Index produced by the Sand Budget Model.

The flow factor represents the relative amount of exposure of sand deposits on a 0–1 scale that occurs for each day of the windy period (March–June). The daily flow factor was calculated as follows:

FF = 1 for maximum daily flows less than or equal to 8,000 cfs, indicating maximum exposure of sand to wind transport;

FF = 0 for maximum daily flows greater than 31,500 cfs, indicating minimum exposure of sand to wind transport;

FF = 1.34 – (0.00004255 × maximum daily flow), for flows between 8,000 and 31,500 cfs. This equation represents the linear decrease in flow factor from 1 at flows of 8,000 cfs to 0 for flows of 31,500 cfs.

The yearly flow factor was calculated by averaging the daily flow factors for the March–June period.

The *SLI* is the ratio of the cumulative sand load transported by high flows (i.e., flows >31,500 cfs) to total cumulative sand load transported by all flows for the alternative (range 0–1; higher index indicates greater likelihood of sediment deposition for wind transport).

Wind Transport Index is a value of 0–1, where a value of 1 has the most exposure to possible movement of sediment by the wind and is therefore the most desirable.

The mean annual Wind Transport Index value for the 20-year modeling period was used as the performance metric for each alternative.

The metric reflects when alternatives create the conditions for movement of sediment by wind, and therefore the potential for cultural resources to be protected, under each alternative. Although windblown sand deposited from sandbars created by dam operations may provide some benefit to archaeological site preservation in Grand Canyon, both the extent to which this occurs and the extent to which wind-deposited sand provides long-term preservation of archaeological sites are not known.

- **Flow Effects on Historic Properties in Glen Canyon Index.** Within Glen Canyon, there is concern that significant archeological sites could be negatively affected by flow levels of certain magnitudes.

  Ninemile Terrace, which is considered representative of other archeological sites situated on terraces within Glen Canyon, is potentially affected by higher flows, which inundate and could erode the slope of the terrace. The toe of the slope begins to be inundated at flows above 23,200 cfs. Consequently, the flow metric is calculated as the mean number of days/year the maximum daily flow is greater than 23,200 cfs.

- **Time Off River Index.** In the Grand Canyon, higher flow levels increase the potential for discretionary time off the river for visitors. There is concern that there may be a greater potential for archaeological sites to be visited and possibly affected, if visitors have more time to explore during the day because of increased travel rates at higher flows.

  The calculated index is a yearly value ranging from 0 to 1, where 1 indicates the most potential for discretionary time for visitors (and the highest potential for increased visitation of archaeological sites).

  Calculation of the index involved computing mean daily flow from the hourly flow data and using this value to calculate an off river flow factor. The off river flow factor (ORFF) was calculated as follows:

  – *ORFF* = 0 for mean daily flows less than or equal to 10,000 cfs, indicating the increased time visitors would spend on the river.

  – *ORFF* = 1 for mean daily flows greater than 31,500 cfs, indicating faster river travel times and potentially increased time spent off the river.

  – *ORFF* = (0.0000465 × mean daily flow) – 0.465, for flows between 10,000 and 31,500 cfs. This equation represents the linear increase in the metric from 0 at flows of 10,000 cfs (lease negative effect) to 1 for flows of 31,500 cfs (greatest negative effect). Flows greater than 31,500 cfs are assigned flow metric values of 1 because of the increased potential for visitation of cultural sites that occur at elevations above normal operating flows.

  ORFF values for each season were summed and weighted to reflect the uneven use of the river throughout the year; 0.15 for winter months (Nov., Dec., Jan., Feb.), 0.31 for spring and fall months (March, April, Sept., Oct.), and 0.54 for summer months (May, June, July, Aug.) and normalized by the number of days in each season as shown in the following equation.

$$TOR = \{0.15\left(\frac{\sum_{winter} ORFF}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{\frac{spring}{fall}} ORFF}{\sum Days_{\frac{spring}{fall}}}\right) + 0.54\left(\frac{\sum_{summer} ORFF}{\sum Days_{summer}}\right)\}$$

B.3 HYDROPOWER AND ENERGY

Resource Goal: Maintain or increase Glen Canyon Dam electric energy generation, load following capability and ramp rate capability, and minimize emissions and costs to the greatest extent practicable consistent with improvement and long-term sustainability of downstream resources.

Performance Metrics[1]

- **Combined Value of Hydropower ($).** This composite performance metric combined (1) the value of energy production, (2) the value of capacity, and (3) the value of operational flexibility, to provide a mean annual and total value estimate for Glen Canyon Dam hydropower under each of the alternatives. Performance metrics were developed that quantify the potential value of hydropower production under the limitations imposed by each alternative. These components were estimated using the GTMax-Lite power systems modeling and post-processing analysis, based on monthly and hourly release estimates for the LTEMP period:

  - **Value of Energy Production ($).** Results show mean annual and total quantities of energy production (MWh) and corresponding energy values ($), based on market price estimates ($/MWh) for the time periods generated. (Market price estimates were used to characterize the economic value of energy delivered to the grid.) This metric was obtained directly from GTMax-Lite hourly results and market price estimates.

  - **Value of Capacity ($).** Results show mean annual and total quantities of capacity available (MW) and corresponding capacity values ($), based on market price estimates ($/MW) for the relevant time periods. This metric, derived from GTMax-Lite results and market price estimates, represents an initial proxy for detailed capacity replacement analyses completed in other stages of the LTEMP analysis.

B.4 NATURAL PROCESSES

Resource Goal: Restore, to the extent practicable, ecological patterns and processes within their range of natural variability, including the natural abundance, diversity, and genetic and ecological integrity of the plant and animal species native to those ecosystems.

This resource goal incorporates many different physical and biological processes and ecological components of the river system. As a consequence, the goal does not lend itself to expression in a quantitative metric. Instead of a quantitative metric, alternatives were compared in the EIS by qualitatively evaluating each alternative's performance relative to this goal, considering impacts on various natural processes such as flow, sediment transport, water temperature, riparian vegetation, aquatic organisms, and terrestrial wildlife. This resource goal was not included in the structured decision analysis process.

---

1 Hydropower performance metrics presented here were used for structured decision analysis and calculating the costs of experiments. Additional hydropower modeling was performed using the AURORA model to project economic impacts of alternatives on electric utilities in the Western Interconnection power grid (see Figure 4-1 in the EIS).

B.5 RECREATIONAL EXPERIENCE

Resource Goal: Maintain and improve the quality of recreational experiences for the users of the Colorado River ecosystem. Recreation includes, but is not limited to, flatwater and whitewater boating, river corridor camping, and angling in Glen Canyon.

B.5.1 Grand Canyon Metrics

- **Camping Area Index.** It is important to develop and retain adequate medium (16–25 people) and large (>25 people) campsites to meet the visitor capacities established in the NPS Colorado River Management Plan. The availability of camping area above the stage of normal operations (25,000 cfs) is considered as part of the index.

  Camping area and campsite size are a function of the amount of sand deposited and retained. The output from the Sand Load Index, which simulates sediment conditions between RM 0 and 61 provides a proxy for indicating whether the alternatives are likely to create the conditions conducive to creating/retaining adequate campsite area.

  Camping area and campsite size also are a function of flow level. Lower flows provide more camping area (i.e., there is more camping area at 8,000 cfs than at 25,000 cfs).

  The index was calculated as follows:

  $$Camping\ Area\ Index = SLI \times SWFF$$

  where *SLI* is the Sand Load Index and *SWFF* is the seasonally weighted flow factor.

  SLI is a ratio of the cumulative sand load transported by high flows (i.e., flows >31,500 cfs) to the total cumulative sand load transported by all flows for an alternative (range 0–1; higher index indicates greater likelihood of sediment deposition for campsites).

  SWFF consists of a seasonal weighting (*SW*) and a flow factor (*FF*) component.

  SW is as follows: 0.15 for winter months (Nov., Dec., Jan., Feb.); 0.31 for spring and fall months (March, April, Sept., Oct.), and 0.54 for summer months (May, June, July, Aug.).

FF is as follows: 1 for daily maximum flows that are less than or equal to 8,000 cfs, 0 for daily maximum flows greater than 31,500 cfs, and 1.34 – (0.00004255 × maximum daily flow), for flows between 8,000 and 31,500 cfs. This equation represents the linear decrease in flow factor from 1 at flows of 8,000 cfs to 0 for flows of 31,500 cfs.

The computation of the *SWFF* involved taking hourly flow data and computing daily maximum flows resulting in a time series of daily maximum flows. The next step was to assign these daily maximum flows into seasonal compartments defined by *SW* for each year. *FF* values for each season were summed and normalized by the number of days in each season. The *SWFF* was then calculated as:

$$SWFF = 0.15\left(\frac{\sum_{winter} FF}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{spring/fall} FF}{\sum Days_{spring/fall}}\right) + 0.54\left(\frac{\sum_{summer} FF}{\sum Days_{summer}}\right)$$

SWFF is a yearly value ranging from 0 to 1, where 1 is better for camping.

The Camping Area Index (*CAI*) is a yearly value that ranges from 0 to 1, where 1 is better for camping area.

- **Visitor Experience Indices.** Visitor experience in Grand Canyon is related to navigational safety, the magnitude of within-day flow fluctuations, and the amount of time visitors can spend off river. These factors are affected by flow levels and fluctuation regimes. This relationship is based on studies documenting difficulties of motor rigs navigating rapids at lower flows, and with oar boats having their travel time and time for off-river activities affected at lower flows. The highest level of recreational impacts occurs when flows are low.

  – **Navigational Risk Index.** The Navigational Risk Index (*NRI*) was calculated in a similar fashion to the *SWFF* component of the camping area index. The *NRI* was a yearly value ranging from 0 to 1, where 1 indicates the least risk, and 0 the most.

  The seasonal weighting for *NRI* was the same as the *SW* component of the *CAI*, specifically: 0.15 for winter months (Nov., Dec., Jan., Feb.); 0.31 for spring and fall months (March, April, Sept., Oct.), and 0.54 for summer months (May, June, July, Aug.).

  The main parameter involved with the calculation of the *NRI* was the number of days where the daily minimum flow was less than 8,000 cfs.

  The computation of the *NRI* involved taking hourly flow data and computing daily minimum flow resulting in a time series of daily minimum flows. The next step was to assign these daily minimum flows

into seasonal compartments defined by *SW* for each year. Then days where daily minimum flow was less than 8,000 cfs ($Days_{min}$) were identified for each season and the *NRI* was then calculated as:

$$NRI = 1 - \left\{0.15\left(\frac{\sum_{winter} Days_{min}}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{spring/fall} Days_{min}}{\sum Days_{spring/fall}}\right) + 0.54\left(\frac{\sum_{summer} Days_{min}}{\sum Days_{summer}}\right)\right\}$$

– **Fluctuation Index.** The Fluctuation Index (*FI*) examined the daily range in flow fluctuations relative to a defined threshold, and is a yearly value ranging from 0 to 1, where 1 indicated a desirable recreational and wilderness experience.

The daily range was the difference between the daily maximum and daily minimum flows.

Daily flow fluctuations were described as whether they are "tolerable" for recreational river use (as identified by river guides) (Table B-1) in the pertinent study by Bishop et al. (1987).

We made two assumptions in using this table of fluctuation thresholds: (1) the river flow ranges shown in the left-hand column above were determined based on the mean daily flow, and (2) that the maximum fluctuation (in italics) given in the range of tolerable fluctuations in the right-hand column serves as the daily range threshold ($DR_{threshold}$) condition, above which fluctuations become increasingly more unacceptable to river users. At daily fluctuation levels greater than 10,000 cfs, fluctuations are clearly noticeable and have strong adverse effects on river users.

Fluctuations that are less than or equal to the threshold fluctuation ranges shown in Table B-1 were assigned a value of 1, indicating an optimal condition. As daily fluctuations increased above those thresholds, the *FI* decreased linearly until it reached 0 when fluctuations were at or above

TABLE B-1 Tolerable Flow Fluctuations for Recreational River Use

River Flow (cfs)	"Tolerable Fluctuation" (cfs)
5,000–8,999	2,400–*3,400*
9,000–15,999	3,900–*4,800*
16,000–31,999	6,400–*7,200*
32,000 and up	7,200–*9,800*

10,000 cfs. The equations used to calculate the FI when daily fluctuations exceeded the threshold flows shown in Table B-1 were as follows:

- For mean daily flows between 5,000 cfs and 8,999 cfs: (–0.00015 × daily fluctuation) + 1.5151)
- For mean daily flows between 9,000 cfs and 15,999 cfs: (–0.00019 × daily fluctuation) + 1.923)
- For mean daily flows between 16,000 cfs and 31,999 cfs: (–0.00036 × daily fluctuation) + 3.5714)
- For mean daily flows at or above 32,000 cfs: (–0.005 × daily fluctuation) + 50.000)

Calculation of the *FI* involved computing mean daily flow, minimum daily flow, maximum daily flow, and daily range from the hourly flow data.

The seasonal weighting for *FI* was the same as the *SW* component of the *CAI*, specifically: 0.15 for winter months (Nov., Dec., Jan., Feb.), 0.31 for spring and fall months (March, April, Sept. Oct.), and 0.54 for summer months (May, June, July, Aug.).

The daily flow values and daily ranges were defined by seasonal use. Then for each day, mean daily flow was examined to set the value of $DR_{threshold}$ (italicized flow values in the table). The *FI* then identified days that $DR_{threshold}$ was exceeded ($Days_{exceed}$) according to:

$$FI = \left\{0.15\left(\frac{\sum_{winter} Days_{exceed}}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{spring/fall} Days_{exceed}}{\sum Days_{spring/fall}}\right) + 0.54\left(\frac{\sum_{summer} Days_{exceed}}{\sum Days_{summer}}\right)\right\}$$

– **Time Off River Index.** The Time Off River Index examined the amount of time visitors were able to engage in onshore activities such as hiking or visiting attractions, and was a yearly value ranging from 0 to 1, where 1 indicated the most available time off river for visitors. Calculation of the Time Off River Index involved computing mean daily flow from the hourly flow data and using this value to calculate an off river flow factor (*ORFF*).

The *ORFF* was determined as follows: 1 for mean daily flows that are greater than 31,500 cfs, 0 for flows less than 10,000 cfs, and a linear

function for flows between 10,000 and 31,500 cfs ([0.0000465 × mean daily flow] – 0.465).

The seasonal weighting for *TOR* was the same as the *SW* component of the *CAI*, specifically: 0.15 for winter months (Nov., Dec., Jan., Feb.), 0.31 for spring and fall months (March, April, Sept., Oct.), and 0.54 for summer months (May, June, July, Aug.).

ORFF values for each season were summed and normalized by the number of days in each season. The Time Off River Index was then calculated as:

$$0.15\left(\frac{\sum_{winter} ORFF}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{spring/fall} ORFF}{\sum Days_{spring/fall}}\right) + 0.54\left(\frac{\sum_{summer} ORFF}{\sum Days_{summer}}\right)$$

B.5.2 Glen Canyon Metrics

- **Glen Canyon Rafting Use Metric.** This metric represents the amount of recreational use lost in average number of visitors affected by HFEs. The metric is a single value for the 20-year analysis period (note that the range is not 0–1, but some value that is larger than 1 representing the number of lost visitor-days), where a higher value means greater adverse impact. The Glen Canyon rafting use metric uses an estimate of the average daily visitor (*ADV*) use for the months in which HFEs occur (March, April, May, Oct., Nov.). The number and duration of individual HFEs (T_{HFE}) are modeled as a part of the Sand Budget Model.

  The number of days lost for rafting because of an HFE (D_{lost}) is the duration of the HFE plus 2 days prior and 2 days post HFE ($D_{lost} = T_{HFE}$ + 2 days + 2 days) that represent the amount of time required to de-mobilize and re-mobilize rafting operations.

  The Glen Canyon rafting use metric is calculated as follows:

$$\sum_{20\ years} (ADV_{of\ HFE\ month}\left[\frac{visitors}{day}\right] \times D_{lost\ from\ HFE}[days])$$

  The units of the Glen Canyon rafting use metric are in number of visitor-rafting days lost.

- **Glen Canyon Inundation Metric.** The Glen Canyon inundation metric represents the percentage of time that flow is above critical flow elevations that affect recreational experiences. The Glen Canyon inundation metric is a

yearly value ranging from 0 to 1, where 1 indicates an optimal recreational experience.

The flow metric is calculated daily such that:

- Flow metric = 0 for daily maximum flows less than 3,000 cfs, indicating flows below 3,000 cfs are poor for boating and fishing.

- The flow metric between 3,000 cfs and 8,000 cfs was calculated using the linear function, (0.0002 × maximum daily flow) – 0.60, and flow metric values between 0 and 1. Fishing is better above 5,000 cfs, and flows for boating get progressively better up to 8,000 cfs.

- Flow metric = 1 for daily maximum flows between 8,000 and 20,000 cfs, indicating optimal conditions for boating, fishing, and shoreline access.

- The flow metric between 20,000 cfs and 31,500 cfs was calculated using the linear function, 2.739 – (0.00008695 × maximum daily flow), and flow metric values between 1 and 0. Flows above 20,000 cfs get progressively worse for boating, fishing, and shoreline access.

- Flow metric = 0 for daily maximum flows greater than 31,500 cfs. Flows above 31,500 cfs are poor for rafting, campable area, shoreline access, and fishing, and can adversely impact onshore recreational facilities.

B.6 RIPARIAN VEGETATION

Resource Goal: Maintain native vegetation and wildlife habitat, in various stages of maturity that is diverse, healthy, productive, self-sustaining, and ecologically appropriate.

Performance Metrics

- **Riparian Native States and Diversity Index.** The Riparian Native States and Diversity Index considers predicted changes over the 20-year LTEMP period in the relative cover of native vegetation community types and the relative diversity of community types. This metric was developed using a state-and-transition model developed by the GCMRC (Ralston et al. 2014), which uses characteristics of annual operations to predict transitions from one vegetation type to another on different geomorphic features of the riparian zone. The model evaluates the effects of five operations (extended low flow, extended high flow, HFE, pre-dam flow, and default operation) on transitions among seven vegetation states (bare sand, common reed/cattail, horsetail/coyote willow, tamarisk, Baccharis/coyote willow, arrowweed, and mesquite). The model divides operations into growing (April–September) and non-growing

seasons (October–March) and incorporates upper and lower bar submodels, using stage elevation as a division.

Operational characteristics of each alternative were used as input to the riparian model. Output from the model was used to calculate the following component indices, which together were used to develop the overall Riparian Native States and Diversity Index:

- Relative change in cover of native vegetation community types (PM_1) (other than arrowweed) on sandbars and channel margins using the total % increase in native states predicted by an existing state and transition model for riparian vegetation communities.

$$PM_1 = \text{cover}_{\text{final}}/\text{cover}_{\text{initial}}$$

- Relative change in diversity of native vegetation community types (PM_2) (other than arrowweed) on sandbars and channel margins using the Shannon Weiner Index for richness/evenness using the results of the state and transition model.

$$PM_2 = \text{diversity}_{final}/\text{diversity}_{initial}$$

- Relative change in the ratio of native (other than arrowweed)/nonnative dominated vegetation community types (PM_3) on sandbars and channel margins using the ratio of native/nonnative communities predicted by the state and transition model.

$$PM_3 = \text{ratio}_{\text{final}}/\text{ratio}_{\text{initial}}$$

- Relative change in the arrowweed state (PM_4) on sandbars and channel margins using the total % decrease in arrowweed states predicted by the state and transition model.

$$PM_4 = \text{arrowweed}_{initial}/\text{arrowweed}_{final}$$

These individual components were combined as follows:

$$PM_n = (\Sigma w_i PM_i)$$

Where: PM_n = the performance score for Alternative n
PM_i = the score for Performance Metric i

Therefore:

$$PM_n = (PM_1 + PM_2 + PM_3 + PM_4)$$

B.7 SEDIMENT

Resource Goal: Increase and retain fine sediment volume, area, and distribution in the Glen, Marble and Grand Canyon reaches above the elevation of the average base flow for ecological, cultural, and recreational purposes.

Performance Metrics

Two metrics were used to reflect sandbar area in Marble and Grand Canyons above 8,000 and 25,000 cfs using existing sediment modeling tools:

- **Sand Load Index.** The Sand Load Index was defined as the cumulative sand load transported by high flows (flows > 31,500 cfs) divided by cumulative sand load for entire alternative (range 0–1; higher index means a greater likelihood of larger sandbars).

- **Sand Mass Balance Index.** The Sand Mass Balance Index was defined as the mean annual sand mass balance between RM 0 and RM 61 (sand mass value, thousand metric tons; higher index means larger mass of sand in the river on average).

B.8 TRIBAL RESOURCES

A large number of resource goals have been identified in discussions with stakeholder Tribes. Although all of these goals are important to the Tribes, not all of the resources were affected by the alternatives being considered in the LTEMP EIS. In the discussion below, resource goals that are likely to differ across LTEMP alternatives (and so matter in the selection of a preferred alternative) are listed separately from resource goals that are not likely to differ across LTEMP alternatives.

For those resource goals that are likely to distinguish LTEMP alternatives, performance metrics are identified. Performance metrics are ways that the achievement of the resource goal might be measured; these were the metrics used to evaluate the alternatives in the EIS. For some of these resource goals, specific metrics that were amendable to quantifying differences among alternatives were not identified. Instead, the Tribes developed narrative evaluations of alternatives that were included in the EIS. Resource goals that would be evaluated in this way in the EIS are identified below.

1. *Increase the health of the ecosystem in Grand, Marble, and Glen Canyons*. The ecosystems in the Canyons is more than the sum of its parts, and should be healthy as a whole. Historically, in the Glen Canyon Dam Adaptive Management Program (GCDAMP), the overall health of the ecosystem has been determined by evaluating the status of each part, but this reductionist approach might possibly miss some important aspects. There are a variety of indicators of ecosystem health, including, but not limited to: the health of the

river and its ability to sustain life; the color of the water; the absence of contaminants, pollutants, and disease in the water; the potability of the water; the quality of the water that reaches Lake Mead; and the viability and health of wildlife and plants in the Canyons. It is important to understand that for many Tribes, the Colorado River is a sentient being and the spiritual center of the ecosystem, as it has the capability of giving and taking life, and it is prone to anger if mistreated; the health of the ecosystem depends on the health of the River.

This resource goal requires consideration of traditional ecological knowledge (TEK), and an evaluation of alternatives applying TEK was included in the narrative EIS analysis, but not the structured decision analysis.

2. *Protect and preserve sites of cultural importance*. There are specific sites within the Canyons that are important for cultural reasons and for preservation of Tribal/religious society/kiva group/clan history (e.g., shrines, sacred sites, ancient burial sites, springs, plant collection areas, mineral collection areas, offering places, and other elements). These sites can be threatened by erosion, loss of sediment inputs, and intrusive human use (especially, non-Tribal, outside visitors). Both flow and non-flow actions (e.g., education, permitting, research/monitoring, and interpretation) may affect these sites.

    a. Performance metric: *Wind Transport of Sediment Index* (see Section B.2). This index focuses on the availability of fine sediment for wind transfer to protect NRHP eligible or listed sites (see Archaeological and Cultural Resources).

        It should be noted that the sites and resources that are individually NRHP eligible or listed do not represent a full set of Tribal concerns. Tribal input was necessary to identify impacts to other culturally important sites or resources, and to develop an appropriate measure of their protection and preservation.

    b. Performance Metric: *Flow Effects on Historic Properties in Glen Canyon Index* (see Section B.2). In Glen Canyon, flow levels could affect resources through inundation (see Archaeological and Cultural Resources).

    c. Performance Metric: *Time Off River Index* (see Section B.2). In Grand Canyon, flow levels could increase the potential for discretionary time off the river for visitors, which could in turn result in an increased potential for archaeological sites to be visited and possibly adversely affected (see Archaeological and Cultural Resources).

d. Performance metric: *Riparian Diversity Index*. Using results from the "Riparian Vegetation" state and transition model, this metric employed the Shannon-Weiner Index for richness and evenness to compare relative changes in diversity of six vegetation states found on sandbars and channel margins. The equation for the Shannon-Weiner Index is:

$$-\sum_{i=1}^{n}(p_i)(\log_2 p_i)$$

where p_i is the proportion of the *i*th state of the total bar-years. The Riparian Diversity Index was the proportion of model run diversity divided by the initial diversity found on sandbars and channel margins.

e. Performance metric: *Marsh Habitat.* Using results from the "Riparian Vegetation" state and transition model, this metric modeled change in marsh habitat. This metric compared the modeled change in marsh vegetation states (clonal wet marsh and perennial marsh) for each alternative.

f. Performance metric: *Native Fish*. Temperature suitability reflects protection and preservation of a resource important to Tribes (see Section B.1.2).

g. Assessment: *Access to Springs.* For most Tribes, all springs and seeps are sacred. Access to culturally important springs may be affected by flow levels. Springs were evaluated in the EIS to determine if alternatives differ in terms of the ability of Tribes to access them under varying flow conditions.

3. *Preserve and enhance respect for life*. The Tribes see life itself as sacred and believe that human activities should protect and promote life, not destroy life. There are two aspects to this objective: first, minimize the taking of life; and second, encourage the expansion and proliferation of life forms. These are both complex concepts. The Tribes recognize that it is appropriate for humans to take other life in some circumstances, especially when it promotes other life (particularly our own consumption for survival), but this taking needs to be minimal and respectful because there are spiritual consequences associated with the taking of life. The promotion of life does not necessarily imply a return to historical or "natural" conditions—the Glen Canyon Dam has encouraged new life in Glen, Marble, and Grand Canyons, so a return to pre-Dam conditions is not necessarily implied by this objective, nor is there a strong distinction between native and nonnative species among all Tribes.

a. Performance metric: *The average number of years in which trout mechanical removal trips occur.* As a coarse measure of the impact of killing trout, this allows a distinction between alternatives that minimize mechanical removal. But the nature of the take, the purpose behind it, the methods of take, the disposition of the trout taken, and the mindset of those killing the fish also affect the sacred treatment of living beings. This performance metric was calculated from the coupled trout-humpback chub models.

b. Performance metric: *The average number of years in which trout management flows occur*. Trout management flows, designed to reduce reproduction or survival of juvenile trout, are considered to be killing by some Tribes, and should be minimized. Alternatives that include trout management flows are likely to differ in how often the flows are triggered, so this performance metric might ultimately help to distinguish the alternatives. This performance metric was calculated from the coupled trout-humpback chub models.

4. *Preserve and enhance the sacred integrity of Grand, Marble, and Glen Canyons*. Grand, Marble, and Glen Canyons are sacred to many Tribes, and the preservation of their sacred integrity is important. The sanctity of the Canyons may be threatened by human impacts and behaviors, development, and the presence of artificial structures and activities. An important aspect of the sanctity is the intentionality of visitors: when outsiders enter the Canyons (on boat or hiking trips), the respect they show to the Canyons and Colorado River can affect the spiritual integrity. There are many consequences of the disturbance of this sanctity, including, but not limited to, a reduction of the spiritual strength of plants gathered and used by the Navajo for medicinal and cultural purposes; an inability to retire Navajo sacred objects into the Colorado River when they have become too old for continued use; weakening of the sacred role the Canyons play as a final resting place for Hopi; and an overall disruption of the state of mind and spirit of Zuni religious leaders and their experience of being within a very sacred place that embodies the Zuni emergence, migrations, creation of medicine bundles, and the communion with the spirits of Zuni ancestors.

a. Assessment: This resource goal, while of profound importance to the Tribes, is not thought to differ measurably across the alternatives under consideration in the LTEMP EIS, because it is not driven by flow operations from the dam or currently envisioned attendant activities. Future science plans could include activities that are objectionable to the Tribes. Future science planning should include meaningful consultation with the Tribes. This goal was evaluated in the narrative EIS analysis, but not the structured decision analysis.

5. *Maintain and enhance healthy stewardship opportunities*. Several of the Tribes have been given a sacred stewardship responsibility for the preservation and harmony of the world. For example, the Hopi have a covenant with *Ma'saw* to be stewards of the earth; other Tribes have similar stewardship ethics grounded in spiritual traditions. To maintain these stewardship responsibilities, the Tribes need to be an active part of stewardship of the Canyons. This stewardship includes ceremonial activities, whether performed in the Canyons or in the villages; participation in management of the Canyons, including water management, both through traditional practices and Western management activities; and education, to maintain cultural knowledge and connection with the Canyons. The Tribes note that the federal government also has stewardship responsibilities that arise out of federal legislation; because this federal involvement has sometimes taken stewardship responsibility from the Tribes, it is critical that the federal government be accountable for its stewardship. At times, the colonial presence of the federal government has made it more difficult for Tribes to carry out their stewardship responsibilities; the Tribes need the autonomy to undertake their responsibilities. Successful development of joint stewardship among the Tribes and federal government will require continued building of mutual respect and trust between those entities.

    a. Assessment: Tribal stewardship opportunities are not tied to individual alternatives being considered in the LTEMP EIS, but could be crafted to apply to any of the alternatives. Thus, this resource goal, while of critical importance to the Tribes individually, as well as to the ongoing relationship between the Tribes and the federal government, may not help distinguish among the alternatives. This goal was evaluated in the narrative EIS analysis, but not the structured decision analysis.

6. *Maintain and enhance the Tribal connections to the Canyons*. The spiritual, historical, and cultural connections that Tribes have to the Canyons require the protection of sacred sites and the integrity of the Canyons as a whole, but protection alone is not enough. The Tribes also need opportunities for access, education, and stewardship to keep their connections vibrant. Access can be undermined by physical barriers, by the requirement of permits from a colonial authority, and by the effects of human activity that decrease the power of those sites and the experience when at them (e.g., lack of privacy, disturbance of the soundscape and viewshed).

    a. Assessment: Like the sacred integrity and stewardship resource goals, this resource goal is not thought to differ across the alternatives. The flow operations of Glen Canyon Dam are not likely to affect Tribal access, education, spiritual ceremonies, or other connections to the Canyons. This resource goal may be more appropriately addressed through government-to-government consultation in other forums. This goal was evaluated in the EIS, but not the structured decision analysis.

7. *Increase economic opportunity*. The Canyons, the Colorado River, and the dam are sources of economic benefit for the Tribes in the area. The Canyons provides tourism and other opportunities that enhance the economic well-being of Tribes. (As an important note, tourism can also undermine the well-being of Tribes in aspects other than economic; see the other Tribal resource goals.). Glen Canyon Dam provides affordable electricity for Tribal needs, as well as for development projects.

    a. Assessment: *projected annual economic benefit for the Hualapai Tribe associated with river-running tourism.* During discussions with Tribal representatives, one particular economic concern was raised by Hualapai river runners, namely, the effect on tourism operations of extensive sediment deposition downstream of Diamond Creek. There is a narrative analysis of the effect of dam operations on Hualapai River running in the EIS.

    b. Assessment: Note that the economic benefit directly associated with hydroelectric power is measured through the hydroelectric performance metrics. A recreation economics model was used to determine the value of recreational use of Lake Powell, Lake Mead, and the Colorado River downstream of Glen Canyon Dam.

8. *Maintain Tribal water rights and supply*. Tribes in the area depend on the Colorado River for many of their water needs, so the preservation of established, traditional, and desired water rights, both now and into the future, is important. There are a number of claims to water rights that have been asserted by the Tribes, but for which there are not yet quantified rights through decree or negotiated settlement; these water rights are as important as the established water rights.

    a. Sidebar for LTEMP EIS alternatives: based on its purpose and need, the LTEMP EIS is not intended to include any alternatives that violate agreed-upon Tribal water rights.

    b. Performance metric: *Lake Powell water elevation.* This metric evaluates the frequency with which Lake Powell elevations drop below critical levels where existing or proposed intakes are.

9. *Process objectives*. There are several important process objectives—objectives that govern *how* the LTEMP decision is made, rather than what decision is made. The first of these is the genuine incorporation of Tribal input to the LTEMP process, as a reflection of Federal trust responsibilities. The second is the importance of incorporating learning, to improve management over time; in this spirit, an experimental approach that can result in adaptive management is favored.

a. Assessment: (a) It is the intention of the U.S. Department of the Interior and the joint-lead federal agencies to genuinely incorporate Tribal input into the LTEMP process, and this has been undertaken through face-to-face meetings with individual Tribes who have requested such meetings, as well as regular conference calls with Tribal representatives. The Tribes are included in all Cooperating Agency and stakeholder meetings. Continued involvement of Tribes in the LTEMP process will occur. (b) The evaluation of experimental alternatives and the development of a long-term monitoring program associated with the LTEMP EIS will occur in a later stage of analysis. The purpose and need for the EIS include the appropriate incorporation of learning. Thus, this resource goal is an important part of how the process was designed for LTEMP, but it does not help distinguish among the alternatives (because the alternatives do not differ in this regard).

B.9 WATER DELIVERY

Resource Goal: Ensure that water delivery continues in a manner that is fully consistent with and subject to the Colorado River Compact, the Upper Colorado River Basin Compact, the Water Treaty of 1944 with Mexico, the decree of the Supreme Court in *Arizona v. California*, and the provisions of the Colorado River Storage Project Act of 1956 and the Colorado River Basin Project Act of 1968 that govern allocation, appropriation, development, and exportation of the waters of the Colorado River Basin.

Calculated Metrics (not used in the structured decision analysis process)

- Frequency of deviation from Alternative A (No Action Alternative) to Lake Powell Annual Operating Tier as specified by the 2007 Interim Guidelines (Reclamation 2007). The Operating Tier was predicted using the CRSS RiverWare model.

- Probability over time of Lake Powell being in each Operating Tier as specified in the 2007 Interim Guidelines (Reclamation 2007). The Operating Tier was predicted using the CRSS RiverWare model.

- Frequency and volume of exceptions to meeting the annual release target volumes specified by the 2007 Interim Guidelines (Reclamation 2007). The target and actual annual release volumes were predicted using the CRSS RiverWare model.

Acknowledgments

A project this large owes a debt of gratitude to many people who generously offered their support, insights, and expertise. The authors thank Anne Castle and Lori Caramanian from the Department of the Interior for their vision and support for the inclusion of decision analysis methods in the development of the Environmental Impact Statement. Ted Melis (U.S. Geological Survey Grand Canyon Monitoring and Research Center) provided extensive insights during the first 2 years of this project, helping shape the design of this analysis. Jack Schmidt and Scott VanderKooi (U.S. Geological Survey Grand Canyon Monitoring and Research Center) shared their expertise and leadership, and provided access to the scientific experts at their Center.

This project required expertise from many agencies outside of the U.S. Geological Survey. Too numerous to list here, the many members of the subject-matter expert teams provided critical input to the development of performance metrics and the quantitative evaluation of alternatives. The efforts to articulate and attempt to quantify tribal viewpoints would have been impossible without the dedication and expertise of many representatives, including Kurt Dongoske (Pueblo of Zuni), Mike Yeatts (Hopi Tribe), Loretta Jackson-Kelly and Peter Bungart (Hualapai Tribe), Charley Bulletts (Southern Paiute Consortium), Robert Kirk and Tony Joe (Navajo Nation), and Sarah Rinkevich (U.S. Fish and Wildlife Service). Terry Walshe and David Smith provided insightful comments on an earlier draft of this report. Rich Valdez and Carl Walters shared their depth of knowledge and astute perspectives on many aspects of the Grand Canyon ecosystem. The authors are deeply grateful to the representatives from the stakeholder agencies who participated in the swing-weighting exercise; and worked diligently, enthusiastically, and with integrity to share their perspectives.

Funding for this project was provided by the Bureau of Reclamation.

Knowles[3]

1 Abstract

The U.S. Geological Survey, in cooperation with the Bureau of Reclamation, National Park Service, and Argonne National Laboratory, completed a decision analysis to use in the evaluation of alternatives in the Environmental Impact Statement concerning the long-term management of water releases from Glen Canyon Dam and associated management activities. Two primary decision analysis methods, multicriteria decision analysis and the expected value of information, were used to evaluate the alternative strategies against the resource goals and to evaluate the influence of uncertainty.

A total of 18 performance metrics associated with 8 out of 12 resource goals (fundamental objectives) were developed by the Bureau of Reclamation and National Park Service in partnership with subject-matter teams composed of Federal, State, tribal, and private experts. A total of 19 long-term strategies associated with 7 alternatives were developed by the Bureau of Reclamation, National Park Service, Argonne National Laboratory, U.S. Geological Survey, and Cooperating Agencies. The 19 long-term strategies were evaluated against the 18 performance metrics using a series of coupled simulation models, taking into account the effects of several important sources of uncertainty. A total of 27 Federal, State, tribal, and nongovernmental agencies were invited by the Assistant Secretary of Interior to participate in a swing-weighting exercise to understand the range of perspectives about how to place relative value on the resource goals and performance metrics; 14 of the 27 chose to participate. The results of the swing-weighting exercise were combined with the evaluation of the alternatives to complete a multicriteria decision analysis. The effects of uncertainty on the ranking of long-term strategies were evaluated through calculation of the value of information.

The alternatives and their long-term strategies differed across performance metrics, producing unavoidable tradeoffs; thus, there was no long-term strategy that was dominated by another across all performance metrics. When the performance of each alternative was weighted across performance metrics, three alternatives (B, D, and G) were top-ranked depending on the set of weights proposed: Alternative B was favored by those stakeholders that placed a high value on hydropower; Alternative G was favored by those stakeholders that placed a high value on the restoration of natural processes, like beach-building and natural vegetation; and Alternative D was favored by the remaining stakeholders. Surprisingly, these rankings were not sensitive to the critical uncertainties that were evaluated; that is, the choice of a preferred long-term strategy was sensitive to the value-based judgment about how to place relative weight on the resource goals but was not sensitive to the uncertainties in the system dynamics that were evaluated in this analysis. The one area of uncertainty that did slightly affect the ranking of alternatives was the long-term pattern of hydrological input; because of this sensitivity, some attention to the possible effects of climate change is warranted.

The results of the decision analysis are meant to serve as only one of many sources of information that can be used to evaluate the alternatives proposed in the Environmental Impact Statement. These results only focus on those resource goals for which quantitative performance metrics could be formulated and evaluated; there are other important aspects of the resource goals that also need to be considered. Not all the stakeholders who were invited to participate in the decision

analysis chose to do so; thus, the Bureau of Reclamation, National Park Service, and U.S. Department of Interior may want to consider other input.

2 Introduction

The Glen Canyon Dam is on the Colorado River in Arizona, United States, within the boundaries of Glen Canyon National Recreation Area and upstream from Grand Canyon National Park (fig. 1) and is managed by the Bureau of Reclamation (hereinafter referred to as "Reclamation"). The Glen Canyon Dam Adaptive Management Program (GCDAMP) was established in 1997 to provide research and monitoring of downstream resources to Reclamation and the U.S. Department of the Interior (DOI). The GCDAMP project area stretches along the Colorado River from the forebay of Glen Canyon Dam to the westernmost boundary of Grand Canyon National Park. Locations along the Colorado River are indexed by river miles (RM) with a reference point at Lees Ferry (RM 0). The Glen Canyon Dam is at RM -15.5 (15.5 mi upstream from Lees Ferry). Other important locations that are referenced in this report include the following: Paria River (RM 1.0), Little Colorado River (RM 61.4), and Bright Angel Creek (RM 87.8) (fig. 1). The reach from Glen Canyon Dam to Lees Ferry is known as Glen Canyon, the reach from Lees Ferry to the Little Colorado River is known as Marble Canyon, and Grand Canyon proper begins at the Little Colorado River.

In October 1996, the Secretary of the Interior signed a Record of Decision (ROD) documenting the selection of operating criteria for Glen Canyon Dam (Bureau of Reclamation, 1996) as analyzed in the 1995 Final Environmental Impact Statement (Bureau of Reclamation, 1995). The preferred alternative, known as Modified Low Fluctuating Flow (MLFF), has governed the operation of Glen Canyon Dam for the last 19 years (1996 to present) with important modifications described in "Final Environmental Impact Statement—Colorado River interim guidelines for lower basin shortages and the coordinated operations for Lake Powell and Lake Mead" (Bureau of Reclamation, 2007), "Environmental Assessment—Development and implementation of a protocol for high-flow experimental releases from Glen Canyon Dam" (Bureau of Reclamation, 2011a), "Environmental Assessment—Non-native fish control downstream from Glen Canyon Dam" (Bureau of Reclamation, 2011b), and many other regulatory documents. The Bureau of Reclamation (1996) also established the GCDAMP and Grand Canyon Monitoring and Research Center (GCMRC), which has led extensive monitoring and research aimed to improve the management of the Colorado River and its environs below Glen Canyon Dam.

In July 2011, the Secretary of the Interior announced the intent to develop a Long-Term Experimental and Management Plan (LTEMP) and Environmental Impact Statement (EIS) for Glen Canyon Dam as the first comprehensive review of dam operations in 15 years and as an opportunity to integrate the considerable scientific information collected since the GCDAMP began in 1996. The Bureau of Reclamation and National Park Service (NPS) are serving as joint-lead agencies for the EIS. The following agencies are participating as Cooperating Agencies in development of the EIS: Arizona Game and Fish Department (AGFD), Bureau of Indian Affairs (BIA), Colorado River Board of California, Colorado River Commission of Nevada, the Havasupai Tribe, the Hopi Tribe, the Hualapai Tribe, the Kaibab Band of Paiute Indians, the Navajo Nation, the Pueblo of Zuni, Salt River Project (SRP), U.S. Fish and Wildlife Service (FWS), Upper Colorado River Commission, Utah Associated Municipal Power Systems (UAMPS), and Western Area Power Administration (WAPA).

The purpose of the LTEMP is to provide a comprehensive framework for adaptively managing Glen Canyon Dam over the next 20 years consistent with the Grand Canyon Protection Act of 1992 (GCPA) and other provisions of federal law (Bureau of Reclamation and National Park Service 2015); thus, the preferred alternative ultimately selected for the LTEMP will govern the management of water releases at Glen Canyon Dam for the next 20 years, specifying condition-dependent seasonal, weekly, and daily patterns of release, as well as nonflow actions, including vegetation management and the potential for mechanical removal of nonnative fish. The goals for the LTEMP are to meet the requirements of the GCPA; and to minimize, consistent with the law, adverse effects on the downstream natural, recreational, and cultural resources in Glen Canyon National Recreation Area and Grand Canyon National Park, including resources of importance to American Indian Tribes, while ensuring water delivery and maintaining or increasing hydroelectric capacity and generation. The need for the LTEMP arises from scientific information developed since the 1996 record of decision (Bureau of Reclamation, 1996), the use of which will better inform DOI decisions on dam operations and other management and experimental actions so that the Secretary of the Interior may continue to meet statutory obligations to protect resources downstream from Glen Canyon Dam for future generations, conserve species listed under the Endangered Species Act of 1973 (ESA), avoid or mitigate effects on National Register eligible properties, and protect tribal interests, while meeting water delivery obligations and providing hydropower generation. The list of resources of concern in the analysis of alternatives includes the following: tribal resources and interests, sediment deposition and retention, riparian vegetation, humpback chub (HBC) (*Gila cypha*) and other native fish, historic properties, recreation, the rainbow trout fishery in Glen Canyon, water delivery, and hydropower. There is uncertainty about how management actions in this system affect the resources of concern, which complicates the analysis of alternatives. There is an acknowledged need for adaptive management (Walters, 1986), perhaps even for experimental actions chosen to accelerate learning for the benefit of selecting future management actions. The decision problem, therefore, can be characterized as one of multiple objective tradeoffs in the face

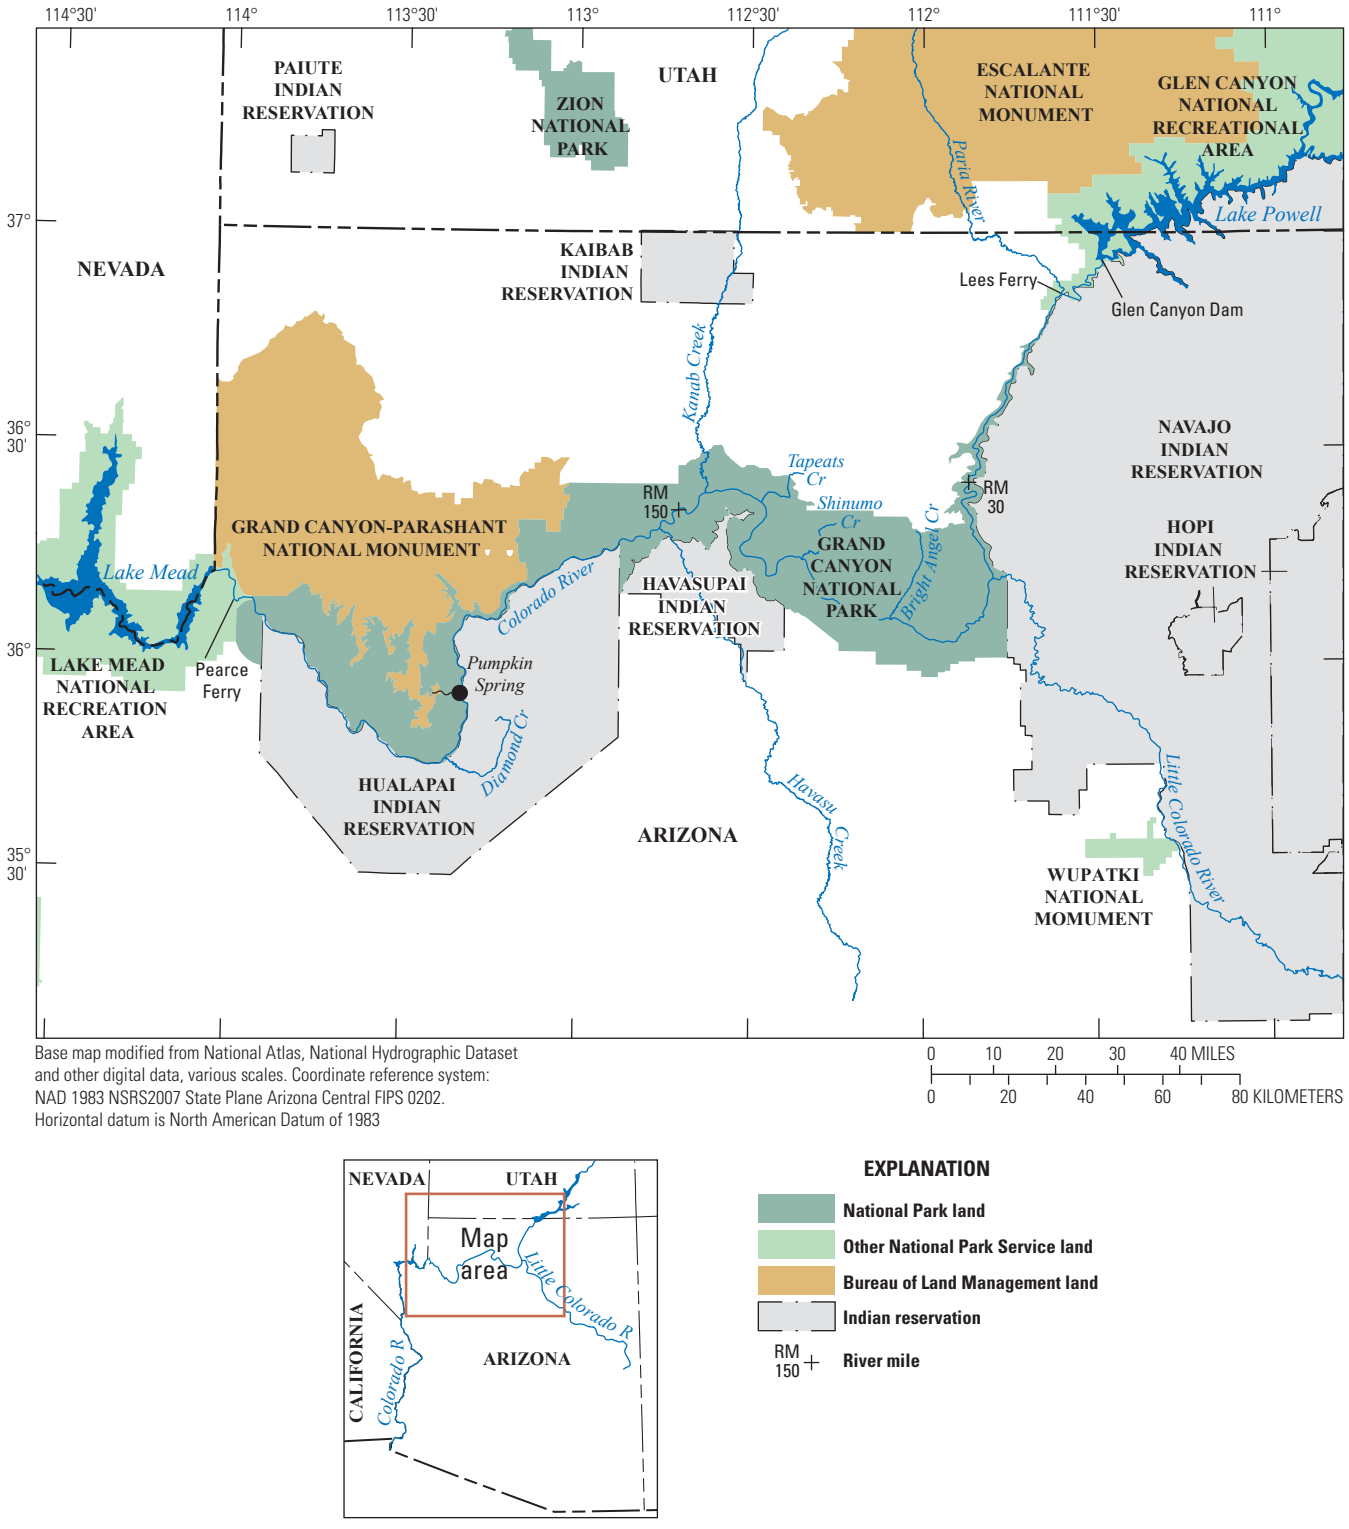

Figure 1. The Colorado River ecosystem below Glen Canyon Dam, depicting the Glen Canyon Dam Adaptive Management Program project area.

of uncertainty, where the management actions themselves are condition-dependent, information-dependent, and complex; and where there is the opportunity to reduce uncertainty early on to improve later actions through adaptive implementation.

In July 2012, the Assistant Secretary of the Interior for Water and Science, Reclamation, and NPS embraced the idea of using structured and formal decision analysis as one of several tools to evaluate alternatives in this EIS. Formal decision analysis was seen as a way to address multiple objectives, engage stakeholders, and evaluate the degree to which uncertainty is an impediment to the selection of management actions.

The purpose of this report is to document the formal decision analysis completed by the U.S. Geological Survey, in cooperation with the Bureau of Reclamation, National Park Service, and Argonne National Laboratory, as one component of the evaluation of alternatives for the LTEMP EIS. This report is a stand-alone document and an appendix to the Draft EIS (Bureau of Reclamation and National Park Service, 2015); it is also anticipated to be an appendix to the Final EIS. The emphasis in this report is on the decision analysis; the reader is referred to the Draft EIS (DEIS) and its appendixes for many other details, including the following: the legal, ecological, and cultural context of the LTEMP; an indepth description of the alternatives; the details of the quantitative models used to evaluate the alternatives; and a comprehensive comparison of the alternatives and their effects on resources of concern, including qualitative assessments that were not included in the decision analysis.

3 Decision Analysis

The DOI is including formal decision analysis tools to accompany more traditional qualitative tools to evaluate alternatives in the Glen Canyon Dam LTEMP EIS. The LTEMP EIS concerns the management of a very complex system with many, possibly competing, resources of interest and considerable uncertainty about the relations between management strategies and the responses of resources of interest to management strategies; furthermore, there are multiple stakeholder viewpoints to consider, and the DOI wants to use a structured process as one of the tools for better evaluating and understanding stakeholder viewpoints. This section provides an overview of decision analysis and describes the quantitative methods the DOI used to analyze the alternatives.

3.1 Structured Decision Making

"Structured decision making" (SDM) is a term of art, used by a community of practitioners in the United States, Canada, and Australia, to refer to the application of a broad array of decision analysis tools to natural resource management (Gregory and others, 2012). The analytical tools used in any application will depend on the specific needs of that decision setting, so SDM can look quite different from case to case. The set of analytical tools that might be used include the following: multicriteria decision analysis (MCDA), decision trees, expert elicitation, objectives hierarchies, value of information, stakeholder involvement, predictive modeling, utility theory, dynamic optimization, portfolio analysis, and many others. The common features in any application of decision analysis are (1) an attention to value-focused thinking (Keeney, 1996), recognizing that any decision is an attempt to achieve something of value to the decision maker; and (2) decomposing the decision problem into basic elements (objectives, alternatives, consequences, and tradeoffs) (Runge, 2011). The goal of SDM is to provide a transparent process for articulating objectives, developing alternatives, and evaluating those alternatives against the objectives. Note, however, that SDM does not substitute for a decision maker, and the application of the SDM process does not make a decision; rather, SDM only serves to aid the decision maker in understanding and organizing the complexities of the problem. The DOI prefers to use the term "structured decision analysis" or simply "decision analysis" for the LTEMP EIS process because the Secretary of the Interior retains the responsibility and authority to make a decision. In the context of the LTEMP EIS, two key decision analysis tools are used to evaluate the alternatives: MCDA and the expected value of perfect information (EVPI).

3.2 Multicriteria Decision Analysis

Many objectives associated with management of Glen Canyon Dam are important to stakeholders, including tribal cultural and spiritual values, endangered species, hydropower generation, sediment conservation, and recreation. It is possible that some of these objectives compete; if so, no single strategy will be best at achieving all the objectives. One of the difficulties the decision maker faces, then, is the value judgment regarding how to weight this host of objectives based on the many statutes governing Glen Canyon Dam operation and resource protection. Multicriteria decision analysis is a formal decision analysis tool designed to help evaluate the competing objectives and explore how to weight them within the context of the statutes (Figueira and others, 2005), and has been applied to a wide variety of natural resource management problems (Herath and Prato, 2006). Considerable literature advocates the use of MCDA in National Environmental Policy Act (NEPA) processes (Gregory and others, 1992; Kulkarni and others, 1993; Prato, 1999; Sheehy and Vik, 2002; Kiker and others, 2005; Linkov and others, 2006a, 2006b, 2006c; Stich and Holland, 2011; Marcot and others, 2012). Although not common, a few examples of NEPA documents explicitly incorporate MCDA methods (National Oceanic and Atmospheric Administration, 1995a, 1995b; Kimbrough and others, 2008; Nobrega and others, 2009; Bureau of Reclamation, 2011b; Runge and others, 2011a). Notably, the value of using MCDA for evaluation of management alternatives for Glen Canyon Dam has been argued by Flug and others (2000).

One of the key advantages of MCDA in the context of the LTEMP EIS is that it provides a structured and transparent method for receiving detailed stakeholder input about the resource goals, ways to evaluate performance of the alternatives against the resource goals, and the value of resource goals relative to each other. Stakeholders have legitimate differences in viewpoint about the relative importance of the objectives affected by the LTEMP alternatives, differences that stem from policy judgments rather than scientific judgments. Multicriteria decision analysis provides a way for stakeholders to articulate those judgments. By clearly understanding those different viewpoints, Reclamation and NPS (hereinafter referred to as the "joint-lead agencies") were better able to analyze and compare the alternatives and ultimately advise the Secretary of the Interior regarding her choice of a preferred alternative. In selecting a preferred alternative, the Secretary of the Interior needed to consider the appropriate suite of laws, regulations, agency guidance, and policies; the language in the purpose and need statement; stakeholder input; and the public input at various points in the process. The MCDA helped organize at least part of that complex input.

3.2.1 A Full Articulation of Resource Goals

The first step in a MCDA is a full articulation of the resource goals important to the decision maker, stakeholders, and the public. The set of resource goals should be (1) complete because it should cover the full range of concerns relevant to the decision; (2) concise because it should not contain redundant or irrelevant resource goals; (3) sensitive so that the resource goals are able to distinguish the performance of the alternatives under consideration; (4) understandable so that the resource goals directly communicate what matters; and, if possible, (5) independent so that the resource goals describe unique aspects of the problem (Gregory and others, 2012). The completeness of the set of resource goals is often very important because it provides objectivity and transparency to otherwise invisible values (Turner and others, 2008).

In an MCDA, the focus of the resource goals should be should be on objectives that are fundamental (called "fundamental objectives") to the decision maker, stakeholders, and public. Fundamental objectives, as distinguished from means objectives, are objectives that are important in their own right—they are the desired outcomes of the decision, not because they lead to something else of importance but because of their inherent value. Means objectives are pursued as a pathway to fundamental objectives but are not themselves of inherent value to the decision maker; for example, a high juvenile survival rate of HBC is important as a means to achieving a sustainable population of HBC in the Colorado River below Glen Canyon Dam, but juvenile survival is not itself the objective that the decision maker fundamentally cares about. Achieving population sustainability with low or moderate juvenile survival rates of HBC, if possible, would be acceptable; thus, the fundamental objective concerns population sustainability.

The joint-lead agencies, in consultation with the tribes and Cooperating Agencies and with input from public scoping comments, developed a set of resource goals, which represent the fundamental objectives to be pursued in the LTEMP EIS. Some of these resource goals are closely aligned with the desired future conditions (DFCs) developed by the Adaptive Management Working Group (AMWG); and are grounded in the laws, regulations, and policies relevant to the joint-lead agencies. In a few instances, the resource goals differ from the DFCs to more clearly identify a set of fundamental objectives for the specific context of the LTEMP EIS that meet the characteristics described previously in this section (complete, concise, sensitive, understandable, and independent). In a parallel effort, the joint-lead agencies worked directly with interested tribes to develop resource goals that are specific to tribal perspectives.

3.2.2 Performance Metrics

Performance metrics are scales of measurement on which the fundamental objectives (resource goals) can be evaluated. By developing performance metrics that are closely tied to the resource goals, the assessment of alternatives can include a quantitative, rather than solely narrative, analysis. Also, articulation of performance metrics forces considerable clarity about the resource goals; thus, using performance metrics encourages a high degree of transparency in the analysis of alternatives. It is difficult, however, to express all the resource goals in quantitative form. The use of performance metrics, therefore, does not preclude use of narrative analyses to evaluate additional resource goals in a NEPA process.

Ideally, performance metrics should directly reflect the resource goals, but this is often very difficult to achieve because the resource goals can be subtle, nuanced, complex, and difficult to quantify. There are also cases where a desired performance metric can be articulated, but the scientific tools do not exist to predict the performance of alternatives on that scale; thus, development of performance metrics is a very important science-policy interface. For the management agency, the desire is to have performance metrics that closely track the corresponding resource goals, but for the scientists, the desire is to have performance metrics that can be predicted with high confidence. When the difference between these desires is large, the question is how far the quantitative assessment can stretch toward the desired performance metric while maintaining a robust scientific foundation. There is, of course, a tendency to want to use proxy metrics that can be reliably predicted (for example, temperature as a proxy for HBC recruitment), but this only shifts a difficult burden to the decision maker who has to then make invisible judgments about how closely the proxy aligns with the underlying resource goal. The performance metrics developed for this decision analysis span the gamut from direct, natural measures of resource goals to distant proxies, depending on the science available to support their assessment. An effort has been made

to transparently articulate the relation between each performance metric used and the resource goal it represents.

The joint-lead agencies in conjunction with subject-matter expert (SME) teams from all relevant disciplines developed performance metrics corresponding to the resource goals that were used as the scales on which alternatives were quantitatively evaluated. During the course of development, the joint-lead agencies sought feedback on draft performance metrics from the Cooperating Agencies, tribes, and other stakeholders.

3.2.3 Transparent and Quantitative Evaluation of Alternatives

As part of the effects analysis for the LTEMP EIS, and as a supplement to the traditional narrative analysis, Argonne National Laboratory (hereinafter referred to as "Argonne") and collaborators completed quantitative analyses of the alternatives against the performance metrics. These quantitative analyses are an exercise in forecasting—predicting the relative performance of the alternatives against the resource goals using the best available science. In some cases, existing models were available for this task; in other cases, new predictive models were developed; and in still other cases, formal methods of expert elicitation (Martin and others, 2012) were needed. But, in all cases, the methods for assessing the alternatives provide transparency to the evaluation.

The ecological, economic, and social systems being evaluated in the LTEMP EIS are complex, and even though the systems are some of the best studied systems in the world, they are nevertheless incompletely understood; thus, the models used to predict performance of the alternatives were necessarily simplifications of the real world and had to account for uncertainty. Specific details about how uncertainty was handled in the decision analysis are described in section 3.3, "Uncertainty, Value of Information, and Adaptive Management."

A traditional, narrative evaluation of alternatives has to make all the same assumptions as a quantitative evaluation does. The use of a quantitative approach raises the degree of transparency about these assumptions and allows better inspection by interested parties. Also, quantitative analysis of the alternatives provides the raw material for later steps in a decision analysis.

3.2.4 Tradeoff Analysis

The outcome of the assessment phase can be viewed as a "consequence table"—a summary of how each alternative is expected to perform against each resource goal (as expressed by the corresponding performance metric). That assessment phase is a scientific endeavor—an evaluation of the current knowledge of the system to forecast how the system will respond to any proposed alternative. The consequence table provides a visual way to compare the alternatives and is an important analytical and communication step. Selection of a preferred alternative involves a policy choice based on sound science, which requires a values judgment about how to comply with the laws applicable to the proposed action while achieving a multitude of fundamental objectives, particularly if there are tradeoffs among the objectives. Some fundamental objectives, because of legal and policy considerations, may take precedence over other objectives; the remaining objectives need to be balanced appropriately. The joint-lead agencies, in evaluating the alternatives and providing a recommendation to the Secretary of the Interior, wanted to understand how Cooperating Agencies and other stakeholders would individually value the range of resource goals. This structured input was not the only consideration; in the NEPA process, decisions are also informed by the legal and policy framework, including relevant laws, regulations, agency policies and guidance, court cases, consultation with tribes, and public comment at various points in the process.

Multicriteria decision analysis provides tools for eliciting and investigating the values judgments associated with balancing tradeoffs. There are a variety of MCDA methods; we used the Simple Multi-Attribute Rating Technique (SMART) (Edwards, 1971; Goodwin and Wright, 2004) with swing weighting (Winterfeldt and Edwards, 1986). Stakeholders were asked to individually complete a swing-weighting exercise to express how they valued the resource goals relative to one another, while accounting for the range in performance across alternatives. The weights derived were combined with the consequence table to rank the alternatives from the viewpoint of each participating stakeholder. These individual viewpoints were provided as input to the joint-lead agencies and are documented in this report.

3.3 Uncertainty, Value of Information, and Adaptive Management

The second major set of tools from decision analysis that were used in the development and assessment of alternatives for the LTEMP EIS concern how to articulate, evaluate, and address uncertainty in an adaptive design. The primary analytical tool that informed this process is the expected value of information (Raiffa and Schlaifer, 1961; Howard, 1966). In a decision analysis context, the value of information is the best method for sensitivity analysis (Felli and Hazen, 1998). Runge and others (2011b) describe how the value of information can be used to design an adaptive management program that focuses on finding the best management strategy (rather than reducing the most uncertainty).

3.3.1 Adaptive Management Versus Experimental Management

Several different schools of adaptive management, which differ in their emphasis on various decision analysis tools and approach to experimental design, exist (McFadden and others, 2011). All the schools trace their lineage back to Walters

(1986), but their current approaches can look very different. In the Resilience-Experimentalist (RE) school of adaptive management, emphasis is placed on experimental design focused on policy choices (management alternatives) as the elements of uncertainty. To some extent, the RE school is most focused on "unknown unknowns"—uncertainty that cannot be anticipated in advance—and, therefore, advocates robust experimental designs composed of management alternatives to provide accelerated learning about the system dynamics in response to management. This accelerated learning might not be formally linked to subsequent long-term management planning because of a sense that there is too much hubris in making long-term plans when so much surprise is expected. The RE school perhaps draws more inspiration from Walters and Holling (1990) than from the seminal text (Walters, 1986). Examples of adaptive management that are often associated with the RE school include management in the Columbia River Basin, water management in the Everglades, and past management in the GCDAMP (McFadden and others, 2011).

In the Decision-Theoretic (DT) school of adaptive management, the emphasis is placed on a priori articulation of uncertainty through alternative hypotheses about system response to management and derivation of optimal strategies that solve the "dual-control problem" of achieving long-term management objectives by balancing the benefits and costs of learning in the short term. The DT school is most focused on known unknowns—uncertainty that can be explicitly articulated—and, therefore, advocates adaptive design that seeks resolution of this uncertainty but only to the degree that such resolution will improve future management. Learning is explicitly linked to future management decisions by associating particular courses of action with the degree of evidence in support of the alternative hypotheses; in this way, long-term management is articulated as part of the adaptive program, so the natural transition from experimentation to implementation is specified up front. The tenets of the DT school are arguably a more direct expression of Walters (1986) than other schools of adaptive management. The example most commonly associated with the DT school is the adaptive harvest management of mallards in North America (Johnson and others, 1997).

It seemed appropriate that the 1995 Glen Canyon Dam Final EIS and the GCDAMP embraced an RE school approach to adaptive management. At the time, there was very significant uncertainty about the dynamics of the Colorado River system below Glen Canyon Dam, so an approach that emphasized learning about unknown unknowns made sense. Several policy experiments have been completed, and a great deal has been invested in research; together these have greatly advanced the state of knowledge. It would have been difficult in 1995 to anticipate all the discoveries and specify clearly how and when management of Glen Canyon Dam would move from an experimental phase to a long-term implementation phase. The current question for the joint-lead agencies is if the last two decades of research and experimentation have generated enough knowledge to allow the articulation of uncertainty as known unknowns and pursue a DT school approach to adaptive management. The joint-lead agencies believe this is the case, and approached the development of the LTEMP EIS with this philosophy in mind.

3.3.2 Articulating Uncertainty as Competing Hypotheses

For many, if not all, of the resource goals, the performance of the alternatives is uncertain. Some of that uncertainty can be captured simply by including estimates of variance around the forecasts, but some uncertainty is pervasive enough that it could change the ranking of the alternatives relative to a particular resource goal and, thus, could impede the identification of a preferred alternative. For these critical uncertainties, the SME teams characterized the uncertainty in the predictive models as a set of competing hypotheses. The focus of the uncertainty was on the mechanisms or parameters in the models, not on a holistic statement of uncertainty about whether a particular management intervention will work or not; thus, for example, rather than state the uncertainty as whether or not a particular management alternative will build and sustain beaches, the uncertainty was expressed as competing hypotheses about the long-term rate of sediment input from the Paria River. Likewise, whether trout management flows (TMFs) work or not was expressed as competing hypotheses about the rate of recruitment of juvenile rainbow trout when TMFs are used.

Development of competing hypotheses to capture critical uncertainty is challenging. It requires very deliberative thought about the limits of knowledge and the nature of uncertainty that would affect the ranking of management alternatives. To do so with a small number of discrete hypotheses requires a simplification of the full degree of uncertainty. But careful thought along these lines allows a transparent and explicit statement of the uncertainty that is the focus of experimental and adaptive design. In a NEPA context, such explicit articulation of critical uncertainty allows full disclosure of the motivation for experimental design and explanation of how subsequent management will respond to newfound knowledge.

3.3.3 Deconstructing Complex Alternatives

Several of the alternatives under consideration in the DEIS (especially Alternatives C, D, and E; see explanations of each in the "Alternatives" sections 5.4, 5.5, and 5.6) include, either explicitly or implicitly, complex experimental or adaptive designs (see, for example, figs. 2–13 and 2–14 in Bureau of Reclamation and National Park Service, 2015). These strategies prescribe different management interventions depending on state and information conditions. It is particularly important to distinguish state-dependent triggers from information-dependent triggers. State-dependent triggers are conditions of the state of the system that would lead to implementation of a different management action, primarily in recognition that the Colorado River is a stochastic ecosystem, and it is important

to be able to respond to natural variation. Most obviously, all the alternatives contain state-dependent triggers under the Bureau of Reclamation (2007) guidelines that specify, among other parameters, the annual volume for water release from Glen Canyon Dam. Other state-dependent triggers are designed to guard against chance reductions in HBC or other resources of concern. State-dependent triggers are in contrast to information-dependent triggers, which are indications that the state of knowledge has changed substantially and a new approach to management is warranted; for example, Alternatives C and E propose experimental implementation of TMFs, and it is at least implicit in both that if those TMFs are ineffective in reducing downstream migration of rainbow trout from Lees Ferry, they would be discontinued. This is an information-dependent trigger. To the extent possible, information-dependent triggers should be explicit in that they specify the weight of evidence that would be needed on one hypothesis or another to induce a change in management strategy.

A complex experimental or adaptive strategy can be viewed as a portfolio of simpler strategies combined and implemented in a manner to reduce critical uncertainty, with the ultimate intention to implement one of the simpler strategies as the operational standard in the long term. The information-dependent triggers govern the switch between these simpler strategies. To evaluate such a complex design, the first step is to understand what the simpler strategies are; thus, the complex strategies were deconstructed into simpler long-term strategies, each of which might have state-dependent triggers but not information-dependent triggers. In other words, an experimental or adaptive strategy can be viewed as a set of simpler, operational strategies arrayed against a set of competing hypotheses. Resolution of the competing hypotheses would lead to identification of a long-term strategy, but of course, in the short term, an experimental design is needed to achieve that resolution. The first step in development of such a complex strategy is the articulation of the simpler component strategies and the attendant competing hypotheses; the development of the experimental design is a later step.

3.3.4 Value of Information

The essence of the DT school of adaptive management is a focus on uncertainty that is an impediment to the decision maker; that is, resolution of the uncertainty could affect the choice of the long-term management strategy. To evaluate the importance of a source of uncertainty, we used a technique known as the value of information (Raiffa and Schlaifer, 1961; Howard, 1966; Runge and others, 2011b), which was also advocated by Walters (1986) as the motivation for adaptive management. The idea behind the value of information is to compare the expected performance if a decision has to be made in the face of uncertainty with the expected performance if uncertainty can be resolved before committing to a decision. This contrast, known as the EVPI, sets an upper bound on the value of experimental or adaptive management measured on the scale of the management objective(s). To make a decision in the face of uncertainty, a decision maker chooses to implement an action that achieves the highest expected performance against the uncertainties, but that decision carries the risk of being wrong (because some other action could have performed better); the value of information measures how important it is to eliminate that risk. There are two related methods: (1) the expected value of partial information (EVXI) allows calculation of the value of reducing some component of uncertainty, while remaining uncertain about the rest; and (2) the expected value of sample information takes into account the noise in the monitoring.

To calculate the value of information, uncertainty must be explicitly articulated (as competing hypotheses with evidentiary weights or as a probability distribution on a set of parameters). With a small set of competing hypotheses, the calculations involve several steps: (1) forecasting the performance of each long-term strategy under each hypothesis, (2) calculating a weighted performance across hypotheses to identify an optimal decision in the face of uncertainty, (3) calculating the expected performance if uncertainty could be fully resolved before the management alternative was chosen, and then (4) comparing the expected values in steps 2 and 3.

In a single-objective setting, the EVPI is measured on the scale of that objective; thus, it could be expressed, for example, as the expected increase in the probability of persistence of HBC if uncertainty could be resolved before committing to a long-term management strategy. In a multiple-objective setting, EVPI is calculated on the composite utility scale (in which the full array of objectives is weighted); thus, an evaluation of the importance of uncertainty cannot be calculated without first completing a MCDA to understand the value weights on the resource goals. The sequence of assessment matters; the LTEMP EIS process was crafted to accommodate this series of steps. First, the long-term strategies (the elements of the full alternatives broken down into their constituent parts) were analyzed against the array of performance metrics under all the competing hypotheses. Second, using the expected value across hypotheses, MCDA (with input from stakeholders) was used to generate a preliminary weighting of fundamental objectives. Third, with those weights, the individual competing hypotheses were investigated, and the expected value of information (perfect and partial) was calculated.

3.3.5 Experimental and Adaptive Design

The motivation for the EVPI analysis was to provide guidance useful for developing an experimental or adaptive design for implementing management actions, taking into account their value as long-term strategies and the value of reducing uncertainty. This report only describes the results from the decision analysis, with a brief discussion of the implications of the results for experimental design (section 9.2, “Motivation for Adaptive Management”); the development of the experimental design is described in the DEIS.

4 Resource Goals and Performance Metrics

In February 2010, the Assistant Secretary of the Interior asked an ad hoc group of the AMWG to develop a set of DFCs, which were outcomes of fundamental importance that were "achievable through the operation of Glen Canyon Dam, subject to the Law of the River and consistent with the Grand Canyon Protection Act" (Castle, 2010, p. 2) During the next 2 years, this ad hoc group worked with the AMWG and DOI to develop the set of DFCs, which were adopted by the AMWG and recommended to the Secretary of the Interior in February 2012. The set of DFCs formed the basis for the development of the resource goals for the LTEMP EIS. The resource goals express the fundamental objectives for the LTEMP EIS and are described in the nine subsections that follow (4.1 through 4.9).

Associated with the resource goals, the joint-lead agencies developed metrics to evaluate the relative performance of the LTEMP alternatives. These scientifically based performance metrics were developed in a series of workshops among SMEs working on the LTEMP EIS and were revised to incorporate feedback from Cooperating Agencies and other stakeholders. The performance metrics are intended to be objective measures of the performance of alternatives relative to goals for each affected resource being evaluated in the LTEMP EIS. Note that these performance metrics are not the full impacts analysis for the LTEMP EIS. Other sources of quantitative and qualitative information, in addition to the performance metrics, were used to assess the overall and relative performance of alternatives and their constituent elements for the LTEMP EIS. A summary of the performance metrics used in the decision analysis is given in table 1.

4.1 Aquatic Ecology

The resource goals associated with aquatic ecology focused on the persistence of HBC and other native fish, the quality of the rainbow trout (RBT) (*Oncorhynchus mykiss*) fishery, and absence or containment of nonnative aquatic species.

4.1.1 Humpback Chub

Resource Goal.—Meet HBC recovery goals including maintaining a self-sustaining population, spawning habitat, and aggregations in the natural range of the HBC in the Colorado River and its tributaries below the Glen Canyon Dam.

Performance Metric 1.—Expected minimum number of adult (greater than or equal to [≥] 200 millimeters [mm]) HBC in the Little Colorado River population during the LTEMP planning period (20 years).

Performance Metric 2.—Average temperature suitability index (scale 0–1) for HBC at RM 157 (Havasu Creek) and RM 213 (Pumpkin Spring) (fig. 1). The potential for a self-sustaining aggregation of HBC at each of these locations was based on a temperature suitability model that considered how well water temperatures met requirements for important HBC life-history stages (spawning, egg incubation, and growth) using triangular probability functions based on the reported ranges of suitable temperatures for each life-history stage (Valdez and Speas, 2007). The composite temperature suitability index was the geometric mean of the suitability indices for each of the life-history stages.

4.1.2 Other Native Fish

Resource Goal.—Maintain self-sustaining native fish species populations and their habitats in their natural ranges on the Colorado River and its tributaries.

In the analysis for the EIS, temperature suitability indexes for other native fish, similar to the one for HBC, were developed. They did not, however, show much differentiation among alternatives, and they did not differ much from each other and from the HBC temperature suitability metric. These metrics were not, subsequently, used in the decision analysis; the HBC temperature suitability metric was assumed to stand in for other native fish as well.

4.1.3 Rainbow Trout Fishery

Resource Goal.—Achieve a healthy high-quality recreational RBT fishery in the Glen Canyon National Recreation Area and reduce or eliminate downstream RBT migration consistent with NPS fish management and ESA compliance.

Performance Metric 3.—Rainbow trout catch rate in Glen Canyon National Recreation Area (age 2+ fish per angler-hour).

Performance Metric 4.—Rainbow trout emigration rate (number of age-0 RBT moving into Marble Canyon from Glen Canyon per year).

Performance Metric 5.—Abundance of high-quality RBT (greater than [>] 16 inches total length) in the Glen Canyon reach.

4.1.4 Nonnative Aquatic Species

Resource Goal.—Minimize or reduce the presence and expansion of aquatic nonnative invasive species.

In the analysis for the EIS, temperature suitability metrics for nonnative warm-water and cold-water fish and aquatic parasites, similar to the one for HBC, were developed. They did not, however, provide much differentiation among the alternatives. These metrics are reported in the EIS but were not used in the decision analysis.

Table 1. Summary of the 18 performance metrics used in the decision analysis.

[The range for each performance metric captures the amount of variability in the metric because of the effects of the different alternatives, the hydrological and sediment traces, and structural and parametric uncertainty. The range shown was used in the swing-weighting elicitation. HBC, humpback chub; RBT, rainbow trout; #, number; >, greater than]

Number	Resource goal	Performance metric	Units	Desired direction	Range
1	Humpback chub	Minimum number of adult HBC	# adults	Increase	3,000–8,500
2		HBC temperature suitability	Index (0–1)	Increase	0.0–0.2
3	RBT fishery	RBT catch rate	Fish/angler-hour	Increase	1.0–5.0
4		RBT emigration rate	Trout/year	Decrease	15,000–125,000
5		Abundance of high-quality RBT	# fish > 16 inches	Increase	400–1,200
6	Archaeological and cultural resources	Wind transport of sediment index	Index (0–1)	Increase	0.0–0.5
7		Glen Canyon flow index	Days/year	Decrease	0–75
8		Time-off-river index	Index (0–1)	Increase	0.60–0.95
9	Hydropower and energy	Hydropower generation	Million $/year	Increase	120–200
10		Hydropower capacity	Million $/year	Increase	10–50
11	Recreation	Camping area index	Index (0–1)	Increase	0.0–0.5
12		Fluctuation index	Index (0–1)	Increase	0.0–1.0
13		Rafting use index	Visitor-days/year	Decrease	0–1,300
14	Riparian vegetation	Riparian vegetation index	Sum of ratios	Increase	2.0–6.0
15	Sediment	Sand load index	Proportion (0–1)	Increase	0.0–0.6
16	Tribal resources	Marsh vegetation ratio	Ratio	Increase	0.0–1.5
17		Mechanical removal	Years (out of 20)	Decrease	0–5
18		Trout management flows	Years (out of 20)	Decrease	0–20

4.2 Archaeological and Cultural Resources

Resource Goal.—Maintain the integrity of potentially affected National Register of Historic Places eligible or listed historic properties in place, where possible, with preservation methods used on a site-specific basis.

Performance Metric 6.—Wind transport of sediment index (WTSI). This WTSI metric captures the availability of fine sediment for movement by wind. The potential settlement of such sediment over historic properties may provide protection from erosion. The WTSI is the product of the sand load index (SLI; see section 4.7, "Sediment"), which is a proxy for the availability of sediment, and a flow factor, which is higher when low flows happen during the windy season. The WTSI can range between 0 and 1, with higher values indicating more opportunity for transport of sediment.

Performance Metric 7.—Glen Canyon flow index (number of days per year that the maximum daily flow is greater than 23,200 cubic feet per second [ft^3/s]). There are a number of archaeological sites within the Glen Canyon National Recreation Area that could be negatively affected by high flows. Ninemile Terrace is considered representative of other archaeological sites on terraces within the Glen Canyon National Recreation Area; the toe of its slope is at an elevation that corresponds to flows from Glen Canyon Dam of 23,200 ft^3/s.

Performance Metric 8.—Time-off-river index. This metric reflects the availability of discretionary time off river for rafting parties, which allows for greater visitation of archaeological sites. From the standpoint of protection of archaeological and cultural sites, such discretionary time is not desirable. The time-off-river index is calculated from the mean daily flow levels in the river: daily flows less than 10,000 ft^3/s receive a score of 1 (because rafting progress is slow and there is little discretionary time); daily flows greater than 31,500 ft^3/s receive a score of 0 (because rafting progress is fast, allowing the most discretionary time); and daily flows between 10,000 and 31,500 ft^3/s receive a score based on linear interpolation. The daily scores are averaged within seasons: summer (May–August), winter (November–February), and spring and fall (March–April and September–October, respectively). An annual value is calculated using a weighted average across seasons, with higher weight (0.54) given to summer than to spring and fall (0.31) or winter (0.15). The final metric ranges between 0 and 1, with higher values indicating better potential to protect archaeological resources.

4.3 Hydropower and Energy

Resource Goal.—Maintain or increase Glen Canyon Dam electric energy generation, load following capability, and ramp rate capability; and minimize emissions and costs to the greatest extent practicable, consistent with improvement and long-term sustainability of downstream resources.

Performance Metric 9. —Value of hydropower generation (million dollars per year). The value of hydropower energy production over a 20-year trace is discounted at 3.375 percent per year. The total net present value of energy production is divided by 20 to provide an annualized measure.

Performance Metric 10.—Value of hydropower capacity (million dollars per year). The WAPA enters into long-term firm contracts that obligate them to deliver firm electric service to their customers. For the purpose of the LTEMP EIS, the value of these contracts is estimated by first calculating the amount of power (megawatt [MW]) that can be contracted, then multiplying by the replacement cost for that capacity (dollars per MW-year). The capacity itself is calculated by finding the 90-percent exceedance value (10th percentile) for the daily maximum generation in August (August is the month with the highest demand) during a 20-year trace. The replacement cost used was $50,100/MW-year based on a natural gas combustion turbine.

Additional metrics associated with hydropower generation, including the retail rate effects on residential and nonresidential consumers, are examined in the LTEMP EIS but were not available in time to be included as part of the decision analysis.

4.4 Natural Processes

Resource Goal.—Restore, to the extent practicable, ecological patterns and processes within their range of natural variability, including the natural abundance, diversity, and genetic and ecological integrity of the plant and animal species native to those ecosystems.

A quantitative performance metric to capture this resource goal was not developed because of its multifaceted complexity. In the EIS, the alternatives are compared qualitatively against this resource goal, but it was not used in the decision analysis.

4.5 Recreational Experience

Resource Goal.—Maintain and improve the quality of recreational experiences for the users of the Colorado River ecosystem. Recreation includes, but is not limited to, flatwater and whitewater boating, river corridor camping, and angling in Glen Canyon.

Performance Metric 11.—Camping area index. This metric captures the availability of medium (16–25 people) and large (>25 people) campsites on beaches along the Colorado River. The camping area index is the product of the SLI (see section 4.7, "Sediment"), which measures the availability of sediment for beach forming, and a flow factor, which reflects exposure of the beaches. The flow factor is calculated from the maximum daily flows. A score of 1 is given to flows less than 8,000 ft^3/s (because the lower flow means a lower elevation of the water and hence more beach exposure); a score of 0 is given to flows greater than 31,500 ft^3/s; and an intermediate score is determined by linear interpolation for flows between 8,000 and 31,500 ft^3/s. The flow factor is averaged over days within each season, and then over seasons, with higher weight given to the summer season (0.54) than the spring and fall (0.31) or winter (0.15) seasons. The camping area index can range between 0 and 1, with higher values indicating greater availability of medium and large campsites.

Performance Metric 12.—Fluctuation index. This index measures the fraction of time that the daily fluctuations in flow are within a tolerable range; tolerable is defined based on the study by Bishop and others (1987). As the mean daily flow increases, greater fluctuations are tolerable. For mean daily flow in the range from 5,000 to 8,999 ft^3/s, the daily fluctuation index is 1 if the daily fluctuation is less than 3,400 ft^3/s; for daily flow in the range from 9,000 to 15,999 ft^3/s, the fluctuation index is 1 if the daily fluctuation is less than 4,800 ft^3/s; for daily flow in the range from 16,000 to 31,999 ft^3/s, the fluctuation index is 1 if the daily fluctuation is less than 7,200 ft^3/s; and for daily flow greater than 32,000 ft^3/s, the fluctuation index is 1 if the daily fluctuation is less than 9,800 ft^3/s. In all cases, the daily fluctuation index is 0 if the daily fluctuation is greater than 10,000 ft^3/s. For fluctuation index values between 1 and 0, the index is determined by linear interpolation between the tolerable threshold and 10,000 ft^3/s. The daily values for the fluctuation index are averaged within seasons, then averaged across seasons with higher weight (0.54) given to summer months than to spring and fall (0.31) or winter months (0.15). The fluctuation index can range between 0 and 1, with higher values indicating a better visitor experience as influenced by fluctuation in water levels.

Performance Metric 13.—Glen Canyon rafting use metric (average boat seats lost per year because of high-flow experiments [HFEs]). During HFEs and for 2 days before and after, Glen Canyon day-rafting operators cannot take recreational passengers. This metric calculates the average number of boat seats lost per year.

Several other metrics reflecting the recreational experience were analyzed in the LTEMP EIS. In some cases, these did not help to discriminate among the alternatives, and in other cases, these metrics were highly correlated with other metrics. For these reasons, the metrics were not included in the decision analysis and are not described here.

4.6 Riparian Vegetation

Resource Goal.—Maintain native vegetation and wildlife habitat, in various stages of maturity, such that they are

diverse, healthy, productive, self-sustaining, and ecologically appropriate.

Performance Metric 14.—Riparian vegetation index. This index summarizes predicted changes during the 20-year LTEMP period in the relative cover of native vegetation community types and the relative diversity of community types, as described by a seven-state state-and-transition model (Ralston and others, 2014). The index is calculated as the sum of four component ratios: the ratio of final to initial native vegetation cover, the ratio of final to initial vegetation state diversity, the ratio of final to initial native to nonnative dominant vegetation state, and the ratio of initial to final cover of arrowweed. An index value of 4.0 indicates an unchanged vegetation condition; values greater than 4.0 indicate improved vegetation conditions; values less than 4.0 indicate degraded vegetation conditions.

4.7 Sediment

Resource Goal.—Increase and retain fine sediment volume, area, and distribution in the Glen, Marble, and Grand Canyon reaches above the elevation of the average base flow for ecological, cultural, and recreational purposes.

Performance Metric 15.—The SLI (the cumulative sand load transported by high flows [greater than 31,500 ft^3/s] divided by the cumulative sand load transported in total). The range of this metric is 0–1, with higher values reflecting the potential for larger sandbars because more of the sediment is transported at higher river volumes and hence higher elevations. A number of other metrics that summarize the transportation and deposition of sediment were analyzed in the LTEMP EIS. They were all fairly highly correlated; only the SLI was used in the decision analysis.

4.8 Tribal Resources

Resource Goal.—Maintain the diverse values and resources of traditionally associated tribes along the Colorado River corridor through Glen, Marble, and Grand Canyons.

In discussions with tribal representatives during the course of the development of the LTEMP EIS, a large number of important resource goals were identified. A concerted effort was made to understand these goals as clearly as possible, but it was challenging to express some of them in terms amenable to measurement. Although all these goals are important aspects of the importance to the tribes of the Grand Canyon, the Colorado River, and their management, not all of them will be affected by the alternatives being considered in the LTEMP EIS. All of these resource goals are discussed and evaluated in the LTEMP EIS. The full set of goals is described in this section, but only those for which performance metrics were identified are included in the decision analysis.

4.8.1 Health of the Ecosystem

The ecosystem in Glen, Marble, and Grand Canyons is more than the sum of its parts and, in the view of the tribes, should be healthy as a whole. Historically, in the GCDAMP, the overall health of the ecosystem has been examined by evaluating the status of each part, but this reductionist approach might possibly miss some important aspects. There are a variety of indicators of ecosystem health that could be considered including, but not limited to, the following: the health of the river and its ability to sustain life; the color of the water; the absence of contaminants, pollutants, and disease in the water; the potability of the water; the quality of the water that reaches Lake Mead; and the viability and health of wildlife and plants in Glen, Marble, and Grand Canyons. It is important to understand that, for many tribes, the Colorado River is a sentient being and the spiritual center of the ecosystem because it has the capability of giving and taking life and is prone to anger if mistreated. The health of the ecosystem depends on the health of the Colorado River.

Because of the holistic nature of this resource goal, it was difficult to find a single performance metric that summarized it. A narrative analysis of this resource goal is found in the LTEMP EIS, but it was not included in the decision analysis.

4.8.2 Sites of Cultural Importance

There are specific sites within Glen, Marble, and Grand Canyons that are important for cultural reasons; and for preservation of tribal, religious society, kiva group, and clan history (for example, shrines, sacred sites, ancient burial sites, springs, plant collection areas, mineral collection areas, offering places, and other elements). These sites can be threatened by erosion, loss of sediment inputs, and intrusive human use (especially nontribal, outside visitors). Flow and nonflow actions (for example, education, permitting, research and monitoring, and interpretation) may affect these sites.

Performance Metric 16.—Marsh vegetation ratio (ratio of frequency of wetland states during the course of 20 years to frequency of wetland states if the initial abundance remained unchanged). Wetlands are a rare and important habitat type along the Colorado River; within Glen, Marble, and Grand Canyons, there are currently approximately 4.6 acres of such habitat. Maintenance and increase of marsh vegetation is important from a tribal perspective. The metric is calculated by looking at the marsh and shrub wetland states in the riparian state-and-transition model (Ralston and others, 2014) during the course of a 20-year projection and comparing that to the current abundance. The metric is a ratio; thus, a value of 1.0 indicates an unchanged abundance of marsh (on average), a value greater than 1.0 indicates an average increase, and a value less than 1.0 indicates an average decrease.

A number of aspects of this resource goal are also reflected in other performance metrics described in previous sections. The WTSI (performance metric 6) focuses on the availability of fine sediment for transfer to protect National

Register eligible or listed sites. Such sites, however, do not represent the full set of places of tribal concern, so other metrics must also be considered. The Glen Canyon flow index (performance metric 7) reflects the protection of some important sites in Glen Canyon. The time-off-river index (performance metric 8) measures the degree to which the discretionary time off river of rafters might affect cultural resources, including those of tribal importance.

In additions to these performance metrics, a number of other considerations are evaluated narratively in the LTEMP EIS, including riparian vegetation diversity, native fish diversity, and access to springs.

4.8.3 Respect for Life

To many of the tribes associated with the Colorado River and Glen, Marble, and Grand Canyons, life itself is sacred. Human activities should protect and promote life, not destroy it. There are two aspects to this resource goal: first, minimize the taking of life; and second, encourage the expansion and proliferation of life. These are both complex concepts. The tribes recognize that it is appropriate for humans to take other life in some circumstances, especially when it promotes other life (particularly, our own consumption for survival), but this taking needs to be minimal and respectful because there are spiritual consequences associated with the taking of life. The promotion of life is also important but does not necessarily imply a return to historical or "natural" conditions. The Glen Canyon Dam has encouraged new life in Glen, Marble, and Grand Canyons, so a return to predam conditions is not necessarily implied by this objective. It is worth noting that many of the tribes do not make a strong distinction between native and nonnative species.

Performance Metric 17.—Frequency of mechanical removal, as measured by the average number of years in which trout mechanical removal trips happen. Several of the alternatives considered in the LTEMP EIS include the use of electrofishing and removal of nonnative trout at the confluence of the Colorado River with the Little Colorado River in an effort to reduce the piscivory of juvenile HBC by trout. A number of tribes, especially Hopi and Zuni, have raised concerns about this taking of life. As a coarse measure of the cultural, spiritual, and ethical effects of killing trout, this performance metric allows distinctions among alternatives, favoring those that make an effort to minimize mechanical removal. But the nature of the take, the purpose behind it, the methods of the take, the disposition of the trout taken, and the mind set of those killing the fish all also affect the sacred treatment of living beings.

Performance Metric 18.—Frequency of trout management flows, as measured by the average number of years in which TMFs happen. Several of the alternatives considered in the LTEMP EIS include the potential for use of TMFs. The TMFs, designed to reduce reproduction or survival of juvenile trout, are considered to be killing by some tribes and should be minimized. Alternatives that include TMFs are likely to differ in how often the flows are triggered, so this performance metric helps to distinguish among the alternatives.

4.8.4 Sacred Integrity of Grand, Marble, and Glen Canyons

Glen, Marble, and Grand Canyons are sacred to many tribes, and the preservation of their sacred integrity is important. The sanctity of Glen, Marble, and Grand Canyons may be threatened by human activities and behaviors, development, and the presence of artificial structures and activities. An important aspect of the sanctity is the intentionality of visitors: when outsiders enter Glen, Marble, and Grand Canyons (on boat or hiking trips), the respect they show to the canyons and Colorado River can affect the spiritual integrity. There are many consequences of the disturbance of this sanctity, including, but not limited to, the following: a reduction of the spiritual strength of plants gathered and used by the Navajo for medicinal and cultural purposes; an inability to retire Navajo sacred objects into the Colorado River when they have become too old for continued use; weakening of the sacred role the canyons play as a final resting place for Hopi; and an overall disruption of the state of mind and spirit of Zuni religious leaders and of their experience of being within a very sacred place that embodies the Zuni emergence, migrations, and communion with the spirits of Zuni ancestors.

This resource goal, although of profound importance to the tribes, is not thought to differ measurably across the alternatives under consideration in the LTEMP EIS because it is not driven by flow operations from Glen Canyon Dam or currently envisioned attendant activities. This goal is evaluated in the narrative EIS analysis but not in the formal decision analysis.

4.8.5 Stewardship

According to their traditions, several of the tribes understand that they have been given a sacred stewardship responsibility for the preservation and harmony of the world; for example, the Hopi have a covenant with the caretaker of this world, Masaw, to be stewards of the earth; other Tribes have similar stewardship ethics grounded in spiritual traditions. To maintain these stewardship responsibilities, the tribes need to be an active part of stewardship of the Glen, Marble, and Grand Canyons. This stewardship includes the following: ceremonial activities, whether performed in the canyons or in the villages; participation in management of the canyons, including water management, through traditional practices and western management activities; and education to maintain cultural knowledge and connection with the canyons. The tribes note that the Federal government also has stewardship responsibilities that arise out of Federal legislation; because Federal involvement has sometimes taken stewardship responsibility from the tribes, it is critical that the Federal government be accountable for its stewardship. At times, some tribes believe

the presence of the Federal government has made it more difficult for them to carry out their stewardship responsibilities. Successful development of joint stewardship among the tribes and Federal government will require continued building of mutual respect and trust between those entities.

Tribal stewardship opportunities are not tied to individual alternatives being considered in the LTEMP EIS but could be crafted to apply to any of the alternatives; thus, this resource goal, although of critical importance to the tribes individually and to the ongoing relationship between the tribes and Federal government, may not help distinguish among the alternatives. This goal is evaluated in the narrative EIS analysis but not in the formal decision analysis.

4.8.6 Tribal Connections to the Canyons

The spiritual, historical, and cultural connections that tribes have to Glen, Marble, and Grand Canyons require the protection of sacred sites and the integrity of the canyons as a whole, but protection alone is not enough. The tribes also need opportunities for access, education, and stewardship to keep their connections vibrant. Access can be undermined by physical barriers and by the effects of human activity that decrease the power of those sites and the experience when at them (for example, lack of privacy, disturbance of the soundscape, and viewshed).

Like the sacred integrity and stewardship resource goals, this resource goal is not thought to differ across the alternatives. The flow operations of Glen Canyon Dam are not likely to affect tribal access, education, spiritual ceremonies, or other connections to Glen, Marble, and Grand Canyons. This resource goal may be more appropriately addressed through government-to-government consultation in other forums. This goal is evaluated in the narrative EIS analysis but not in the formal decision analysis.

4.8.7 Economic Opportunity

The Glen, Marble, and Grand Canyons, Colorado River, and Glen Canyon Dam are sources of economic benefit for the tribes in the area. The canyons provide tourism and other opportunities that enhance the economic well-being of tribes. (As an important note, tourism can also undermine the well-being of tribes in aspects other than economic; see the other tribal resource goals.) The Glen Canyon Dam provides affordable electricity for tribal needs and for development projects.

The hydroelectric performance metrics (especially hydroelectric generation, performance metric 9) may reflect one aspect of economic opportunity in that provision of affordable hydroelectricity is a component of economic development. Other economic effects are evaluated in the narrative EIS but were not included in the formal decision analysis.

4.8.8 Tribal Water Rights and Supply

Tribes in the area depend on the Colorado River for many of their water needs; so the preservation of established, traditional, and desired water rights, now and into the future, is important to them. There are a number of claims to water rights that have been asserted by the tribes but for which there are not yet quantified rights through decree or negotiated settlement; some Tribes have indicated that these claims to water rights are as important as established water rights.

Based on its purpose and need, the LTEMP EIS was not intended to include any alternative that violated agreed-upon water rights. The effect of the Lake Powell water elevation on Navajo access to water was examined and was not determined to differ across alternatives.

4.8.9 Process Objectives

The tribes also expressed several important process objectives—objectives that govern how the LTEMP decision is made, rather than what decision is made. The first of these is the genuine incorporation of tribal input to the LTEMP process as a reflection of Federal trust responsibilities. The second is the importance of incorporating learning to improve management with time; in this spirit, an experimental approach that can result in adaptive management is favored.

Because these were process objectives, they were not evaluated in the formal decision analysis, which focused on objectives that could help discern among the alternatives.

4.9 Water Delivery

Resource Goal.—Ensure that water delivery continues in a manner that is fully consistent with and subject to the Colorado River Compact, Upper Colorado River Basin Compact, Water Treaty of 1944 with Mexico, decree of the Supreme Court in *Arizona* v. *California*, and provisions of the Colorado River Storage Project Act of 1956 and the Colorado River Basin Project Act of 1968 that govern allocation, appropriation, development, and exportation of the waters of the Colorado River Basin; and consistent with applicable determinations of annual water release volumes from Glen Canyon Dam made pursuant to the Long-Range Operating Criteria for Colorado River Basin Reservoirs, which are currently implemented through the 2007 interim guidelines (Bureau of Reclamation, 2007).

The scope and need of the LTEMP EIS was designed to preserve existing agreements concerning water delivery; thus, none of the alternatives considered were meant to differ with regard to aspects of water delivery. A number of water delivery metrics were evaluated to make certain that this part of the purpose and need was upheld. None of the alternatives were determined to differ with regard to these metrics; thus, they were not included in the decision analysis.

5 Alternatives

Seven alternatives were considered in the LTEMP EIS. Each of these alternatives is a complex combination of flow and nonflow actions, often with condition-dependent and information-dependent triggers for various components. Four of the alternatives (B, C, D, and E) also contain variants (called long-term strategies) to represent different combinations of actions that would be taken once critical uncertainties were resolved. In total, 19 long-term strategies were evaluated. A brief summary of these alternatives is given here to provide context for the decision analysis with an emphasis on those elements that differ across alternatives. A full description of these alternatives, with the rationale for each, is given in chapter 2 of the LTEMP EIS.

5.1 Action Elements

The alternatives are composed of flow actions, which govern how water flow through Glen Canyon Dam is to be managed on hourly, daily, and monthly scales, as well as nonflow actions, which govern other activities meant to complement the flow actions to achieve the resource goals.

5.1.1 Monthly Release Pattern and Other Base Operations

The seven alternatives differ in the operational characteristics that govern flow through Glen Canyon Dam (table 2). All alternatives follow the 2007 interim guidelines (Bureau of Reclamation, 2007), which specifies the annual volume of water to be passed through Glen Canyon Dam. The alternatives differ in how they apportion the annual volume to monthly volumes, ranging from patterns that match releases under the previous EIS to patterns that match monthly demand for electricity to patterns that approximate the unregulated flow in the Colorado River. The minimum flow at any time differs across alternatives, with a range from 5,000 to 8,000 ft^3/s. The maximum flow for base operations is the same for all alternatives (25,000 ft^3/s). The daily range specifies the limit to how much variation there can be between the minimum and maximum flow on a given day and ranges between 0 and 12,000 ft^3/s across alternatives. The ramp rates limit how quickly the flow can change; for all alternatives the ramp rate for increasing flow is 4,000 cubic feet per second per hour (ft^3/s-h); the ramp rate for decreasing flow is lower, ranging from 1,500 to 4,000 ft^3/s-h.

5.1.2 High-Flow Experiments

Since 1996, there have been a number of experimental high-flow releases of water through Glen Canyon Dam, designed to mimic natural high flows and deposit sediment at higher elevations, in an effort to rebuild sandbars and restore other ecosystem processes in Glen, Marble, and Grand Canyons. High-flow releases exceed the operational maximum daily flow and can be as high as 45,000 ft^3/s depending on the number of generation units available. The Bureau of Reclamation (2011a) established a protocol for determining when HFE releases were warranted and how they should be implemented. To date, the HFEs that have been implemented under the 2011 HFE protocol have happened in the fall, although the HFE protocol allows them to happen in the spring after 2015. The LTEMP EIS alternatives differ in if, when, and how they allow fall HFEs and spring HFEs (table 3). In addition, some of the alternatives allow proactive spring HFEs; these are HFE releases designed to protect sand supply in years when the annual guidelines call for high annual volumes (>10 million acre-feet). Most of the HFEs are limited to a maximum duration of 96 hours, but some of the alternatives allow extended-duration HFEs if adequate sediment supply is available (table 3).

5.1.3 Trout Management Flows

High flows, whether through high annual volumes or HFEs, have been determined to increase RBT production in the Glen Canyon reach. Because of the concern about the effect of RBT on HBC, methods have been sought to manage RBT populations. One proposed method is TMFs. These are patterns of high-water release (for example, 20,000 ft^3/s) for 2–7 days to encourage young-of-the-year trout to move to higher elevation shallow-water habitats followed by a rapid drop to a low flow (for example, 5,000 to 8,000 ft^3/s) during the day to strand young trout and expose them to sunlight and heat. The intention is to reduce RBT production and, hence, reduce emigration of trout from Glen to Marble Canyon, lowering the risk to HBC farther downstream. The TMFs have not previously been implemented at Glen Canyon Dam. They are considered an experimental element in several of the alternatives (table 3).

5.1.4 Other Flow Manipulations

A variety of other flow manipulations are built into the alternatives. Low summer flows are designed to produce warmer conditions for juvenile HBC growth in the Colorado River at the confluence with the Little Colorado River by reducing flows from July through September. These flows would be implemented experimentally in those alternatives that allow them (table 3).

Sustained low flows for benthic invertebrate production ("bug flows") are an experimental action considered under Alternative D for restoring mayflies, stoneflies, and caddisflies to Glen and Marble Canyons. If implemented, steady minimum flows would be provided every weekend from May through August, to ensure that eggs laid during weekends would not be subject to drying because of lower water levels during egg development. Demand for electricity is lower on

Table 2. Operational characteristics of Long-Term Experimental and Management Plan alternatives.

[maf,, megaacre-foot; kaf, kiloacre-foot; ft^3/s, cubic foot per second; >, greater than]

Elements of base operations	Alternative						
	A	B	C	D	E	F	G
Monthly pattern in release volume	Historic monthly release volumes.	Same as Alternative A	Highest volume in high electric demand months; February–June volumes proportional to contract rate of delivery; lower volumes August–November	Comparable to Alternative E, but August and September volume increased, with additional volume taken from January through July	Monthly volumes proportional to the contract rate of delivery, but with a targeted reduction in August–October volumes; volume released in October, November, and December=2.0 maf in > 8.23-maf years	Relative to Alternative A, higher release volumes in April–June; lower volumes in remaining months	Equal monthly volumes, adjusted with changes in runoff forecast.
Minimum flows (ft^3/s)	8,000 during day; 5,000 during night	Same as Alternative A	Same as Alternative A	Same as Alternative A	Same as Alternative A	5,000	5,000
Maximum flows (ft^3/s)	25,000	Same as Alternative A	Same as Alternative A	Same as Alternative A	Same as Alternative A	Same as Alternative A	Same as Alternative A.
Daily range (ft^3/s)	5,000, 6,000, or 8,000 depending on monthly volume	December and January: 12,000 February, July, and August: 10,000 October, November, March, June, and September: 8,000 April and May: 6,000	Equal to 7 × monthly volume in kaf in all months; 2,000 ft^3/s following significant sediment input in summer or fall	Equal to 10 × monthly volume in kaf in June–August, and 9 × monthly volume in kaf in other months; not to exceed 8,000 ft^3/s	Equal to 12 × monthly volume in kaf in June–August, and 10 × monthly volume in kaf in other months; 2,000 ft^3/s following significant sediment input in summer or fall	0	0
Ramp rates (ft^3/s-hr)	4,000 up 1,500 down	4,000 up 4,000 down November–March 3,000 down in other months	4,000 up 2,500 down	4,000 up 2,500 down	4,000 up 2,500 down	4,000 up 1,500 down	4,000 up 1,500 down.

Table 3. Triggered and experimental elements of the Long-Term Experimental and Management Plan long-term strategies.

[A filled circle (●) indicates the element in question is implemented fully in the long-term strategy; an open circle (○) indicates the element in question is implemented in some partial degree; and -- indicates that element is not part of that long-term strategy. HFE, high-flow experiment]

Mechanical trout removal	●	●	●	--	--	●	●	●	●	●	●	--	--	●	●	--	--	--	●

weekends, so timing the benthic invertebrate production flows during the weekends minimizes the effect on the value of hydropower generation.

Hydropower improvement flows are an experimental action considered under Alternative B to increase hydropower generation during high-demand months (December–February and June–August) in years when the annual volume is less than or equal to (≤) 8.23 million acre-feet. These flows work largely by allowing a greater daily range and higher ramp rates.

Some of the alternatives use steady flows before an HFE to conserve sediment for the high-flow release, after an HFE to reduce erosion of newly built sandbars, or both (table 3). These steady flows stop the load-following patterns of hourly releases and are sometimes called "load-following curtailment."

5.1.5 Nonflow Actions

Under a 2011 assessment (Bureau of Reclamation, 2011b), experimental methods of controlling trout populations were evaluated and implemented. These methods include mechanical removal of brown trout (*Salmo trutta*) and RBT at the Little Colorado River through electrofishing, selective removal, and beneficial use of the fish removed. Many of the LTEMP EIS alternatives allow for continued use of mechanical removal with specific requirements for when such removal would be triggered (table 3).

Under all alternatives except Alternative A (no-action alternative), the NPS would implement experimental vegetation restoration to modify the cover and distribution of plant communities along the Colorado River. This restoration would include removal of nonnative species, prevention of new introductions, planting of native species, management of vegetation at campsites, and removal of windrows that block wind transport of sediment.

5.1.6 Long-Term Strategies

Four of the seven alternatives (Alternatives B, C, D, and E) were conceived as experimental and adaptive strategies, with elements that would be deployed experimentally to allow resolution of uncertainty and subsequent adaptation of the strategy in response to the information acquired; thus, within each of these alternatives are a number of implicit long-term strategies that might result after resolution of uncertainty. Not all of those possible long-term strategies were analyzed, but a representative set from each alternative was articulated and analyzed to capture the possible range of environmental effects and evaluate the importance of resolving the underlying uncertainty; thus, for example, under Alternative C, whether or not to implement fall HFEs, spring HFEs, TMFs, low summer flows, or mechanical removal will depend on the efficacy of those actions in achieving their intended purpose, the strengths of undesirable side effects of those actions, and the underlying effect of RBT on HBC. The long-term strategies C1, C2, C3, and C4 represent a range of possible solutions once such uncertainty is resolved; if, for instance, spring HFEs have a beneficial effect on sediment deposition and only a small effect on RBT production, TMFs are ineffective, but low summer flows benefit HBC, then long-term strategy C2 might be the best version of Alternative C to use. All of the 19 long-term strategies (table 3) were evaluated against the critical uncertainties described in sections 6.2.1, 6.3.1, and 6.5.1.

5.2 Alternative A (No Action)

Alternative A, the no-action alternative, represents continued operation of Glen Canyon Dam under the existing guidelines in Bureau of Reclamation (1996), interim guidelines in Bureau of Reclamation (2007), and the two 2011 EAs (Bureau of Reclamation, 2011a, 2011b), as well as other applicable guidance. This alternative has a base operation pattern that was called MLFF in Bureau of Reclamation (1996). Both of the 2011 EAs expire after 2020, so the elements specified in them (HFEs and mechanical removal) would cease at that point (Bureau of Reclamation 2011a, 2011b). Beyond the actions discussed in Bureau of Reclamation (2011a, 2011b), there are limited experimental options that can be tested under this alternative.

5.3 Alternative B

Alternative B was designed to increase the value of hydropower generation while limiting negative effects to other resources. This alternative was submitted by the Colorado River Energy Distributors Association (CREDA), a member of AMWG. The base operations are designed to generate more valuable power than Alternative A by increasing the daily range and ramp rates to allow power generation to more closely follow power demand. This alternative limits the implementation of HFEs to one every other year because HFEs release water without generating power and require water volumes to be shifted from months when the value of power is potentially higher to other months. To moderate some of the negative effects of this water-release pattern on other resources, Alternative B includes mechanical removal, evaluation of TMFs, and experimental implementation of vegetation restoration.

5.3.1 Alternative Long-Term Strategies

Alternative B includes two long-term strategies, one with its base operations (B1) and one that includes hydropower improvement flows (B2), maximum power plant capacity flows implemented as many as four times during the LTEMP period, in years when the annual volume is ≤8.23 million acre-feet (table 3). Such years, because of their lower volume of release, typically require the most purchases by WAPA to meet contractual demand, so the higher flows could mitigate costly purchases in high-demand months. Whether B1 or B2 is a better long-term strategy, when the effects across all resource goals are taken into account, depends on the strength of negative effects of greater power generation on other resources. Specific hypotheses for these negative effects, which are uncertain, were not explicitly articulated when Alternative B was submitted. The long-term strategies B1 and B2 were evaluated, however, against the set of uncertainties developed in the context of other alternatives.

5.4 Alternative C

Alternative C was developed by the joint-lead agencies to maintain or improve multiple resources, with some priority placed on HBC, sediment, and hydropower. Called the "condition-dependent adaptive strategy" in interim public documents during the preparation of the EIS (Bureau of Reclamation and National Park Service, 2014), Alternative C has information-dependent and condition-dependent triggers, seeks to test critical hypotheses, and contains explicit instructions for how new insights will affect subsequent implementation of action elements.

Compared to many of the other alternatives, the base operations for Alternative C shift monthly volumes from the monsoon months (August through November) to high-demands months (December, January, and July) to reduce sediment transport during the monsoonal high-sediment-input period and limit effects on the value of power generation. The reduced volume in late summer is also intended to provide warmer river temperatures for the benefit of HBC and other native fish.

Alternative C includes a number of condition-dependent (triggered) elements; among them are fall HFEs, spring HFEs, proactive spring HFEs, extended duration HFEs, TMFs, low summer flows, load-following curtailment, and mechanical removal of trout. The specific details of the triggers for these events are found in chapter 2 of the EIS. Most of these elements are experimental, and so there are information-dependent triggers as well; that is, monitoring and evaluation of all these elements would be completed, and elements would be dropped or retained depending on if the evidence supported their retention.

5.4.1 Alternative Long-Term Strategies

Four long-term strategies (C1, C2, C3, and C4) were developed to capture the range of possible outcomes from adaptive implementation of Alternative C (table 3). The motivation for the creation of these long-term strategies was the recognition that there are critical uncertainties that impede identification of the best long-term strategy. The key questions concerned the following: the magnitude of increase in RBT production in the Glen Canyon reach caused by fall HFEs, the relative effects of temperature and trout density on survival and growth of juvenile HBC at the Little Colorado River, and the effectiveness of TMFs in reducing RBT production. The relevance of these uncertainties arises because of the possible tradeoffs among the objectives of supporting the HBC population, maintaining a strong rainbow trout fishery, increasing sediment deposition and sandbar building, and affirming tribal values concerning the respect for life (especially aquatic life). Each of the action elements under consideration (HFEs, TMFs, low summer flows, and mechanical removal) is meant to increase achievement of one or more of those objectives, but the question is if the benefits to one objective come at the expense of others. Alternative C was designed under the

assumption that the best mix of action elements (the best long-term strategy) depends on resolution of the critical uncertainties.

Long-term strategy C1 allows use of all the triggered elements from Alternative C except for low summer flows and mechanical removals; such a strategy has been hypothesized to be warranted, for instance, if the effect of spring HFEs on trout production was weak, TMFs were effective, and low summer flows were not effective. Long-term strategy C2 is similar to C1 except that it calls for low summer flows but not TMFs. Long-term strategy C3 does not allow HFEs and might be called for if HFEs are determined to cause a very strong increase in trout recruitment and other actions are ineffective at mitigating the effect of trout on HBC. Long-term strategy C4 allows fall HFEs but not spring HFEs and manages the effect of trout on HBC through mechanical removal.

Whether or not the resolution of the critical uncertainties actually matters to the ranking of the long-term strategies is one of the central questions in section 8.3, "Expected Value of Information."

5.5 Alternative D

Alternative D was developed by the joint-lead agencies after a full analysis of the other six LTEMP alternatives had been completed. The initial analysis suggested that there were strong characteristics of Alternatives C and E that contributed to achievement of resource goals and motivated creative thinking about how to achieve more of those benefits in a single alternative. Alternative D adopts characteristics of Alternatives C and E.

The base operations for Alternative D are in many respects a compromise between those of Alternatives C and E (table 2). The monthly pattern of release is most similar to that of Alternative E, with an increase in the August and September volumes (and a corresponding decrease in the January through June volumes). The daily range for flows is about midway between the ranges from Alternatives C and E.

The experimental and adaptive options for Alternative D include all the elements considered in the any of the alternatives, except for hydropower improvement flows (table 3). The experimental implementation calls for early testing of TMFs in the first 2–5 years without having to meet the condition-dependent triggers and delayed consideration of spring HFEs until the third year of implementation.

5.5.1 Alternative Long-Term Strategies

Four long-term strategies (D1, D2, D3, and D4) were developed to capture the range of possible outcomes from adaptive implementation of Alternative D (table 3). The long-term strategies in this set look more similar than in the sets for Alternatives C and E because they were created after an initial analysis of the other six alternatives and, thus, reflect insights from that analysis. For instance, long-term strategies D1 through D4 are all similar with regard to implementation of HFEs because the initial analysis suggested that the benefits of HFEs outweighed the costs, even in the face of the uncertainties tested. There remain, however, other long-term strategies implicit in Alternative D; for example, if spring, proactive, or extended HFEs are determined to have very strong negative effects on resources of importance that cannot be mitigated by other actions, they could be removed from long-term implementation. The four long-term strategies for Alternative D, however, are thought to capture the most important differences that might arise in long-term implementation.

Long-term strategy D4 might be considered the base strategy under Alternative D because all action elements except low summer flows and bug flows are in operation (table 3). Long-term strategy D1 adds low summer flows. Long-term strategy D2 adds implementation of bug flows and would be supported if early experimental tests of bug flows determined they had the intended effects in restoring important native benthic invertebrate communities without having adverse effects on other resources. Under this long-term strategy, low summer flows would only be implemented in the second 10 years. Long-term strategy D3 is similar to D1 but removes TMFs.

The motivations for the different long-term strategies in Alternative D are the same critical uncertainties that motivate the long-term strategies in Alternative C, with a specific focus on the effectiveness of TMFs, the influence of temperature on juvenile HBC growth and survival, and the effect of bug flows on other resources.

5.6 Alternative E

Alternative E was developed by representatives of the seven states in the Colorado River Basin to provide for recovery of HBC while protecting other important resources, including sediment, the RBT fishery at Lees Ferry, aquatic food base, and hydropower resources. Called the "resource-targeted condition-dependent" strategy in interim public documents during the preparation of the EIS (Bureau of Reclamation and National Park Service, 2014), Alternative E has information-dependent and condition-dependent triggers, seeks to test critical hypotheses, and contains explicit instructions for how new insights will affect subsequent implementation of action elements.

The base operations for Alternative E seek greater value of hydropower production than Alternatives C and D (table 2). The monthly volumes largely follow hydropower demand and are proportional to the contract rate of delivery but with a reduction in August through October volumes to conserve sediment during the monsoon period. The daily range is large compared to the other alternatives. The ramp rates are the same as in Alternative C and D.

Alternative E includes a number of condition-dependent (triggered) elements; among them are fall HFEs, spring HFEs, TMFs, low summer flows, load-following curtailment

(before but not after HFEs), and mechanical removal of trout (table 3). Implementation of spring HFEs is delayed until the second 10 years to allow testing of TMFs in the early years (with long-term implementation of spring HFEs conditional on TMFs being an effective tool). An important experimental element of Alternative E is early testing of the response of RBT populations to TMFs and fall HFEs in a 2x2 factorial design, replicated two to three times (in hopes of experiencing both cold and warm water temperatures). The specific details of the triggers for these events are found in chapter 2 of the EIS. Most of these elements are experimental, and so there are information-dependent triggers as well; that is, monitoring and evaluation of all these elements would be completed, and elements would be dropped or retained depending on if the evidence supported their retention.

5.6.1 Alternative Long-Term Strategies

Six long-term strategies (E1, E2, E3, E4, E5, and E6) were developed to capture the range of possible outcomes from adaptive implementation of Alternative E (table 3). The motivation for the creation of these long-term strategies was the recognition that there are critical uncertainties that impede identification of the best long-term strategy. The key questions concerned the following: the magnitude of increase in RBT production in the Glen Canyon reach caused by fall HFEs, the relative effects of temperature and trout density on survival and growth of juvenile HBC at the Little Colorado River, the effectiveness of TMFs in reducing RBT production, and the effect of high flows on sediment retention.

Long-term strategy E1 uses spring and fall HFEs when triggered, along with TMFs to manage the trout populations; this long-term strategy would be favored, for example, if HFEs are determined to be beneficial to sediment conservation and TMFs are effective in controlling trout populations. Long-term strategy E2 also uses spring and fall HFEs but uses low summer flows instead of TMFs; this strategy might be favored if temperature is a more important factor in HBC survival than trout predation and TMFs are ineffective. Long-term strategy E3 does not allow HFEs, TMFs, or low summer flows and uses mechanical removal to manage trout density at the Little Colorado River when needed; such a strategy might be favored if HFEs greatly increase production of trout, TMFs are ineffective in managing trout populations, HBC are strongly affected by trout predation, and low summer flows do not provide enough advantage to HBC to warrant use. Long-term strategy E4 allows fall HFEs but not spring HFEs and relies on mechanical removal to manage trout at the Little Colorado River. Long-term strategy E5 is like E3 in not allowing HFEs but uses low summer flows rather than mechanical removal to support HBC population growth. Long-term strategy E6 also does not use HFEs and uses TMFs when needed to manage trout. As with Alternatives C and D, these long-term strategies are not meant to be a comprehensive set of the possible permutations of Alternative E that might arise from adaptive implementation but, rather, are meant to represent a broad range of possible outcomes, effectively bracketing the strategies that might arise.

As with Alternative C and D, whether or not the resolution of the critical uncertainties actually matters to the ranking of the long-term strategies is one of the central questions in section 8.3, “Expected Value of Information.”

5.7 Alternative F

Alternative F was designed to follow a more natural pattern of flows, limiting sediment transport and providing warmer temperatures in the summer months. The base operations provide higher release volumes in April–June (to mimic spring runoff), including a May 1 high-flow spike of 45,000 ft^3/s (essentially an untriggered HFE) and lower volumes the remainder of the year. The daily flows are steady with no daily fluctuations (no hydropeaking). The only modification to base operations would be sediment-triggered HFEs (fall and spring). In keeping with the desire to have this alternative better match predam conditions than the other alternatives, it does not use TMFs or mechanical removal.

5.8 Alternative G

Alternative G was designed to maximize the conservation of sediment by providing year-round steady flows. The base operations provide equal monthly volumes and steady daily flows. In practice, the monthly volumes would have to be adjusted as the forecasts for annual volume change through the year, but the intent is to keep flows quite steady. This alternative does allow all forms of HFEs to be used to maximize sandbar building and sediment conservation.

6 Quantitative Methods

The 19 long-term strategies were evaluated against the 18 performance metrics and 5 sources of uncertainty: the hydrology during the 20-year LTEMP period of performance, the sediment inputs during the 20-year LTEMP period of performance, the relative effects of temperature and trout predation on juvenile HBC survival and growth, the effectiveness of trout management flows, and the effect of fall HFEs on trout recruitment. A total of 10 modeling teams built a linked set of analyses to simulate the performance of the long-term strategies; the performance metrics were calculated from the simulation outputs. This section describes the methods used to complete these analyses.

6.1 Modeling Overview

The basis of the analysis of the alternatives was a large, linked set of simulation models that were meant to represent the Colorado River ecosystem below Glen Canyon Dam (fig. 2).

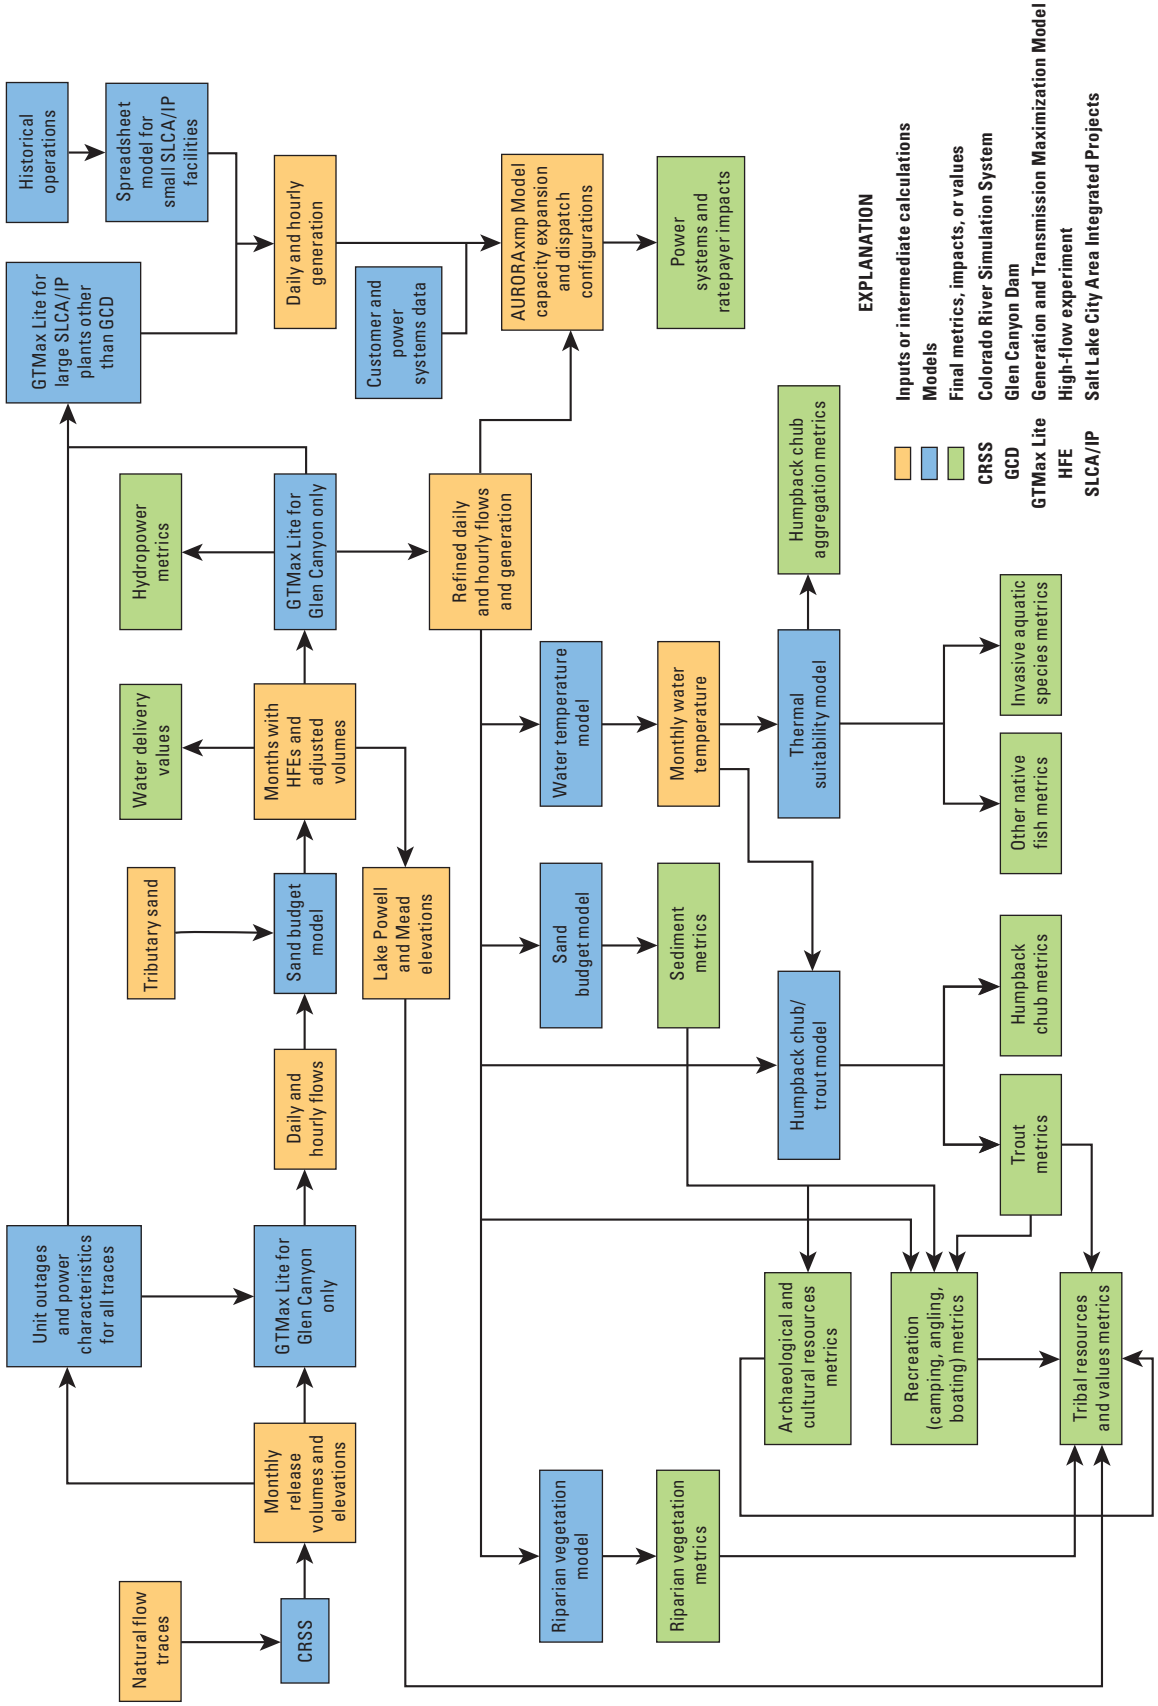

Figure 2. Model flow for the analysis of the Long-Term Experimental and Management Plan long-term strategies against the performance metrics.

Each long-term strategy encoded a set of rules that governed annual, monthly, daily, and hourly flow through the dam, as well as mechanical removal of nonnative fish from the Colorado River at its confluence with the Little Colorado River and vegetation treatments along the river corridor. The long-term strategy, coupled with 21 hydrological traces and 3 sediment traces (to represent environmental variation), determined the flows through the Glen Canyon Dam. The daily and hourly flows then were sent to models for vegetation, sediment, and temperature. The temperature and flow outputs then informed models for RBT, HBC, and other aquatic organisms. The outputs of all these models were collected and used to calculate performance metrics under all the resource goals. The details of all these modeling methods are provided in the technical appendixes to the LTEMP EIS; a synopsis is provided here.

6.2 Hydrology

The hydrological modeling requires three sets of input: a time series of hydrological flow into Lake Powell, a time series of sediment input into the Colorado River from the Paria River and the Little Colorado River, and the operational rules determined by a long-term strategy. The output of the hydrological modeling is the monthly, daily, and hourly flows through Glen Canyon Dam for the 20-year LTEMP period of performance. This requires three modeling systems. First, the Colorado River Simulation System (CRSS), built with the commercial software package RiverWare™ (Zagona and others, 2001), generates monthly volumes and lake elevations taking into account the operations of the 12 primary reservoirs on the Colorado River. Second, the Generation and Transmission Maximization model (GTMax-Lite) generates daily and hourly flows taking into account patterns of demand and supply of electric power in the Colorado River Storage Project (CRSP) region. Third, a sand budget model tracks sediment in Glen, Marble, and Grand Canyons; and is used to indicate when sediment conditions warrant high-flow experiments (if the long-term strategy in question allows them). After the HFEs are identified, a second pass through GTMax-Lite is required to refine the daily and hourly flows. Note that the effect of TMFs on hydrology were not modelled because this would have required a full coupling of the hydrology and fish models (with feedback from the fish models to the hydrology models), which was a computing task that was beyond the resources available.

6.2.1 Critical Uncertainty

To model uncertainty in future inflow, the indexed sequential method (Ouarda and others, 1997) was used to resample the historical record of natural flow in the Colorado River system during the 105-year period from 1906 through 2010. Every fifth trace was selected from this series to produce 21 hydrological traces; every long-term strategy was evaluated against all 21 hydrological traces.

To investigate the possible effects of climate change on the performance of the long-term strategies, CRSS was run with 112 natural flow traces developed from downscaled general circulation model projected hydrological traces (Bureau of Reclamation, 2012). These climate scenarios were based on 16 general circulation models from the Coupled Model Intercomparison Project Phase 3 (CMIP3) using three forcing scenarios (A2, high; A1b, medium; and B1, low) (Maurer and others, 2007). The LTEMP models were not run with the 112 hydrological traces; rather, the 112 hydrological traces from the climate-change scenarios were used to place weights on the 21 index sequential historical traces. The model results are compared using historical (equal) and climate-change weights on the 21 hydrological traces.

6.3 Sediment Dynamics

A sand budget model (Russell and Huang, 2010; Wright and others, 2010) was used to track sand storage and transport from Lees Ferry (RM 0) to Bright Angel Creek (RM 87) (fig. 1). The sand budget model takes as input hourly hydrographs at the reach boundaries (RM 30, RM 61, and RM 87) developed based on release schedules from Glen Canyon Dam and hourly sand delivery from the Paria and Little Colorado Rivers. The model tracks sand storage and movement through three reaches (Upper Marble Canyon, RM 0 to 30; Lower Marble Canyon, RM 30 to 61; and Eastern Grand Canyon, RM 61 to 87) using empirically-based rating curves formulated on a particle-size-specific basis. The outputs of the model include hourly time series of the sand transported at the downstream border of each reach, and the sand budget for each reach. From these outputs a variety of performance metrics, including the SLI (performance metric 15), can be calculated.

6.3.1 Critical Uncertainty

Sediment input to the Colorado River between Lees Ferry and Bright Angel Creek comes primarily from the Paria River and the Little Colorado River (fig. 1). Variation in sediment input is driven by spatial and temporal variation in precipitation. To capture uncertainty about the time series of future sediment input, three 20-year traces of sediment input were created from historical records using an index sequential method. For Paria River input, 49 reconstructed historical traces were available (index years 1964–2012). For Little Colorado River input, 18 reconstructed historical traces were available (index years 1995–2012). The cumulative 20-year sediment delivery for each trace was calculated; and the traces corresponding to the 10th, 50th, and 90th quantiles of cumulative sediment delivery were selected to represent the range of possible uncertainty. The traces from corresponding quantiles for the Paria River and Little Colorado River delivery were coupled in the simulations. Weights were placed on the three sediment traces so that the weighted mean and standard deviation of the 20-year Paria River sediment delivery for the three

traces matched the mean and standard deviation for the full set of index sequential Paria River traces.

6.4 Temperature

The average monthly water temperatures along the river corridor from Glen Canyon Dam to Lake Mead were forecast using the monthly flow and air temperatures forecasts. The release temperature from Glen Canyon Dam was simulated with the CE–QUAL–W2 model (Cole and Wells, 2006). This served as an input to a river temperature model that calculated the gains and losses of heat as the water moved downstream (Wright and others, 2009). For the purposes of the decision analysis, water temperature was an intermediate variable used as input to the fish models but not used directly as a performance metric.

6.5 Coupled Rainbow Trout-Humpback Chub Dynamics

A coupled RBT–HBC model was used to simulate the population dynamics of RBT in the Glen Canyon reach, movement of RBT from Lees Ferry to the Little Colorado River confluence, and the population dynamics of HBC in the Little Colorado River reach. The RBT population dynamics were simulated with an age-structured population model that accounted for the effects of water flow on recruitment, survival, growth, and downstream emigration (Korman and others, 2012). The RBT performance metrics are calculated from this model. The RBT catch rate (performance metric 3) was calculated from the age-specific abundances, age-specific vulnerabilities, and a catchability coefficient. The abundance of RBT greater than 16 inches (considered high-quality RBT; performance metric 5) was calculated from the age-specific abundances and size-at-age characteristics. The annual emigrants (performance metric 4) were computed as a fraction of the recruitment.

The RBT movement model predicts the monthly abundance of RBT in each 1-mile segment of the Colorado River from RM 0 to RM 150 taking into account movement rates, natural mortality, and implementation of mechanical removal. Movement and survival were density independent and were not affected by flow or temperature.

A size- and location-structured population model was used to predict the adult population size of HBC at monthly intervals (Yackulic and others, 2014). The HBC population size in two locations, the Colorado River and the Little Colorado River (a tributary of the Colorado River), was accounted for in the model. Survival of juvenile HBC in the Colorado River depended on the abundance of RBT in the Little Colorado River reach of the Colorado River; their growth depended on RBT abundance and temperature. Growth rates in other size classes in the Colorado River depended on water temperature. From this model, the minimum number of adult HBC during each 20-year trace was calculated, and the expected minimum value (performance metric 1) was calculated by taking the mean across traces.

6.5.1 Critical Uncertainties

A number of critical uncertainties concerned parameters in the RBT and HBC models. Each of these uncertainties was expressed as alternative sets of model parameters. All long-term strategies, with all sediment and hydrology traces, were run separately against the combinations of model parameters. The alternative sets of model parameters were assigned weights to represent their empirical support, and weighted averages of the performance metrics were calculated across them.

Uncertainty about the effect of fall HFEs on recruitment of RBT in the Glen Canyon reach was expressed as two hypotheses: one that there is no effect on recruitment, and another that proposed recruitment would increase at the same rate as seen with spring HFEs (Korman and others, 2011) but for only 1 year instead of 2 years. An expert panel consisting of four fish biologists who were familiar with RBT dynamics in the Colorado River was convened in March 2014. A modified Delphi process with four-point elicitation (Speirs-Bridge and others, 2010) was used to estimate the likelihood of the two hypotheses; the resulting individual estimates were aggregated by simple averaging.

Uncertainty about the effect of TMFs in reducing RBT recruitment in the Glen Canyon reach was expressed as two hypotheses by the expert panel: TMFs reduce recruitment by 10 percent, and TMFs reduce recruitment by 50 percent. The two levels of effectiveness were chosen to represent equally plausible extremes.

The final area of uncertainty concerned the effects of RBT abundance and temperature on the growth and survival of juvenile HBC in the Little Colorado River reach of the main stem Colorado River. Four hypotheses were generated (fig. 3*A* and 3*B*): a strong effect of temperature on growth and a strong effect of RBT on growth and survival (f1), a weak effect of temperature on growth and a weak effect of RBT on growth and survival (f2), a weak effect of temperature and a strong effect of RBT (g1), and a strong effect of temperature and a weak effect of RBT (g2). The parameter values for the four hypotheses were chosen from the ends of diameters on the 90-percent confidence ellipsoid for the joint parameter likelihood (Yackulic and others, 2014) and, thus, were equally weighted.

6.6 Fish Habitat Suitability

Temperature suitability for HBC and other native and nonnative fish at a number of sites between Lees Ferry (RM 0) and Diamond Creek (RM 225) (fig. 1) was evaluated with species-specific models for the effect of temperature on survival, reproduction, and growth (Valdez and Speas, 2007). The details of all these methods and results are in the LTEMP EIS.

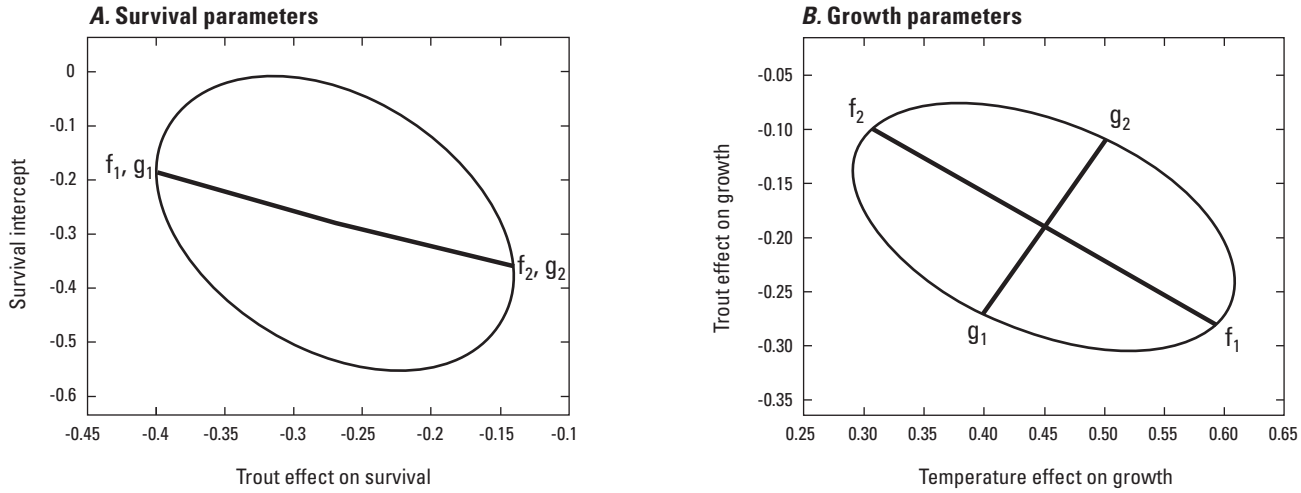

Figure 3. Uncertainty in the humpback chub population dynamics as represented by four alternative sets of parameters. *A*, survival parameters; and, *B*, growth parameters

The only one of those metrics that was retained for the decision analysis was the average temperature suitability for HBC at Havasu Creek (RM 157) and Pumpkin Spring (RM 213) because most of the other metrics exhibited very little difference across alternatives. Monthly water temperatures in the main stem Colorado River at the various sites under each long-term strategy were used to calculate the suitability for spawning, incubation, and growth during critical periods of the annual cycle. The overall temperature suitability at a site was the product of the suitability for the three component processes during the course of the year and could theoretically vary between 0 and 1 (performance metric 2).

6.7 Archaeological and Cultural Resources

The performance metrics associated with archaeological and cultural resources (performance metrics 6–8; table 1) did not require separate models but, rather, were calculated from intermediate sediment and flow variables.

6.8 Hydropower

As noted above in the "Hydrology" section (section 6.2), CRSS, the sand budget model, and GTMax-Lite are used in combination to simulate the water release and, therefore, hydropower generation on an hourly basis for each long-term strategy (fig. 2). The GTMax-Lite optimized the economic value of hourly energy produced at Glen Canyon Dam. This model determined an hour-by-hour pattern of generation (in megawatt hours) and water releases (in cubic feet per second) that satisfied the operating constraints imposed by each alternative, such as upramp and downramp rates, maximum change in the release during a rolling 24-hour period, maximum hourly release, and others. Hourly electricity market prices during the 20-year LTEMP period were determined using the AURORAxmp (Aurora) model to simulate the operation of the Western Interconnection of which Glen Canyon Dam is one of several thousand generating plants. Hourly prices determined by Aurora for 2013 were benchmarked against 2013 day-ahead market prices published by the Intercontinental Exchange. Prices forecast by Aurora for 2013 were compared against historical Intercontinental Exchange prices, and future electricity prices were adjusted accordingly.

For a given long-term strategy, the value of hydropower generation (performance metric 9) was calculated by combining the forecasts of the hourly generation profile and electricity market price. The net present value (NPV) of this 20-year time series was calculated assuming a 3.375 percent discount rate, and then divided by 20 to present the results on an annualized scale.

Hydropower capacity from Glen Canyon Dam is also marketed in the form of long-term firm contracts to provide power up to a given level. Energy demand is highest in August, so to calculate the marketable capacity (in megawatts), the peak daily generation was tabulated for each day in August across the 20 years of a trace (for each long-term strategy). From these 620 daily values (20 years x 31 days in August), the 90-percent exceedance value (10th quantile) was calculated, representing the marketable capacity for that trace. In 90 percent of August days (and much more often in other months), WAPA can be confident of being able to deliver that amount of power without having to purchase it. The net present value of that capacity (performance metric 10) was calculated by multiplying by the levelized cost of capacity plus fixed annual operating and maintenance (O&M) expenses of a thermal power plant constructed to replace capacity lost at Glen Canyon Dam. The selection of the replacement technology was based on insights obtained from the power systems economic analysis. The Aurora model runs made for this analysis determined that a natural gas combustion turbine would be the type of generating unit most likely constructed

as a replacement for lost Glen Canyon Dam capacity. The cost to construct that type of unit, spread over its book life, was determined to be $50,100/MW-year, including capital investment costs, allowance for funds during construction, and fixed O&M costs. The source of cost data for replacement power plant capacity was U.S. Energy Information Administration (2014). In the analysis in the LTEMP EIS (chapter 4 and appendix K), the daily August generation values for all traces were combined before the exceedance value was calculated; this results in some slight differences in the median values presented but not systematic bias.

6.9 Recreation

The performance metrics associated with recreation (performance metrics 11–13; table 1) did not require separate models but, rather, were calculated from intermediate sediment and flow variables.

6.10 Riparian Vegetation

The effects of the long-term strategies on riparian vegetation were simulated with a state-and-transition model for Colorado River riparian vegetation downstream from Glen Canyon Dam (Ralston and others, 2014). The model tracks seven vegetation communities (bare sand, marsh, shrub wetland, tamarisk, cottonwood-willow, arrowweed, and mesquite) on channel margins and sandbars in the New High Water Zone and Fluctuation Zone as affected by the depth, timing, and duration of inundation. Six geomorphic submodels are included: lower separation bar, upper separation bar, lower reattachment bar, upper reattachment bar, lower channel margin, and upper channel margin; only four of these are unique (the parameters for the upper separation bar, upper reattachment bar, and upper channel margin are all equal). The model starts in 1 of 25 possible states (the 7 vegetation communities crossed with the 6 geomorphic submodels; not all of the 42 combinations are possible) and then tracks the vegetation state in each subsequent year as affected by the alternative-specific flows. The output is the number of years spent in each vegetation state during the 20-year LTEMP period of performance. These results are summed across the 25 starting states and then compared to the results that would have happened if the starting state was maintained for the 20-year period. In comparing the native to nonnative states, and in calculating the native diversity, the results are weighted by the current estimated area of each vegetation state.

Four component ratios are calculated as intermediate results: the ratio of cumulative to initial native vegetation cover, the ratio of cumulative to initial vegetation state diversity, the ratio of cumulative to initial native to nonnative dominant vegetation state, and the ratio of initial to cumulative cover of arrowweed. The final value (riparian native states and diversity index; performance metric 14) is the sum of the four component ratios; thus, an index value of 4.0 indicates an unchanged vegetation condition, values greater than 4.0 indicate improved vegetation conditions, and values less than 4.0 indicate degraded vegetation conditions.

7 Consequence Analysis Results

In this section, the results for the individual performance metrics are presented. In most cases, these results are reported as means over all sources of uncertainty with boxplots used to show the variance induced by uncertainty. Unless otherwise noted, the historical weighting of hydrological traces was used; the sensitivity of the results to climate change (as captured by weighting of the hydrological traces) is discussed in section 8.4, “Effects of Climate Change.”

7.1 Humpback Chub Results

Across alternatives, the expected (mean) minimum number of adult HBC during the 20-year LTEMP period of performance differed by about 500 from Alternative A (fig. 4, bottom panel). The variation across hydrological traces within an alternative was greater than the magnitude of variation across alternatives. Many of the long-term strategies were demonstrably better than Alternative A; the biggest exceptions (C2 and F) were long-term strategies that increased RBT recruitment (through HFEs) without tools to manage RBT populations (TMFs and mechanical removal). The best-performing long-term strategy (E6) did not allow HFEs of any type and included triggered use of TMFs if needed. The benefit of low summer flows to HBC (compare D1 to D4) is not discernible, likely because of their infrequent use.

The set of 16 scenarios that captured critical uncertainty did not affect the dominance of long-term strategy E6 (table 4); that is, if the only desired outcome is to maximize the HBC metric, the best long-term strategy is E6 regardless of the effect of fall HFEs or TMFs on RBT recruitment or the relative effects of temperature and RBT on juvenile HBC growth and survival. For the purpose of the HBC objective, therefore, the expected value of information across the critical uncertainties that were articulated is 0.

Across the uncertainty represented by the hydrological traces, there is a small value of information (table 5). For most hydrological traces, the best long-term strategy for HBC was E6; but long-term strategies B2, C3, D1, and E5 were also favored in some traces. In the face of uncertainty, the best strategy is E6 with an expected (mean) minimum adult population size of 5,708. If the hydrological trace could be known in advance of choosing an action, the appropriate strategy (B2, C3, D1, E5, or E6) would be chosen; the expected minimum adult population size would be 5,725, which is an increase of 0.30 percent. Of course, the hydrological trace cannot be known in advance of choosing an action because it represents environmental variation during the next 20 years, but the inclusion of these results is helpful in understanding the value

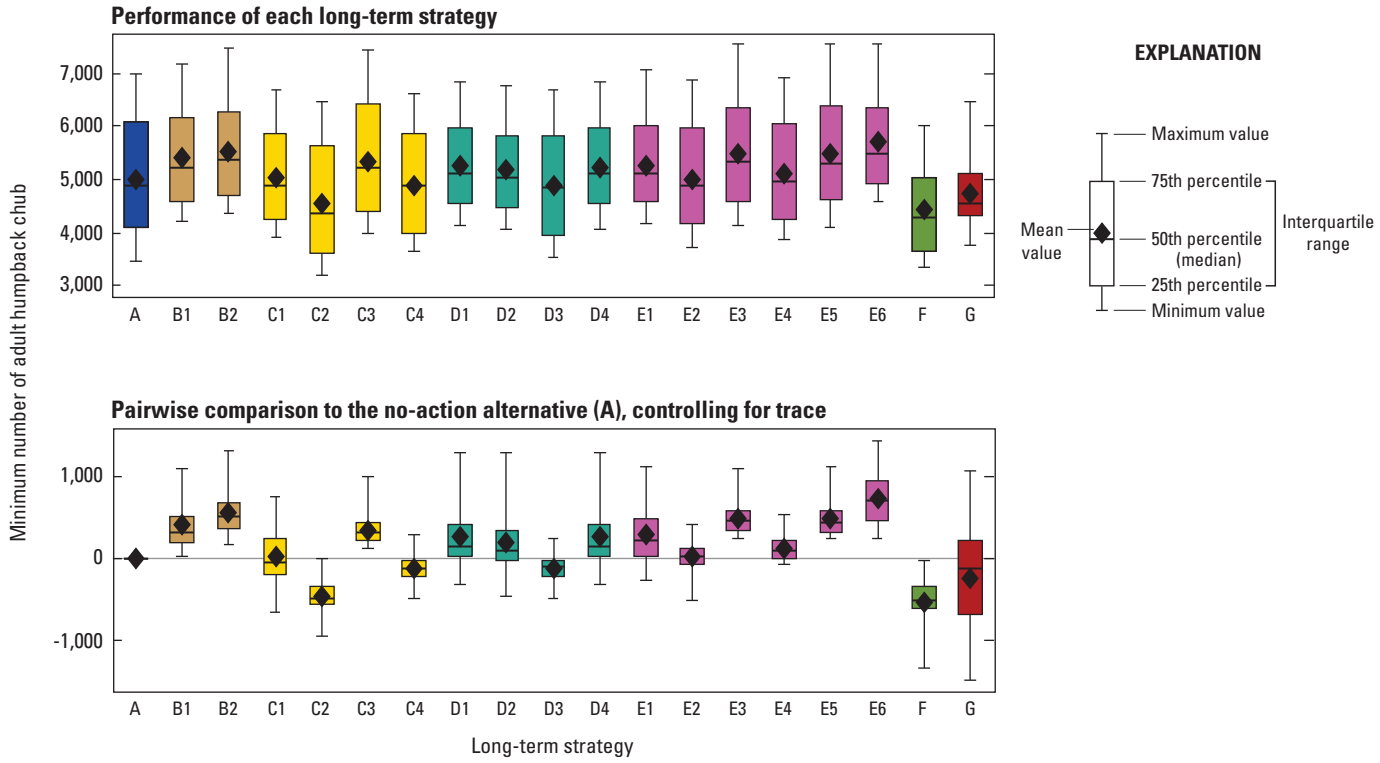

Figure 4. Minimum number of adult humpback chub (performance metric 1) forecast for 19 long-term strategies with equal weighting of traces.

of information for resolvable uncertainty (the 16 scenarios) relative to the value of information for background environmental variation.

The value of information depends on the set of long-term strategies evaluated. The calculations just described assume the decision maker is choosing from the entire set of 19 long-term strategies. In practice, it is more likely that one of the alternatives would be chosen, and the long-term strategy would be chosen from within the set associated with that alternative. The value of information in resolving the critical uncertainties is 0 for all alternatives except Alternative C, which has a value of information of 8.5 adult HBC (table 6).

Temperature suitability for HBC was forecast at a number of locations in the main stem Colorado River, and in most cases the suitability was low (less than 0.03 on a scale of 0 to 1). At the two locations farthest downstream (Havasu Creek, RM 157; Pumpkin Spring, RM 213; fig. 1), the average suitability was around 0.1 (on a scale of 0 to 1). The temperature suitability for HBC was affected more by hydrology than by the long-term strategy; only Alternative F stood out from the other alternatives (fig. 5). Alternative G, with its year-round steady flows, provided the best suitability (mean 0.102); its ranking above the other long-term strategies was not affected by any of the critical uncertainties (table 6). There was a small effect of the hydrological trace on the ranking of alternatives based on temperature suitability (EVXI; 0.77 percent; table 6).

7.2 Rainbow Trout Fishery Results

The RBT performance metrics differed substantially across long-term strategies (figs. 6–8). The RBT catch rate (performance metric 3) and RBT emigration rate (performance metric 4) were highly correlated with one another because both were driven by the RBT population size. Catch rate and emigration rate were highest for those long-term strategies that implemented many HFEs but did not allow TMFs (C2, C4, D3, E2, and F) or that provided steady flows that supported RBT recruitment (G) (figs. 6–7). The abundance of high-quality RBT (greater than 16 inches in length, performance metric 5) was negatively correlated with RBT population size; the best long-term strategies were those that restricted or did not allow HFEs (B1, B2, C3, E3, E5, E6) (fig. 8).

Apart from the HBC metric when only the strategies under Alternative C were considered, the RBT performance metrics were the only ones affected by the critical uncertainties; the fall HFE hypothesis had an EVXI of 0.26 percent, 3.50 percent, and 0.98 percent for the three performance metrics, respectively (table 6). Across all performance metrics and all uncertainties, the strongest effect was the effect of the combined hydrological/sediment trace on the RBT catch rate with an EVXI of 7.53 percent (table 6). The uncertainty about the effectiveness of TMFs did not affect the top ranked long-term strategy for any of the trout or other performance metrics (table 6).

Table 4. Effect of critical uncertainty on minimum adult humpback chub population size (performance metric 1).

[The cell entries show the expected minimum humpback chub population size for each long-term strategy in each combination of hypotheses. The hypotheses are if high-flow experiments increase rainbow trout recruitment (N, no; Y, yes), how effective rainbow trout management flows are (H, high effectiveness; L, low effectiveness), and the relative effects of temperature and rainbow trout on juvenile humpback chub survival and growth (f1, f2, g1, and g2). A solid dot (●) indicates the result is averaged over this uncertainty. The highlighted long-term strategy is the best performing alternative in each row. HFE, high-flow experiments; TMF, trout management flow; RBT, rainbow trout]

Table 5. Effect of hydrological trace on minimum adult humpback chub population size (performance metric 1).

[The cell entries show the expected minimum adult humpback chub population size for each long-term strategy, under each hydrological trace, averaged over the sediment traces and critical uncertainties. The bottom row shows the mean over the hydrological traces. The highlighted long-term strategy is the best performing alternative in each row. The best strategy in the face of uncertainty has an expected minimum population size of 5,708; the expected minimum population size if the hydrological trace could be known before the strategy was selected is 5,725 (average of the highlighted cells). Thus, the expected value of information, for resolving uncertainty about the future hydrology, is an increase of 17 adults in the minimum humpback chub population.]

Table 6. Expected value of information, by performance metric, for resolving critical uncertainty.

[See table 1 for a list of performance metrics. The best performance is the expected value of the performance metric across all uncertainties for the long-term strategy that maximized or minimized the performance metric. The value of perfectly resolving uncertainty across the 16 formal hypotheses about critical parameters is shown when all 19 long-term strategies are considered; only the two long-term strategies of alternative B are considered; and only the four, four, or six long-term strategies of alternatives C, D, and E are considered, respectively. Partial values of information are shown for resolving only the uncertainty about the effects of fall high-flow experiments on rainbow trout recruitment, efficacy of trout management flows, and effects of temperature and rainbow trout on humpback chub. Finally, the partial values of information are shown for resolving uncertainty about the combined hydrological-sediment trace, just the sediment trace, and just the hydrological trace. For the performance metrics not shown, all values of information were 0. min, minimum; HBC, humpback chub; TempSuit, temperature suitability index; Qual, quality; RBT, rainbow trout; WTSI, wind transport of sediment index; GC flow, Glen Canyon flow index; TOR, time-off-river index; CAI, camping area index; Veg, riparian vegetation index; SLI, sand load index; max, maximum; EVPI, expected value of perfect information; EVXI, expected value of partial information; HFE, high-flow experiment; TMF, trout management flow; ~, value less than 0.01 percent]

7.3 Archeological and Cultural Resources Results

The protection of archeological and cultural resources was reflected in three performance metrics. The WTSI (performance metric 6) was largely driven by the SLI (performance metric 15) and was highest for those long-term strategies that implemented HFEs often (fig. 9). The best-performing alternative for WTSI was Alternative G (mean WTSI, 0.465); this ranking was not affected by any of the critical uncertainties or uncertainty in the sediment input (table 6). For some hydrological traces, long-term strategy C1 outperformed G, but the value of information related to hydrological uncertainty was small (0.44 percent).

The Glen Canyon flow index (performance metric 7) differed little among alternatives with a mean of around 20 days per year in which the flow exceeded 23,200 ft^3/s (fig. 10). Only Alternative F differed from the other long-term strategies (mean 36.8 days/year). The long-term strategies that did not allow HFEs (C3, E3, E5, and E6) had the best performance (smallest Glen Canyon flow index). The top ranking long-term strategy was not affected by critical uncertainty or sediment trace (table 6) but did vary depending on the hydrological trace (EVXI, 4.77 percent).

The time-off-river index (performance metric 8) was affected most strongly by the hydrological trace but was also weakly affected by the long-term strategy (fig. 11). Alternatives B and C were indistinguishable from Alternative A; Alternatives D, E, and G performed slightly better than Alternative A; and Alternative F performed noticeably worse because high flows during the peak rafting season allow quicker trips and more discretionary time at camping stops. Long-term strategies E1 and G were the best-performing strategies across hydrological and sediment traces, with only a small value of information associated with the trace uncertainty and no value of information associated with the critical uncertainties (table 6).

7.4 Hydropower Generation and Capacity Results

The best-performing long-term strategy for hydropower generation (performance metric 9) was B2, a long-term strategy designed to match power generation more closely to demand (fig. 12). For most of the long-term strategies, the annual value of hydropower generation is within $3 million of the value from Alternative A, except for Alternatives F and G for which annual generation is $6 million to $8 million less than Alternative A (fig. 12). The effect of hydrology on hydropower generation is much greater than the effect of the alternatives, with the average annual power generation over 20 years varying more than $60 million across hydrological traces (fig. 12). The dominance of B2 as the best long-term strategy for hydropower generation, however, is robust to uncertainty in hydrology with a value of information of only $350,000 per year (EVXI, 0.23 percent, table 6); for 4 out of 21 hydrological traces, long-term strategy E3 outranked B2.

The value of hydropower capacity (performance metric 10) was more sensitive to the choice of long-term strategy than hydropower generation with long-term strategies differing by nearly $20 million per year (fig. 13). Long-term strategy B2 was the best-performing strategy across all uncertainties, including hydrological trace. The long-term strategies in Alternative B outperformed Alternative A; all the remaining long-term strategies had a lower value of hydropower capacity than Alternative A (fig. 13). The value of capacity was somewhat sensitive to hydrological trace (the range of performance within a long-term strategy varied by $8 million to $17 million per year across hydrological traces), but the identification of the best-performing alternative was not (EVXI, 0).

7.5 Recreational Experience Results

The camping area index (performance metric 11), a metric composed from the SLI to represent beach formation and a flow factor to represent beach exposure, was highly correlated with the SLI (performance metric 18). The best-performing long-term strategies (especially C1, F, and G) include frequent implementation of HFEs; the worst-performing long-term strategies (for example, C3, E3, E5, and E6) do not permit HFEs (fig. 14). The identification of the top-ranked long-term strategy was affected by the combination of hydrological and sediment trace (EVXI, 1.96 percent) but not by any other uncertainties (table 6).

The fluctuation index (performance metric 12), which reflects the fraction of time the daily flow fluctuations are in a tolerable range for recreation, was highest for Alternatives F and G and lowest for Alternative B (fig. 15). Alternative D was comparable to Alternative A. The effect of the long-term strategies within an alternative was small compared to the effect of the base operations within each alternative. The fluctuation index was not strongly affected by any of the uncertainties, including hydrological trace.

The Glen Canyon rafting use metric (performance metric 13), which reflects the visitor-days lost per year because of HFEs, was best for those long-term strategies that did not permit HFEs (for example, C3, E3, E5, and E6) and worst for Alternative F (fig. 16). Under Alternative F, nearly 1,000 boat seats per year in Glen Canyon are expected to be lost because of HFEs. The rafting use metric showed variation as a result of hydrological trace, but the identification of the best-performing long-term strategies was not affected by any of the uncertainties.

7.6 Riparian Vegetation Results

The riparian vegetation index (performance metric 14) was the sum of four ratios that represented measures of different aspects of the vegetation community with a score of 4 indicating maintenance of current conditions.

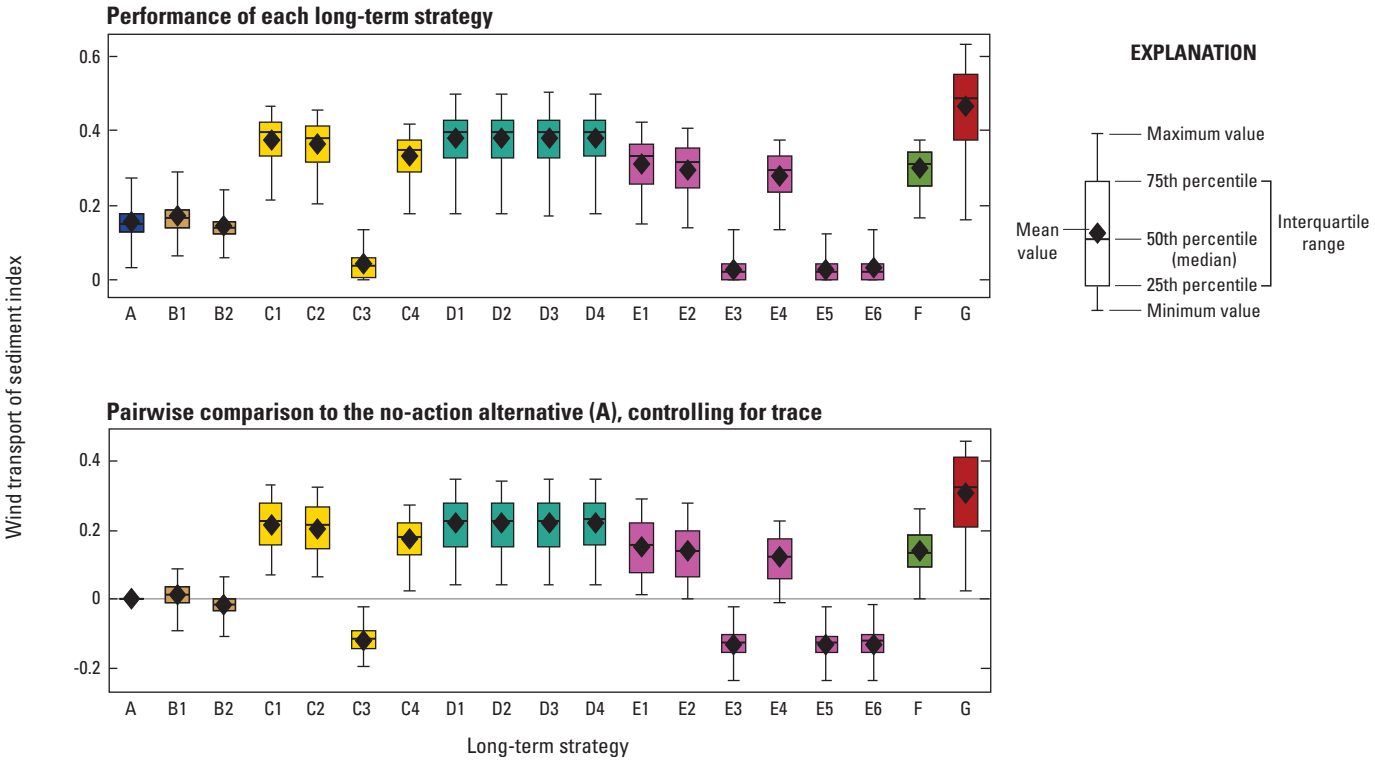

Figure 9. Wind transport of sediment index (performance metric 6) forecast for 19 long-term strategies with equal weighting of traces.

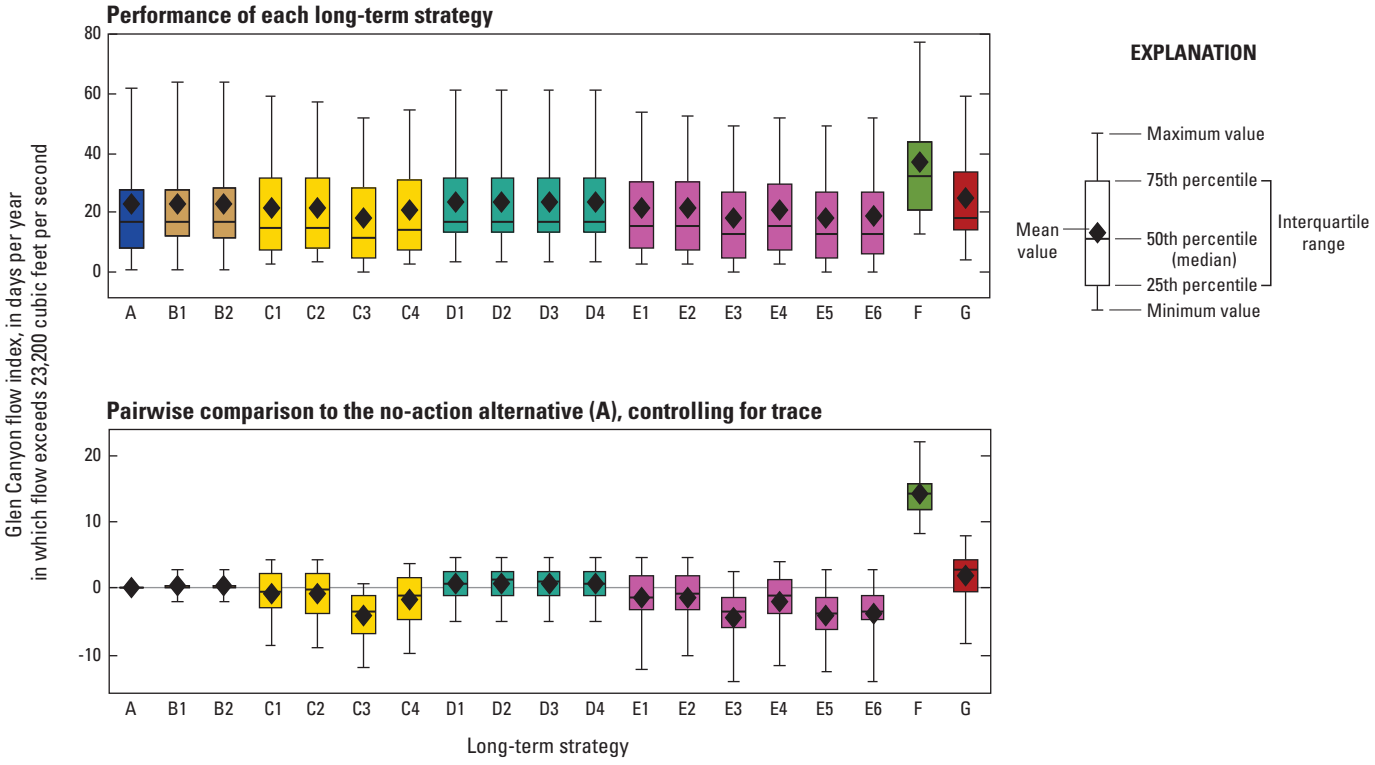

Figure 10. Glen Canyon flow index (performance metric 7) forecast for 19 long-term strategies with equal weighting of traces.

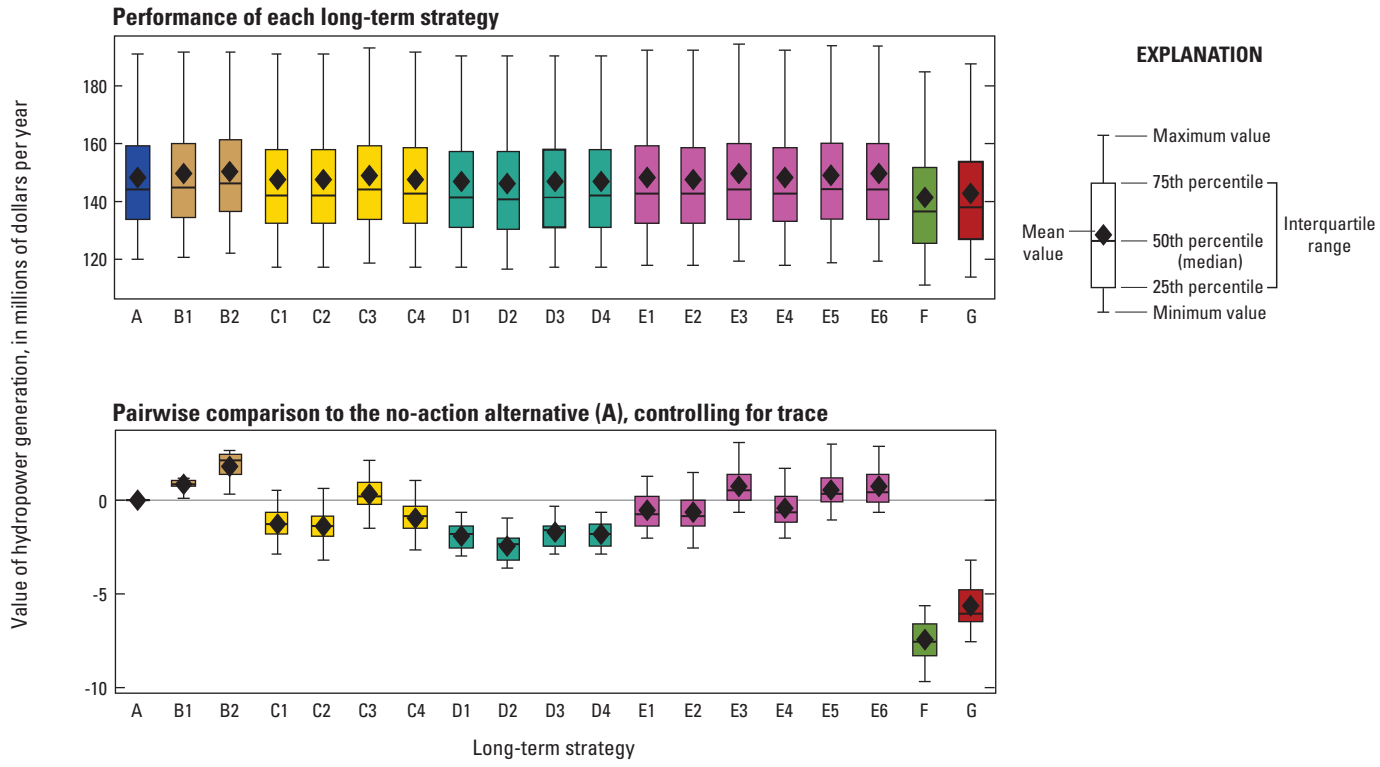

Figure 12. Annualized net present value of hydropower generation (performance metric 9) forecast for 19 long-term strategies with equal weighting of traces.

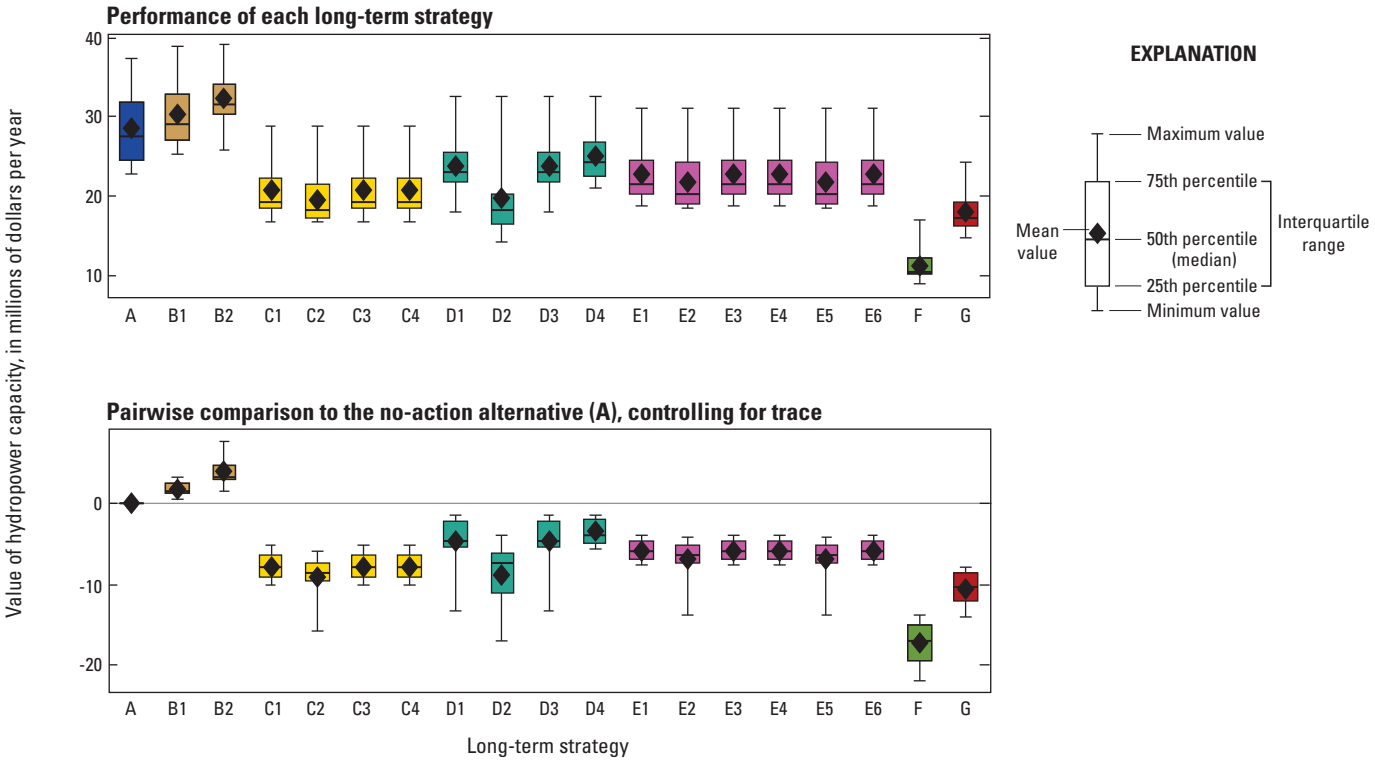

Figure 13. Annualized net present value of hydropower capacity (performance metric 10) forecast for 19 long-term strategies with equal weighting of traces.

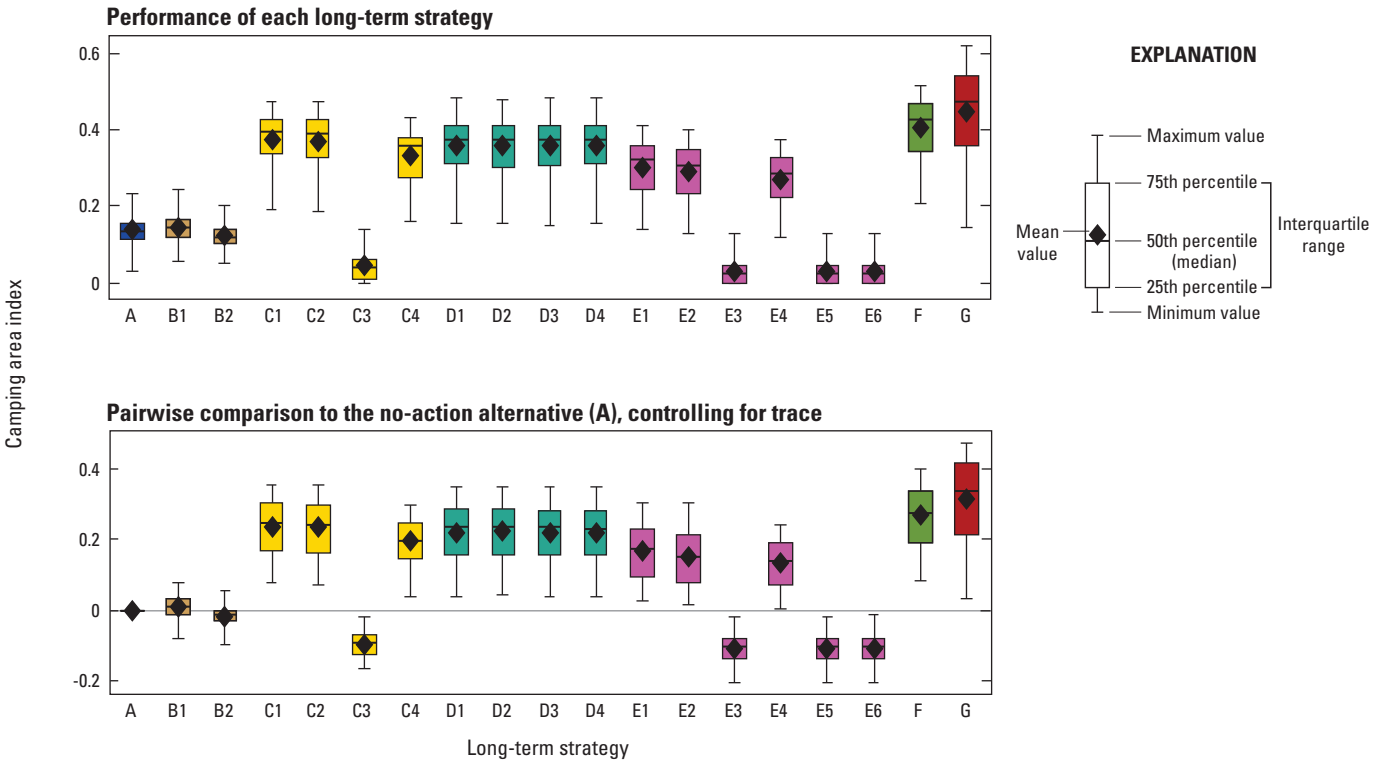

Figure 14. Camping area index (performance metric 11) forecast for 19 long-term strategies with equal weighting of traces.

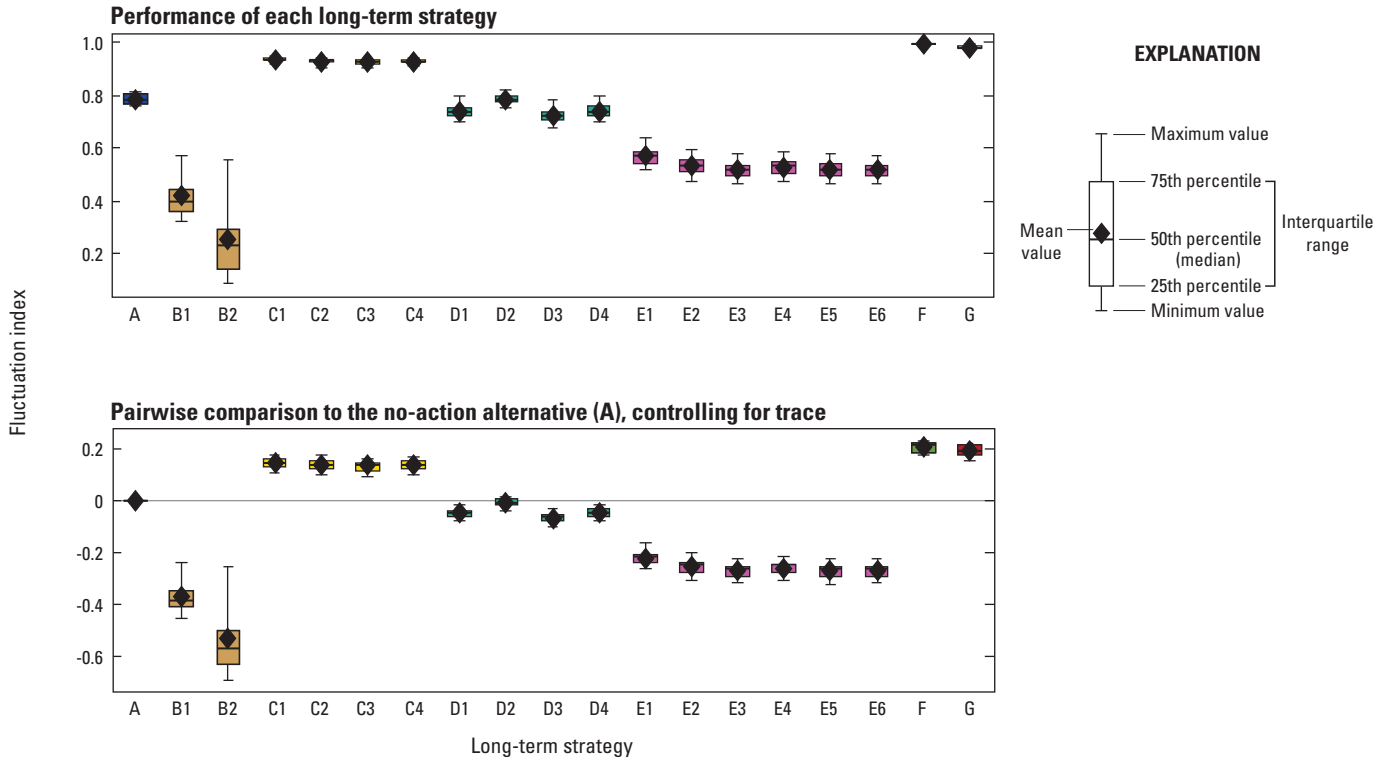

Figure 15. Fluctuation index (performance metric 12) forecast for 19 long-term strategies with equal weighting of traces.

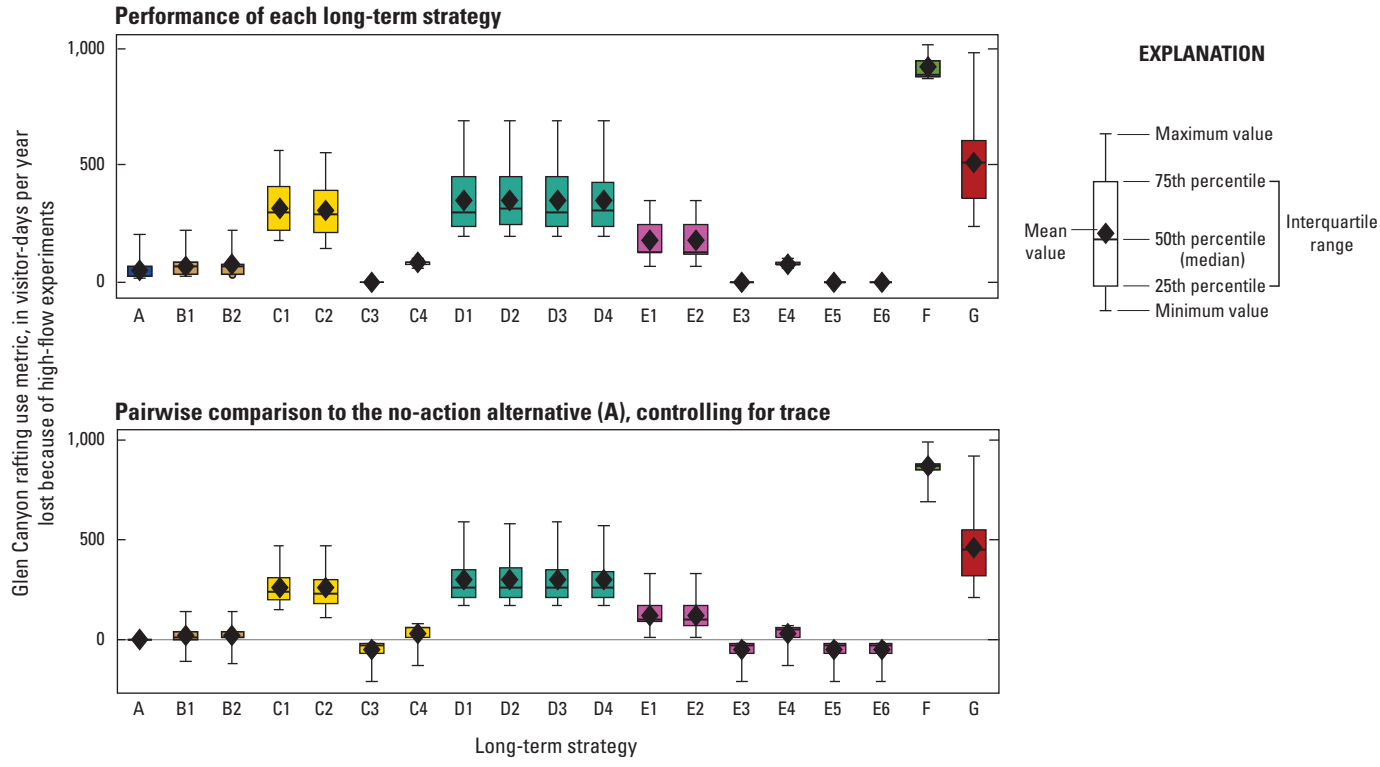

Figure 16. Glen Canyon rafting use metric (performance metric 13) forecast for 19 long-term strategies with equal weighting of traces.

The index ranged between 2 and 6 across alternatives and traces (fig. 17), indicating a 50-percent degradation or a 50-percent improvement in vegetation conditions, respectively. The highest mean vegetation index was associated with long-term strategy D4 (riparian vegetation index, 3.954), but 13 of the 19 long-term strategies were ranked first depending on the hydrological and sediment trace. The value of information for resolving uncertainty about the hydrological and sediment trace before committing to a long-term strategy was 0.224 (an improvement of 5.66 percent; table 6). The choice of the long-term strategy was not affected, however, by any of the critical uncertainties (table 6).

7.7 Sediment Results

The SLI (performance metric 15) measured the potential for sand bar formation by reporting the proportion of sand transported during flows greater than 31,500 ft^3/s. The SLI was most strongly affected by the frequency of HFEs; the long-term strategies with the highest SLI (especially C1, C2, D1, D2, F, and G) allowed frequent HFEs, and the long-term strategies with the lowest SLI (C3, E3, E5, and E6) did not permit HFEs (fig. 18). Uncertainty in the combination of hydrological and sediment trace did affect the ranking of the alternatives (EVXI, 3.57 percent; table 6) with 6 of the 19 long-term strategies favored in at least 1 trace.

7.8 Tribal Resources Results

Several performance metrics were developed to evaluate resources of specific importance from a tribal perspective. The marsh vegetation ratio (performance metric 16) forecast the preservation or expansion of the wetland vegetation communities along the Colorado River (fig. 19). For context, the current extent of marsh vegetation is 4.6 acres. The long-term strategy with the highest mean marsh vegetation ratio was E6 (mean marsh vegetation ratio, 1.101), representing about a 10-percent increase in marsh community area, but long-term strategy E3 was most commonly ranked first among the 63 traces. Alternatives C, F, and G exhibited consistent losses of marsh vegetation compared to Alternative A, whereas Alternatives D and E exhibited modest increases (fig. 19). The variance in the index induced by variation in hydrology was larger than the variance across alternatives (fig. 19). The value of information for resolving hydrological and sediment uncertainty before committing to a long-term strategy was 3.20 percent (table 6).

The frequency of mechanical removal (performance metric 17) was 0 for those long-term strategies that do not permit this management tool (C1, C2, E1, E2, E5, E6, and F) and varied between 0 and 6 years out of 20 for the other long-term strategies (fig. 20). For those long-term strategies that permitted mechanical removal, the frequency was influenced by the emigration rate of RBT from Glen Canyon (performance metric 4), which in turn was influenced by the frequency of HFEs. Because the long-term strategies with the lowest frequency were determined simply by whether mechanical removal was allowed or not, the identification of the top-ranked strategy was not influenced by any of the uncertainties.

The frequency of trout management flows (performance metric 18) was 0 for those long-term strategies that did not allow their use (10 out of the 19 long-term strategies) and varied between 0 and 20 years out of 20 for the remaining strategies (fig. 21). Under Alternative G, TMFs were triggered on average more than one-half of the years, and sometimes in all 20 years, depending on the hydrological trace. For the strategies that allowed TMFs, the frequency of their use was correlated with RBT abundance and, hence, with the RBT catch rate (performance metric 3) and emigration rate (performance metric 4). Again, because the long-term strategies with the lowest frequency of TMFs were determined by the admissible tools in the strategy, the value of information associated with the various uncertainties was 0.

7.9 Full Consequence Table

A summary of the performance of the 19 long-term strategies against the 18 performance metrics is represented in a consequence table (table 7). There is neither a single long-term strategy that performs best for all performance metrics (such a strategy would be shaded in yellow across the corresponding row), nor a single long-term strategy that performs worst for all performance metrics (such a strategy would be shaded dark blue across the row); furthermore, no long-term strategy is either consistently better or consistently worse than Alternative A across all performance metrics. Interestingly, the strategies that are worst for a number of performance metrics (for example, B2, C3, E5, F, and G) are also best for other performance metrics. Other long-term strategies are neither best nor worst on any performance metrics (for example, B1, C4, D1, D2). This pattern of performance indicates that there are important tradeoffs among the long-term strategies, and the best alternative cannot be identified without considering the relative value of the resource goals and performance metrics.

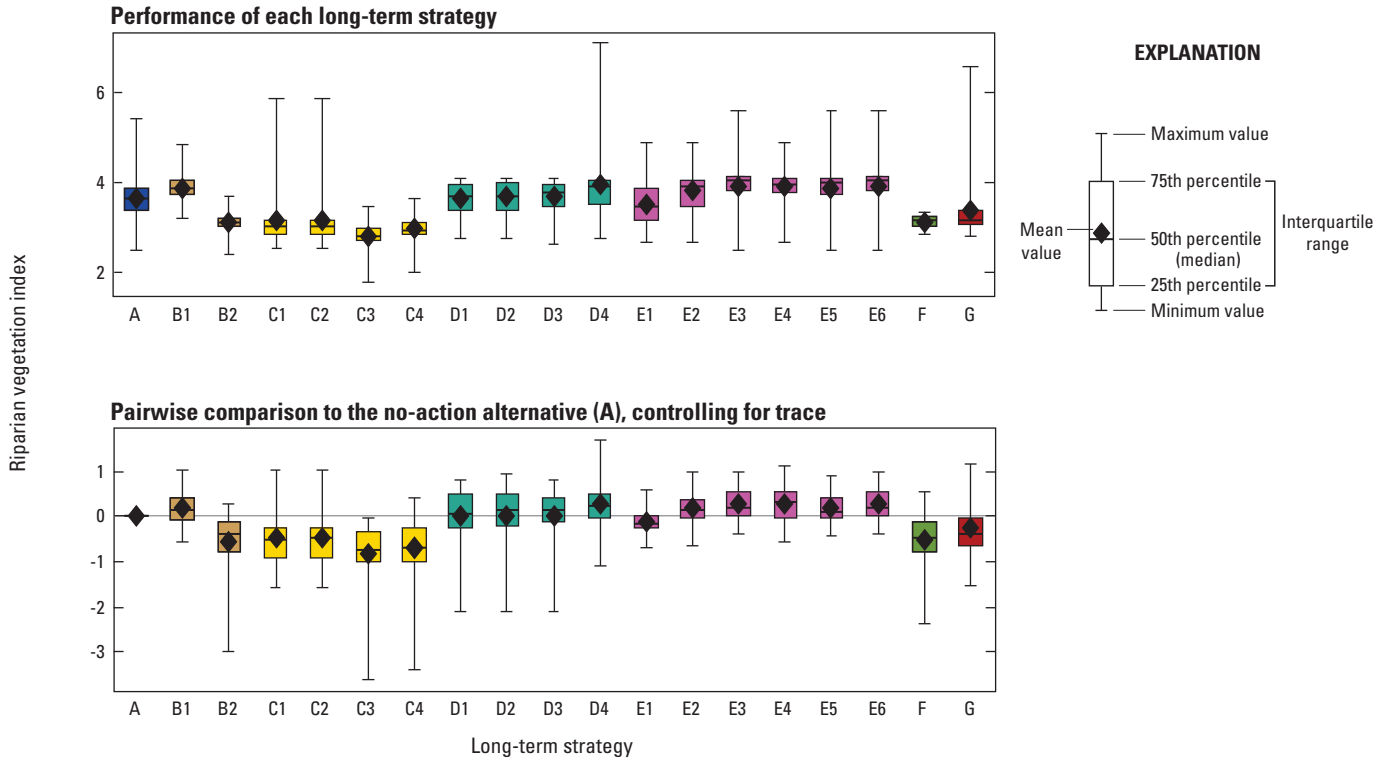

Figure 17. Riparian vegetation index (performance metric 14) forecast for 19 long-term strategies with equal weighting of traces.

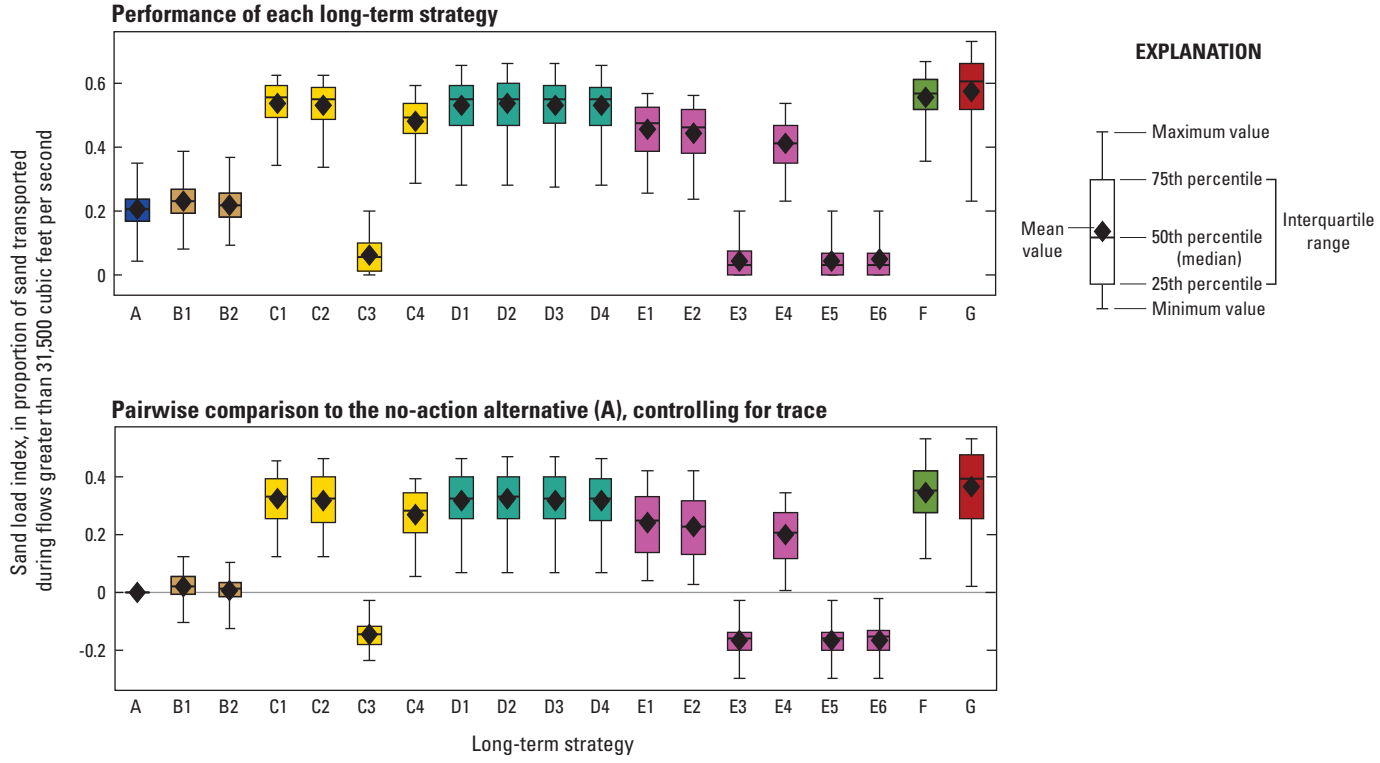

Figure 18. Sand load index (performance metric 15) forecast for 19 long-term strategies with equal weighting of traces.

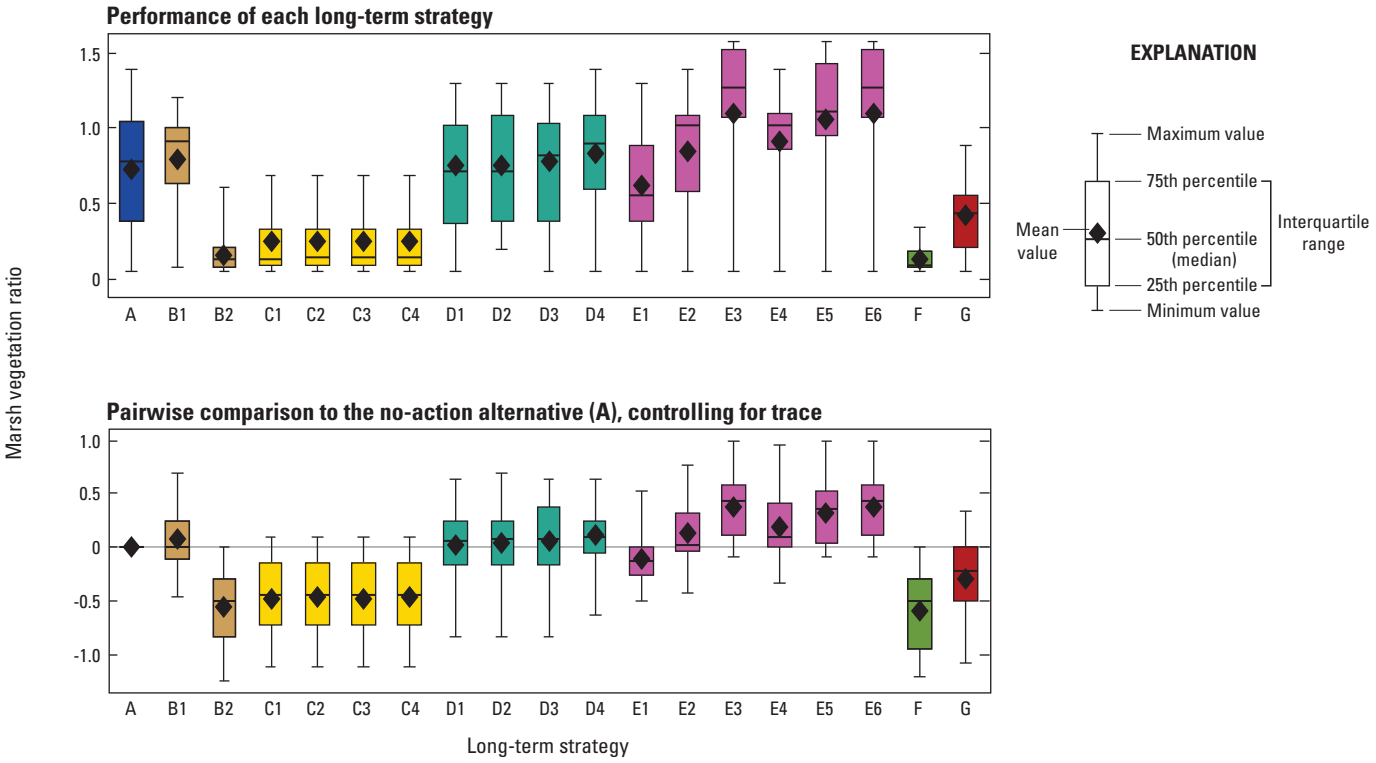

Figure 19. Marsh vegetation ratio (ratio of average marsh cover over 20-year period to current marsh cover, performance metric 16) forecast for 19 long-term strategies with equal weighting of traces.

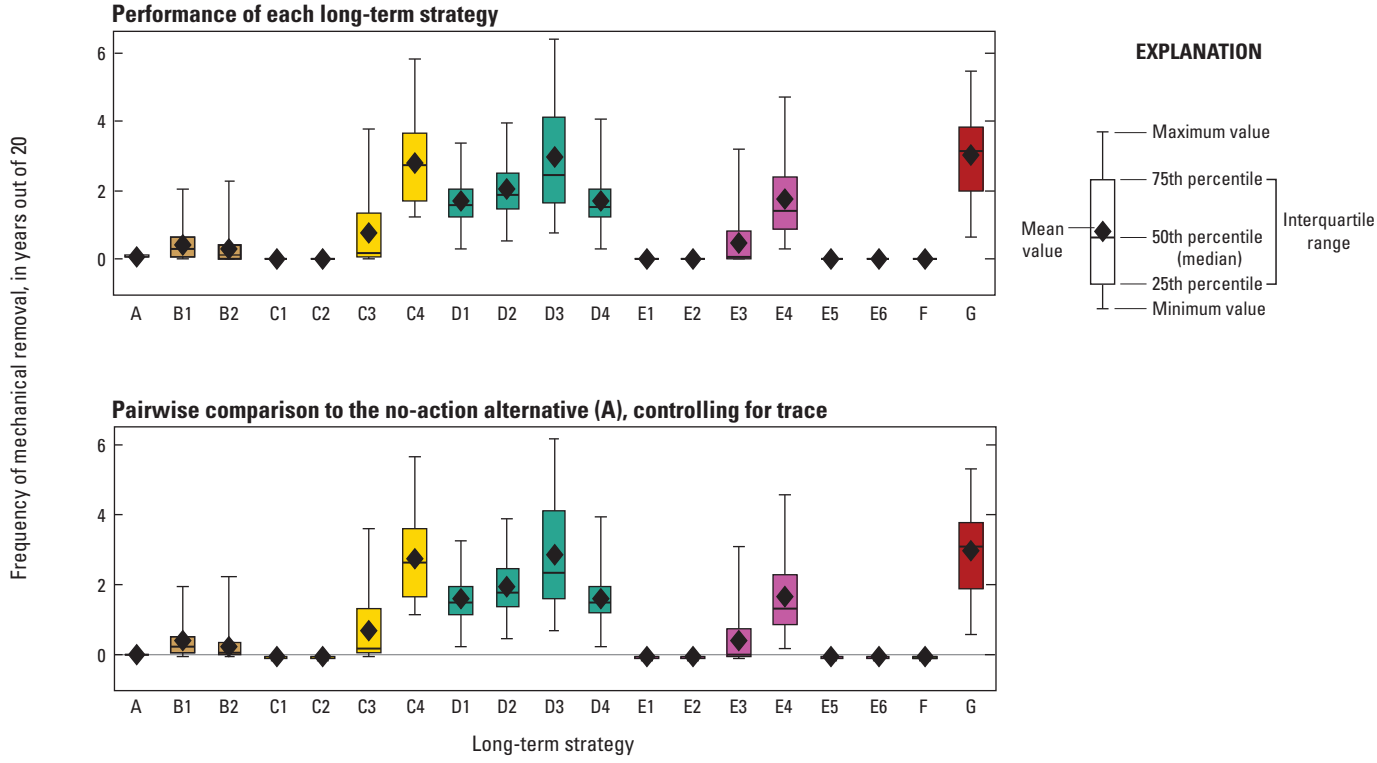

Figure 20. Frequency of mechanical removal (performance metric 17) forecast for 19 long-term strategies with equal weighting of traces.

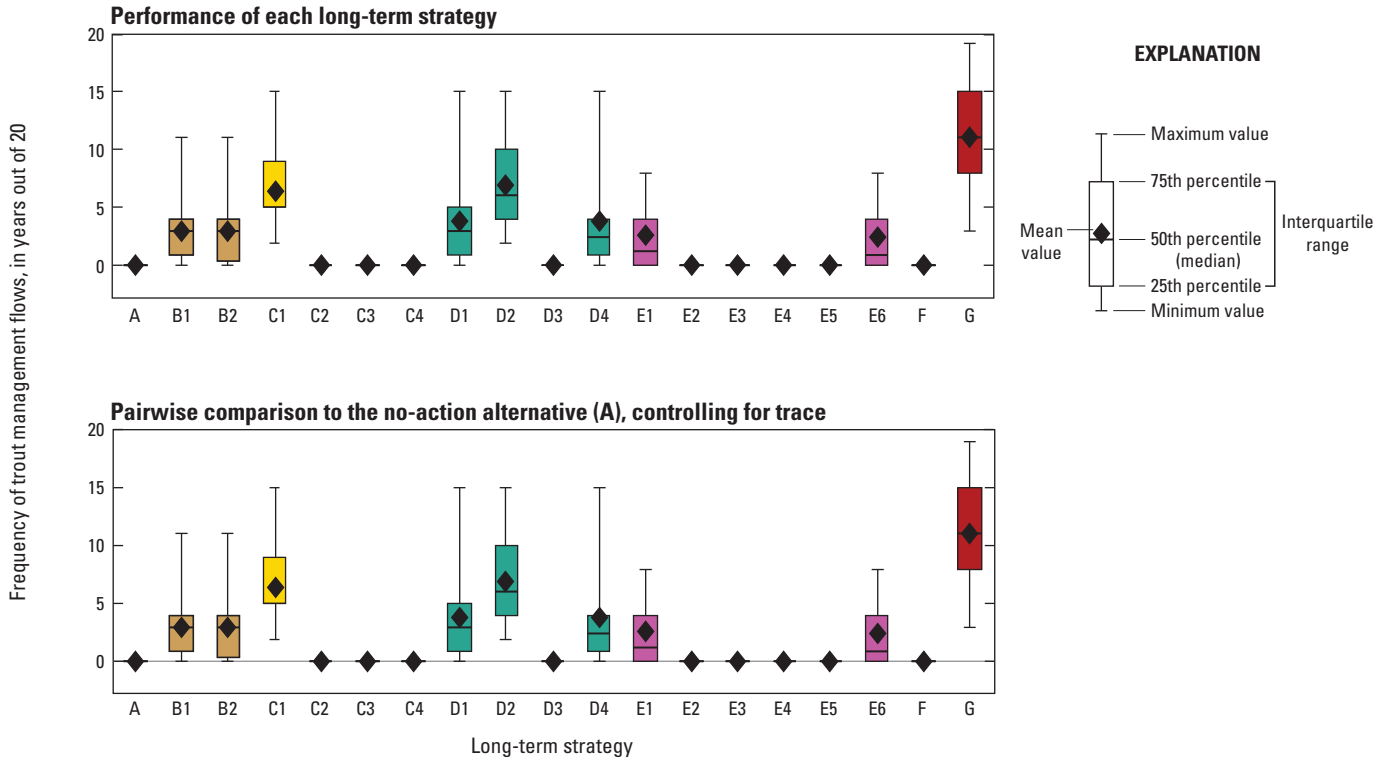

Figure 21. Frequency of trout management flows (performance metric 18) forecast for 19 long-term strategies with equal weighting of traces.

Table 7. Full consequence table showing the mean value of each performance metric for each long-term strategy.

[The columns are the performance metrics, numbered as in table 1. For most performance metrics, higher values are desired (yellow), but for five metrics, lower values are desired (pink). The rows are the long-term strategies. The values in each column are color-coded, with the best-performing long-term strategy shaded in yellow, the worst-performing long-term strategy shaded in dark blue, strategies that perform better than status quo (Alternative A) shaded in orange, and strategies that perform worse than status quo shaded in turquoise. HBC, humpback chub; TempSuit, temperature suitability index; RBT, rainbow trout; WTSI, wind transport of sediment index; GC flow, Glen Canyon flow index; TOR, time-off-river index; CAI, camping area index; FI, fluctuation index; GC raft, Glen Canyon rafting use metric; Veg, riparian vegetation index; SLI, sand load index; MR, mechanical removal; TMF, trout management flow]

8 Decision Analysis Results

The purposes of completing a formal decision analysis as a component of the evaluation in the LTEMP EIS was to explicitly examine the influence of the relative importance assigned to the resource goals on the ranking of the alternatives and long-term strategies, and to understand the effect of uncertainty on this same ranking. As described in section 3, "Decision Analysis," the two primary tools used to support this investigation were MCDA and the expected value of information.

8.1 Swing-Weighting Method and Results

The swing-weighting method (Winterfeldt and Edwards, 1986) was used to develop weights for the performance metrics, reflecting individual stakeholder expressions of the relative importance of those metrics. In April 2014, a 2-day workshop was held to present a preliminary analysis of the long-term strategies against the performance metrics to interested stakeholders. After discussion of the meaning and interpretation of each of the performance metrics, the stakeholders were given a swing-weighting response form with instructions (table 8) to complete within several weeks. The swing-weighting method asks a decision maker or stakeholder to consider each resource goal, the performance metric that reflects it, and the range over which the performance metric varies; and to compare the relative importance of the performance metrics by evaluating how valuable it would be to change the performance of an alternative from the worst score for a performance metric to the best score. The stakeholders were first asked to rank the performance metrics in this manner and then to assign a score between 0 and 100 to each metric to reflect a more nuanced interpretation of the ranking. Because it is difficult to evaluate 18 performance metrics simultaneously, and because there were natural groupings of the metrics, the swing-weighting exercise used a two-level structure. The 18 performance metrics were assigned to 8 higher-level groups (table 8). The stakeholders first ranked and scored the metrics within each group. Then, to rank and score the higher-level groups, the stakeholders were asked to think about the importance of changing the scores of all the metrics within a group for their worst levels to their best levels at the same time. While completing this exercise, the stakeholders had access to a preliminary consequence table (similar to table 7) and a spreadsheet that automatically calculated the weights on the performance metrics as the swing-weighting sheet was filled in.

A total of 27 Federal, State, tribal, and private agencies and organizations were invited to participate in the decision analysis by expressing their view of the relative importance of the performance metrics using the swing-weighting method (Winterfeldt and Edwards, 1986). The invitations were sent to agencies that were either members of AMWG or Cooperating Agencies for the LTEMP EIS; 14 agencies, including the 2 joint-lead agencies, elected to participate (table 9).

From the responses to the swing-weighting exercise, weights were calculated for the 18 performance metrics separately for each participating stakeholder. To compare these vectors of weights, principal components analysis was used to reduce the dimension of the comparison from 18 to 2. The first two principal components explained 52.6 percent of the variation in weights across stakeholders. The first principal component was positively correlated with the weight on the frequency of mechanical removal, SLI, WTSI, fluctuation index, and riparian vegetation index; and negatively correlated with hydropower generation and capacity (fig. 22*A*). The second principal component was positively correlated with HBC population size, Glen Canyon rafting use, and the camping area index; and negatively correlated with RBT emigration and the Glen Canyon flow index (fig. 22*A*). The differences among the participating stakeholders can then be plotted with these two components (fig. 22*B*). Representatives from the utility industry (CREDA, UAMPS, and SRP) tended to put more weight on the hydropower generation and capacity metrics than other stakeholders. The agencies concerned with management of the RBT fishery (International Federation of Fly Fishers [IFFF] and Arizona Game and Fish Department [AZGFD]) were in the middle of the spectrum on the first component but had strong positive values for the second component, reflecting an emphasis on HBC, high-quality RBT, and RBT catch rate. The FWS, Arizona Department of Water Resources (ADWR) and the Hopi, Hualapai, and Navajo Tribes placed relatively more emphasis on increasing vegetation and minimizing RBT emigration than other stakeholders. The principal components for two of the nongovernment organizations (Grand Canyon River Guides [GCRG] and National Parks Conservation Association [NPCA]) placed an emphasis on camping area index, SLI, and WTSI. Note that the joint-lead agencies (Reclamation and NPS) separately completed the swing-weighting exercise, and their separate weights were used as input to the principal components analysis, but they elected to average their weighting vectors for presentation and discussion. The joint-lead principal components fall near the center of the spectrum of stakeholders. Although some of these patterns compare well with the expressed views of the stakeholder agencies, others are harder to explain; it is important to note that the higher-order principal components still contained explanatory power, so not all the differences among agencies can be summarized with the first two components.

8.2 Multicriteria Decision Analysis

The weights on the performance metrics, unique to each agency, tribe, or organization, were combined with the consequence table to generate a weighted performance metric for each long-term strategy, allowing a comparison of the long-term strategies that integrates the differences in response across performance metrics and the relative value

Table 8. Swing-weighting response form.

[Stakeholder agencies were invited to share their perspectives on the relative importance of the resource goals and performance metrics using this swing-weighting exercise. The results were compiled to generate agency-specific weights on the performance metrics; GLCA, Glen Canyon National Recreation Area; GRCA, Grand Canyon National Park; min, minimum; M, million; B, billion; >, greater than; yr, year; hr, hour; #, number; TMF, trout management flow]

Agency:	
Participants:	

Goal	Performance metrics	Units	Desired direction	Worst case	Best case	Higher level		Sublevel	
						Rank	Score	Rank	Score
Humpback chub									
	Number of adult humpback chub (20-yr min)	# of adults	High	3,000	8,500				
	Temperature suitability index (river mile 157 and 213)	index (0–1)	High	0	0.20				
Rainbow trout fishery									
	Angler catch rate index	fish/angler-hr	High	1.0	5.0				
	Lees Ferry trout emigration estimate	trout/yr	Low	125,000	15,000				
	Number of trout > 16 inches total length	# fish	High	400	1,200				
Archaeological and cultural resources									
	Wind transport of sediment index (WTSI)	index (0–1)	High	0	0.50				
	GLCA flow effects of historic properties	days flow > 23.2k	Low	75	0				
	Time-off-river index (TOR)	index (0–1)	High	0.60	0.95				
Hydropower									
	Value of energy generation (mean annual)	Million $/yr Billion $/20-yr	High	120M/ 2.4B	200M/ 4B				
	Value of capacity (mean annual)	Million $/yr Billion $/20-yr	High	10M/ 0.2B	50M/ 1B				
Recreation									
	GRCA camping area index (average of 3)	index (0–1)	High	0	0.50				
	Fluctuation index	index (0–1)	High	0	1.0				
	GLCA rafting use index	boat seats lost/yr	Low	1,300	0				
Riparian vegetation									
	Vegetation index (sum of four ratios)	sum of ratios	High	2.0	6.0			1	100
Sediment									
	GRCA sand load index (sand transported > 31,500)	proportion	High	0	0.6			1	100
Tribal									
	Change in marsh vegetation	ratio	High	0	1.5				
	Mechanical removal (years out of 20)	yrs	Low	5	0				
	Frequency of TMF (years out of 20)	yrs	Low	20	0				

Table 9. Agencies participating in the swing-weighting exercise.

[Representatives from 27 Federal, State, tribal, and private agencies were invited to participate in the swing-weighting exercise. The set of invited agencies included the Adaptive Management Working Group and cooperating agencies for the Long-term Experimental and Management Plan Environmental Impact Statement. Of the 27 agencies invited, 14 participated. AMWG, Adaptive Management Working Group; CA, cooperating agency; NGO, non-governmental organization]

the particular agency places on those performance metrics. For the joint-lead agencies, using their average set of weights, Alternative D (and specifically, long-term strategy D4) performed better than the other alternatives (fig. 23). Alternatives C, D, E, F, and G all substantially outperformed Alternative A (status quo), provided HFEs were implemented. The long-term strategies that did not implement HFEs (C3, E3, E5, and E6) were all demonstrably poorer than Alternative A, as measured by the weighted performance. The weighted performance of Alternative B was similar to that of Alternative A, with long-term strategy B1 slightly better than long-term strategy B2.

Alternative D was created after a preliminary analysis of the other alternatives. In the April 2014 preliminary analysis, the results of which were discussed by the joint-lead agencies and the Cooperating Agencies, Alternative C and E exhibited roughly equivalent performance with some differences in ranking across stakeholders. Alternative D was created as a hybrid between Alternative C and E, taking features of each that had contributed to positive performance in the preliminary analysis. One of the advantages of separating objective weighting from alternative evaluation in MCDA is that the weights only depend on the ranges of the performance metrics, not on the alternatives under consideration, so new alternatives can be evaluated without having to re-elicit the swing weights. Because Alternative D was created from the insights gained in the preliminary analysis of alternatives, it stands to reason that Alternative D outperformed Alternatives C and E. It is interesting, however, that the gain in performance is fairly small, suggesting that only marginal gains in performance remain with the management tools available, against the backdrop

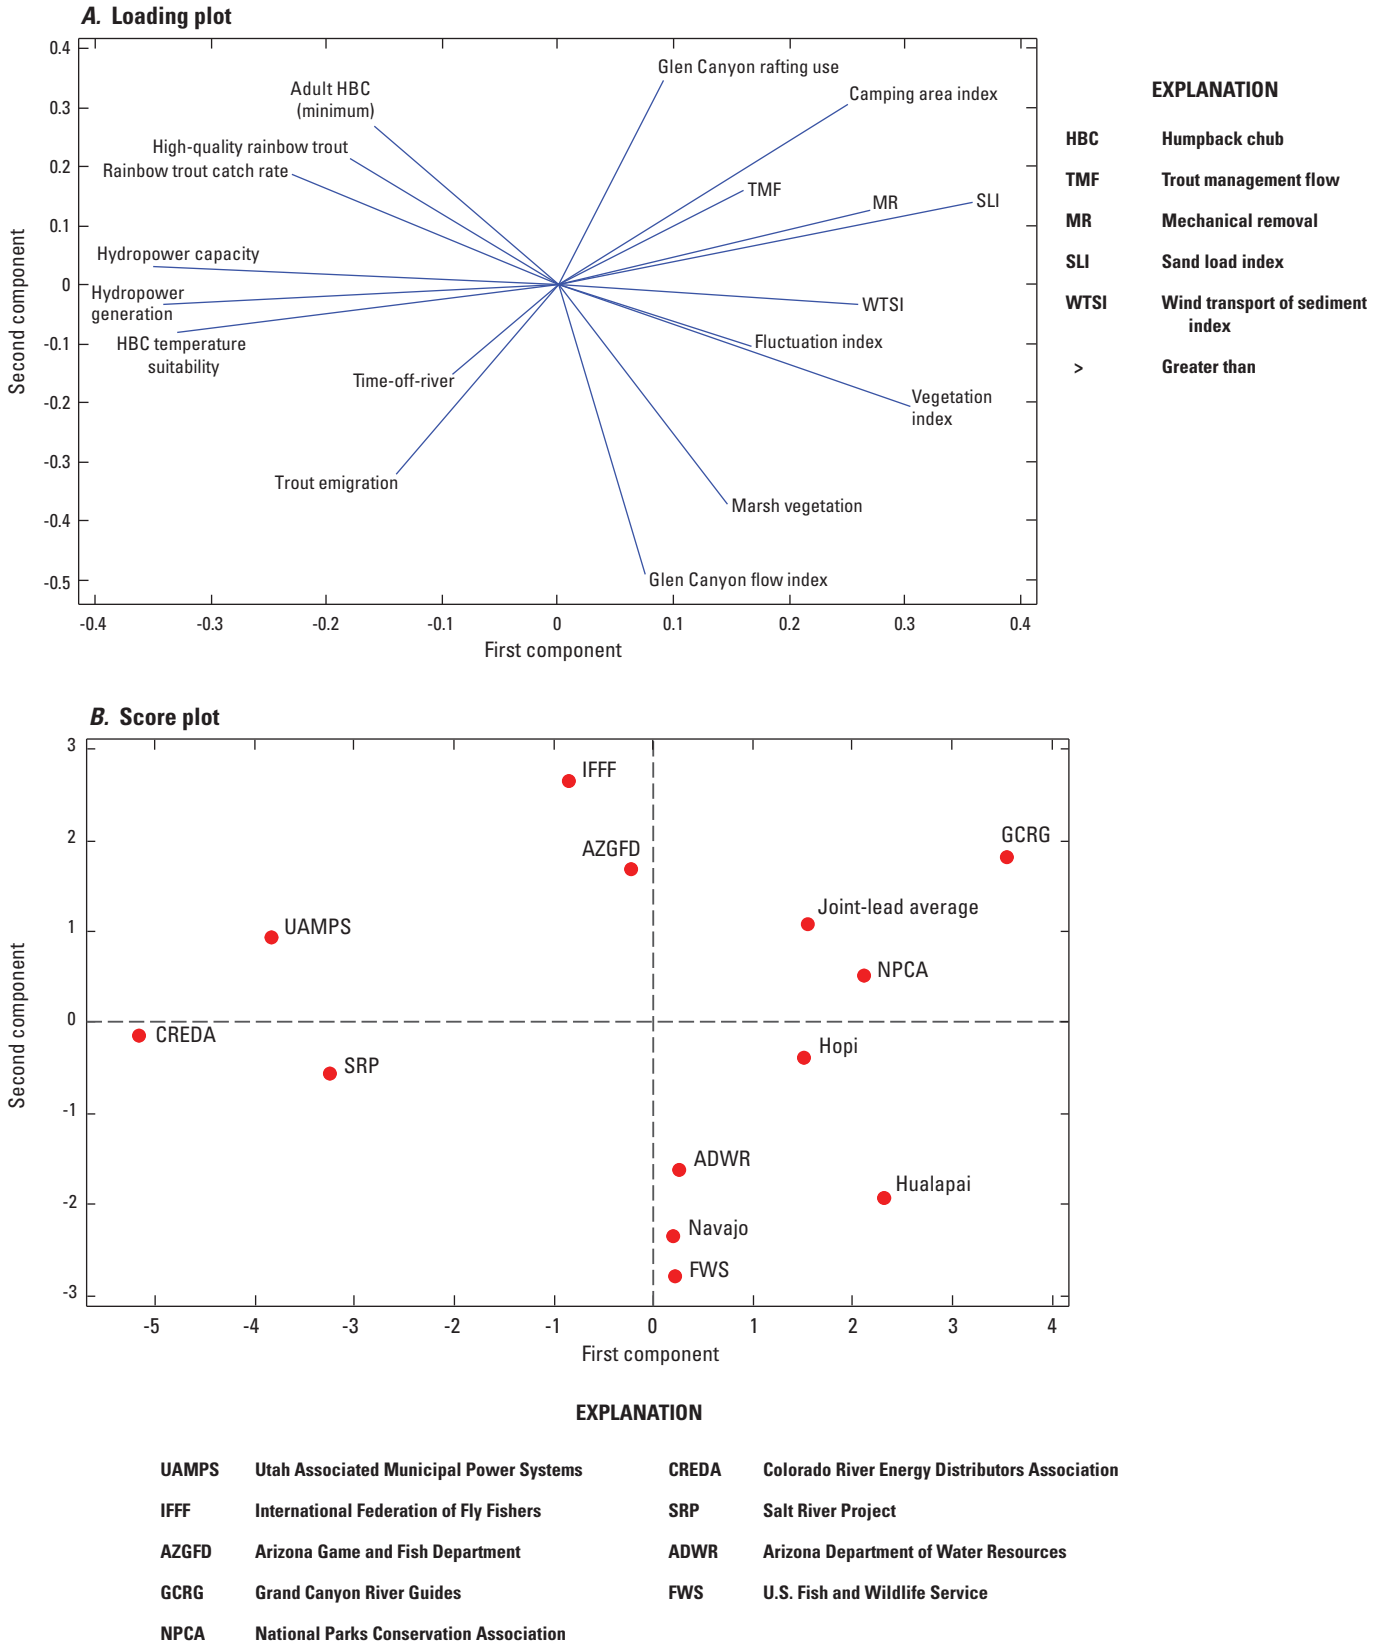

Figure 22. Principal components analysis of the weights on the performance metrics across stakeholder agencies. *A*, loading plot; and, *B*, score plot.

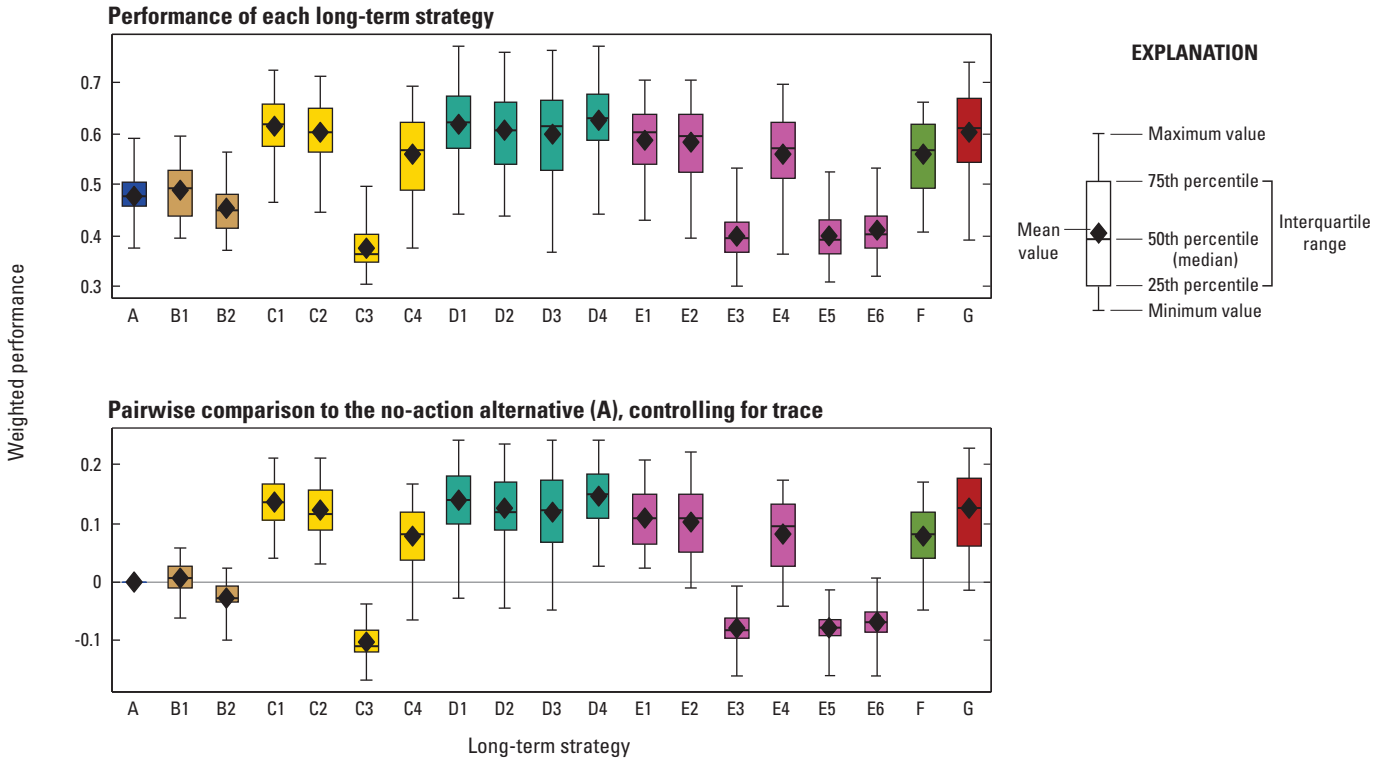

Figure 23. Joint-lead agency weighted performance across 18 metrics forecast for 19 long-term strategies using equal weighting of hydrological traces.

of uncertainty in hydrology and the complex set of tradeoffs among the resource goals.

One of the important motivations for MCDA was the opportunity to include and analyze differing viewpoints from stakeholder agencies regarding the importance of the various resource goals and their performance metrics. The agency-specific weightings did affect the ranking of alternatives (table 10). For most of the participating agencies, long-term strategy D4 had the highest mean-weighted performance (with the mean taken over hydrology and sediment traces and critical uncertainties). For two of the agencies (UAMPS, CREDA), long-term strategy B2 had the highest weighted score, and for one organization (GCRG), Alternative G had the highest weighted score. For all participating agencies except CREDA, long-term strategy D4 outperformed Alternative A. For all agencies, long-term strategy C3 performed worse than Alternative A, and for most of those agencies, it was the worst-performing long-term strategy. Alternative F was a polarizing strategy: for three agencies it was the worst-performing strategy, whereas for four others, it performed better than the status quo. Most of the differences across stakeholders in the MCDA ranking of the long-term strategies can be explained by the first principal component in the weighting (fig. 22). For those agencies that placed more weight on the performance metrics on the left side of the diagram (fig. 22*A*), Alternative B performed very well because it performs best for power generation and capacity; for those agencies that placed more weight on the performance metrics on the right side of the diagram (fig. 22*A*), Alternative B was outperformed by Alternative D. Across all participating stakeholders, the mean values for the long-term strategies in Alternative D were greater than those for Alternatives C and E, suggesting that the improvements made in crafting Alternative D are robust to the weights on the performance metrics.

Across stakeholders, the top-ranked long-term strategy was effectively tied with a number of other long-term strategies, against the backdrop of uncertainty induced by the hydrology and sediment traces; for example, using the joint-lead agency weights on the objectives, Alternative D4 had the highest mean performance, but the differences between D4 and next nine long-term strategies (D1, C1, D2, G, C2, D3, E1, E2, and E4) had ranges that included zero (fig. 24, bottom panel); that is, based on the results of the MCDA, alternatives C, D, E, and G were nearly indistinguishable using the joint-lead agency weights. This pattern held for the weights from most stakeholders as well (fig. 25), with between 2 and 11 long-term strategies effectively tied. For all stakeholders except CREDA, long-term strategies D4 and D1 were either the best-performing or effectively tied with the best-performing long-term strategy.

The differences among the long-term strategies within Alternative D are difficult to discern (fig. 23). The tradeoffs associated with using TMFs are marginal (compare D1 to D3). Similarly, the tradeoffs associated with “bug flows” do not

Table 10. Weighted performance for 19 long-term strategies using the weights on the performance metrics expressed by 14 participating agencies.

[The aggregate scores across performance metrics, weighted using the agency-specific swing-weighting results, are shown for each long-term strategy. For each participating agency, the best-performing long-term strategy is shaded in yellow, the worst-performing strategy is shaded in dark blue, strategies that perform better than Alternative A are shaded in orange, and strategies that perform worse than Alternative A are shaded in turquoise. The 21 hydrological traces were weighted equally. Thirteen additional stakeholder agencies were invited but declined to participate. JL, joint-lead agency average; FWS, U.S. Fish and Wildlife Service; ADWR, Arizona Department of Water Resources; AZGFD, Arizona Game and Fish Department; SRP, Salt River Project; UAMPS, Utah Associated Municipal Power Systems; CREDA, Colorado River Energy Distributors Association; IFFF, International Federation of Fly Fishers; NPCA, National Parks Conservation Association; GCRG, Grand Canyon River Guides]

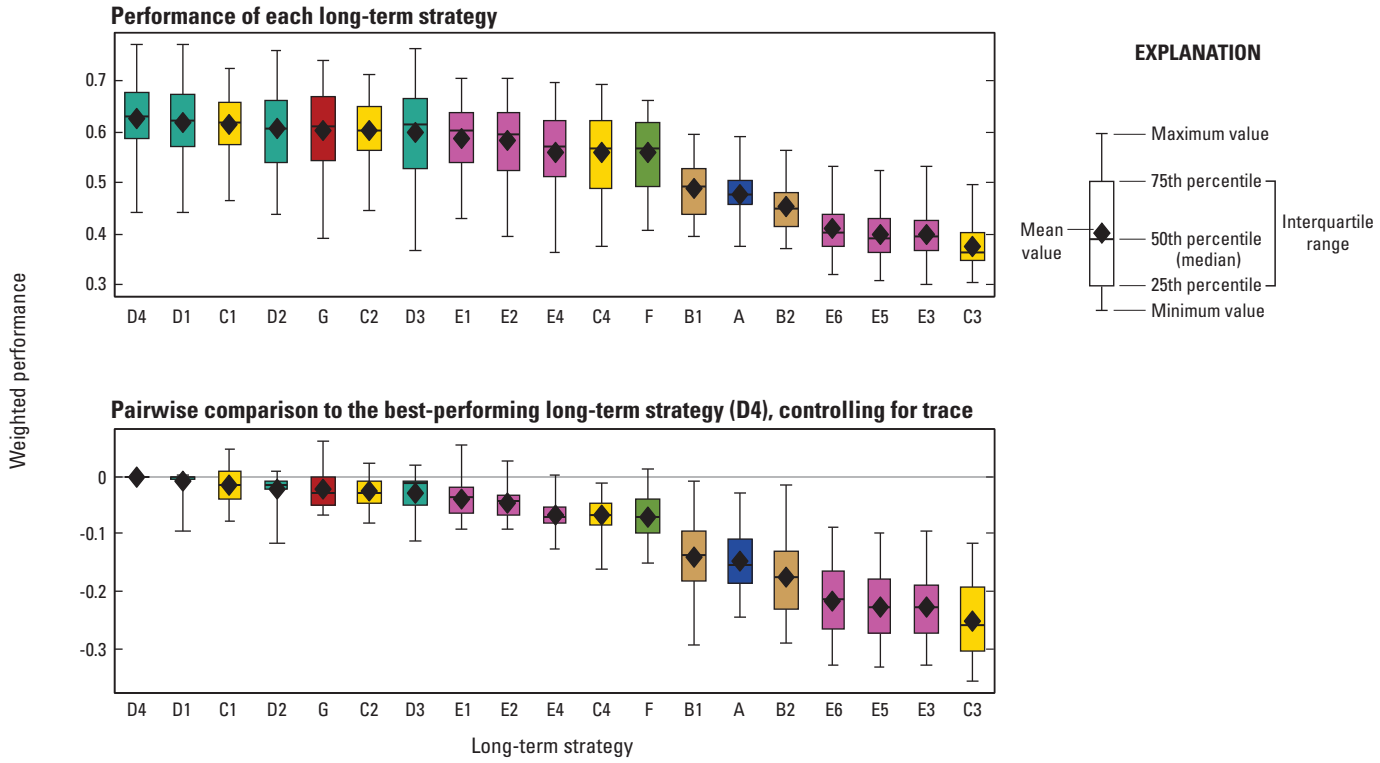

Figure 24. Joint-lead agency weighted performance across 18 metrics, sorted by mean performance, forecast for 19 long-term strategies using equal weighting of hydrological traces.

produce a clear favorite (compare D1 to D2). Finally, although there is the suggestion that the costs of low summer flows outweigh the benefits (compare D1 to D4), the difference is small against the backdrop of the variation driven by hydrology. The patterns within Alternative D are shown for the joint-lead agency weighting (figs. 23–24) but hold for the other stakeholder weightings as well (fig. 25).

8.3 Expected Value of Information

A second important purpose for the use of formal decision analysis tools was to examine the effect of uncertainty on the ranking of the alternatives. Although the effect of uncertainty on the ranking of alternatives based on single performance metrics was generally small (table 6), it is conceivable that the weighted performance could be more sensitive to uncertainty if the effects of the uncertainties affect the subtle balancing of tradeoffs. The analysis of the value of information on the weighted performance, however, revealed that the effect of the uncertainties was nearly 0 (table 11). For the joint-lead agency weighting and all but two of the participating stakeholders, the best-performing long-term strategy was the same across the 16 hypotheses that represented critical uncertainty (table 11); for example, long-term strategy D4 was preferred in the joint-lead agency weighting regardless of whether fall HFEs have an effect on RBT recruitment or not, regardless of whether TMFs are 10 or 50 percent effective in reducing RBT recruitment, and regardless of the relative influence of temperature and RBT on juvenile HBC survival and growth. For two stakeholders, there was a very small effect of the critical uncertainty: for IFFF, C2 was preferred more than D4 in 2 of the 16 hypotheses; and for GCRG, D4 was preferred more than G in 1 of the 16 hypotheses (table 11). Even in these two cases, however, the expected value of information for resolving the uncertainty represented by the 16 hypotheses was less than 0.1 percent.

At first glance, these results may seem puzzling. Many intense discussions within AMWG through the years have focused on concern that uncertainty about the response of the system to management prevents the identification of a best management strategy, and differences concerning recommendations for management have been explained as differences in interpretation of the scientific evidence. The uncertainties examined in this analysis (effect of fall HFEs, effectiveness of TMFs, and relative influence of temperature and RBT on juvenile HBC) have been central to previous discussions. But the results of this analysis do not support the conclusions that resolution of this uncertainty is important in choosing among the long-term strategies examined. There are several explanations for these results. First, there is less uncertainty than informal conversations imply. After several decades of intense study of the resources affected by the operation of Glen Canyon Dam, the AMWG partners have learned a great deal. Uncertainty remains, of course, but it is bounded; for

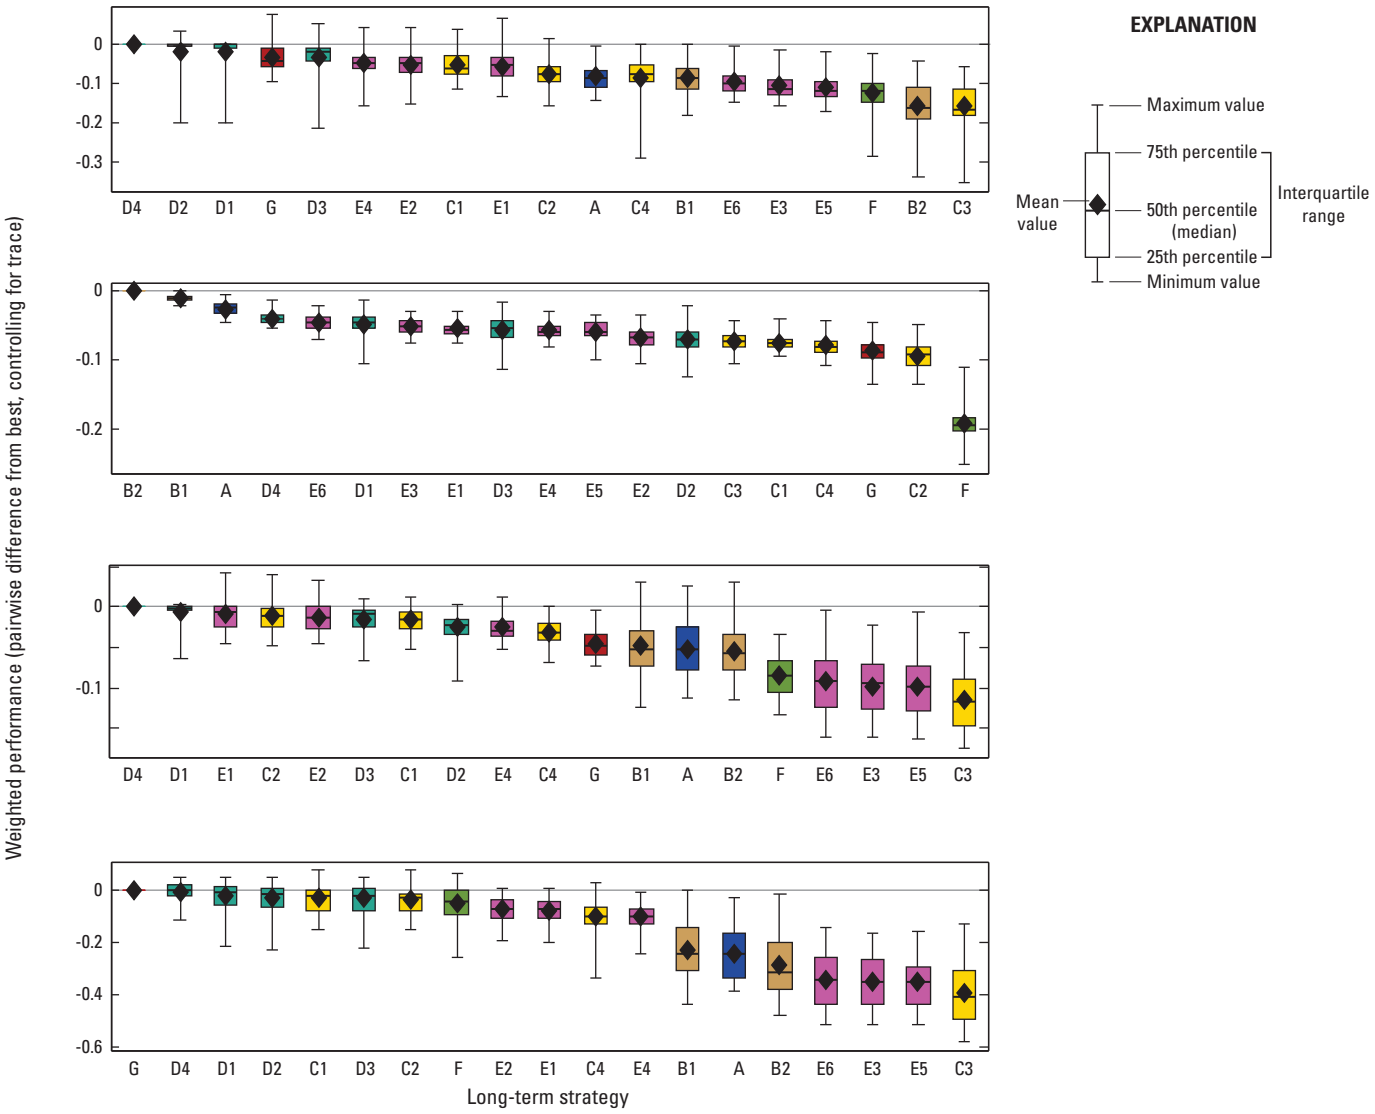

Figure 25. Weighted performance across 18 metrics, for four stakeholder agencies, sorted in descending order of mean performance. The four panels show the results for the stakeholders at the outer boundary of the score plot (fig. 22B; U.S. Fish and Wildlife Service, Colorado River Energy Distributors Association, International Federation of Fly Fishers, and Grand Canyon River Guides).

Table 11. Expected value of perfect information for resolving various uncertainties, as a function of the agency-specific weights.

[For each of the 16 combinations of hypotheses that describe the critical uncertainties, the best-performing long-term strategies are listed, using the agency-specific weights on the performance metrics. The shading of each cell is associated with the alternative from which the best-performing long-term strategy comes. See table 4 for a description of the critical uncertainties. The expected value of information for resolving critical uncertainty is zero for all the stakeholders except IFFF and GCRG. The expected value of partial information for resolving uncertainty about the combination of sediment and hydrology trace, sediment trace alone, and hydrology trace alone is shown. JL, joint-lead agency average; FWS, U.S. Fish and Wildlife Service; ADWR, Arizona Department of Water Resources; AZGFD, Arizona Game and Fish Department; SRP, Salt River Project; UAMPS, Utah Associated Municipal Power Systems; CREDA, Colorado River Energy Distributors Association; IFFF, International Federation of Fly Fishers; NPCA, National Parks Conservation Association; GCRG, Grand Canyon River Guides; HFE, high-flow experiment; TMF, trout management flow; EV, expected value; EVPI, expected value of perfect information; EVXI, expected value of partial information]

example, the uncertainty in the effect of temperature and RBT on juvenile HBC is large, in the sense that the parameters governing those relations are uncertain by a factor of two (fig. 3*A* and 3*B*); the trout effect on survival could be as small as -0.15 or as large as -0.4. But, the decades of study of the interactions of RBT and HBC have indicated conclusively that there is an effect of RBT on juvenile HBC survival, and there are effects of both RBT and temperature on juvenile HBC growth. Second, the value of information is strongly affected by the set of alternatives considered. It only asks if the uncertainty impedes the choice of a best alternative from among the set evaluated. It does not ask if there could be another alternative, not yet identified, that would be sensitive to the uncertainty. So, for example, it was thought that the value of low summer flows would be sensitive to the effect of temperature on HBC growth; therefore, C2, for example, might be favored compared to C1 if model f1 holds, but C1 might be favored compared to C2 if model f2 holds. This presumes, though, that low summer flows are triggered in enough years and involve flows low enough to lead to substantial changes in the temperature in the Colorado River at the confluence with the Little Colorado River to produce a demonstrable difference between models f1 and f2; this was not the case. But, if there were another alternative that could produce large differences in temperature (for example, a temperature control device on Glen Canyon Dam), these uncertainties may have played a greater role. Third, in a multiple-objective decision, the influence of the weights on the objectives might override the effect of uncertainties; for example, the costs associated with low summer flows (on recreation and hydropower, for example) may override the potential benefits (to HBC) enough that the effect of the uncertainty does not matter.

8.4 Effects of Climate Change

Although the value of information associated with resolving critical uncertainty was small, there was an indication that the uncertainty associated with hydrological input had some influence on the ranking of the long-term strategies (table 11). For the joint-lead agency weighting, foreknowledge of the hydrological and sediment trace could lead to a 1.5 percent improvement in the weighted performance across objectives (table 11). Such knowledge is not possible because it would require accurate prediction of the monthly precipitation in the Colorado Basin over the next 20 years. But in demonstrating that hydrological input might be important in the selection of a long-term strategy, it raises the question about the potential influences of climate change.

The 21 reconstructed historical hydrological traces that were used in the LTEMP analysis represent possible 20-year sequences if the future is like the recent past (1906-2010). The 112 hydrological traces generated as part of the Basin Study (Bureau of Reclamation, 2012) represent the best current understanding of what might happen because of climate change. Mean annual inflow to Lake Powell is quite different under these two sets of traces (fig. 26). The median flow over the climate-change traces is lower than for the historical traces, although it is within the interquartile range of the historical traces. About 30 percent of the potential future distribution of flows, however, is not captured by the distribution of the historical traces. The historical 20-year trace with the lowest mean inflow has an annual flow of about 8.5 million acre-feet; 30 percent of the climate-change traces fall below this point, suggesting that the set of historical traces may not be representative of future conditions.

To examine part of the potential influence of climate change, a reweighting of the historical traces was calculated to better match the mean and variance of Lake Powell inflow seen in the climate-change traces. The climate-change weighing put about 18 percent of the weight on the single hydrology trace with the lowest input to Lake Powell. This reweighting of the hydrological traces was then used in all the MCDA calculations to examine the effect of those weights on the performance of the long-term strategies. For the joint-lead agency weights on the performance metrics, the weights on the hydrological traces had a small effect on the aggregate performance but did not change the rankings of alternatives (fig. 27). A similar pattern was seen for other stakeholder weightings. Although this result suggests the ranking of alternatives is robust to uncertainty about climate change, it is important to

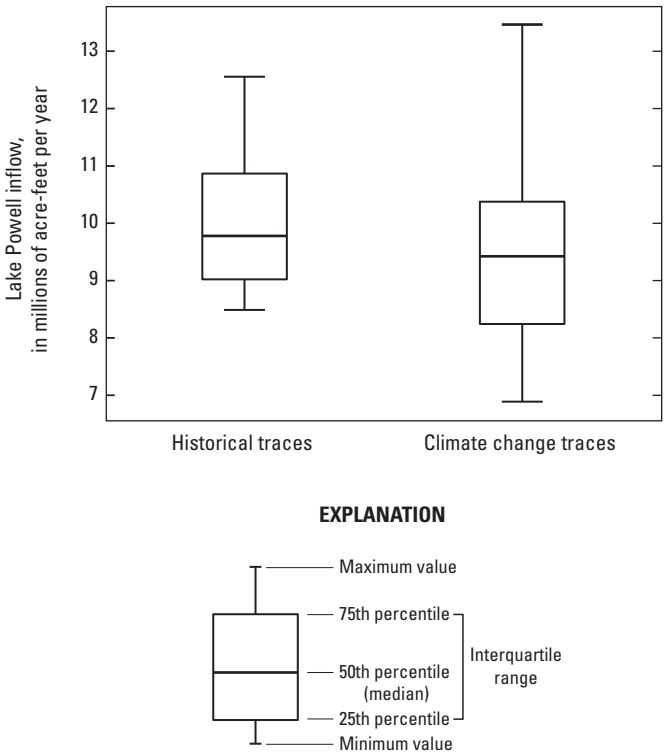

Figure 26. Mean annual inflow to Lake Powell during the 20-year period of the Long-Term Experimental and Management Plan for 21 historical hydrological traces and 112 climate-change-influenced hydrological traces.

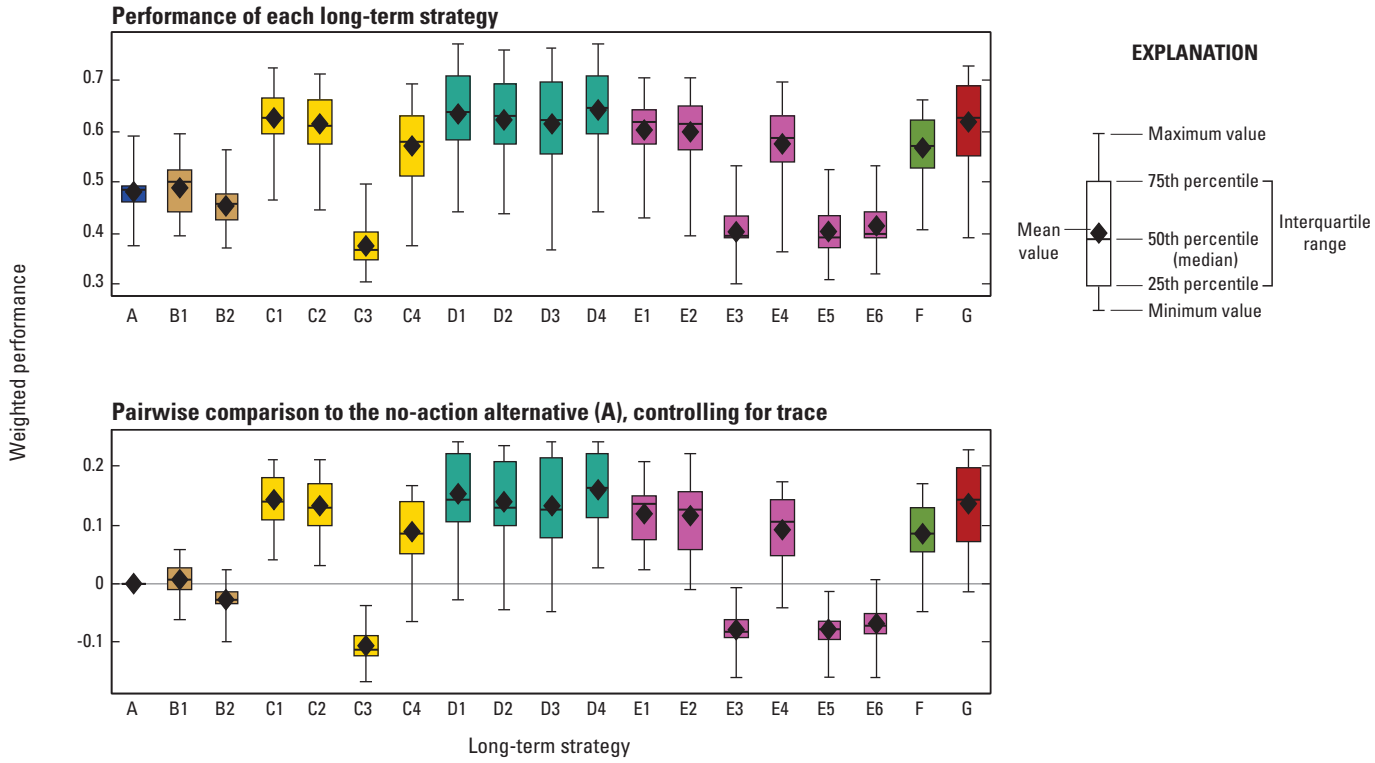

Figure 27. Joint-lead agency weighted performance across 18 metrics forecast for 19 long-term strategies using the climate-change weighting of hydrological traces.

keep in mind that the traces that were run through the modeling did not include plausible scenarios from the low end of the climate-change distribution.

9 Discussion

The analysis in this report is meant to add to the analysis in the LTEMP EIS itself. For those resource goals that could be evaluated with quantitative performance metrics, the tools of decision analysis allowed us to integrate the consequence analysis with the value judgments of stakeholders to formally evaluate the tradeoffs among the resource goals and to examine the influence of uncertainty on the performance of the long-term strategies. It is important to note, however, that not all the resource goals of importance could be evaluated quantitatively. The LTEMP EIS contains a narrative analysis of a greater number of resource goals than were included in the decision analysis, and this greater set of goals may be influential for the stakeholders and joint-lead agencies.

9.1 Evaluation of Alternatives

The alternatives examined in the LTEMP EIS and their long-term strategies differed in performance across the metrics considered. The full consequence table (table 7) shows strong tradeoffs: long-term strategies that perform well on any one performance metric may not perform well on others; thus, the choice of a preferred alternative will require the Secretary of Interior to weigh the importance of the various resource goals. The MCDA was designed as one way to provide input to the Secretary in her decision, by allowing the joint-lead agencies and stakeholders to express their interpretation of the importance of those resource goals and trace that interpretation through to the rankings of the alternatives. The best-performing long-term strategy did depend on the weights given to the performance metrics. Among the participating agencies, three alternatives rose to the top: Alternatives B, D, and G. Alternative B (especially long-term strategy B2) was favored by those agencies that emphasized the importance of the hydropower resource. Alternative G was the top- or second-ranked alternative for those agencies that emphasized restoration of natural processes, like beach building and native vegetation. For the remainder of the participating agencies, the analysis ranked Alternative D (especially long-term strategy D4) the highest. Alternative D was created after preliminary analysis revealed the strengths and weaknesses of the other alternatives and performs marginally better than the alternatives from which it was designed (C and E).

A number of other suggestions arise from the decision analysis regarding the long-term strategies. For most of the stakeholders, the benefits of HFEs seem to outweigh the costs, even in the face of uncertainty about their effects, at least as

measured by the performance metrics included in this analysis. The other modifications (for example, TMFs, mechanical removal, low summer flows, and bug flows) produce equivocal results; their inclusion is neither convincingly demonstrated nor precluded by the decision analysis.

Several caveats are warranted in interpreting this report. First, the performance metrics evaluated represent only a subset of the resource goals that might be influenced by the alternatives. The LTEMP EIS provides a fuller discussion of other goals, and the stakeholders and decision makers will need to judge if the formal decision analysis represents a sufficient degree of completeness. Second, not all stakeholders with an interest in the LTEMP EIS chose to participate in the decision analysis; thus, the array of viewpoints represented (for example, fig. 22 and table 10) may not capture the full range or appropriate distribution of viewpoints. Third, even for those stakeholders that participated, it may be difficult to express a nuanced set of values through the swing-weighting process. The set of MCDA methods used assumes the resource goals can be traded against each other in a linear, additive, and independent fashion. In fact, the value a stakeholder places on one objective might depend on how well an alternative is also performing on another objective; such dependencies require other decision analysis methods that were not used here. Fourth, some of the performance metrics may not have directly captured the resource goals they were meant to represent. For instance, the SLI is a proxy for sediment deposition and retention but not necessarily directly correlated with it. Fifth, some of the performance metrics (like hydropower generation) were expressed on natural scales that can be readily understood, but some of the performance metrics were expressed on proxy scales (for example, SLI) or constructed scales (for example, fluctuation index) that are difficult to understand; this mixture of scales makes the swing-weighting judgments challenging.

The structuring of objectives and the development of appropriate performance metrics are critical steps in MCDA and require diligence to meet the assumptions of a linear, additive value model (the form of MCDA used in this analysis). One of the concerns is the possible inclusion of means objectives, leading to possible double counting in the weighting process; for example, there was considerable discussion about the inclusion of the RBT emigration rate (performance metric 4)—was it fundamental or merely a means to conserving native fish populations? For some stakeholders, it was fundamental as an expression of the conservation of natural processes. But for other stakeholders, weight may have been placed on this objective as an expression of the effect of trout on native fish, thus, leading to possible double counting. Another concern is the possible inclusion of preferentially dependent objectives; for example, were RBT catch rate (performance metric 3) and abundance of high-quality RBT (performance metric 5) treated as independent in the swing-weighting exercise, or did the participants assume that if you had one, you would have the other and so assign weight based on simultaneous achievement? The two-stage swing-weighting may have helped reduce this concern, but with the large number of performance metrics being evaluated, cognitive mistakes in the swing-weighting exercise could still have happened. When applying decision theory to real problems, with all their subtleties and complexities, it is difficult to achieve perfect adherence to the assumptions of the analysis, but diligence toward those assumptions is needed.

All these caveats are fair, and the interpretation of the results should account for them. But the analysis also represents an effort to use the best available science to explicitly examine the ranking of alternatives as influenced by an analysis of consequences and the relative values placed on the resource goals.

9.2 Motivation for Adaptive Management

The purpose of doing the EVPI calculation was to understand the importance of resolving uncertainty (and the relative importance of resolving the different sources of uncertainty) before beginning experimental design. This puts the focus of uncertainty on its value to the decision maker, rather than its value as a point of scientific discovery. Although much has been written about the many scientific uncertainties about how the Colorado River ecosystem responds to management, less has been documented about how resolution of those uncertainties would explicitly affect and improve management decisions. The value of information analysis identifies the following: what long-term management alternative is best assuming each of the competing hypotheses, what long-term management alternative is best in the face of uncertainty (if uncertainty cannot be resolved), how much long-term management can improve through resolution of uncertainty, and which components of uncertainty contribute most to the value of information. Of course, what constitutes “best” depends on how the decision maker values the multiple resource goals within their statutory framework, so the analysis includes the sensitivity of the value of information to the weights on the objectives.

The results presented in this report (including the MCDA and EVPI analyses) provide valuable information for the construction of an experimental or adaptive design that is targeted to the most importance sources of uncertainty and has the best chance of resolving that uncertainty. The design of an adaptive strategy needs to consider three important elements: the value of the information being sought, the power of any experimental or adaptive design to resolve that uncertainty, and the short-term costs to the resource goals of pursuing the reduction of uncertainty. Although there are optimization algorithms to derive adaptive strategies taking these factors into account, for example, active adaptive stochastic dynamic programming (Williams, 1996), such tools are difficult to use in such a complex system.

Interestingly, the EVPI analysis suggests that there is not much advantage in an experimental approach because the resolution of the uncertainties articulated is not expected to alter the choice of long-term strategy. This suggestion, however,

hinges on the assumption that the uncertainties examined are a complete set. What about the "unknown unknowns," the uncertainties that we cannot yet articulate, but which we might nevertheless discover? We cannot analyze their importance, without being able to estimate their effect, and we also cannot design a monitoring system to detect them reliably. But, ongoing monitoring of the important resource goals, coupled with experimental implementation of the novel elements of any chosen alternative, is likely to reveal any surprises that would affect the achievement of the resource goals.

9.3 Decision Analysis and the National Environmental Policy Act

A typical analysis under the NEPA looks quite a bit like a formal decision analysis: resource goals (objectives) are articulated, alternatives are designed and described, and alternatives are evaluated against the individual resources of concern. These analyses are often qualitative, but a mix of qualitative and quantitative tools is also common. What is often missing from such analyses is a formal way to synthesize the results across the resources of concern. To the extent that NEPA is meant as a way to disclose to the public the environmental effects of the considered actions, such a synthesis is not needed. What decision analysis adds is a formal, quantitative way for the decision maker to consider and express the relative importance of the various resource goals in choosing a preferred alternative. In our view, then, decision analysis provides a useful companion to the analyses completed in an EIS.

The use of formal decision analysis in the context of a NEPA process was unfamiliar to a number of the Cooperating Agencies and other stakeholders, and several noted their discomfort with its use in comments to the joint-lead agencies. One-half of those stakeholders invited to participate in the swing-weighting exercise chose not to do so (table 9). They cited a number of concerns: skepticism that all the resources could be evaluated quantitatively, distrust of the methods of MCDA generally, a preference for providing input in a format they felt comfortable with, and a desire not to be forced to make an explicit value judgment on all the resource goals. Underlying the concerns was a stated fear that the decision analysis methods would be used to make the decision rather than just support an understanding of the alternatives. At all points, the joint-lead agencies and DOI leadership assured the stakeholders that the decision analysis was an effort to explore the performance of the proposed alternatives as deeply as possible with quantitative tools but was being used as only one of many sources of input in the transparent, deliberative process sought under NEPA. The effective use of decision analysis tools in the context of future NEPA processes will benefit from the insights of additional case studies, and from improved communication and training with regard to the theory, practice, justification, and benefits of decision analysis.

10 Summary

This report describes a formal decision analysis led by the U.S. Geological Survey, in cooperation with the Bureau of Reclamation, National Park Service, and Argonne National Laboratory, to support the development and evaluation of alternatives for the Glen Canyon Dam Long-Term Experimental and Management Plan. A set of 12 resource goals formed the basis of this evaluation, with 18 performance metrics used to provide quantitative measures of the resource goals. A total of 19 long-term strategies associated with 7 alternatives were evaluated against the performance metrics using a series of linked simulation models. Stakeholder input was elicited using the swing-weighting method, and this input was coupled with the quantitative evaluation of the alternatives in a multicriteria decision analysis. For 10 out of 13 stakeholder weightings presented, Alternative D (in particular, long-term strategy D4) outperformed the other alternatives. For the remaining stakeholder weightings, Alternatives B and G were the top performers. These rankings were robust to the uncertainties examined; the value of resolving uncertainty was never greater than 7.5 percent for any performance metric, and never greater than 2.5 percent for any stakeholder-weighted performance. This analysis is not a substitute for the full qualitative analysis found in the Long-Term Experimental and Management Plan Environmental Impact Statement, but does provide a transparent way to synthesize the analyses that could be quantified.

12 Appendix 1. Disclaimers

In preparatory discussions with the Adaptive Management Working Group (AMWG) stakeholders and Cooperating Agencies, the joint-lead agencies and U.S. Department of the Interior (DOI) wanted to be clear about the role of the decision analysis in the Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS) process. The following disclaimer is to be included in the EIS when describing the use of formal decision analysis. (Note that during the discussions with the stakeholders, the term "structured decision analysis" was used as shorthand for the process being used. In this report, we follow the common practice in the literature and simply refer to the process as "decision analysis." The disclaimers below are reproduced verbatim, and so retain the use of the term "structured decision analysis"). A number of the participating stakeholders added disclaimers of their own when they submitted their swing-weighing results; these are also included below.

12.1 Standard Disclaimer

In an effort to provide multiple opportunities for interested stakeholders to provide input in the LTEMP process, the National Park Service (NPS) and Bureau of Reclamation (hereinafter referred to as "Reclamation") have decided to incorporate facilitated structured decision analysis (SDA) into the LTEMP EIS process. The SDA has been used previously for one aspect of the Glen Canyon Dam Adaptive Management Program (GCDAMP), the "Environmental Assessment for Non-Native Fish Control below Glen Canyon Dam." The use of SDA in the LTEMP process is not required by the National Environmental Policy Act (NEPA), nor does it replace the NEPA impact analysis.

Participation in the SDA process is a voluntary opportunity for stakeholder input. The NPS and Reclamation recognize that any input provided during the SDA effort does not replace the need and opportunities for formal public comment that are required steps in the NEPA process. Such formal comments on the Draft and Final EISs will be regarded as the formal and official positions of any commenting entity.

The use of SDA is an effort to cast a complex decision setting into a transparent, comprehensive but compressed form to help the decision makers and stakeholders see the essential elements; it may not, however, capture all nuances perfectly. The NPS and Reclamation recognize that the metrics for identified resource goals in the SDA do not necessarily reflect consensus or agreement among participants; moreover, the swing-weighting values to be applied to the metrics for identified resource goals may not reflect the broader policies or the importance of issues for any participant or agency. Stakeholders have had and will have formal opportunities to express their values through standard steps in the NEPA process, especially the submission of alternatives and public comments; for some stakeholders, these steps may allow them more flexibility to express their values in a familiar form than the decision analysis.

For these and other reasons, neither the co-leads nor the swing-weighting participants are bound by any outcomes or results of the SDA process. The NPS and Reclamation will use the results of the SDA process as one of multiple sources of information to inform the NEPA process, but the SDA process itself will not be used in isolation from other input to select the preferred alternative; rather, the NPS and Reclamation will choose a preferred alternative based on their statutory missions and responsibilities, giving consideration to legal, economic, environmental, technical, and other factors, as well as formal public input.

12.2 Arizona Department of Water Resources Disclaimer

The Arizona Department of Water Resources (ADWR) understands that the use of SDA in the LTEMP process is not required by NEPA, nor does it replace the NEPA impact analysis; furthermore, the ADWR recognizes that any input provided during the SDA effort does not replace the need and opportunity for formal public comment that are required steps in the NEPA process. Such formal comments on the Draft and Final EISs, in addition to the attached swing-weight exercise input, will be regarded as the formal and official positions of the ADWR.

The ADWR further recognizes that the swing-weighting values that have been applied to the metrics for identified resource goals do not reflect the broader policies or the importance of issues for the State of Arizona. The importance and priority of the values of ADWR are more accurately reflected within the "Resource Targeted Condition-Dependent" alternative, being necessarily incorporated during alternative creation. For these and other reasons, the ADWR is not bound by any outcomes or results of the SDA process.

Moreover, ADWR understands that the NPS and Reclamation will not solely rely on the results of the SDA process to select a preferred alternative; rather, the NPS and Reclamation will choose a preferred alternative based on their statutory missions and responsibilities, giving consideration to legal, economic, environmental, technical formal public input and other factors.

12.3 Arizona Game and Fish Department Disclaimer

The Arizona Game and Fish Department (AGFD) understands that the use of SDA in the LTEMP process is not required by NEPA, nor does it replace the NEPA impact analysis; furthermore, the AGFD recognizes that any input provided during the SDA effort does not replace the need and opportunity for formal public comment that are required steps in the NEPA process. Such formal comments on the Draft and Final EISs will be regarded as the formal and official positions of the AGFD, in addition to the attached swing-weight exercise.

The AGFD further submits that the swing-weighting values that we have provided for the metrics for identified resource goals do not reflect the broader policies or the importance of issues for the State of Arizona as a whole; rather, they represent AGFD values as they relate to our specific statutory authority and mission. For these and other reasons, the AGFD is not bound by any outcomes or results of the SDA process.

The AGFD understands and expects that the NPS and Reclamation will not solely rely on the results of the SDA process to select a preferred alternative; rather, the NPS and Reclamation will choose a preferred alternative based on their statutory missions and responsibilities, giving consideration to legal, economic, environmental, technical, formal public input and other factors.

12.4 Salt River Project Explanatory Letter

The Salt River Project (SRP) submits the attached swing-weighting exercise response under the following conditions:

- that this letter entitled "SRP's SDA Evaluation" remain attached to the SRP swing-weighting response table, and
- that the information submitted herein is not authorized for use, or attribution, beyond the purposes of this specific exercise in the current LTEMP EIS process.

1. *Hydropower (100).*—The SRP believes that the hydropower resource goal is the only one that represents both societal and environmental benefits. Greater quantities of hydropower provide cost effective service to people who value electricity to support many aspects of their lives. Greater quantities of this renewable, carbon-free resource also serve to avoid emissions and water use by other electric generating facilities. In the initial round of swing weighting, energy and capacity are valued equally.
    1. The energy metric does not appear to function in a consistent, intuitive manner; for example, a more flexible alternative with more energy production in higher-value months sometimes performs worse than a less flexible alternative with less energy production in higher-value months.
    2. While the capacity metric currently looks at July, SRP's peak demand requirement most often occurs in August, and our understanding from the Western Area Power Administration (WAPA) is that August is a better choice for peak planning purposes from their perspective as well. The SRP believes that utilizing August for peak demand planning would produce more credible capacity metric results.
2. *Humpback Chub (75).*—The SRP recognizes the environmental significance of the endangered humpback chub (HBC) (*Gila cypha*). The SRP supports the assembly of scientific evidence that establishes clear cause and effect relationships between flow regimes and a recovery of this endangered species. The "Number of Adult Humpback Chub" metric looks specifically at chub population, so the SRP places more emphasis on this metric than the "Temperature Suitability Index" metric.
3. *Archaeological and Cultural Resources (60).*—The Archeological and Cultural Resources goal represents an important societal benefit that the SRP supports; furthermore, SRP's perception is that, as presently crafted, the Archeological and Cultural Resources goal contains a more accurate representation of tribal interests than the "Tribal" resource goal. The SRP supports alternatives that science shows will preserve these resources.
    1. At the April Workshop, it was mentioned that the Time-off-river index was the issue that could lead to degradation of archeological and cultural resources; thus, this metric was scored highest.
    2. There has been some discussion about the wind transport of sediment index (WTSI). Specifically, some LTEMP representatives indicated that they would not want architectural and cultural sites buried by sand. This metric was, therefore, scored less highly.
    3. Based on new data from high-flow experiments (HFEs), it is unclear how HFEs and sediment affect downstream architectural and cultural sites. Because there are some winners and some losers, it is uncertain how the single "GLCA flow effects of historic properties (Ninemile)" metric can be representative of all sites; for example, science shows that HFEs will not increase sand bars before river mile (RM) 30 since there is no silt inflow. Even below RM 30, some sandbars cannot be built up to previous levels because even the maximum output of GCD cannot push sand high enough; thus, the SRP is not weighing this option as heavily as the others.
4. *Trout Fishery (40).*—The SRP recognizes the recreational value of the trout fishery and weighs the benefits against the environmental dangers of trout migration on downstream resources in the Grand Canyon ecosystem.

Since science appears to show that trout stay relatively close to Lees Ferry, SRP would not weigh "Lees Ferry trout emigration estimate" metric as heavily as if trout emigrated more through the canyon. As long as trout are not affecting downstream resources, the other metrics are also important to the trout fishery; thus, the "Angler Catch Rate Index" and "Number of trout > 16 inches total length" sublevel metrics are scored lower than the emigration metric but are still valued.

5. *Recreation (20).*—The SRP recognizes the societal value of recreation and believes Glen and Grand Canyons should be enjoyed by anyone who visits. While most visitors who visit the Grand Canyon do not raft down the canyon, the subset of people who do so should be considered.

    1. The "GRCA camping area index" is an important metric because people need safe areas to camp for the night. This is the highest rated metric.

    2. The fluctuation index is less highly rated because it does not take the time of day of the fluctuation into account.

    3. The GLCA rafting use index does not appear to have enough swing from low to high values to be rated highly. The swing of 600 people per year that could not take a trip down the river is not the same scale of an impact as a 1,000 fish population increase for HBC or a $9 million per year increase in hydropower energy value.

6. *Riparian Vegetation (20).*—The SRP recognizes the effect of riparian vegetation on the ecosystem of the Grand Canyon and believes it is has valuable environmental impacts. The aggregation of all metrics into this single metric hides some of the complexities; for example, CDAS and SASF perform worst for native/nonnative ratio but best for arrowweed. These are not able to be considered separately, which makes specific value judgments difficult.

7. *Sediment (0).*—The SRP observes that the effects of sediment are accounted for in the HBC, Archaeological & Cultural, Recreation, and Riparian Vegetation metrics. The SRP's perception is that sediment is a means to an end. We believe that a separate sediment metric does not make sense in the same manner that a separate temperature or HFE metric does not make sense.

8. *Tribal (0).*—The SRP believes that tribal interests should be recognized as a valued dimension of the LTEMP EIS process; however, as presented assembled and stated, the Tribal Resource goal does not appear to effectively represent tribal interests. The results for "Change in Marsh Vegetation" were questioned at the April Workshop and were not changed before this swing weighting. Trout should only be removed when they are endangering HBC, and the decision of how to remove them would preferably comply with tribal interests.

12.5 Utah Associated Municipal Power Systems Explanatory Letter

Utah Associated Municipal Power Systems (UAMPS) representing over 30 UAMPS members contracting for power generating output of Glen Canyon Dam is pleased to submit our response to the swing-weight exercise related to the LTEMP EIS process. The UAMPS is both an LTEMP EIS Cooperating Agency, a member of Glen Canyon Dam Adaptive Management Workgroup, and has been involved with most activities related to the operation of Glen Canyon Dam since environmental studies began in the mid-1980s. The UAMPS is grateful for the opportunity to participate in the EIS process as a member of the AMWG and as a Cooperating Agency contributor. We are appreciative of the great amount of work performed by both Federal government employees and contractors performing studies and assembling vast amounts of reporting documents, as well of those interested parties who have been following this LTEMP process.

We continue to be concerned with the valuation of the electric generation from Glen Canyon Dam and the reduction of power capacity and see this loss will be required to be replaced by resources using fossil fuels emitting carbon dioxide, which create other environmental problems and considerations. Thus far, we have not seen any expression of impacts of capacity switching except for some costs of capacity data for natural gas generation. In that regard, we wish to support the comment submitted by the Colorado River Energy Distributors Association (CREDA) that the cost estimates for natural gas combined-cycle generation in today's costs included in the performance metrics are way undervalued and should be corrected. We also hope additional cost analysis will eventually be included to address the lost power generating flexibility at Glen Canyon Dam needed for the western power grid. The flexibility provided by this hydropower is not free and will need to be made-up by some other power generating resource paid for by all utilities connected to the WECC power grid. Thus far, this loss of generating flexibly and the environmental impacts resulting from the shift to fossil fuels has only been casually addressed. We see the environmental objectives in this EIS seem to have priority over the far reaching climate change impacts that the electric industry in the west faces more and more as it struggles meet electric demands.

12.6 Colorado River Energy Distributors Association Submittal Letter

This letter [dated April 18, 2014] is an integral part of CREDA's SDA swing-weighting exercise submittal. CREDA members are all non-profit wholesale customers of the Salt

Lake City Area Integrated Projects (SLCA/IP) firm electric and transmission resources, of which Glen Canyon Dams is the largest generating facility. Although all members are non-profit entities, CREDA membership is diverse. Therefore, responses provided on the attached exercise cannot be ascribed to any individual CREDA member, as individual members did not have the ability to participate in the 5 days of workshop nor complete the exercise individually. Further, the responses are submitted with the understanding that the results will be reported with participant attribution and included in the draft/final Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS). Further, it is not clear to CREDA in what other forums this submittal is intended for use or attribution. Given those assumptions, CREDA submits its SDA swing-weighting response under the conditions that a) this letter shall remain attached to the SDA swing-weighting response table, and 2) the information submitted herein is not authorized for use or attribution beyond purposes of this specific exercise in the LTEMP EIS processes and documents.

SDA AND LTEMP: Having participate fully in the August and March-April SDA workshops, it has become clear to CREDA this this process may not lend itself readily to a system and resources as complex and interdependent as we see in the resources of interest in the LTEMP. As the performance metrics and models have been developed and evolved, CREDA still has concerns about some of the underlying Resource Goals, and their inconsistency with the AMWG-approved Desired Future Conditions. Although many comments and concerns have been expressed on some of the Goals in various forums and through various medium, the Goals have remained unchanged since LTEMP scoping, As we were advised on April 1, if a participant still has concerns with a Resource Goal, or if the participant believes the elements of a metric are contradictory, inappropriately "linked" to a Resource Goal, or a create a potential legal or policy conflict, the participant should value the metric with a very low or 0 value. We appreciate the time and effort involved in developing and facilitating the SDA process, but suggest that it may be more applicable and useful for either determining stakeholder values of individual attributes of a resource, or analyzing a reduced number of alternatives (particularly when many of the LTEMP alternatives were "split up" for this exercise). We commend the stakeholders who devoted a significant amount of time and effort to the August 2013 and this year's process.

SDA, HYDROPOWER ANALYSIS AND LTEMP: As you are aware, CREDA is participating in this process as a member of the Glen Canyon Dam Adaptive Management Work Group (AMWG), representing "contractors for the purchase of Federal power produced at Glen Canyon Dam". As such representative, CREDA's submittal of the Balanced Resource Alternative represents the value we ascribe to the hydropower resource, notwithstanding we have some outstanding questions about how this alternative was ultimately modeled for the SDA process. Participants in the April workshop were advised that the hydropower performance metric was incomplete, and that a key component of the metric, capacity, had to be developed by Argonne in an inordinately short period of time (April 1–8), further, that the "ratepayer analysis" portion of the hydropower analysis was noted as "still under discussion" in the Performance Metrics document provided to the workshop participants. CREDA offers detailed comment herein on the energy, capacity and ratepayer analysis components of the hydropower resource, as we were invited to do as soon as possible after the April 1 workshop. We understand and expect that the electric resource flexibility component of the metric will be assessed as part of the draft/full EIS process, and that air quality impacts, such as carbon offsets will also be a part of the overall hydropower analysis. We offer the following comments and suggestions for use in assessing hydropower resources going forward in the LTEMP process.

ENERGY: The information provided to the SDA workshop participants on April 1 has results that are unintuitive. For example, one can compare RTCD4 with BR1. Both have Fall HFEs. BR1 has an average output of 14,500 cfs during July and August, while RTCD4 has an average output of 12,000 cfs and 11,000 cfs respectively. Furthermore, BR1 has an average fluctuation range that is 140% of MLFF, while RTCD4 has an average fluctuation range that is 114% of MLFF. Based on common knowledge, BR1 should perform better for energy than RTCD4. However, based on modeling results, RTCD4 performed better. This example, along with others discussed during the April 4 meeting, call the energy results into question. *We urge the LTEMP co-leads to utilize the expertise of the cooperating agency utility experts in energy analysis. We would also like to see more detailed energy results, as was agreed in the April 4 conference call.*

CAPACITY: The information provided to the SDA workshop participants on April 10 indicates that the capacity metric uses July as its peak month. CREDA reaffirms its suggestion on March 31 that August be used as the peak month to reflect actual utility peak demand experience, both past and as projected for the period of the LTEMP EIS. Also included in the April 10 information is a capacity value of $65,000/MW-yr to be used in the swing-weighting process, based upon the following factors:

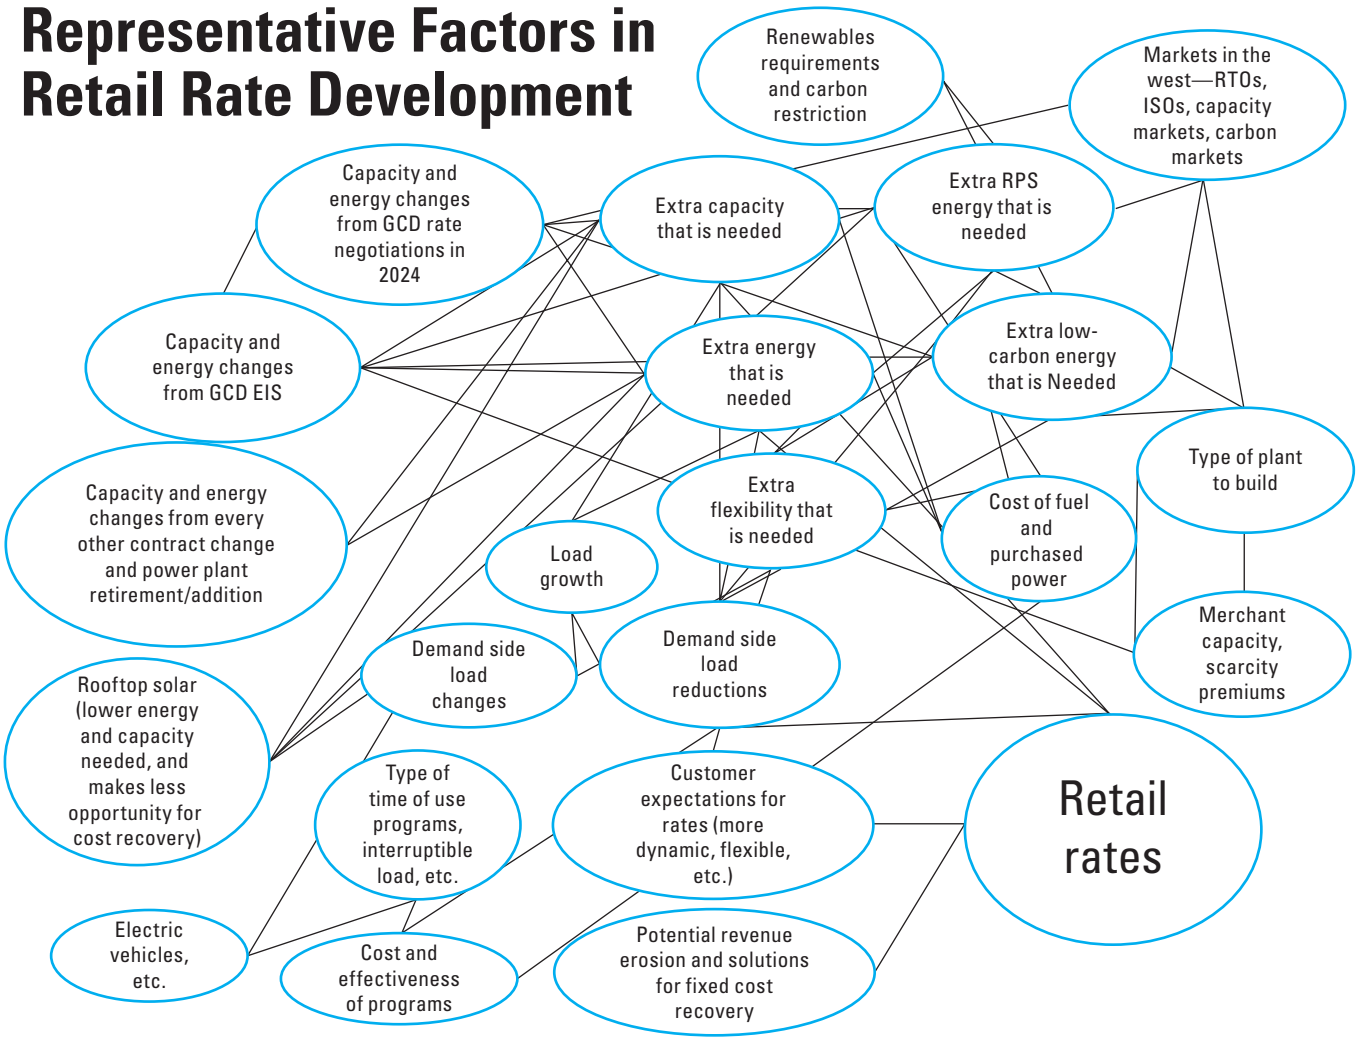
- 620-MW natural gas combined cycle plant
- Capital cost of $917/kW
- Fixed operation and maintenance cost of $13.17/kW
- 30-year lifetime
- Discount rate of 3.8%

CREDA believes, based on discussion with its utility members who are also cooperating agencies in the LTEMP, that a more accurate estimate of the capacity value for a large, natural gas combined cycle facility is in the range of $82,000/MW-yr–$132,000/MW-yr.

As a consulting service to the electric utility industry, the Electric Power Research Institute (EPRI) regularly

prepares estimates of the costs associated with developing various types of energy resources, including gas-fired combined cycle facilities. EPRI's publicly available Generation Technology Options Report (published 2/19/2013) can be accessed at the linked site. EPRI information provided below can be found in Table 1-2 of their report.

Having worked with EPRI for a number of years with respect to resource characteristics and cost information for various electric resource technologies, a CREDA member's experience suggests that EPRI's valuations often do not fully account for the generally higher elevations and harsher ambient conditions that exist in CREDA member service regions relative to the assumptions used in EPRI's technology assessment efforts. Consequently, the CREDA member's internal cost estimates are higher. A comparison of key factors is provided below.



In summary, CREDA believes that the currently proposed values for LTEMP capacity valuation result in an understatement of Glen Canyon hydropower capacity value on the basis of a credible, publicly available, industry standard source for such information (EPRI) as well as on the basis of utility specific information and experience. *We urge the LTEMP co-leads to utilize the expertise of the cooperating agency utility experts in capacity analysis.*

RATEPAYER ANALYSIS: As was recently communicated to Ass't. Secretary Castle, CREDA and its electric utility members believe that this analysis must be based on and reflect impacts to the product/resource produced through the operation of Glen Canyon Dam, which is *wholesale* electric power and energy. On 4/1/14, we again objected to an attempt to develop and include a *retail* rate analysis, which is not required by NEPA, and which will likely be incorrect and misleading because it will not be possible to obtain sufficient and credible data given the time constraints and budget dollars associated with the LTEMP process. The chart below provides some perspective about the complexities involved in electric utility retail rate development. *Consistent with the scope of federal agency responsibility, to the extent any ratepayer analysis is required (which we don't believe is the case under NEPA), we urge the LTEMP co-leads to focus on the wholesale level, and consider utilizing cooperating agency utility expertise.*

Finally, CREDA recognizes the time and effort spent by all the SDA participants and believes that a key outcome from the workshops and exercises is the opportunity afforded the AMWG stakeholders, LTEMP co-leads, Argonne National Labs and GCMRC personnel and contractors to learn more about and appreciate the complexities and interdependencies of the resources addressed through the Adaptive Management Program, as well as the challenges faced by the Secretary of the Interior in balancing the resources associated with the operation of Glen Canyon Dam. It has also become clear through the model development and results supporting the SDA process that the resources of concern are "performing well" under the current operational and management parameters. The LTEMP co-lead and cooperating agencies should strongly consider this information.

	Factor	LTEMP	EPRI	CREDA
1	Capital Cost	$917/kw	$1,025/kw–1,325/kw	$1,130/kw–$1,426/kw
2	Fixed O&M Cost	$13.17/kw-yr	$15/kw-yr	$23/kw-yr–$25/kw-yr
3	Discount Rate (1)	3.8%	5%	Higher than 5%
4	Resulting Capacity Cost (2)	$65,000/MW-yr	$82,000/MW-yr–$101,000/MW-yr	$108,000/MW-yr–$132,000/MW-yr

(1) The discount rates of CREDA members are proprietary and confidential information.
(2) Lower cost represents wet cooling, higher cost represents dry cooling.

APPENDIX D:

HYDROLOGY TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX D:

HYDROLOGY TECHNICAL INFORMATION AND ANALYSIS

D.1 ANALYSIS METHODS

The Colorado River Simulation System (CRSS) is the modeling tool used to assess the effects of the Long-Term Experimental and Management Plan (LTEMP) alternatives on water resources and to provide relevant information for other models used to assess other resources. This section provides a background on CRSS, all relevant modeling assumptions used in CRSS, and a description of any changes made to CRSS, specifically for the LTEMP modeling.

D.1.1 Background

CRSS, the Bureau of Reclamation's (Reclamation's) long-term planning model that covers the Colorado River Basin from the natural inflow points in the Upper Basin (see Figure D-3) to Imperial Dam, was the first model used in the LTEMP Environmental Impact Statement (EIS) analysis process. CRSS simulates future system conditions based on different hydrologic inflow scenarios and assumed reservoir operations for the evaluation period (2013–2033). The model framework used for this process is a commercial river-modeling software called RiverWare™ (Zagona et al. 2001), a generalized river-basin-modeling software package developed by the University of Colorado through a cooperative arrangement with Reclamation and the Tennessee Valley Authority. CRSS was originally developed by Reclamation in the early 1970s and was implemented in RiverWare in 1996.

CRSS simulates the operation of the major reservoirs on the Colorado River and provides information on the projected future state of the system on a monthly basis in terms of output variables, including the amount of water in storage, reservoir elevations, releases from the dams, the amount of water flowing at various points throughout the system, and the diversions to and return flows from the water users throughout the system. The basis of the simulation is a mass balance (or water budget) calculation that accounts for water entering the system, water leaving the system (e.g., from consumptive use of water, trans-basin diversions, evaporation), and water moving through the system (i.e., either stored in reservoirs or flowing in river reaches). The model was used to project the future conditions of the Colorado River system on a monthly time-step for the period 2013–2033.

The input data for the model include monthly natural inflows,[1] various physical process parameters such as the evaporation rates for each reservoir, initial reservoir conditions on January 1, 2013, and the future diversion and depletion schedules for entities in the Basin States and for the United Mexican States (Mexico). These future schedules were based on the current

[1] Calculated as gaged flow corrected for the effects of upstream reservoirs and depletions. Natural flow data and supporting documentation are available at http://www.usbr.gov/lc/region/g4000/NaturalFlow/index.html.

projected demand scenario (Schedule A) from the Colorado River Basin Water Supply and Demand Study (Reclamation 2012b).

The rules of operation of the Colorado River mainstream reservoirs including Lake Powell and Lake Mead are also provided as input to the model. This set of operating rules describes how water is released and delivered under various hydrologic conditions and aims to reflect actual operations. However, limitations inherently exist in the model's ability to reflect actual operations, particularly when responding to changing hydrological conditions and other operational constraints such as dam maintenance.

The future hydrology used as input to the model consisted of samples taken from the historical record of natural flow in the river system over the 105-yr period from 1906 through 2010 and the "Downscaled GCM Projected" water supply scenario from the Basin Study (Reclamation 2012a). For the climate change analysis presented in Section 4.16.1.2 of the EIS, the 21 hydrologic traces used in the analysis were weighted according to their frequency of occurrence (based on mean annual inflow to Lake Powell) in the Basin Study's 112 simulations. Each sequence is input as natural flow at 29 individual inflow points (or nodes) on the system. The future hydrology is merely a projection of what future conditions might be based upon the 105-yr record and is not a prediction of the likelihood of these future hydrologic conditions occurring.

The following sections describe the CRSS modeling assumptions and configuration associated with the modeling undertaken for the LTEMP EIS process. The version of CRSS used for the LTEMP modeling started from the version of CRSS used for the Basin Study and was updated with more recent initial conditions and other changes necessary to reflect the different alternatives, as described below.

D.1.2 Initial Conditions

The model was initialized with the observed 2012 end-of-calendar-year (EOCY) reservoir conditions shown in Table D-1.

D.1.3 Reservoir Operations

D.1.3.1 Upper Basin Reservoirs above Lake Powell

The Taylor Park, Fontenelle, and Starvation reservoirs are operated in accordance with their existing rule curves (Reclamation 2007), although Fontenelle's operating rules in CRSS have been updated since the 2007 Interim Guidelines (DOI 2007). Aspinall Unit operations do not reflect the *Record of Decision* (ROD) *for the Aspinall Unit Operations Final Environmental Impact Statement* (Reclamation 2012c) because the modeling for the LTEMP EIS began before the latest Aspinall ROD could be reflected in CRSS. Instead, the Aspinall Unit is also operated in accordance with its previous rule curves as documented in the *Colorado River Interim*

TABLE D-1 Initial Reservoir Conditions
(2012 Observed End-of-Calendar-Year Values)

Reservoir	Elevation (ft AMSL)	Storage (ac-ft)
Fontenelle	6,485.19	196,963
Flaming Gorge	6,020.63	3,001,912
Starvation	5,734.92	255,000
Taylor Park	9,301.09	56,647
Blue Mesa	7,452.65	327,537
Morrow Point	7,146.50	106,381
Crystal	6,749.11	15,830
Navajo	6,024.73	956,630
Powell	3,609.82	12,712,205
Mead	1,120.36	13,636,479
Mohave	638.30	1,572,110
Havasu	446.41	550,689

Guidelines for Lower Basin Shortages and Coordinated Operations of Lake Powell and Lake Mead Final Environmental Impact Statement (2007 Interim Guidelines Final EIS [Reclamation 2007]).

Navajo and Flaming Gorge operations reflect the recent RODs (Reclamation 2006a,b, respectively). In general, both RODs contain downstream flow targets that the reservoirs attempt to meet according to the rules within the RODs. In summary, Flaming Gorge operations are governed by the April–July unregulated inflow into the reservoir, which determines the downstream flow targets that should be met; for example, in a wet year (larger inflow into the reservoir), higher downstream flows are targeted. The flow targets are specified at the sub-monthly time-step, which historically could not be reflected within CRSS. In order to capture the sub-monthly component of the flow targets, and thus Flaming Gorge's operations, the model was programmed to determine typical daily operations before summing to a monthly release (Butler 2011).

Similarly, Navajo's ROD contains multiple downstream flow targets, specified at sub-monthly time intervals. In this case, a September 30 storage target guides Navajo's operations. A release pattern is selected to bring Navajo as close as possible to the September 30 storage target while helping meet the downstream flow targets stated in the ROD (Butler 2011).

D.1.3.2 Lake Powell and Lake Mead

For 2013–2026, Lake Powell and Lake Mead would be operated according to the 2007 Interim Guidelines (DOI 2007). For modeling purposes, after the expiration of the 2007 Interim Guidelines in 2026, operations are assumed to conform to those specified in the

No-Action Alternative from the 2007 Interim Guidelines Final EIS (Reclamation 2007). Both operations are briefly described below.

Lake Mead flood control procedures are in effect for the entire simulation period. In addition, if Lake Mead elevation falls below 1,000 feet above mean sea level (AMSL), deliveries to the Southern Nevada Water Authority (SNWA) are assumed to continue.

If Lake Mead is sufficiently low such that after the maximum shortage (per the 2007 Interim Guidelines or No-Action Alternative post 2026) is applied and water is still unavailable to meet the remaining deliveries, the remaining deliveries are shorted hydrologically with respect to their physical location on the river.

Operations during the Interim Guidelines (2013–2026)

Operations of Lake Powell and Lake Mead are coordinated as specified in the 2007 Interim Guidelines (DOI 2007). Figure D-1 summarizes the different operating tiers at both reservoirs. Based on rules programmed in the model, CRSS determines which tier Lake Powell is operating in and simulates releases consistent with the selected tier. Similarly, CRSS is configured to simulate normal, shortage, and surplus deliveries in the Lower Basin, consistent with the Interim Guidelines.

Operations after the Interim Guidelines Expire (2027–2033)

The operating rules reverted to the rules of the 2007 Interim Guidelines Final EIS No-Action Alternative for simulations starting in 2027 and continuing through 2033. The No-Action Alternative assumed the following for shortage, surplus, and coordinated operations. There was no intentionally created surplus (ICS) assumed in the No-Action Alternative, however; consistent with the 2007 Interim Guidelines, ICS deliveries would be permissible through 2036. See Appendix A of the 2007 Interim Guidelines Final EIS (Reclamation 2007) for additional details regarding the No-Action Alternative.

Three factors that affect Lake Powell's release are (1) the minimum objective release of 8.23 maf, (2) equalization, and (3) spill avoidance. For equalization to occur, the 602(a) storage requirement must be met.[2]

Stage 1 shortage is triggered to prevent Lake Mead from declining below 1,050 feet AMSL. Stage 1 shortages range in volume from approximately 350 to 500 kaf. If Lake Mead's elevation continues to decline, a Stage 2 shortage is imposed to keep Lake Mead above 1,000 feet AMSL. Stage 2 shortages can be up to 3.0 maf.

2 See Appendix A of the 2007 Interim Guidelines Final EIS (Reclamation 2007) for the full 602(a) storage requirement computation.

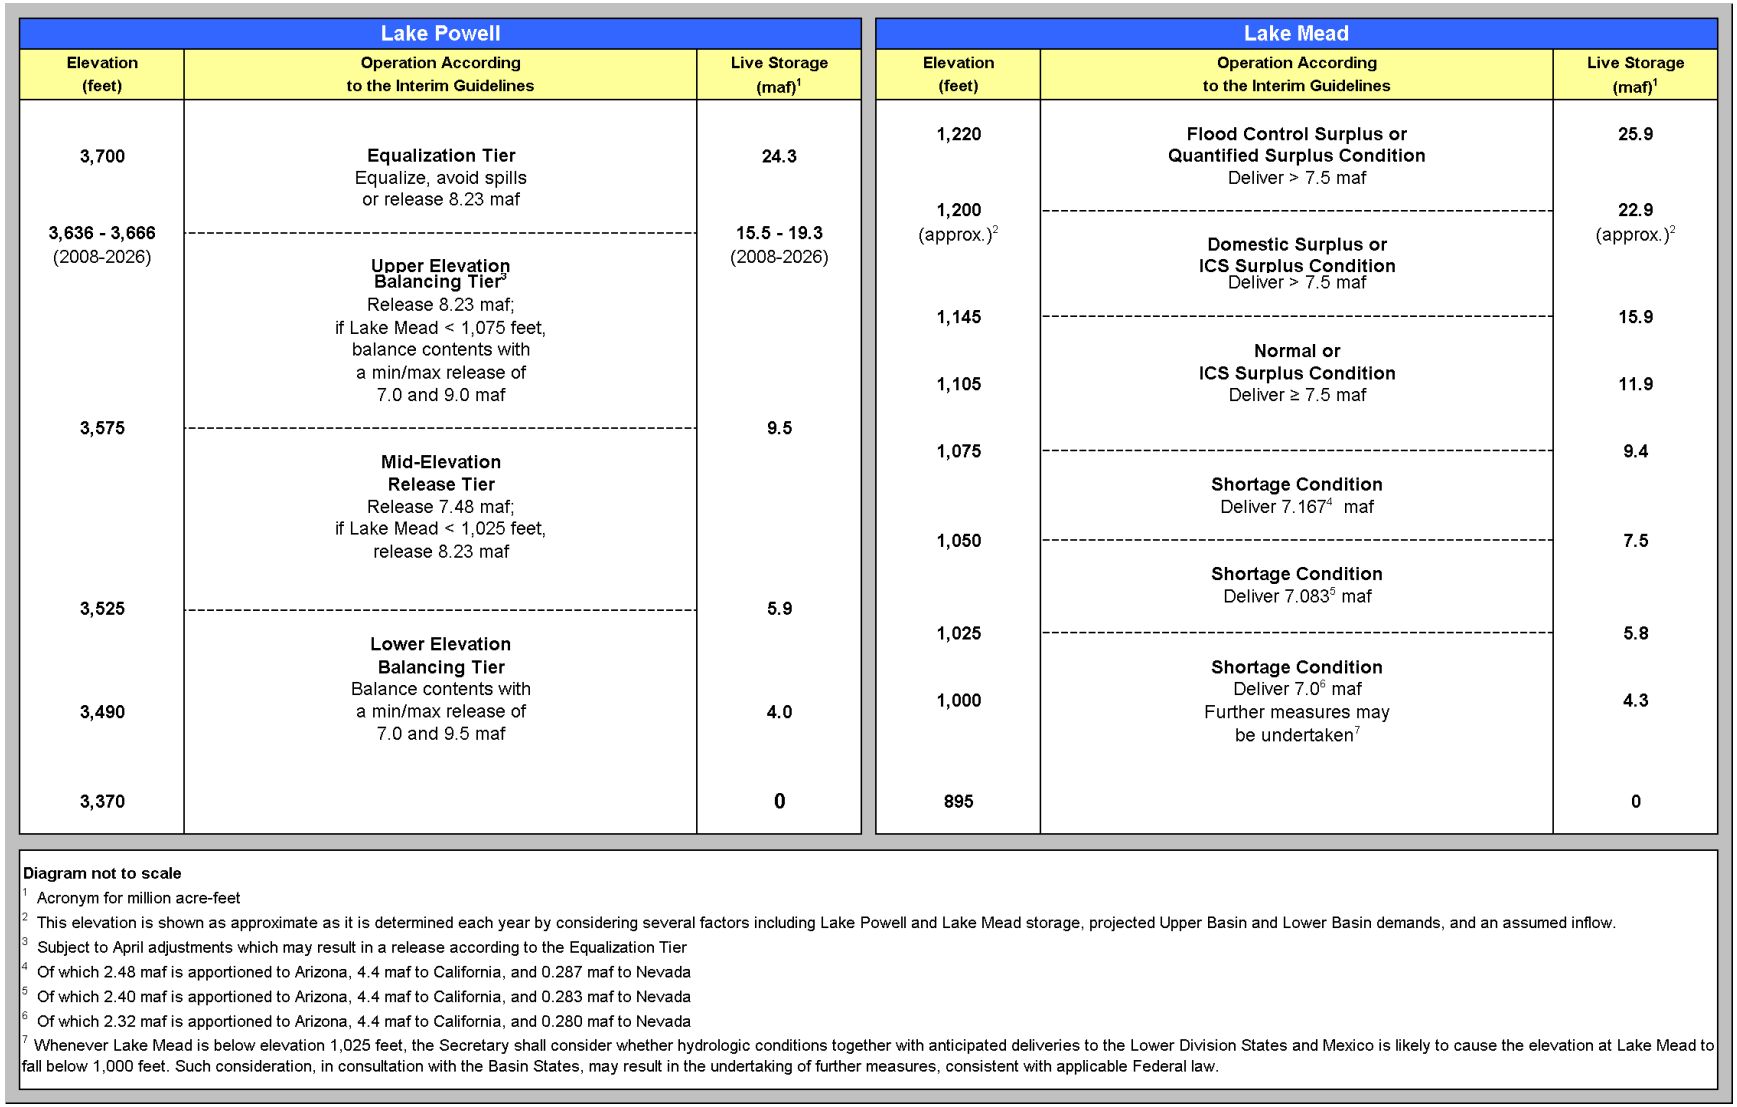

Diagram not to scale

[1] Acronym for million acre-feet

[2] This elevation is shown as approximate as it is determined each year by considering several factors including Lake Powell and Lake Mead storage, projected Upper Basin and Lower Basin demands, and an assumed inflow.

[3] Subject to April adjustments which may result in a release according to the Equalization Tier

[4] Of which 2.48 maf is apportioned to Arizona, 4.4 maf to California, and 0.287 maf to Nevada

[5] Of which 2.40 maf is apportioned to Arizona, 4.4 maf to California, and 0.283 maf to Nevada

[6] Of which 2.32 maf is apportioned to Arizona, 4.4 maf to California, and 0.280 maf to Nevada

[7] Whenever Lake Mead is below elevation 1,025 feet, the Secretary shall consider whether hydrologic conditions together with anticipated deliveries to the Lower Division States and Mexico is likely to cause the elevation at Lake Mead to fall below 1,000 feet. Such consideration, in consultation with the Basin States, may result in the undertaking of further measures, consistent with applicable Federal law.

FIGURE D-1 Operating Tiers as Specified by the 2007 Interim Guidelines (DOI 2007) for the Operations of Lake Powell and Lake Mead

Surplus determinations are per flood control surplus conditions or the 70R Strategy.[3]

Modeling Assumptions for Annual Releases Extending beyond the Water Year

Modeling assumptions for equalization operations need to be performed for a full analysis of monthly and annual operations in this EIS. These assumptions are for analytical purposes only and do not, and cannot, modify the Secretary's approach to operations of equalization releases that are made pursuant to the Colorado River Basin Project Act of 1968. Modeled equalization release volumes can be affected by the annual pattern of monthly volumes. Alternatives that have higher releases earlier in the water year are able to release more water in years when the maximum release through the powerplant becomes a potential limiting factor to equalizing within the water year, which is consistent with the objectives of the Law of the River. A limitation of the current modeling assumptions is that they cannot fully mimic or predict operator judgment or actions to achieve full equalization within the relevant timeframe. Reclamation will continue to operate Glen Canyon Dam to achieve equalization releases in a manner fully consistent with the Law of the River and in consultation with the Colorado River Basin States.

For LTEMP modeling, logic was added to CRSS to handle instances in which Lake Powell could not meet annual release requirements by the end of the water year. If the computed remaining release in September is greater than Lake Powell's powerplant capacity, then the volume above powerplant capacity necessary to meet annual release requirements is released in the subsequent months. Releases, beginning in October, are increased above the normal release requirements (e.g., 600 kaf in an 8.23-maf release year of Alternative A, the No-Action Alternative), up to powerplant capacity, for as many months as necessary to release the remaining equalization volume. The volume of annual releases extending beyond the water year and the frequency at which these releases would be necessary were reported as one of the calculated water resource metrics.

Setting Powell's Monthly Release Volumes

In order to more efficiently model the different alternatives being evaluated in the LTEMP EIS, CRSS logic was modified to use an input release table and to allow minimum release constraints to vary among alternatives. The tables include monthly release volumes for water-year releases of 7.0, 7.48, 8.23, 9.0, 9.5, 10.5, 11.0, 12.0, 13.0, and 14.0 maf. In fixed-release-volume years (e.g., 8.23-maf release years), the monthly volumes used were directly from the input release tables presented in Section D.1.4, subject to other constraints such as

[3] Under the 70R Strategy, a surplus condition is based on the system space requirement at the beginning of each year. Based on the 70th percentile historical runoff, a normal 7.5-maf delivery to the Lower Division states, the Upper Basin scheduled use, and Lake Powell and Lake Mead volumes at the beginning of the year, the volume of water in excess of the system space requirement at the end of the year is estimated. If that volume is greater than zero, a surplus is declared. See Appendix A of the 2007 Interim Guidelines Final EIS (Reclamation 2007) for the full 70R computation.

ensuring Lake Powell stays at a safe operating capacity. In years with computed release volumes (e.g., equalization releases), the necessary water-year-release volume is computed, and the monthly release is interpolated between the two closest water-year releases. For example, if the equalization release is computed to be 12.5 maf, then the monthly release would be interpolated between the 12.0- and 13.0-maf monthly release volumes.

The minimum release constraints were also incorporated into CRSS because there are certain instances when the release from Lake Powell may be computed to be less than the alternative's minimum release constraints. In these cases, the alternative's minimum release constraint is used, subject to the physical ability to release the water. Furthermore, the implementation of these constraints does not result in a modification of the annual release volume.

D.1.3.3 Lake Mohave and Lake Havasu

Lake Mohave and Lake Havasu are operated in accordance with their existing rule curves.

D.1.4 Representation of the Different Alternatives in CRSS

For each alternative, tables were developed that include the monthly release volumes that are modeled to occur under differing water-year release volumes. In most cases, the volumes in the tables represent some desired aspect of the alternatives and were developed by proportionally scaling monthly volumes to the water-year volume. However, in the minimum-water-release (7.0-maf) years and in the high-water-release years, the proportionally scaled monthly volumes in the tables were sometimes adjusted up to meet minimum release constraints or down to meet powerplant capacity. All alternatives met the minimum release constraints and were within powerplant capacity in an 8.23-maf release year. However, in some months for some alternatives, the proportionally scaled monthly volumes in the tables required adjustment to meet these constraints.

For example, the proportionally scaled monthly volumes in a 7.0-maf year were not always adequate to meet the minimum release requirement, as computed by the minimum hourly releases and ramping constraints. In these instances, the monthly release volume was set to the volume necessary to maintain minimum flow throughout the entire month. Similarly, in high-volume water-release years, the proportionally scaled monthly volumes in the tables were sometimes greater than the physical capacity of the Glen Canyon powerplant. In these instances, the monthly release volume in the table was set to powerplant capacity, reallocating the excess into other months of the water year. The annual release volume was not affected by these modifications.

In addition to the physical capacity of the powerplant represented in the monthly tables input to CRSS, the maximum release capacity of Glen Canyon Dam (powerplant and bypass volume) can also affect modeled monthly release volumes, particularly in years with an annual

release volume greater than 14.0 maf. The maximum release was modeled explicitly in CRSS as a function of reservoir head. In general, the maximum release was computed as 45,000 cfs; this flow was converted to a daily volume and then multiplied by the number of days in the month to determine the monthly maximum release volume. In months when the monthly release prescribed by the alternative was greater than the maximum capacity for the month, the monthly volume was capped at the physical capacity, and the remaining volume was released in the following month(s).

Monthly release volume can also be affected by high-flow experiments (HFEs). For HFEs that required more water than was already allocated for the given month of the HFE, water was reallocated from later months to ensure the water-year release volume remained the same. For this EIS, the monthly reallocation of water for HFEs was modeled as a post-process to the sand-budget model (i.e., after the model determined the magnitude and duration of the HFE). Reservoir mass balance was computed for the affected months, and the resulting monthly releases and reservoir elevations were then passed to the hydropower model.

The monthly reallocation of releases to support an HFE does not affect the Lake Powell operating tier (and thus did not need to be explicitly modeled in CRSS). Operationally, the magnitude and duration of a HFE would be determined in either October–November or March–April. Because the Lake Powell annual operating tier is determined based on the August projection of the January 1 elevation, it is not yet known whether an HFE will take place that water year. Therefore, a modeled reallocation of water into November, for example, should not be considered in determining the annual operating tier because, operationally, this information would not be known until after the operating tier was already set.

Tables D-2 through D-11 are the monthly release tables used for all alternatives in CRSS, and Table D-12 summarizes the minimum release constraints used for each alternative. Figure D-2 shows the 8.23-maf release-year pattern for all alternatives. In addition, the experimental components of LTEMP that are modeled in CRSS are also discussed.

Long-term strategies (various implementations of the seven LTEMP alternatives; described in Appendix C) that would not affect monthly or annual releases from Lake Powell were not simulated in CRSS. These long-term strategies are labeled in the figures in this appendix as identical to another long-term strategy. For example, the only difference between long-term strategies D1 and D3 is that D1 includes trout management flows. Because trout management flows were not included in CRSS, results for D1 and D3 are identical and labeled as such in the water delivery results.

TABLE D-12 Minimum Release Constraints (cfs) Used for Each Alternative

Alternative	Minimum Release (cfs)
A	6,562.50
B	6,500.00
C	6,520.83
D[a]	6,520.83
E	6,520.83
F	5,000.00
G	8,000.00

[a] For Alternative D, with steady weekend flows for invertebrate production, the May–August minimum release constraint is 8,000 cfs.

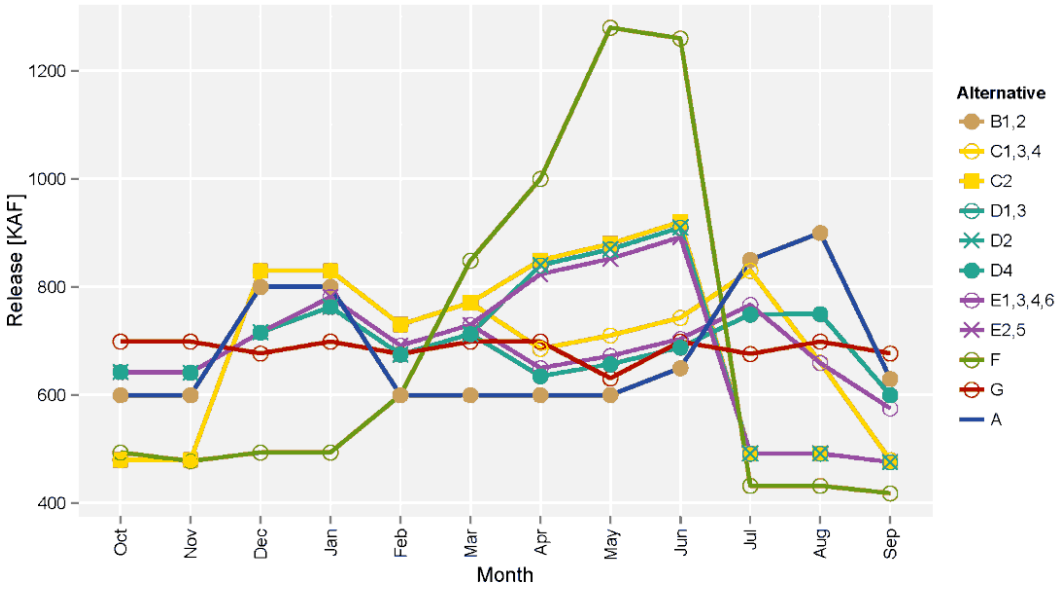

FIGURE D-2 Monthly Releases (kaf) for Each Alternative in an 8.23-maf Release Year (Note that long-term strategies C2, D1, D2, D3, E2, and E5 are shown with the monthly distributions when low summer flows are implemented. Low summer flows would not be implemented in all years.)

D.1.4.1 Experimental Components Modeled in CRSS

Specific to the LTEMP EIS, both experimental treatments—low summer flows and May–August steady weekend flows for invertebrate production—were incorporated into CRSS. The following sections discuss how these experimental components were modeled in CRSS.

Low Summer Flows

Low summer flows were implemented in CRSS as an experimental component under Alternatives C, D, and E. The objective of low summer flows is to produce warmer temperatures (i.e., greater than 13°C [55°F] for Alternatives C and E and greater than 14°C [57°F] for Alternative D) at the confluence with the Little Colorado River (T_{LCR}) in July, August, and September. In May, these alternatives would switch to a low summer flow pattern, releasing less water during these months, if all three of the following conditions are true: (1) the projected annual water-year release is <10 maf, (2) projected T_{LCR} is cold[4] in any of the three target months using the base release pattern, and (3) switching to the low-summer-flow pattern would result in warm[5] temperatures in all three of the target months. Alternatives that have low summer flows as an experimental component would use the base release tables, unless these three conditions were met. For example, Alternative E (long-term strategy 2) would use release volumes from Table D-8, but would switch to the release volumes in Table D-9 if the above conditions were met. Note that Alternatives C and E were modeled with low summer flows during the entire 20-yr LTEMP period, whereas Alternative D was modeled with implementation of low summer flows only during the second 10 yr of the LTEMP period.

The projected temperature conditions were calculated using regression equations that considered monthly elevations and releases and the calendar-year inflow at Lake Powell, and were empirically developed from observed conditions. The regression equations[6] to solve for T_{LCR} in July, August, and September were as follows:

July: $T_{LCR} = T_o + 3.791 \div (0.000461 \times \textit{Apr Projected Release}_{JUL})^{0.63} \times (36.31 - T_o)$,
where: $T_o = 249.4 - (0.0668 \times \textit{Apr Projected EOM Elev}_{JUL}) + (3.766\text{E-}7 \times \textit{Apr Projected CY Inflow})$

4 Cold is defined as <13°C (55°F) for long-term strategies C2, E2, and E5 and <14°C (57°F) for long-term strategies D1, D2, and D3.

5 Warm is defined as >13°C (55°F) for long-term strategies C2, E2, and E5 and >14°C (57°F) for long-term strategies D1, D2, and D3.

6 Regression equations were log-transformed for inclusion into CRSS.

August: $T_{LCR} = T_o + 3.791 \div (0.000461 \times Apr\ Projected\ Release_{AUG})^{0.63} \times (34.81 - T_o)$, where: $T_o = 297.2 - (0.0802 \times Apr\ Projected\ EOM\ Elev_{AUG}'') + (4.915E\text{-}7 \times Apr\ Projected\ CY\ Inflow)$

September: $T_{LCR} = T_o + 3.791 \div (0.000476 \times Apr\ Projected\ Release_{SEP})^{0.63} \times (30.01 - T_o)$, where: $T_o = 327.9 - (0.0886 \times Apr\ Projected\ EOM\ Elev_{SEP}) + (5.342E\text{-}7 \times Apr\ Projected\ CY\ Inflow)$

where:

T_{LCR} = temperature at the Little Colorado River Confluence, °C

T_o = Lake Powell release temperature, °C

EOM Elev = Lake Powell projected end-of-month elevation, ft

CY Inflow = Lake Powell projected calendar-year inflow, ac-ft

Release = Lake Powell projected monthly release volume, ac-ft

Steady Weekend Flows for Invertebrate Production

Steady weekend flows for invertebrate production were an experimental component of Alternative D. For the long-term strategy that included these flows, the May–August minimum release constraint was increased to 8,000 cfs.

D.1.5 Input Hydrology

The future hydrology used as input to the model consisted of samples taken from the historical record of natural flow in the river system over the 105-yr period from 1906 through 2010, from 29 individual inflow points (or nodes) on the system. The locations of the hydrologic input sites are shown in Figure D-3.

Typically, CRSS is run with the full suite of available natural flow traces created using a resampling technique known as the Indexed Sequential Method (ISM) (Ouarda et al. 1997). Using the ISM on a 105-yr record (1906–2010) results in 105 inflow traces (i.e., plausible inflow sequences). For this EIS, however, because of the complexity, resource and timing constraints, and number of loosely coupled models used to analyze other resource impacts, every fifth trace from the 105 natural flow traces was selected, resulting in 21 traces.

Figures D-4 and D-5 compare the differences between using 105 traces and using 21 traces, and indicate that the distribution of 21 traces is very similar to the distribution of the full 105 traces for Lake Powell annual inflow, annual and monthly releases, and end-of-December pool elevation.

D.1.6 Input Demands

The LTEMP modeling utilized the Basin Study current projected demand scenario (Reclamation 2012b) for the input demands into CRSS. Table D-13 summarizes the demands by state.

D.1.7 Other Key Assumptions

A number of changes to CRSS were described in the Basin Study (Appendix G-2) including how the model treats implementation of Upper Colorado River water rights and intentionally created surplus.

Future water deliveries to Mexico were modeled as follows:

1. The model accounts for the entire delivery to Mexico at the Northerly International Boundary (NIB).

2. Water deliveries to Mexico are pursuant to the requirements of the 1944 Treaty. This provides annual deliveries of 1.5 maf to Mexico and up to 1.7 maf during Lake Mead flood control release conditions.

3. For modeling purposes, it is assumed that during shortage conditions, Mexico shares shortage in proportion to U.S. users in the Lower Basin (16.67%). This assumption is consistent with that used in the modeling supporting 2007 Interim Guidelines Final EIS (Reclamation 2007).[7]

4. Minute No. 318 and Minute No. 319 were not modeled as part of the LTEMP EIS because modeling began before they could be incorporated into CRSS.

The Warren H. Brock Reservoir was assumed to operate every year beginning in 2013 and is assumed to conserve approximately 90% of non-storable flows. This reduces the average annual volume of non-storable flows delivered to Mexico from 73 kaf/yr (historical average from 1964 through 2010, excluding flood years on the Gila or flood control releases) to 7 kaf/yr.

Bypass of return flows from the Welton-Mohawk Irrigation and Drainage District to the Cienega de Santa Clara in Mexico was assumed to be 109 kaf/yr (historical average from 1990 through 2010) and was not counted as part of the 1944 Treaty delivery to Mexico.

The Yuma Desalting Plant was assumed to not operate during the LTEMP period.

---

[7] Allocation of Colorado River water to Mexico is governed by the 1944 Treaty. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico.

TABLE D-13 Input Demands by State

	Input Demand (ac-ft)						
	Upper Division States				Lower Division States		
Year	Colorado	New Mexico	Utah	Wyoming	Arizona[a]	California	Nevada
2013	2,524,327	592,772	1,017,031	539,545	2,800,000	4,400,000	300,000
2014	2,524,552	601,496	1,018,144	539,755	2,800,000	4,400,000	300,000
2015	2,524,776	610,220	1,019,258	539,965	2,800,000	4,400,000	300,000
2016	2,536,669	618,944	1,020,371	542,900	2,800,000	4,400,000	300,000
2017	2,548,562	627,668	1,021,485	545,835	2,800,000	4,400,000	300,000
2018	2,560,455	636,392	1,022,599	548,769	2,800,000	4,400,000	300,000
2019	2,572,347	645,116	1,023,712	551,704	2,800,000	4,400,000	300,000
2020	2,584,240	653,840	1,029,826	554,639	2,800,000	4,400,000	300,000
2021	2,596,133	658,483	1,033,820	557,574	2,800,000	4,400,000	300,000
2022	2,608,026	663,126	1,037,813	560,509	2,800,000	4,400,000	300,000
2023	2,619,919	667,769	1,041,807	563,443	2,800,000	4,400,000	300,000
2024	2,631,812	672,412	1,045,801	566,378	2,800,000	4,400,000	300,000
2025	2,643,705	677,055	1,049,794	569,313	2,800,000	4,400,000	300,000
2026	2,655,597	681,698	1,053,788	572,248	2,800,000	4,400,000	300,000
2027	2,667,490	686,341	1,057,781	575,183	2,800,000	4,400,000	300,000
2028	2,679,383	690,984	1,061,775	578,117	2,800,000	4,400,000	300,000
2029	2,691,276	695,627	1,065,769	581,052	2,800,000	4,400,000	300,000
2030	2,703,169	700,270	1,074,762	583,987	2,800,000	4,400,000	300,000
2031	2,715,062	702,863	1,080,156	586,922	2,800,000	4,400,000	300,000
2032	2,726,954	705,456	1,085,550	589,857	2,800,000	4,400,000	300,000
2033	2,738,847	708,049	1,090,943	592,791	2,800,000	4,400,000	300,000

[a] There are an additional 50,000 ac-ft/yr of Arizona demands within the Upper Basin, represented in CRSS.

D.2 SUPPLEMENTAL INFORMATION ON IMPACT MODELING

The following sections provide more detailed information on the impacts of the different LTEMP alternatives, particularly for low summer flows, the carryover equalization release metric, and alternative-specific comparisons to Alternative A (No-Action Alternative). These results supplement those covered in Section 4.1 of this EIS.

D.2.1 Low Summer Flows

During years with low summer flows, releases would be lower than typical in July, August, and September and proportionally higher in May and June, in order to maintain the same annual release volume. In years when the required annual release volume is not known until the end of the water year (e.g., during balancing or equalization), the low-summer-flows monthly volumes may end up being higher or lower than those originally projected in April because of changing hydrologic conditions. Figure D-6 shows the modeled frequency of occurrence of low summer flows. Note that Alternatives C and E were modeled with implementation of low

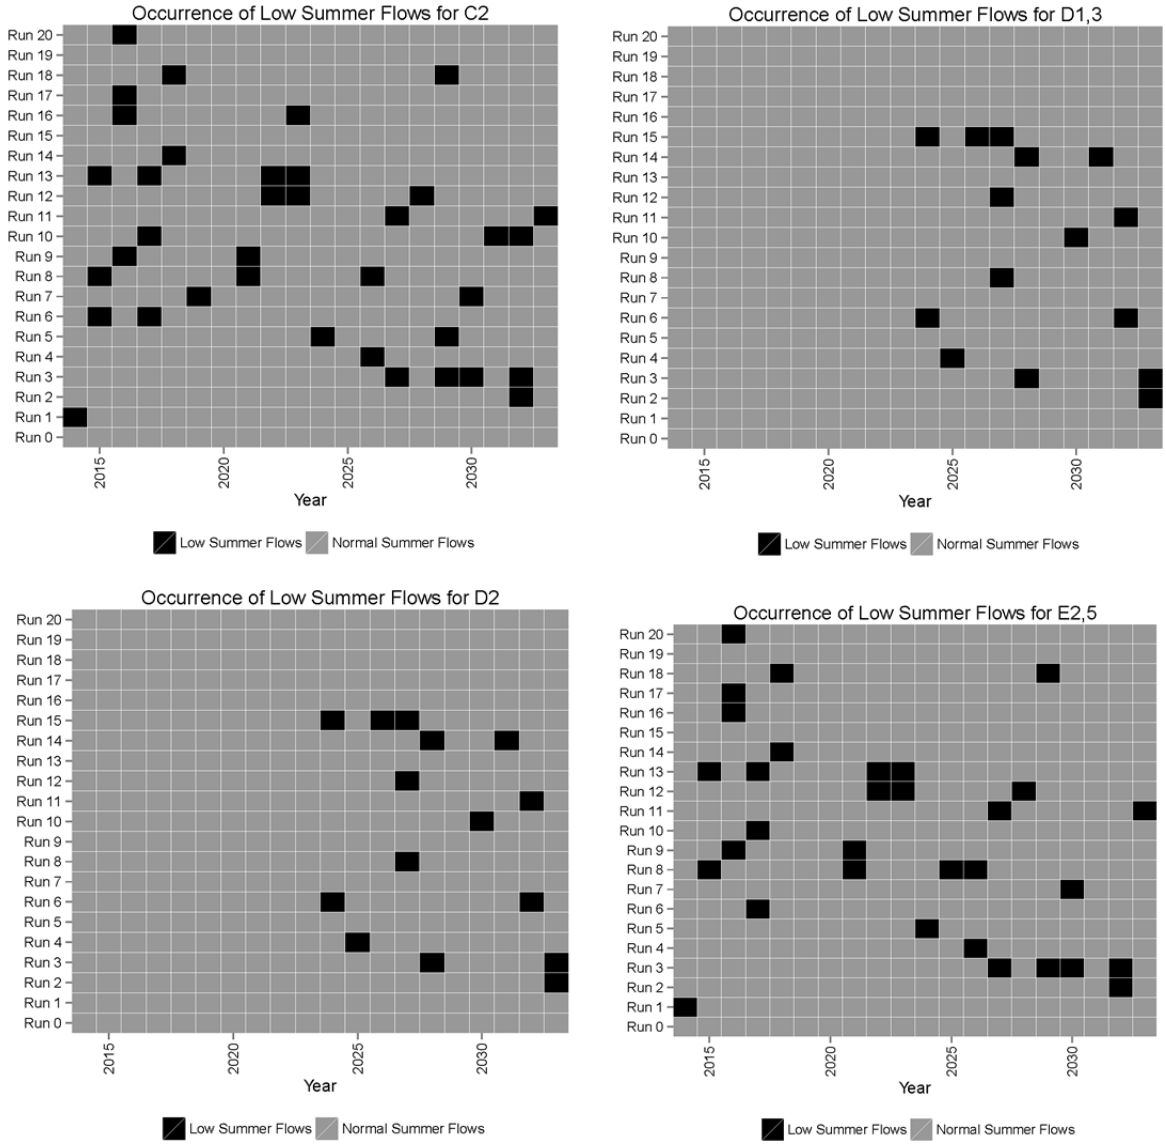

FIGURE D-6 Occurrences of Low Summer Flows in Applicable Alternatives (Numbers after alternative letter designations represent the long-term strategies that would implement low summer flows.)

summer flows during the entire 20-yr period, whereas Alternative D was modeled with low summer flows only during the second 10 yr of the LTEMP period. For those alternatives with low summer flows, the modeled number of low summer flows in the 20-yr period ranged from zero to four occurrences per trace. Depending on the alternative, the average ranged from 0.7 to 1.8 low summer flows per 20-yr run.

D.2.2 Modeled Annual Releases Extending beyond the End of the Water Year

The frequency (Figure D-7) and volume (Figure D-8) of exceptions to meeting the annual release target volumes specified by the Interim Guidelines were one of the calculated water

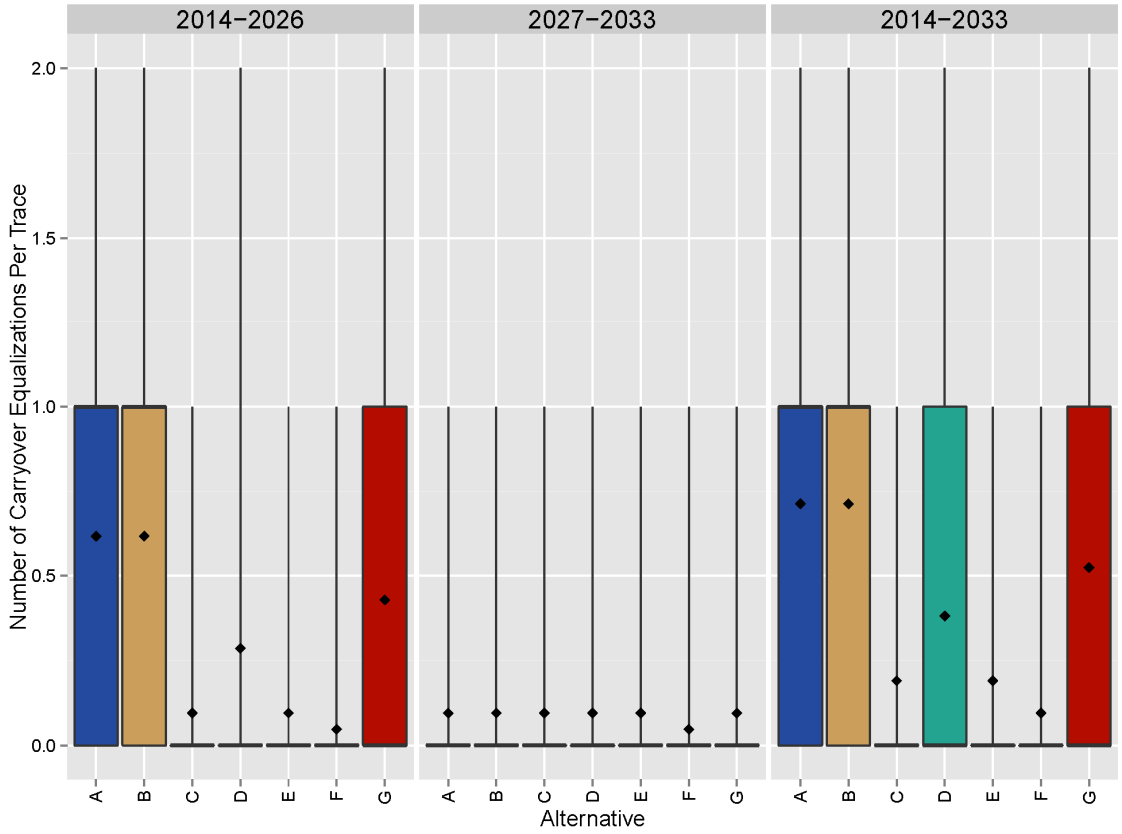

FIGURE D-7 Frequency of Occurrence of Modeled Annual Releases Extending beyond the End of the Water Year per 20-yr Trace for Each of the Alternatives (See Figure 4-2 for an explanation of how to interpret this graph. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

resource metrics. Note that there is the possibility of exceptions occurring under all alternatives, including Alternative A (the No-Action Alternative).

D.2.3 Lake Elevation

Figures D-9 through D-14 present end-of-December elevations for Lake Powell and Figures D-15 through D-20 present percentage of traces below Lake Powell's minimum power pool for each alternative, and compare them to Alternative A. These graphs show different implementations of each alternative (referred to here as long-term strategies). These strategies are given the letter designation of the alternative (A–G) and a number designating the long-term strategy for the alternative. See Section 4.1 and Appendix C for descriptions of the experiments included in each long-term strategy. For both of these parameters, only very small differences between Alternatives B–G and Alternative A were found.

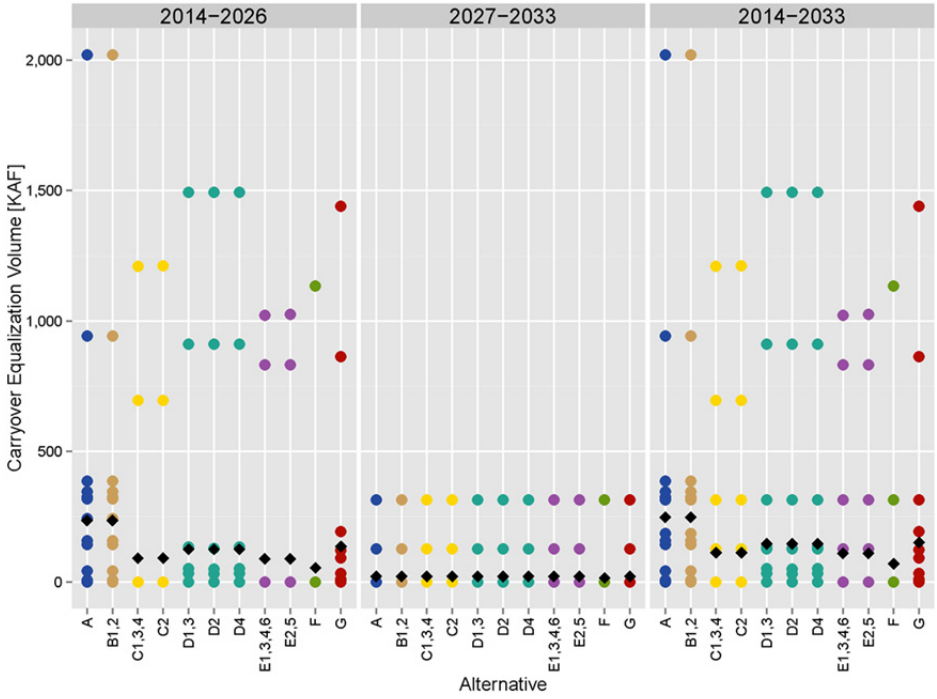

FIGURE D-8 Median Volume of Modeled Annual Releases Extending beyond the End of the Water-Year Releases by Trace for Each of the Alternatives (Each value represents the median carryover equalization volume for one trace. Because there are few traces with more than one occurrence, the median value typically represents the only nonzero instance. For each alternative there are 21 possible carryover equalization values for each period and alternative combination [21 traces].)

SEDIMENT RESOURCES TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX E:

SEDIMENT RESOURCES TECHNICAL INFORMATION AND ANALYSIS

E.1 INTRODUCTION

This technical appendix focuses on sediment resources. The sediment resource goal is to increase and retain fine sediment volume, area, and distribution in the Glen, Marble, and Grand Canyon reaches above the elevation of the average base flow for ecological, cultural, and recreational purposes. One interpretation of this goal is to promote and maintain sandbars downstream of Glen Canyon Dam for the benefit of other resources. Currently, there is no peer-reviewed model or program that can simulate or predict sediment bar response to Glen Canyon Dam operations. Because no such model is available, other information and analyses were used in this Environmental Impact Statement (EIS) to analyze the effects alternatives would have on sediment resources. The sand budget model, which is peer reviewed and was used in the 2011 high-flow experiment (HFE) protocol environmental assessment (EA) (Reclamation 2011), provides the best available modeling method to estimate the effects of different flows on the potential for sandbar growth.

Seven alternatives were analyzed. Some of these alternatives would use condition-dependent or experimental elements that would be implemented under an adaptive management framework that would allow modification of flow and non-flow actions as new information is obtained. Critical uncertainties were identified that could lead to changes in flow and non-flow actions; these were used to identify multiple long-term strategies for those alternatives with condition-dependent actions (Alternatives B, C, D, and E). These long-term strategies were essentially different versions of the analyzed alternatives. The condition-dependent experimental elements included in the 19 strategies that were analyzed are presented in Appendix C; a full description of the alternatives can be found in Chapter 2 of this EIS.

E.1.1 Analysis Period

Sediment analysis spanned water years 2014 through 2033 (i.e., October 1, 2013, to September 30, 2033) (Figure E-1). However, the hourly dam release data developed for the hydropower analysis (GTMax-Lite) followed a calendar-year framework (i.e., January 1, 2013, through December 31, 2033). Development of sediment data for simulation input were analyzed in terms of sediment years (i.e., July 1, 2013, through June 30, 2033), which coincides with the accounting periods currently used by the Bureau of Reclamation (Reclamation) for determining whether or not a HFE should be conducted (Russell and Huang 2010).

E.1.2 General Scope

In order to address uncertainty, the analysis conducted for this EIS covered a range of hydrology scenarios and tributary sediment delivery scenarios. Hydrologic futures were

developed using the Colorado River Simulation System (CRSS) (Appendix D). One-hundred and five 20-year hydrologic traces were developed from the 105-year period of record; for modeling (Section 4.2.1.1 of this EIS), every fifth hydrologic trace was used, yielding 21 potential hydrologic futures to be analyzed.

Three sediment input time series were developed to address uncertainty in the future delivery of sand to the Colorado River from tributaries. Two main tributaries—the Paria River and the Little Colorado River—deliver sand to the Colorado River downstream of Glen Canyon Dam and upstream of Lake Mead. Three 20-year sediment traces were developed for the two tributaries (Section E.2.1.3), spanning the available historical data.

In summary, there were 19 long-term strategies, 21 hydrology traces per long-term strategy, and three sediment traces per hydrology trace. This produced 63 simulations per long-term strategy, 1,197 simulations in all.

E.2 METHODS

Resource models were used to evaluate and compare the impacts of alternatives. Figure E-2 illustrates the inputs, intermediate calculations, and output of the models. This appendix will describe and discuss those parts of the flowchart circled in red: the modified sand budget model (including development of model inputs) and the sediment metrics.

E.2.1 Sand Budget Model

E.2.1.1 Model Description

A reach-based sediment budget model for the Colorado River from Lees Ferry (river mile [RM] 0) to approximately Bright Angel Creek (RM 87) was developed by the U.S. Geological Survey (USGS) (Wright et al. 2010). Using gage data at RM 30, RM 61, and RM 87, the model was calibrated and validated to the time period of 2002–2009. The model uses empirically based rating curves, which are formulated on a particle-size-specific basis. On the basis of observed transport rates, the transport function changes when flows exceed 25,000 cfs. Initial sand bed size and thickness are user-specified for each reach (RM 0–RM 30, RM 30–RM 61, and RM 61–RM 87), and a budget is developed by tracking the incoming and outgoing suspended sand flux for each reach. The incoming sand flux for RM 0–RM 30 consists mainly of Paria River inputs, and ungaged tributaries in the reach are assumed to be 10% of Paria River inputs. The ungaged tributaries for RM 30–RM 61 are assumed to be negligible, so the flux into the reach equals the flux out of RM 0–RM 30. The flux into RM 61–RM 87 consists of the flux out of RM 30–RM 61, contributions from the Little Colorado River, and ungaged tributaries, which are assumed to be negligible. Figure E-3 provides a schematic of the sand budget model.

E.2.1.2 Sand Budget Model Modifications

The sand budget model has been updated to meet the specific analytical needs since its inception. During analysis for the 2011 High Flow Experiment (HFE) Environmental Assessment (EA) (Reclamation 2011), a protocol was developed to determine whether a HFE could be implemented to improve/maintain the sandbar sediment resource (Russell and Huang 2010). The model was updated to include the HFE protocol and to identify the largest HFE that could be implemented within each sediment accounting period without causing the Marble Canyon sediment balance to be negative for that period. Marble Canyon is the focus of the sediment balance because (1) the sand budget model was calibrated and validated for the first 87 mi downstream of Lees Ferry; and (2) the gage record for the Little Colorado River is relatively short, and therefore there is less confidence in using the data for predictive purposes. The protocol in the model assumes that the implementation of an HFE occurs on April 1 for the spring accounting period and on November 1 for the fall accounting period.

For the LTEMP EIS, the water volumes used by each HFE were accommodated by adjusting monthly volumes in the rest of the water year instead of simply adjusting the releases for the remainder of the implementation month as was done for the HFE EA. One of two different reallocation schemes is implemented depending on the alternative: a sequential reallocation scheme or an average reallocation scheme.

The sequential reallocation scheme was applied to Alternatives A and B (because they have the same monthly release volume allocations). The months from which to reallocate water were specified in order, along with the minimum release volume for each month and the minimum release flow rate. Water was reallocated from the months, in order, until the water volume needed for an HFE was achieved. If the volume needed for an HFE could be borrowed from the first month in the list, then no water was borrowed from the following listed months. If the necessary HFE volume could not be taken from the first month without violating either the minimum monthly volume or the minimum release discharge, then the next month in the list was accessed for additional volume.

The average reallocation scheme was applied to the rest of the alternatives because their monthly release volume distributions differed from Alternative A. This method borrowed a percentage of the monthly volume from each month specified. The volume of water borrowed was not the same across months, but the percentage borrowed from each month was consistent; a higher monthly volume before reallocation means more water taken and applied to the HFE volume. There is a user-specified minimum release discharge that cannot be violated for the average reallocation scheme.

Another modification made to the sand budget model (which did not affect the triggering of an HFE) was to track the necessary parameters to determine whether a trout management flow (TMF) would be triggered for a water year. For a description of TMFs, see Chapter 2 of this EIS. A simple binary file was developed to identify water years meeting the requirement for a TMF; parameters indicating trout recruitment and the triggering of a TMF are all flow related.

The primary results from the first iteration of the modified sand budget model are two files per simulation: one identifying the timing and size of HFEs, and one identifying the timing of TMFs. This information is fed back to the GTMax-Lite model (Figure E-2) for refined hourly dam release hydrographs.

E.2.1.3 Modified Sand Budget Model Inputs

Primary model inputs to the sand budget model are (1) flow hydrographs and (2) tributary sand inputs. The initial conditions of sand bed thickness and average bed grain size were also specified; these values are constant across simulation and are not alternative dependent.

Flow Hydrographs

The model-predicted suspended sand transport rates were calibrated and validated (as part of the model development; Wright et al. 2010) at gage measurement locations, namely the gages at RM 30, RM 61, and RM 87. The flow hydrograph at these locations needs to be specified for the sand budget model and are developed using the Colorado River Flow, Stage, and Sediment (CRFSS) model. The CRFSS model has a one-dimensional unsteady-flow model component that routes a dam-release flow hydrograph and provides hydrographs at locations requested by the user. The CRFSS model uses average channel geometry based on previously measured cross-sections in Marble and Grand Canyons (Wiele and Smith 1996; Wiele et al. 2007). For each dam release hydrograph provided by GTMax-Lite (Figure E-2), there were three hydrographs developed by the CRFSS model (at RM 30, RM 61, RM 87) for use in the modified sand budget model.

Tributary Sand

Both the Paria River and the Little Colorado River have sediment records that were used to develop a time series of sand load (a sediment trace). Although the Little Colorado River record is for only 18.5 years, it is the best available dataset. Three sediment traces were developed for each tributary to address uncertainty in future tributary sand delivery. Sediment data were obtained from two sources: published data from the Grand Canyon Monitoring and Research Center (GCMRC 2015) and from Topping (2014). The period of record for the two tributaries and the sources of the data are presented in Table E-1.

The model simulation period covers 21 calendar years, which corresponds to 41 sediment accounting periods, or ~20.5 sediment years (Figure E-2). An index sequential approach was used to develop statistics for each record. In general, an index sequential method cycles through each year in a historic record and generates time series (or traces) for a specific duration; for years toward the end of the record, the requisite time period is achieved by "wrapping around" to the beginning of the record. This technique is typically used for hydrologic data cycling through water years (Reclamation 2007; Ouarda et al. 1997), whereas the method is employed here for sediment data and cycles through sediment years. The "wrap around" for the sediment analysis

means that for the Paria River, the fall 2013 accounting period is followed by the spring 1964 accounting period; likewise, for the Little Colorado River the fall 2013 accounting period is followed by the spring 1994 accounting period. The record for the Little Colorado River is short enough relative to the 21-year period that every index sequential sediment trace covers the entire period of record.

Paria River. Because fall 2013 is the first full accounting period for which an HFE would be considered in the simulation, only index sequential segments beginning with fall accounting periods are used in the statistical analysis. The three traces selected were approximately the 10%, 50%, and 90% non-exceedance traces from the index sequential statistics. The three selected traces for the Paria River also cover the entire period of record. Figure E-4 presents the sand input from the Paria River for the historical record grouped into accounting periods, along with the index sequential 41-accounting period (20.5-year) sand loads. Only the 20.5-year sand load sequences beginning with a fall accounting period are presented in Figure E-4; these are the data from which the statistics are developed for identifying three representative traces. Figure E-5 presents the cumulative sand load for the three traces that were identified for the use in the EIS modeling. Again, these traces were identified based on cumulative sand load and to ensure the entire historical record is represented in the modeling.

These three traces are not consistently low, medium, and high relative to each other throughout the 20-year period. Moving from beginning to end of the simulation period, s1 (sediment trace 1) is not always less than s2, and s2 is not always less than s3. In fact, s3 is comparable to s2, except in the last couple of years when the s3 trace jumps significantly; this jump corresponds to the fall 1980 accounting period. In addition, s1 has the most sediment contributions for approximately the first 3 years. These are three different sediment traces that were selected to be representative of the historical record.

Once the three sets of 41 accounting periods were identified for use in the simulation, the necessary simulation records (traces) were completed by applying the appropriate sections of the historical record. The periods of record used for s1, s2, and s3 are presented in Table E-2.

Little Colorado River. The record for the Little Colorado River is shorter than the simulation period, so every trace covers the entire period of record. In addition, the HFE protocol as implemented in the modified sand budget model assesses the balance of sand in Marble Canyon to determine whether an HFE is simulated. The balance of sand in Eastern Grand Canyon—and therefore the sediment input from the Little Colorado River—is less critical to the simulations and analysis performed for this EIS.

The index sequential method for the Little Colorado River was performed on a calendar year basis, and the simulation periods for s1, s2, and s3 are presented in Table E-3. Figure E-6 presents the sediment traces used as input for the modified sand budget model.

Initial Conditions

The initial conditions to be specified in the sand budget model for each reach are bed thickness and median bed sediment grain size, D_{50}. The initial conditions specified for the EIS analysis come from the best available data nearest the simulation start date of January 1, 2013. Wright et al. (2010) found that varying initial bed D_{50} by ±10% from the initial estimated values (0.4, 0.3, and 0.3 mm for Upper Marble Canyon [UMC], Lower Marble Canyon [LMC], and Eastern Grand Canyon [EGC], respectively) yielded between 3 and 7% difference in total flux for the three reaches; varying initial bed thickness from the initial estimated values (0.4, 0.5, and 0.5 m for UMC, LMC, and EGC, respectively) by ±10% yielded a difference in total sand flux of less than 0.5%. The simulations conducted for this analysis used initial condition values for UMC, LMC, and EGC of 0.46, 0.38, and 0.43 mm, respectively, for grain size and 0.30, 0.37, and 0.27 m, respectively, for bed thickness.

High Flow Experiments

The modified sand budget model identified the largest HFE that would not violate water and sediment availability rules. The HFEs that the model considered are user specified. Eighteen HFEs that are specified for this analysis (Table E-4), and HFEs 1–13 are consistent with the HFEs considered for the HFE EA (Reclamation 2011). Longer-duration HFEs (A–E in Table E-4) were suggested for consideration in the EIS, and two alternatives consider HFEs lasting longer than 96 hours: Alternative D and Alternative G. HFE C in Table E-4 was originally defined as lasting 240 hours at 45,000 cfs for Alternative G. Alternative D was crafted after seeing the results of the Alternatives A, B, C, E, F, and G (Section 2.2.4 of this EIS), and HFE C in Table E-4 was defined as 250 hours for this alternative.

Proactive spring HFEs would be triggered based on hydrology. Conceptually, a large snowpack in the mountains leads to a prediction of a wet year; if the predicted annual runoff volume is great enough (greater than 10 million ac-ft, or 10 maf), then a proactive spring HFE would be implemented. The purpose of this HFE is to redistribute the available bed sediment onto sandbars and channel margins so that it would be stored at elevations above those of the subsequent large runoff volume. The proactive spring HFE implemented in the model is identical to HFE 6 in Table E-4 in terms of peak discharge and duration at peak discharge.

E.2.2 Sediment Metrics

Prior to modeling for the LTEMP EIS, a number of metrics were crafted to evaluate the alternatives in terms of their performance with regard to the sediment resource goal. The metrics developed prior to modeling were surrogates intended to be representative of sediment resource response; it was assumed that if the surrogate performed well, the sediment resource also would respond well. The metrics developed were the sand load index (SLI), the standard deviation of high flows (SDHF), and the sand mass balance index (SMBI).

E.2.2.1 Sand Load Index (SLI)

The potential for building sandbars was estimated using the SLI, which is a comparison of the mass of sand transported at RM 30 when river flows ≥31,500 cfs relative to the total mass of sand transported at all flows, as shown in equation 1:

$$SLI = \frac{Q_{s,Q>31.5}}{Q_{s,total}} \quad (1)$$

where:

SLI = sand load index

$Q_{s,Q>31.5}$ = sand flux at RM 30 when river flows at RM 30 are greater than 31,500 cfs

$Q_{s,total}$ = total sand flux at RM 30 during analysis period.

The index varies from 0 (no sand transported at flows ≥31,500 cfs) to 1 (all sand transported at flows ≥31,500 cfs). An SLI of 0 would indicate that there are no flows above 31,500 cfs during a simulation; the alternative that there are flows above 31,500 cfs but no sediment flux occurring is for all practical purposes impossible.

The larger the SLI for an alternative, the more potential there is for bar growth. The SLI only estimates the potential for (and not actual) bar growth, because all sandbars have a maximum potential deposition volume; the closer any given bar is to full, the less deposition will occur (Wiele and Torizzo 2005).

E.2.2.2 Standard Deviation of High Flows (SDHF)

This index was intended to represent a greater likelihood of more robust sandbars. Historical sandbar surveys indicate that individual bars respond differently to different HFEs (Hazel et al. 2010). Some sandbars are smaller after a 45,000 cfs experiment. Equation 2 shows how this value is calculated for each water year, and the metric is averaged across the 20-water-year analysis period.

$$SDHF = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2} \quad (2)$$

where:

SDHF = standard deviation of high flows

N = sample size (in this case, 63 per alternative)

x_i= individual observed peak discharge, cfs

$\bar{x}$ = sample mean of peak discharges, cfs.

E.2.2.3 Sand Mass Balance Index (SMBI)

This index quantifies the amount of sand that is left in storage in Marble Canyon (RM 0 to RM 61) at the end of a simulation relative to the amount of sand that is present at the beginning of the simulation. This is the most direct application of the modified sand budget model; it tracks the amount of sand that comes into the individual reaches compared to the amount of sand that leaves the individual reaches (Figure E-7). This index is not directly representative of the resource goal. However, this metric does provide insight into how the amount of sediment in Marble Canyon is affected by dam operations. If more sand comes into Marble Canyon than leaves Marble Canyon, there will be an increase in stored sand, and a positive SMBI. Conversely, a greater amount of sand leaving Marble Canyon than entering will yield a negative SMBI.

E.3 RESULTS

Two iterations of the modified sand budget model were completed for each simulation (Figure E-2). The first iteration determined the timing and size of triggered HFEs, as well as identifying whether TMFs would be triggered. This information was passed back to GTMax-Lite where the hourly dam release hydrographs were refined based on the HFE schedule and TMF schedule.

The second iteration of the modified sand budget model did not allow additional HFEs to be implemented because the refined GTMax-Lite dam releases already include the HFEs and TMFs. The second iteration was used to obtain sediment-related data for sediment metrics to be calculated for each alternative.

E.3.1 HFEs Determined by Alternative

The sediment metrics for each alternative are closely related to the number of HFEs that occur for the alternative. The number of HFEs is not a sediment metric itself, but understanding the HFEs that occur under an alternative helps to clarify the sediment metrics discussed in the following sections. The average number of HFEs that occur (across 63 simulations per alternative) is compared, along with the number of HFEs that occur based on sediment trace (average across 21 simulations). Results for long-term strategies C3, E3, E5, and E6 are not presented in this section, because HFEs are not included in these long-term strategies.

Figure E-8 presents the breakdown of the average number of HFEs for each long-term strategy (across 21 hydrology and 3 sediment traces) by HFE type (Table E-4). Only Alternatives D and G allow for HFEs longer than 96 hours, and Alternative G has the most HFEs on average. Alternatives A and B have the fewest HFEs on average. Under Alternative A (no-action alternative) the HFE protocol would expire in 2020, so a little more than half of the

simulation period does not have HFEs simulated. Alternative B stipulates that HFEs would not be implemented more often than once every 2 years. This limits the number of HFEs to one-fourth of the simulation period. Alternative F has a 24-hour 45,000-cfs flow at the beginning of the spring peak period (e.g., on May 1) as part of the alternative definition. Those experiments are not captured in Figure E-8; this figure represents the sediment-triggered and hydrology-triggered HFEs identified from the modified sand budget model. More information on the alternative definitions can be found in Chapter 2 of this EIS.

Figure E-9 compares the average number of HFEs simulated (not by HFE type) for the three different sediment traces. Remember that s1, s2, and s3 do not equate to low, medium, and high; they are three sediment traces intended to be representative of the historical sediment records in terms of exceedance probability, as well as ensuring that the entire period of record is represented by the three traces. Figure E-9 shows some variability among the sediment traces, although the general trends between alternatives as shown in Figure E-8 are maintained. Sediment trace s2 commonly has the lowest number of simulated HFEs. Sediment trace s1 has the most simulated HFEs for Alternatives A, B, and F. Sediment trace s3 has the most simulated HFEs for Alternatives C (except long-term strategy C4), D, and G. Sediment traces s1 and s3 are very similar for Alternatives E (except long-term strategy E4) and F with regard to the number of HFEs triggered.

The majority of HFEs are triggered in the fall, because sediment from the Paria is related to monsoonal precipitation and the majority of the sediment delivery occurs in the fall. Fall HFEs account for 77% of all HFEs simulated; the remaining 23% of HFEs that occur in the spring include proactive spring HFEs, which are triggered by hydrology (wet years) and not by sediment delivery.

E.3.2 Metrics

Plots have been developed for each metric to statistically describe the alternative performance from the 63 different simulations for each long-term strategy. The statistics represented in these plots include a weighting scheme based on each sediment trace's exceedance probability. The weighting scheme for the box and whisker plots is as follows: s1 = 0.1754, s2 = 0.6313, s3 = 0.1933. In addition, a different set of weights was used for a climate change analysis to represent the fact that future hydrology in the Upper Colorado River Basin is expected to be drier than the historical hydrology (Section 4.16.1.2 of this EIS). Plots using climate change weighting are provided for each sediment resource metric in Section E.3.3.

The box and whisker plots provide information on the following statistical representations of the distribution of performance across 63 simulations per long-term strategy: minimum, maximum, mean, median, 25th percentile, and 75th percentile, as described in Figure E-10.

E.3.2.1 Sand Load Index (SLI)

The SLI as described in Section E.2.2.1 reflects the potential for sandbar growth. Figure E-11 presents SLI values for all long-term strategies. Overall, Alternative G has the highest SLI values, followed by Alternatives F, D, C, and E. Alternatives A and B have the lowest SLI values, which is consistent with the number of HFEs that can be triggered under each alternative.

Figure E-11 matches the general pattern of the number of HFEs shown in Figure E-8. One notable exception is Alternative F; Figure E-8 represents the sediment-triggered and hydrology-triggered HFEs, whereas Figure E-11 includes data from the alternative-defined spring experiments that occur each year under Alternative F regardless of sediment availability.

There is a nonzero SLI for long-term strategies C3, E3, E5, and E6, even though there are no HFEs simulated for these long-term strategies. Some hydrologic years are wet enough to necessitate flows above 31,500 cfs being released from Glen Canyon Dam as normal (non-HFE) operations. The sand transported while flows are above 31,500 cfs under these conditions contributes to a nonzero SLI.

E.3.2.2 Standard Deviation of High Flows (SDHF)

As described in Section E.2.2.2, this metric was intended to reflect variability in flow, which was thought to be positively related to the ability to build more robust sandbars. Figure E-12 presents the statistical distribution of SDHF values for the long-term strategies, which is similar to the general pattern shown for the SLI in Figure E-11.

The SDHF mean is plotted against the SLI mean in Figure E-13. A strong correlation exists between the SDHF and the SLI. Therefore, the SDHF was not considered with the SLI for alternative comparison in this EIS.

E.3.3 Sand Mass Balance Index (SMBI)

This metric does not represent the sediment metric directly (Section E.2.2.3); however, it does provide an index to relative changes in sediment balance that would result under different alternatives. If an alternative reduces the overall sediment balance (the amount of sediment in the sandbars and eddies, and on the channel bed) then this net depletion will result in less sediment being available for bar building during future HFEs.

The only long-term strategies that do not significantly reduce the sediment balance over the duration of the simulation period are those that do not have HFEs (long-term strategies C3, E3, E5, and E6), as shown in Figure E-14. The mass balance of sediment is affected by high flows. HFEs have been called a “double-edged sword” by Rubin et al. (2002) because they necessarily export relatively large volumes of sand in order to transfer sand to high-elevation portions of some sandbars (Wright et al. 2008). There is an inverse relationship between sandbar

building potential and sediment balance; more sandbar building potential reduces the sediment remaining within the channel. Figure E-15 plots the mean SMBI relative to the mean SLI. Although there is variation among the alternatives, a higher SLI tends to create a larger net deficit of sand (lower SMBI value) in Marble Canyon. Two exceptions are Alternatives B and D. Alternative B would produce a large net deficit in SMBI but has a relatively low SLI; the relatively low SLI is a result of the limited number of HFEs under this alternative, but this does not produce a correspondingly low SMBI because the larger daily fluctuations during intervening flows transport more sediment. Alternative D has relatively high SMBI and SLI values; more HFEs (including longer duration HFEs) yields the higher SLI value and the combination of relatively even monthly distributions along with relatively small daily fluctuations contributes to a higher SMBI.

E.3.4 Alternative Performance under Climate Change Scenarios

Weights were applied to hydrology traces to reflect expected changes in hydrology under climate change. This weighting scheme was intended to represent future hydrology in the basin, which is expected to be drier than the historical hydrology (Section 4.16.1.2 of this EIS). Figure E-16 presents SLI values calculated under the long-term strategies using the climate change weights. Figure E-17 shows that there is little difference in long-term strategy performance in terms of SLI when comparing the climate change weights to the historical weights. The small difference that does exist could be described as a slight improvement in performance under the climate change weighting.

Figure E-18 presents SDHF values under long-term strategies when the climate change weights were used. Figure E-19 shows that there was little difference between SDHF values calculated using the climate change weights and those calculated using the historical weights. The most notable difference is a slight reduction in the 75th percentile, which indicates less variability in the metric when climate change weights are used.

Figure E-20 presents SMBI values under long-term strategies when the climate change weights were used. Figure E-21 shows that there was some difference between SMBI values calculated using the climate change weights and those calculated using the historical weights. When climate change weights were used, the interquartile ranges and the means were higher, which indicates less net depletion. Interestingly, the minima and maxima do not change appreciably, meaning these extremes are likely due to specific simulations (combination of hydrology and sediment traces).

E.3.5 Relative Impacts of Dam Operations and Hydrology on Performance

Modeling results were evaluated to determine the effect of the following management actions on sediment resources: proactive spring HFEs, spring HFEs, fall HFEs, TMFs, daily fluctuations and intervening flows, load-following curtailment, low summer flows, and general hydrology (wet vs. dry). These evaluations were made using the model runs of the various long-

term strategies, which included some, but not necessarily all, elements. Additional modeling did not take place to answer these questions.

HFEs, whether they are proactive spring HFEs, spring HFEs, or fall HFEs, are the most influential management action in terms of sediment resources. Whether a given HFE type (magnitude and duration) occurs in the fall or the spring does not affect the sediment resource differently. The timing of sediment delivery from the Paria River (during the summer-fall monsoon season) leads to larger and more frequent fall HFEs, but that is due to input, not management actions.

TMFs did not show a significant impact on the sediment resource. This is due in part to the fact that one of the primary factors in triggering a TMF is a spring HFE, which, in the model, increased trout recruitment (Section 4.4.1.2 of this EIS). Spring HFEs have a relatively large effect on the SLI and SMBI that tends to mask a TMF's impacts on sediment. Another reason TMFs have little impact on sediment because of their effect on release volume. In order to provide the flow for TMFs, the average flow in the remainder of the late spring/early summer period tends to be lower than if there were no TMF. The effect of higher flows for the TMFs and the lower flows means a very minor difference in net sediment transport.

Figure E-22 shows the time series of flow (Q) at RM 30, the SLI, and the SMBI for the simulation hydrology trace 1/sediment trace 3 (t01s3) for the period March 1, 2021, to August 1, 2021. Long-term strategies C1 and C2 are plotted for comparison. Both simulations have the same HFE triggered in spring 2021; however, TMFs are implemented under long-term strategy C1 but not under long-term strategy C2. In the figure, the TMF flows can be seen in early May, June, and July in the top graph. Notice the time series of SLI and SMBI show a strong signal response in early April due to the HFE, and practically no signal response from the TMF flows.

Alternatives C and E differ in daily fluctuation levels, as well as monthly volume allocations; this is the best comparison we can make (without performing targeted modeling) on the effects of daily fluctuations. Alternative C has lower daily fluctuations than Alternative E, but has relatively high spring volume compared to the more even monthly pattern of Alternative E. Although lower daily fluctuations reduce sediment transport, higher monthly volumes increase transport. It was not possible to reconcile the relative importance of daily fluctuations and monthly volume allocations without additional modeling. However, Alternative C and Alternative E were compared using the long-term strategy where no HFEs are allowed (long-term strategies C3 and E3). This comparison takes into account both daily fluctuations and monthly volume allocations. There was no difference in SMBI values between long-term strategies C3 and E3 (Figure E-23), and there was a minor difference in SLI values (Figure E-24). Because there are no HFEs in long-term strategies C3 and E3, all of the values for SLI are below 0.2 and any differences between these alternatives are minor.

Load-following curtailment is a management action intended to retain sediment for HFEs by reducing daily fluctuations before and/or after the HFE for a period of weeks or months. Load-following curtailment is specified as fluctuations being limited to ±1,000 cfs about the mean daily flow (a 2,000 cfs range of fluctuation). This management action does not appear to

make a difference in the modeled metric values, because an HFE will necessarily reduce the non-HFE mean flow around which daily fluctuations occur; the daily fluctuations associated with lower means tend to have fluctuation ranges not much greater than the ±1,000 cfs specified for load-following curtailment. Figure E-25 shows the smaller fluctuation range leading up to a fall HFE and the associated impact on SLI and SMBI (hydrology trace 6, sediment trace 3). Long-term strategies E1 and E2 are compared here, but the same comparison could be made using other long-term strategies (C1 and C2 or D1 and D2) with similar trends. Although there are differences in metric values between long-term strategies E1 and E2 for the months following the HFE, the SMBI is different by only 9 ktons at the end of the water year, and the SLI is the same by the end of the water year.

Low summer flows are a management action intended to provide warmer water for humpback chub during the summer. These lower flows would also be expected to conserve sediment inputs during the monsoon period. Implementing low summer flows in the summer requires increasing average monthly release volumes in other non-summer months (especially in the spring), thereby counteracting, in the long term, any short-term increase in sediment conservation (Figure E-26).

Annual inflow volume that reflects annual variation in precipitation and runoff is the main driving force on sediment processes. Release volumes are governed by legal release requirements (Section 1.9 of this EIS). For the SLI, wetter hydrology means a lower metric value (Figure E-27). This is true for the long-term strategies that do not have limitations on the number of HFEs that can be triggered. The trend lines with a positive slope in Figure E-22 are Alternative A (no HFEs after 2020), Alternative B (long-term strategies B1 and B2; not more than one HFE every 2 years), and long-term strategies C3, E3, E5, and E6 (no HFEs). Based on modeled SMBI values, wetter hydrology is expected to transport more sediment downstream under all long-term strategies (Figure E-28).

E.4 LAKE DELTAS

The impact of sediment delta formation due to different alternatives must be inferred, because there are no models for this physical process. The following discussion and conclusions are based on existing data and on some of the modeling data for the sediment resource alternative analysis.

Lake deltas are formations that occur when sediments transported in high-energy riverine flow fall out of the water column as the river enters a lake and loses energy. The Colorado River, along with a number of smaller rivers (that used to be tributaries to the Colorado River but are now emptying directly into Lake Powell or Lake Mead) have deltas that form in locations determined by reservoir elevation. As the elevations of the reservoirs change, the locations of the deltas will also change (Figure E-29).

Lake Powell and Lake Mead deltas can be grouped into two categories: those deltas whose size and location would be affected by dam operations, and those whose location, but not size, would be affected by dam operations.

Only the Colorado River delta in Lake Mead can be affected in terms of both location and size; all other deltas' positions are affected by reservoir elevation (and their delta size is unaffected by dam operations). Using historical data from the GCMRC data portal (http://www.gcmrc.gov/discharge_qw_sediment/stations/GCDAMP), less than half (approximately 46%) of the suspended sand load reaching the gage above Diamond Creek (USGS gage 09404200) since October 2002 can be accounted for as suspended sand leaving Marble Canyon (USGS gage 09383100). The other half of the suspended sand reaching Diamond Creek comes from tributaries downstream of Marble Canyon, most notably the Little Colorado River. Figure E-30 compares the cumulative sand load above Diamond Creek (RM 225) to the cumulative sand load at Desert View (RM 61). This figure demonstrates that the amount of sediment passing RM 225 is approximately 22,000 ktons in the approximately 12.5-year time span since October 2002; this can be extrapolated to about 35,200 ktons of sand for a 20-year period (the same duration as the LTEMP analysis period). Similarly, the approximately 10,000 ktons of sand that have passed RM 61 since October 2002 can be extrapolated to approximately 16,200 ktons of sand for a 20-year period.

The mean SMBI resulting from the 20-year simulations indicates that there may be anywhere from 1,000 to 3,300 ktons of net loss in Marble Canyon sand, depending on the alternative. This decrease in Marble Canyon sand increases the amount of sand going past RM 61 by approximately 6% for Alternative A and 20% for Alternative F, as compared to historical data. Assuming all of the sand leaving Marble Canyon eventually passes Diamond Creek, these increased fluxes leaving Marble Canyon represent less than a 10% change in sand flux at RM 225 compared to the historical data.

The alternatives considered will have minimal impacts on the size of the Colorado River delta in Lake Mead, which is the only delta that could be affected in terms of size and location by Glen Canyon dam operations.

The positions of deltas in Lake Powell and Lake Mead are directly affected by reservoir elevation (Figure E-29). Changes to reservoir elevations are calculated in the CRSS model (Section 4.1 and Appendix D of this EIS). The elevation of the reservoirs is compared to full pool elevations of 3,700 ft for Lake Powell and 1,229 ft for Lake Mead. The reservoir elevations from the alternatives are compared on a monthly basis and minima, means, and maxima were determined for the 63 simulations under each alternative. Figure E-31 presents the pool elevation for Lake Powell and Figure E-32 presents the pool elevation for Lake Mead. There is more variability related to differences in hydrology (compare the minimum and maximum for a given month) than there is related to different alternatives (compare colors across months). Pool elevations are ultimately controlled by regional hydrologic conditions and will not be affected by the alternatives. Alternative F is slightly different than the other alternatives because the monthly release volumes are low through winter. This small difference is not as pronounced as the variability due to annual inflow.

E.5 LIMITATIONS AND KNOWN ISSUES

E.5.1 Geographic Scope

The geographic scope of this EIS includes the Colorado River from Glen Canyon Dam downstream, and west, to Lake Mead (Section 1.5.1 of this EIS). This geographic scope in terms of Colorado River Mile is from RM 15 (Glen Canyon Dam; RM 0 is at Lees Ferry) to RM 347 (Hoover Dam). The numerical model upon which the sediment resource analysis is based extends from RM 0 to RM 87, although uncertainty in sand load from the Little Colorado River limited the analysis to Marble Canyon (RM 0 to RM 61).

E.5.2 Modeling Improvements

The average reallocation scheme (Section E.2.1.2) requires specification of a minimum flow rate about which fluctuations occur. The modeling for alternatives that use the average reallocation scheme and that allowed for daily fluctuations (Alternatives C, D, and E) have a fluctuation range specified at 5,000 cfs to 8,000 cfs. Due to differing up- and down-ramp rates, the average discharge is not 6,500 cfs, but is closer to 6,521 cfs. Alternatives C and E used a specified flow rate of 6,500 cfs, but this error was found before modeling of Alternative D, and 6521 cfs was used for this alternative. Fixing the minimum flow rate for Alternatives C and E may result in a small adjustment to the results, but should not change relative rankings among alternatives.

Load-following curtailment was not implemented for all long-term strategies of Alternatives C and E. Fixing this issue is not expected to affect modeling results.

In a few cases during the modified sand budget modeling, sufficient water volume was identified to sustain an HFE; however, the water surface elevation in Lake Powell was below the minimum power pool intake elevation. This did not allow GTMax-Lite to develop refined hourly flows. In such cases, the sand budget model for the appropriate simulation(s) was run again without allowing an HFE to occur during the problem accounting period. A potential fix for this issue could result in the occurrence of a small HFE. This fix is expected to affect results for a given simulation; however, when considering the averaging across 63 simulations, the net effect is expected to be small.

Initial conditions for bed thickness and bed material size may not have been consistent between the first and second runs of the modified sand budget model for all long-term strategies. Wright et al. (2010) found that varying initial conditions by ±10% made less than a 7% difference in model results, so this fix is not expected to make a difference in alternative analysis.

One of the long-term strategies for Alternative D (D2) included sustained low flows for benthic invertebrate production (Section 2.2.4 of this EIS). The set of months from which water is reallocated to support an HFE is not the same set of months when these sustained low flows

are implemented, and implementing this in the model proved iterative and perhaps not as representative as it could be. Further modification to the sand budget model may improve the implementation of this flow management action; anticipated effects of this effort are unknown.

APPENDIX F:

AQUATIC RESOURCES TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX F:

AQUATIC RESOURCES TECHNICAL INFORMATION AND ANALYSIS

F.1 INTRODUCTION

This technical appendix provides information pertaining to analyses of effects on aquatic ecological resources for the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS), including the aquatic food base, native and nonnative fishes, and fish parasites. It is intended to supplement the information presented in Sections 3.5 and 4.5 of the EIS.

Methods used to evaluate resources, including modeling methods, are described and results regarding effects of alternatives and associated long-term strategies are presented. Analysis of effects on the aquatic food base is based upon a review of literature pertaining to past studies and extrapolation of those results to qualitatively evaluate effects of alternatives and the associated long-term strategies. The evaluation of impacts on rainbow trout (*Oncorhynchus mykiss*), endangered humpback chub (*Gila cypha*), other native fish, nonnative fish, and fish parasites is based upon reviews of the scientific literature and upon the evaluation of performance metrics that were developed for the LTEMP assessment process. The values for the performance metrics were calculated using models developed to examine effects of alternatives on the various aquatic resources.

The potential effects of six action alternatives are compared to the no-action alternative (Alternative A), which describes how the dam is currently operated. Operations under Alternative A employ a release pattern established in the 1996 Record of Decision (ROD) (Reclamation 1996) associated with the 1995 Environmental Impact Statement (EIS) on operations of Glen Canyon Dam (Reclamation 1995). This operational release pattern, referred to as Modified Low Fluctuating Flows, moderated the releases relative to operations practiced in the 1960s through 1980s. As described in Chapter 2 of the EIS, Alternative A also includes various operational decisions and non-flow actions that have been established since the 1996 ROD.

Some of the alternatives under consideration in the EIS (especially Alternatives C, D, and E) are complex experimental or adaptive designs. These alternatives prescribe different management interventions depending on resource conditions. Various condition-dependent triggers govern the implementation of experiments. To understand effects of alternatives that incorporate multiple adaptive components, especially components that might be considered experimental, the complex alternatives were decomposed into 19 versions referred to as long-term strategies, with specific experimental elements included or excluded in each long-term strategy. Table 4.1-1 identifies the experimental elements included in each of the long-term strategies associated with the LTEMP alternatives. Descriptions of each alternative, including the elements included in the long-term strategies, are presented in Sections 2.2 and 4.1 of the EIS. Modeling to evaluate potential effects on aquatic resources was conducted similarly for each long-term strategy and results were compared using various performance metrics to evaluate how

inclusion of experimental elements as part of an alternative affected the modeled outcome for the resources of concern. As discussed in Section 4.1 of the EIS, the long-term strategies used to represent the alternatives in Section 4.5 are A, B1, C1, D4, E1, F, and G.

A full range of potential hydrologic and sediment conditions were modeled for a 20-year period (water years 2013–2033) that represented the 20 years of the LTEMP. Twenty-one potential Lake Powell inflow scenarios (known as hydrology traces) for the 20-year LTEMP period were sampled from the 105-year historic record (water years 1906 to 2010) using the Index Sequential Method and selecting every fifth sequence of 20 years. Using this approach, the first 20-year period considered was 1906–1925, the second was 1911–1930, and so forth. As the start of traces reach the end of the historic record, the years needed to complete a 20-year period are obtained by wrapping back to the beginning of the historical record. For instance, the trace beginning in 1996 consists of the years 1996–2010 and 1906–1910, in that order. This method produced 21 hydrology traces for analysis that represented a range of possible conditions from dry to wet.

In addition to these 21 hydrology traces, three 20-year sequences of sediment inputs from the Paria River sediment record (water years 1964–2013) were analyzed that represented low (water years 1982 to 2001), medium (water years 1996 to 1965), and high (water years 2012 to 1981) sediment input conditions. In combination, the 21 hydrology traces and 3 sediment traces resulted in an analysis that considered 63 possible hydrology-sediment conditions for each alternative and long-term strategy.

Section F.2 of this appendix describes analyses conducted to evaluate impacts of alternatives on the aquatic food base. Section F.3 presents methods, results, and conclusions from modeling conducted to evaluate population-level effects of alternatives on rainbow trout and humpback chub. Section F.4 presents methods, results, and conclusions for modeling conducted to evaluate how alternatives would affect the suitability of mainstem water temperatures for sustaining populations of humpback chub and other native fish species, nonnative fish species, and fish parasites.

F.2 AQUATIC FOOD BASE ASSESSMENT

This section provides information on flow and temperature effects of LTEMP alternatives on the aquatic food base. It serves as the basis for descriptions and conclusions provided in Sections 3.5.1 and 4.5 of this EIS.

F.2.1 Description of the Aquatic Food Base Downstream from Glen Canyon Dam

Determining the impacts of LTEMP alternatives on the aquatic food base requires an evaluation of changes in the aquatic food base from pre-dam years through various post-dam operations, changes in the food base that occur with increasing distance from the dam, and the effects of intentional and unintentional species introductions. The following discussion provides this information and supplements the aquatic food base information presented in Section 3.5.1.

F.2.1.1 The Aquatic Food Base Prior to Construction of Glen Canyon Dam

Prior to the construction of Glen Canyon Dam, the productivity of the Colorado River was low due to scouring and high turbidity levels that limited the colonization and growth of benthic macroalgae and invertebrates (Woodbury 1959; Stevens et al. 1997; Ward et al. 1986). Generally, the more productive habitats for algae and invertebrates occurred at the lower edge of deltas formed at the mouths of tributaries, on and behind boulders, and on woody debris carried by floodwaters (Woodbury 1959). A pre-dam survey of 171 mi of the Colorado River between Dirty Devil River, Utah, and Lees Ferry, Arizona (collections made along the banks of the Colorado River and in tributaries or side canyons), included 28 species of green algae, 5 species of cyanobacteria, 20 species of diatoms, and 91 species of insects including mayflies, dragonflies, true bugs, fishflies, caddisflies, aquatic snout moths, beetles, and true flies (Woodbury 1959). Sixteen insect species were collected from sites along the river bank while 77 species were collected from tributary streams. From a sample of fish stomachs, it appeared that organisms derived from tributaries and terrestrial habitats played an important role in the diet of river fishes (Woodbury 1959). Pre-dam reports of invasive aquatic food base species in the Grand Canyon are limited. In 1932, 50,000 amphipods (*Gammarus lacustris*) were introduced into Bright Angel Creek. They apparently washed into the mainstem of the Colorado River where they became abundant (Carothers and Minckley 1981), particularly within the Glen Canyon reach, where they are associated with *Cladophora* beds (Blinn and Cole 1991; Blinn et al. 1992; Hardwick et al. 1992).

Stanford and Ward (1986) suggested that the lower Green and Colorado Rivers in Canyonlands National Park, Utah, may provide the best examples of the pre-regulated Colorado River, as these reaches retain similar hydrographs to pre-dam conditions and are the farthest downstream from the large dams in the upper Colorado River basin. High suspended sediment concentrations limited the growth of primary producers; thus, the primary carbon source for benthic invertebrates was terrestrial organic matter. The invertebrate community was composed of 49 taxa, mostly mayflies, caddisflies, and true flies. Stoneflies and dragonflies comprised a smaller portion of the community (Haden et al. 2003).

F.2.1.2 The Aquatic Food Base of the Colorado River Downstream from Glen Canyon Dam

Section 3.5.1 of the EIS provides an overview of the aquatic food base of the mainstem of the Colorado River following installation of Glen Canyon Dam. The following supplements that information. Glen Canyon Dam altered the primary carbon source from terrestrial (e.g., leaf litter) to aquatic (e.g., algae and detritus), the temperature regime from seasonally warm to stenothermically cool, and discharge patterns from low daily variations to high daily variations (Benenati et al. 2002). Nevertheless, riparian and upland vegetation still contribute energy to the impounded river system, particularly during flood events (Blinn et al. 1998, 1999). The large quantity of driftwood that occurred in the pre-dam river is now replaced by lower quantities of woody debris derived from tributaries during floods, or from occasional scouring flows of the vegetated post-dam shoreline (Stevens et al. 1997). Benthic detrital standing mass is generally low and variable, increasing through the more turbid downstream reaches (Shannon et al. 1996).

The Paria and Little Colorado Rivers, the primary sediment delivery systems downstream from Glen Canyon Dam, divide the Colorado River into three distinct turbidity zones that have a significant impact on mainstem aquatic food base communities (Stevens et al. 1997). The first 16 mi downstream from Glen Canyon Dam account for 60% of the total phytobenthic standing biomass throughout the remaining 242 mi of the river corridor (Blinn et al. 1995). Algae production decreases from Glen to Marble Canyon and is even lower in the Grand Canyon (Hall et al. 2010) because of the increasing suspended sediment loads that reduced light availability (Kennedy et al. 2013). *Cladophora* grows best in continuously submerged clear-water stable habitats, whereas *Oscillatoria* forms dense mat-like matrices of filaments and sand in the varial zone and other habitats with high suspended sediments that are more typical of many southwestern streams (Shaver et al. 1997).

Oscillatoria tends to colonize relatively early in disturbed or newly inundated zones, while colonization by *Cladophora* is reduced or occurs more slowly (McKinney et al. 1997). As *Oscillatoria* supports tenfold fewer invertebrates than *Cladophora*, the input of terrestrially derived carbon has become vital to support the aquatic food base organisms. However, the leaves of the common nonnative *Tamarix ramosissima* along the river are an inferior food source for macroinvertebrates due to their high tannin content and slower decomposition rate compared to leaves of native cottonwoods and willows (Bailey et al. 2001).

Zooplankton is an important food resource for larval and juvenile native fish in the Colorado River system. The zooplankton found in regulated rivers is composed of both plankton derived from the reservoir (lentic species) and those derived from the streambed, backwaters, and tributaries of the river (lotic species) (Haury 1986). Lotic zooplankton and detritus are positively correlated with distance downriver from Glen Canyon Dam, increased discharge, and nearshore versus midchannel locations. Lentic zooplankton abundance also increases at higher discharges and in nearshore habitats, but is negatively correlated with distance downriver. It is possible that lentic zooplankton cannot survive and reproduce under the cold temperatures in the mainstem, although nearshore habitats provide a more stable environment than the mainstem, which may enhance rearing and development of lentic zooplankton (Benenati et al. 2001). Copepods are the most abundant zooplankton species in the Colorado River (AZGFD 1996). The biomass, productivity, and abundance of zooplankton (cladocerans, copepods, and ostracods originating primarily from Lake Powell) are highest in the Glen Canyon reach and drop sharply downstream (Tables F-2 through F-4).

There is evidence that Lake Powell zooplankton can survive downstream passage to Diamond Creek with only a small mortality rate due to abrasion. Thus, the zooplankton derived from Lake Powell has the potential of contributing to the aquatic food base throughout the river system to Lake Mead (Haury 1986). However, the Colorado River between Lake Powell and Lake Mead has a highly constricted channel and for the most part lacks backwaters of any significant area, which may account for the limited importance of zooplankton drift in the river (Blinn et al. 1995). Zooplankton may also have an affinity for *Cladophora* and other algae in the Glen Canyon reach, and are consumed by macroinvertebrates and fish in that reach (Benenati et al. 2001). These factors may also account for the diminished importance of zooplankton in the Marble and Grand Canyon reaches.

Generally, the responses of macroinvertebrates downstream of dams depend largely on the depth of the reservoir, the depth from which water is drawn, and on the ratio of low to high discharges (Jones 2013). Information on macroinvertebrates collected before and after closure of the Flaming Gorge Dam on the Green River in northeastern Utah is applicable to events that may have occurred in the Colorado River below Glen Canyon Dam (Blinn and Cole 1991; Pearson et al. 1968). Following closure of the Flaming Gorge Dam, macroinvertebrate genera declined from >70 to <30, while the mean macroinvertebrate abundance increased from 1,000 to 10,000/m^2 (Vinson 2001). Mayflies declined from 30 species to a single common species and two rare species. Midges and blackflies were the only other common post-dam insect taxa (Vinson 2001). Colonization of tailwaters by insects can be somewhat limited by lack of drift and small downstream insect population sizes that may limit recruitment from upstream flying adults (Vinson 2001).

River regulation by Glen Canyon Dam decreases turbidity in the tailwaters and permits increased algae growth on bottom substrates (Angradi 1994; Shannon et al. 1994), leading to an increased expansion of macroinvertebrate populations in the tailwater reach of Glen Canyon Dam (Blinn et al. 1992; Stevens et al. 1997). Algae biomass and production decrease downstream as water clarity decreases (Carothers and Brown 1991; Stevens et al. 1997; Hall et al. 2010). As is evident in Table F-1, this drives a downstream decrease in aquatic invertebrate biomass (e.g., *Gammarus*, midges, snails, and aquatic worms) (Carothers and Brown 1991; Stevens et al. 1997; Kennedy and Gloss 2005; Rosi-Marshall et al. 2010).

Various studies in the 1990s demonstrated that over 80% of the invertebrate biomass below Glen Canyon Dam was composed of *Gammarus*, midges, aquatic worms, and snails, many of which graze on epiphytes and other fine particulate matter (Blinn et al. 1998). Predation on insect eggs (e.g., by *Gammarus*) may contribute to the absence of mayflies and stoneflies below dams (Vinson 2001). In Glen Canyon, blackflies and midges support more than half of rainbow trout (*Oncorhynchus mykiss*) production but represent under 10% of total invertebrate production and abundance (Tables F-3 and F-4) (Kennedy et al. 2013). Midges and blackflies dominate invertebrate production in Marble and Grand Canyons (Table F-2); cobble bars are "hotspots" for midge and blackfly production (e.g., 2 to 10 times higher than other habitat types) (Kennedy et al. 2013). New Zealand mudsnails (*Potamopyrgus antipodarum*), *Gammarus*, aquatic worms, and midges dominate the current composition of the benthic community at Lees Ferry (Table F-3). In cobble substrates, New Zealand mudsnails and aquatic worms dominate the benthic biomass. They also dominate depositional habitats, although these areas tend to support lower benthic biomass (Cross et al. 2013). *Gammarus* dominates talus slopes and cliff faces, but these habitats generally have the lowest benthic biomass in the Lees Ferry reach. Blackflies (*Simulium arcticum*) are present in the Lees Ferry reach, but their biomass and abundance are generally low (Tables F-2 and F-4).

Cold water temperatures and daily fluctuations in discharge associated with hydropower production are likely responsible for the low diversity and abundance of aquatic insects downstream of the Paria River (Stevens et al. 1997; Kennedy et al. 2016). The decrease in stream clarity lowers primary production and favors the growth of the less nutritious *Oscillatoria* in the

TABLE F-4 Distribution, Ecological Importance, and Favorable Temperature Range for Select Primary Producers

Taxa	Distribution	Ecological Importance	Favorable Temperature Range
Upright epiphytic diatoms	Throughout the river, but most abundant in the Glen Canyon Dam–Paria River reach	High, easily consumed by grazers	10–15°C (50–59°F)
Adnate epiphytic diatoms	Throughout the river, but most abundant in the Glen Canyon Dam–Paria River reach	Medium, not as easily consumed by grazers	15–20°C (59–68°F)
Cladophora glomerata	Throughout the river, but most abundant in the Glen Canyon reach	High, substrate for epiphytic diatoms	13–17°C (55–63°F)
Oscillatoria spp.	Throughout the river, but most abundant below Little Colorado River	Low, not generally consumed directly, poor substrate for diatoms	18–21°C (64–70°F)
Egeria densa	Glen Canyon reach	Medium-high, substrate for epiphytic diatoms, cover for fish	15–21°C (59–70°F)
Potamogeton spp.	Throughout the river, but most abundant in the Glen Canyon reach	Medium-high, substrate for epiphytic diatoms, cover for fish	20–22°C (68–72°F)
Fontinalis spp.	Glen Canyon reach	Medium-high, secondary substrate for epiphytic diatoms	10–15°C (50–59°F)
Chara spp.	Throughout the river, but most abundant in the Glen Canyon reach	Medium-high, substrate for epiphytic diatoms, cover for fish	18–25°C (64–77°F)

lower reaches of the Colorado River (Blinn et al. 1999). Macroinvertebrates are not generally associated with *Oscillatoria* because it is very compact, has little surface area for colonization, and largely lacks epiphytic diatoms (Blinn et al. 1995). For example, *Gammarus*, a major food source for trout and other fishes, prefers *Cladophora* due to its epiphytic diatoms. This relationship is strong from Glen Canyon Dam to Lees Ferry and weak from Lees Ferry to Diamond Creek (Patten 1998). This relationship does not exist between *Gammarus* and *Oscillatoria*. If *Cladophora* declines, then the contribution of *Gammarus* to the aquatic food base also declines, except perhaps in the drift (Patten 1998).

Drifting macroinvertebrates provide an important food resource for rainbow trout and other native and nonnative fish species. Flow regime, discharge, and distance from the dam influence drift of macroinvertebrates in the Colorado River (Shannon et al. 1996; Stevens et al. 1998; Sublette et al. 1998; McKinney et al. 1999). In general, a positive correlation exists between stream drift and discharge; however, reduced flows can increase stream drift through behavioral factors such as crowding, reduced oxygen concentrations, and avoidance of desiccation (Blinn et al. 1995). Kennedy et al. (2014) concluded that benthic density is the primary control on drift concentrations over long timescales (e.g., weeks to months), because increased benthic production will also increase drift. In contrast, changes in flow such as those

occurring from hydropeaking have an important control on drift concentrations, but primarily on a shorter timescale (e.g., days) (Kennedy et al. 2014).

Tributary and terrestrial insects comprise a small portion of the stream drift in the Colorado River (Shannon et al. 1996). It is possible that terrestrial invertebrate drift increases during and immediately after rainstorms and is therefore an uncommon but locally important resource for river fishes through Grand Canyon (Shannon et al. 1996). Terrestrial and tributary insects contribute <0.001 and <0.1% of the total invertebrate biomass in the mainstem drift, respectively (Blinn et al. 1995). Fish production throughout Glen and Grand Canyon appears to be limited by the availability of midges and blackflies, and fish may exert top-down control over them (Carlisle et al. 2012). While blackflies and midges support between 43 and 50% of trout production, they only comprise a small percentage of total invertebrate secondary production and abundance in the Glen Canyon reach (Tables F-3 and F-4) (Cross et al. 2011).

Generally, physical, chemical, and biological attributes in the lower reaches of the Colorado River peak at or immediately downstream of tributaries. The connection between tributaries and the mainstem is important for the flow of nutrients, sediment, and wood that contribute to habitat heterogeneity and biodiversity in the mainstem (Kiffney et al. 2006). However, tributary sediment inputs can limit light availability and reduce algal production, thereby reducing food for aquatic invertebrates. High sediment loads may also limit the ability of fish to see their prey (Coggins and Yard 2011).

The Colorado River between Glen Canyon Dam and Lake Mead contains more than 400 ephemeral and 40 perennial tributaries; however, as many of the Colorado River tributaries are dry except during heavy summer rains, they contribute little to the mainstem aquatic food base (Haury 1986). All of the tributary streams have a natural seasonal range of temperatures and discharges unaffected by Glen Canyon Dam (NPS 2005). Oberlin et al. (1999) indicated that primary productivity and detritus, the major food resource for macroinvertebrates, are higher overall in clear-water tributaries and highest in those originating inside the Grand Canyon. Phytoplankton species richness also increases in clear-water tributaries (Crayton and Sommerfield 1979; Oberlin et al. 1999), increasing primary productivity and food quality in those environments (Henery 2005).

Common macroinvertebrates in the tributary streams include caddisflies, mayflies, stoneflies, midges, and blackflies. Drift of tributary macroinvertebrates into the mainstem contributes, at least locally, to the aquatic food base in the Colorado River. Macroinvertebrate productivity and diversity in the tributaries are lowest in the spring and summer, as flash floods in these seasons disrupt the benthic invertebrate communities (Oberlin et al. 1999). Tributaries provide ≤25% of the total organic stream drift in the Colorado River through Grand Canyon National Park (Blinn et al. 1995).

Tributary streams with travertine deposits (e.g., Havasu Creek) or those dominated by bedrock (e.g., Matkatamiba Creek) have little inhabitable substrate for macroinvertebrates. Steep channel gradients and erosional habitat also limit benthos in some tributaries. Overall, standing biomass of the Little Colorado River macroinvertebrate community was an order of magnitude lower (0.056 g/m^2 ash-free dry mass [AFDM]) than at the confluence with the Colorado River

(0.25 g/m^2 AFDM). A high discharge with increased suspended sediment loads negatively affects macroinvertebrate biomass (Haden et al. 1999). Even extended periods of base flow (which tends to increase macroinvertebrates and algae) do not increase productivity for the areas of the Little Colorado River that contain most of the river's humpback chub population (Haden et al. 1999).

Some of the tributaries also contain New Zealand mudsnails, probably spread by recreationists (NPS 2005). Shannon et al. (2003a) reported the New Zealand mudsnail in cobble bars of 5 of 18 tributaries they sampled, but the snail did not extend more than 32 m upstream in those streams. Since New Zealand mudsnails prefer habitats with constant temperatures and flows and high primary productivity, flash floods may diminish their long-term establishment in tributaries (Shannon et al. 2003a). The risk of quagga mussel (*Dreissena rostriformis bugensis*) introduction to tributaries also appears low. Reservoirs on the upper reaches of the Little Colorado River may eventually support the quagga mussel. Establishment of the quagga mussel in many of the tributaries is unlikely due to high summer water temperatures above the mussel's upper lethal limit (Kennedy 2007).

F.2.1.3 Influence of New Zealand Mudsnail on the Aquatic Food Base

In addition to changes brought about by Glen Canyon Dam, the loss of native species and the addition of numerous nonnative species modified the aquatic ecosystem of the Colorado River within Grand Canyon (Johnson and Carothers 1987). This applies to the aquatic food base and fish species. Nonnative species, including those intentionally introduced, are often better competitors in the homogeneous habitats of regulated rivers (Stanford et al. 1996). To date, nonnative periphyton and rooted aquatic macrophytes have not caused adverse impacts on the aquatic food base in the Colorado River below Glen Canyon Dam. Section 4.17.3.4 discusses potential impacts that could occur if the diatom *Didymosphenia geminata* ("didymo") becomes established in the Colorado River.

The New Zealand mudsnail can tolerate a wide range of water temperatures (except freezing), salinity, and turbidity. It can also withstand short periods of desiccation. Densities of New Zealand mudsnail are usually highest in systems with high primary productivity, constant temperatures, and constant flow. It occurs in all types of aquatic habitats, from eutrophic mud bottom ponds to clear rocky streams (USGS 2002; Sorensen 2010). Fitness of the New Zealand mudsnail peaks at 18°C (64°F), declining at cooler and warmer temperatures (NZMMCPWG 2007).

Numerous adaptations of the New Zealand mudsnail aid its spread within watersheds. For instance, adults can pass through the digestive systems of some fish species alive, adults can float on masses of algae, and juveniles can float freely on the water surface (Kerans et al. 2005; NZMMCPWG 2007). While the New Zealand mudsnail is not common in streams prone to periods of sediment-moving flood flows, its tough shell, small size, and hydrodynamic shape make it likely to survive scouring flows (Holomuzuki and Biggs 2006; NZMMCPWG 2007). Most New Zealand mudsnails in North America are asexually reproducing females that are born with developing embryos already present in their reproductive system (Sorensen 2010). Clonal

reproduction increases the probability of success of introduction as only a single female can establish a new population (NZMMCPWG 2007). One female can carry up to 20 embryos and under proper conditions may account for over one million snails within one year (Shannon et al. 2003a).

Vinson et al. (2007) suggest that the New Zealand mudsnail introduction into the Green River below Flaming Gorge Dam may have led to a decline of total invertebrate abundance by over 25%. They concluded that decreases in mayflies due to competition from New Zealand mudsnails may jeopardize mayfly recolonization of the Green River following implementation of a more natural springtime flood flow regime. Where the New Zealand mudsnail dominates invertebrate production, it could become the dominant forage base for fishes that prey on macroinvertebrates (Vinson and Baker 2008). Field survey data in the Green River below Flaming Gorge Dam showed a sharp annual increase in the number of brown trout (*Salmo trutta*) and rainbow trout that consumed New Zealand mudsnail between 2001 and 2005 (Vinson and Baker 2008). Bioenergetic simulations suggest that fish diets high in New Zealand mudsnail would not meet energy requirements of fish, resulting in reduced growth and weight loss (Vinson et al. 2007; Vinson and Baker 2008) as discussed previously. For example, when the New Zealand mudsnail comprised between 71 and 81% of brown trout diet, the trout did not gain weight, and when the diet consisted of more than 81% New Zealand mudsnails, brown trout lost weight. Rainbow trout fed a diet of 42% New Zealand mudsnail began losing weight over the course of the experimental study (Harju 2007).

The New Zealand mudsnail represents a trophic dead end in Glen Canyon because it has a high production and consumption of primary producers, but it does not support a substantial amount of production for higher trophic levels (i.e., fish). Minnows and suckers that possess pharyngeal teeth may be capable of consuming and crushing the shells of New Zealand mudsnails (NZMMCPWG 2007). However, the New Zealand mudsnail offers little or no energy compared to other common food items in those fish successful in crushing its shell (Ryan 1982).

F.2.2 Impacts of LTEMP Alternatives on the Aquatic Food Base

The desired future conditions (DFCs) for the Colorado River ecosystem domain (Appendix A of the EIS) include these two DFCs for the aquatic food base goals:

- The aquatic food base will sustainably support viable populations of desired species at all trophic levels.

- Assure that an adequate, diverse, productive aquatic food base exists for fish and other aquatic and terrestrial species that depend on those food resources.

Attaining these DFCs while meeting existing water delivery requirements is complex. Biological resources in regulated rivers are subject to a number of spatial and temporal changes in conditions downstream from a dam: reductions in seasonal flow variability, alterations in the timing of extreme flow events, pulses in flow during periods of peak power demands, reduced turbidity and increased water clarity, diel and seasonal constancy of water temperatures,

armoring of substrates in the tailwaters, modified nutrient regimes, and the appearance of lentic plankton below the reservoir (Blinn and Cole 1991; Blinn et al. 1995; McKinney and Persons 1999). Flow and temperature are the two major factors that influence the condition and availability of the aquatic food base in the Colorado River between Glen Canyon Dam and Lake Mead. The following discussion supplements the analyses presented in Sections 4.5.2.1 and 4.5.3 of the EIS.

F.2.2.1 Flow Effects on the Aquatic Food Base

Hydropeaking is the mode of hydroelectric generation that most alters the quantity and quality of habitats available to aquatic organisms. Effects can be direct (e.g., stranding, mortality, and habitat loss) or indirect (e.g., downstream displacement, depleted food production, increased stress) (Clarke et al. 2008). Impacts of flow fluctuations are typically greatest within the tailwaters of a dam and decline with distance downstream due to flow attenuation and the increasing influence of tributaries (Clarke et al. 2008; Patterson and Smokorowski 2011). Flow attenuation occurs downstream of Glen Canyon Dam; however, because of the constrained nature of the channel through most of Marble Canyon and the Grand Canyon, flow fluctuations from dam releases are still apparent in the lower Grand Canyon near Lake Mead (see Section 3.2.1.2 of the EIS). The following sections discuss flow effects on the aquatic food base with respect to the elements of base operations, adjustments of base operations, and trout management actions for the LTEMP alternatives.

Effects of Base Operations

Potential alternative-specific effects of base operations (i.e., operations in those years when no condition-dependent or experimental actions are triggered) on the aquatic food base depend on the differences in the monthly pattern in release volumes, minimum and maximum flows, daily flow ranges, and ramp rates. Monthly increases in release volumes may increase the permanently wetted zone, which could increase benthic production, if the increased monthly flows last long enough for benthic development to occur (e.g., weeks to months). Months of higher release volumes would also improve hydraulic connectivity with and maintenance of backwater habitats. Backwaters with more permanency potentially support increased planktonic and benthic communities. A decrease in the permanently wetted zone would occur when decreases in monthly release volumes occur (Reclamation 1995; Hoffnagle 2001; Melis et al. 2006; Behn et al. 2010). Pools of water left after high spring or summer flow months potentially provide habitat for mosquitoes (Blinn et al. 1995). While mosquitoes may contribute to the aquatic and terrestrial food base, they pose a potential health concern to humans.

Daily minimum flow is an important determinant of benthic standing crop because of the strong negative effects of desiccation on algae and invertebrates (Melis et al. 2006). Periods of low steady summer/fall releases (e.g., 5,000 to 8,000 cfs) are expected to result in warmer and more stable nearshore and backwater habitats and longitudinal river warming, while similar flows in winter are likely to produce greater overwinter algal and macroinvertebrate production (Blinn et al. 1995; Valdez et al. 2000). Wet channel area in low-angle habitats within the Glen

Canyon reach is reduced by about 10% at 5,000 cfs compared to 8,000 cfs. This area reduction consists of about 16 ha; however, the effects on the aquatic food base from this habitat reduction may not be detectable (Melis et al. 2014).

Restricted minimum and maximum flows and reduced ramping rates of the Modified Low Fluctuating Flow regime adopted in the Glen Canyon Dam Record of Decision (Reclamation 1996) were intended to stabilize the area available for colonization by benthic algae, thereby decreasing losses through desiccation or freezing while increasing primary and secondary production (Blinn et al. 1995). Midges, blackflies, and *Gammarus* were not observed in the varial zone above the 10,600-cfs stage (Blinn et al. 1995).

The interactions between cycles of inundation and dewatering in varial zones play a major role in structuring algal communities in regulated desert rivers (Blinn et al. 1998). Periodic exposure of nearshore and backwater habitats can result in loss of invertebrates and primary producers through desiccation, while inundation can impact the aquatic food base through sediment deposition (Valdez et al. 1998). Atmospheric exposure of benthos can be more severe than flooding because organisms are directly killed rather than displaced or buried (Blinn et al. 1995). Fluctuating flows (>10,000 cfs/day) can fragment *Cladophora* from its basal attachment and increase its occurrence in the drift. Consuming drifting *Cladophora* (with its attached epiphytes and any invertebrates) allows rainbow trout to expend less energy in searching for food (Leibfried and Blinn 1987). Daily range in flows >10,000 cfs only occur during December and January (12,000 cfs) for Alternative B.

A stabilized discharge regime could increase algae production downstream of Glen Canyon Dam. In turn, this may have positive effects on invertebrate and fish production (Kennedy et al. 2013). Basal holdfasts of *Cladophora* can dry following periods of exposure as short as 4 hours in summer (Pinney 1991). Exposure to subzero winter air temperatures for only one night resulted in ≥50% loss of chlorophyll a and mass of *Cladophora* (Blinn et al. 1995). Recovery time may take several months (Blinn et al. 1992). Since algal communities provide the dominant food resource below dams, restricting the extent of the varial zone and maintaining wetted perimeter can be important to maintaining the overall food base (Blinn et al. 1998). Potential differences among alternatives based on daily range in flows are provided in Section 4.5.3 of the EIS.

Warm or subfreezing air temperatures could cause mortality of invertebrates stranded in the varial zone (Gislason 1985). The varial zone provides poor habitat for species with multiple life history stages (Jones 2013) by dewatering of emergence and oviposition sites (Vinson 2001; Kennedy et al. 2016). High rates of egg mortality due to exposure may partially explain the rarity of mayflies in the Colorado River. For example, adult female *Baetis* species land on rocks protruding from the water surface and then crawl underwater to lay their eggs on the underside of the rocks. These rocks may become dry for possibly 12 hours during the hydropeaking cycle, causing egg mortality (Kennedy et al. 2016). The fact that midges and blackflies have more generalized egg laying behaviors that are not strictly dependent on river edges may explain why they are the predominant insects in the mainstem. Nevertheless, hydropeaking still appears to limit egg survival and thus recruitment for midges in the mainstem (Kennedy et al. 2016). In the Glen Canyon Dam tailwaters, *Gammarus* standing stock and fecundity are lower, seasonal

recruitment of young is briefer, and fewer young are recruited into the population in the varial zone compared to the permanently wetted zone. In addition, *Gammarus* mortality increases in the varial zone (Angradi and Kubly 1993; Ayers and McKinney 1996; Ayers et al. 1998).

Invertebrates are continually moving and drifting to different positions in the river, thus stranding of a significant number of invertebrates in the varial zone would reduce the overall abundance in the river including that in the permanently wetted zone (Smokorowski 2010). However, there may be little colonization of shoreline areas during daily high flows, and as discharge decreases, large numbers of insects may not be present to enter the drift from areas being dewatered (Perry and Perry 1986). Nevertheless, reduction in the amplitude and duration of power peaking flow fluctuations may be an effective management strategy for enhancing aquatic insect biomass with the potential for increasing the survival and growth of fishes dependent on them (Gislason 1985).

Flow fluctuations may increase the amount of organisms available to drift-feeding fish, although this may only occur for a short period (e.g., a few days or less), depending on the density and replacement capacity of benthic invertebrates. For example, a twofold daily variation in discharge resulted in a greater than tenfold increase in drift concentrations of *Gammarus* and New Zealand mudsnails while blackfly drift concentrations decreased by more than 80% as discharge doubled. Midge drift concentrations increased proportional to discharge (Kennedy et al. 2014).

As the daily range in flows increases, there is greater divergence in habitat conditions between low and high flows, and there will likely be fewer taxa that can withstand such variability. Consequently, the ratio of the regulated high and low flows may become as important as the base flow as an influencing factor determining biotic composition (Jones 2013). Ramping rate restrictions may allow sufficient time for aquatic macroinvertebrates to respond to daily flow fluctuations (Patterson and Smokorowski 2011). Rapid up-ramping can result in rapid increases in shear stress, potentially causing catastrophic drift or the large-scale displacement of invertebrates from the sediment (Gibbins et al. 2007). Perry and Perry (1986) observed a greater number of aquatic invertebrates stranded when the down-ramping rate was rapid; indicating that unlimited down-ramping is a potential cause of increased invertebrate mortality (Smokorowski 2010). In addition, high ramping rates potentially favor adnate diatom species over the more upright species, the latter of which macroinvertebrates and fishes more readily consumed (Hardwick et al. 1992; Pinney 1991; Biggs 1996).

Miller and Judson (2014) observed that, during a daily hydropeaking schedule, macroinvertebrate drift biomass below Flaming Gorge Dam in the Green River increased during the rising limb of the daily hydrograph and declined prior to the cessation of the peak. Macroinvertebrate drift increases were correlated with the biomass of drifting vegetation. As the study by Miller and Judson (2014) occurred over winter, the rate of vegetation export declined over time due to senescence caused by decreased light levels and cooler temperatures. This at least partly accounted for the observed declines in macroinvertebrate drift after 30 to 60 days (Miller and Judson 2014).

During base operations, up-ramping rates are the same at 4,000 cfs for all alternatives except for Alternatives F and G that would not have a daily range in flows. Down-ramping rates would be highest for Alternative B (4,000 cfs for November through March and 3,000 cfs in the other months), followed by the Alternatives C, D, and E (2,500 cfs) and Alternative A (1,500 cfs). Alternatives F and G both feature steady flows in all months.

Experimental Treatments

High-Flow Experiments. Most experimental adjustments of base operations relate to high-flow experiments (HFEs). The existing HFE protocol calls for spring HFEs to occur in March–April and fall HFEs to occur in October–November, with magnitudes ranging from 31,500 to 45,000 cfs (Reclamation 2011a). Most HFEs would last from less than 1 hour to 96 hours, although HFEs longer than 96 hours could occur under Alternatives C, D, and G. There is a potential for more than one HFE to occur within the same year or between years, with a potential for up to 40 HFEs during the LTEMP period (Alternatives C, F, and G). Food webs close to Glen Canyon Dam are more energy inefficient and are expected to exhibit lower resistance to experimental flood perturbations compared to food webs downstream of major tributaries (Cross et al. 2013).

HFEs conducted in the spring and fall represent contrasting conditions, particularly with regard to light, temperature, and invertebrate biomass. Plant and macroinvertebrate recovery times may be shorter for spring HFEs than for fall HFEs as a result of longer day lengths and warmer river temperatures in spring and summer. Spring HFEs can cause ponding of tributary flows that enter the Colorado River, creating temperature refuge areas within the mainstem (Valdez et al. 2000). Spring HFEs can also re-suspend organic material stored along the shoreline and redistribute it into the mainstem (Valdez et al. 2000). The majority of the aquatic food base taxa would recover within 1 to 4 months after a spring HFE as observed for the spring 1996 and 2008 HFEs (Blinn et al. 1999; Rosi-Marshall et al. 2010), although some taxa may recover more slowly (Cross et al. 2011). Shannon et al. (2001) reported high rates of invertebrate drift for 2 months after the spring 1996 HFE. A post-flood increase in production and drift of midges and blackflies is expected after a spring HFE (Cross et al. 2011), likely due to the flushing of fines in the interstitial spaces between gravel and around macroalgae holdfasts used by these invertebrates for cover. *Gammarus* is expected to be slower to recover because of its greater susceptibility to being exported by river currents than most invertebrate species (Reclamation 2011a). In addition, slow-growing taxa such as *Gammarus* take longer to recover to pre-flood levels relative to faster growing taxa with aerial life stages such as blackflies and midges (Robinson and Uehlinger 2008).

Fall HFEs precede winter months of minimal insolation, low temperatures, and reduced gross primary productivity. Thus, recovery times for aquatic food base organisms take longer than for spring HFEs (Melis et al. 2006). Following the fall 2004 HFE, *Gammarus* was extremely scarce for many months in Lees Ferry (Melis et al. 2006). Even longer recovery times could occur if a fall HFE is followed by a spring HFE. The 4 to 5 months between a fall and spring HFE could preclude full recovery of most benthic invertebrate assemblages. The

following spring HFE could scour the remaining primary producers and susceptible invertebrates and further delay recovery. A spring HFE followed by a fall HFE may not have as great an impact because of the rapid recovery of the food base expected over the summer (Reclamation 2011a).

The 2008 spring HFE reduced annual invertebrate production in the Lees Ferry tailwater by >50%, driven primarily by significant reductions in production of New Zealand mudsnails and *Gammarus*. Large numbers of *Gammarus* dislodged during high flows are transported considerable distances downstream, making them available to fishes. Windrows of stranded *Gammarus* carcasses along some shorelines following the spring 1996 controlled flood (Valdez 1999) became available to terrestrial consumers such as shorebirds, lizards, and spiders. Reductions in mudsnails and *Gammarus* persisted at least 15 months after the HFE (when the study concluded) and coincided with a significant decline in the annual production of these taxa (e.g., New Zealand mudsnail production declined from 11 to 13 g AFDM/m^2/yr to 2 g AFDM/m^2/yr and *Gammarus* production from 7 to 8 g AFDM/m^2/yr to 3 g AFDM/m^2/yr). Reductions in aquatic worms recovered in about 4 to 6 months (Rosi-Marshall et al. 2010). However, midges and blackflies increased by 30 and 200%, respectively, in the year following the HFE, and they supported a 200% increase in rainbow trout production (Cross et al. 2011). During the flood, the concentrations of invertebrate prey available in the drift increased from an average of 0.093 mg/m^3 AFDM before the flood to an average 0.163 mg/m^3 after the flood (Rosi-Marshall et al. 2010; Cross et al. 2011).

The concentrations of midges and blackflies in the drift increased 400 and 800%, respectively, after the 2008 HFE, and this effect persisted for at least 15 months. Biomass and production of both groups also increased after the HFE (Rosi-Marshall et al. 2010; Cross et al. 2011). The March 2008 HFE resulted in an increase in the area of backwater habitat that persisted for at least two months, but returned to conditions similar to those before the HFE by about 6 months after the HFE (Melis 2011). In addition to scouring benthic algae and invertebrates, high flows can capture large quantities of terrestrial organic matter that may temporarily increase the amount of food base available for drift-feeding fish (Valdez and Hoffnagle 1999; Gloss et al. 2005).

Generally, more frequent HFEs may cause a shift to more resistant taxa or to new taxa that would colonize the river. However, if such taxa are not present, more frequent HFEs may reduce macroinvertebrate diversity and possibly abundance, resulting in a reduction in the aquatic food base (Reclamation 2011a). Any benefits from HFEs along downstream segments of the Colorado River (particularly the lower portion of the Grand Canyon reach) will likely be smaller in magnitude than in the Lees Ferry reach (Melis 2011; Kennedy et al. 2013). The average number of HFEs during the LTEMP period would be 39.3 under Alternative F; range from 17.1 to 24.5 under Alternatives C, D, E, and G; and be only 7.2 under Alternative B and 5.5 under Alternative A.

The most notable differences among the alternatives is for Alternative A, which would not have HFEs after 2020; Alternative B, which would not exceed one spring or fall HFE every other year; and Alternative E, which would not have spring HFEs during the first 10 years (Table 2-2 of the EIS).

A comprehensive study on the ecological effects of repeated HFEs in the River Spöl in Switzerland indicated that one or two high-flow events per year can enhance and sustain long-term ecological integrity (Scheurer and Molinari 2003) and that such releases must be repeated on a regular basis (annually) to maintain their benefits (Robinson and Uehlinger 2008). The first experimental flood in the River Spöl reduced macroinvertebrate abundance by about 50%. However, subsequent experimental floods had less effect, indicating that a new assemblage had established that was more resilient to flood disturbance. The response of macroinvertebrates to experimental floods occurs over a period of years, rather than months, as species composition adjusts to the new flow conditions (Robinson and Uehlinger 2008). Robinson et al. (2003) observed that the abundance of amphipods and planarians decreased while the abundance of baetid mayflies, blackflies and midges increased. Some mayfly, stonefly, and caddisfly taxa initially decreased in abundance but subsequently increased. The results of experimental floods in the River Spöl imply that the experimental flood regime needs maintaining to sustain the development of a more natural macroinvertebrate assemblage (Robinson et al. 2003). While three to five consecutive HFEs from Glen Canyon Dam may alter the aquatic food base composition, the absence of an HFE for one or more seasons might reset the current aquatic food base community (Reclamation 2011a). It is anticipated that, regardless of the HFE regimen, midges and blackflies would remain important components of the aquatic food base downstream of Glen Canyon Dam.

A large portion of the aquatic food base in the Lees Ferry reach would likely be scoured by an HFE of 41,000 to 45,000 cfs regardless of the time of year. The initial hydrostatic wave produces the scouring effect, and the duration of the flow is an important factor in transporting the material downstream (Rosi-Marshall et al. 2010). The HFE conducted in March 1996 (7-day discharge of 45,000 cfs) resulted in benthic scour and entrainment of both primary and secondary producers at all study sites along the 239-mi river corridor. Over 90% of the benthos was removed by the hydrostatic wave or within 24 hr from the start of the test flood. In addition, drift mass reached highest levels during the first 2 days of the HFE (an order of magnitude higher than under normal dam operations) and subsided after that period (Shannon et al. 2001). Recovery rates to pre-flood levels were fast for benthic algae (1 month) and invertebrates (2 months) (Blinn et al. 1999). Recovery of the macrophytes *Chara*, *Potamogeton*, and *Elodea* to pre-flood conditions took 1 to 7 months (Shannon et al. 2001).

It is hypothesized that mucilaginous algae found in miscellaneous algae, macrophytes, and bryophytes (MAMB) can outcompete *Cladophora* under the combination of reduce nutrient conditions and elevated discharge regimes of about 25,000 cfs. However, if discharge increases to 45,000 cfs or more, MAMB will scour, allowing *Cladophora* to recolonize regardless of nutrient conditions because of strong holdfast attachment and lack of competition (Benenati et al. 2000). HFEs up to 45,000 cfs may occur under Alternatives C, D, and G.

HFEs longer than 96 hours may also occur under Alternatives C, D, and G. These longer-duration HFEs could scour much of the aquatic food base, especially within the Glen Canyon reach, and reduce the standing crop of benthic invertebrates. The extended-duration HFEs may increase the aquatic food base available for drift-feeding fishes, particularly during the initial hours of the flood. An extended-duration HFE may also help to control the abundance of

New Zealand mudsnails in the Glen Canyon reach, but it may possibly contribute to their downstream abundance. Potential effects of sustained spring flows include:

- High, turbid main-channel flow and a surge of increased macroinvertebrate drift, increased feeding opportunities for non-sight feeders, and increased density of terrestrial invertebrates washed from shoreline.

- Rebuilt backwater habitats and increased primary and secondary production in backwaters following redistribution of organics (Valdez et al. 1998).

Steady Flows. Steady flows (or nearly steady flows with some instantaneous fluctuations associated with ancillary services) would occur prior to or following spring and/or fall HFEs (prior to spring and fall HFEs under Alternative C and before fall HFEs only for Alternatives D and E; Alternatives F and G already feature steady flows). Potential effects of steady flows include (1) warmer shoreline and backwaters and an increase in backwater production; (2) warmer main channel and an increase in primary and secondary production and potential for parasite maturation and proliferation; and (3) stable main channel and less turbidity and an increase in shoreline primary and secondary production and reduced macroinvertebrate drift as food for fish (Valdez et al. 1998). However, mainstem warming, particularly in the Glen Canyon and Marble Canyon reaches, would be limited. Ralston et al. (2007) observed that biological and physical parameters were unaffected by daily fluctuations in flow of 2,700 cfs and steady-flow releases. Reduced flow fluctuations prior to an HFE could increase production of primary producers and consumers. The HFE could increase drift biomass. Reduced flow fluctuations following an HFE could hasten benthic recolonization.

Low Summer Flows. Low summer flows may be tested under Alternatives C, D, and E; and are an annual component of Alternative F. Low summer flow tests would involve flows between 5,000 and 8,000 cfs to warm the Colorado River at the confluence with the Little Colorado River to at least 13°C (55°F), 14°C (57°F), or 16°C (61°F) under Alternatives C, D, and E, respectively. Dropping to low flows in the summer would necessitate increasing mean daily flows in other months relative to base operations. Low summer flow tests may increase primary and secondary benthic production but reduce macroinvertebrate drift. In particular, the density of New Zealand mudsnails may increase under low summer flows. However, the opposite conditions, compared to base operations without low summer flow tests, may occur in non-summer months. Potential impacts on the aquatic food base from low summer flows under Alternative F are described in Section 4.5.3.6 of the EIS.

Hydropower Improvement Flows. Hydropower improvement flows (increased fluctuation levels proposed as an experiment under Alternative B) would entail a daily change from a minimum flow of 5,000 cfs to a maximum flow of 15,000 to 25,000 cfs (depending on season). This could decrease primary and secondary production, although macroinvertebrate drift may increase. Down-ramp rates of 5,000 cfs/hr may increase stranding of organisms in the varial zone compared to base operations that range from 1,500 cfs/hr (Alternatives A, F, and G) to 4,000 cfs/hr (Alternative B from November through March). Conversely, higher up-ramp rates of 5,000 cfs/hr coupled with sustained high flows may flush increased amounts of terrestrial invertebrates (and other items such as leaf litter) from shoreline areas into the drift compared to base operations for all alternatives (up-ramp rates of 4,000 cfs/hr).

Sustained Low Flows for Benthic Invertebrate Production. An aquatic resource-related experiment unique to Alternative D would be to test the effects of macroinvertebrate production flows in May through August on benthic invertebrate production and diversity. It has been demonstrated that the large varial zone created by fluctuating flows limits recruitment of mayflies (order Ephemeroptera), stoneflies (order Plecoptera), and caddisflies (order Trichoptera), collectively referred to as EPT, due to high egg mortality. Because EPT taxa cement eggs principally along the river edge habitats, eggs laid during stable low flows over the weekend would not be subjected to drying prior to hatching. Depending on the findings from the first test, this experiment may be conducted two to three times during the LTEMP period, but not during the first 2 years. In addition to potentially increasing EPT, macroinvertebrate production flows may benefit other aquatic food base organisms that have terrestrial adult life stages such as dragonflies and true flies (including midges and blackflies). Some loss of benthic production is possible in the shoreline areas that remain dewatered over the weekend. If this results in an unacceptable risk (e.g., decreased benthic production), the experiment would not be repeated. There is also the possibility that this experimental procedure may result in confounding interactions with trout management flow (TMF) experiments, which are also expected to be conducted during the LTEMP period.

Trout Management Flows. The 2003 Ecological Restoration Flows that began on January 1, 2003, consisted of daily fluctuations between 5,000 and 20,000 cfs in an attempt to disadvantage nonnative fish, particularly trout, during their winter spawning period. Overall, the 2003 Ecological Restoration Flows caused a drop in benthic biomass at cobble bars in Glen Canyon during the January to March flows followed by recovery through the summer (Shannon et al. 2003b). The flows did not have a long-term adverse impact on New Zealand mudsnail biomass and densities throughout the river. For example, at –3 Mile Bar, mudsnail biomass dropped by 70% between December and January collections; however, by June, New Zealand mudsnails had recovered to 90% of the December estimate (Shannon et al. 2003b).

TMFs conducted in spring and summer months (May–July), featured in all alternatives but Alternative A, would consist of several days at relatively high sustained flows (e.g., 20,000 cfs) followed by a rapid drop to low flows (e.g., 5,000 cfs), which would be held for a brief period (e.g., <24 hr). This pattern would be repeated for a number of cycles. Conditions for primary production should decrease slightly with increased turbidity during the higher

discharge portion of TMFs (Reclamation et al. 2002). Although a temporary increase in total wetted area would occur under TMFs, areas would not be inundated for sufficient time to allow for benthic colonization (Benenati et al. 1998; Blinn et al. 1995). Thus, desiccation losses due to substrate exposure from dewatering of the varial zone would be minimal. Aquatic food base drift may increase during up-ramping to 20,000 cfs/hr associated with TMFs. Drift biomass has been observed to increase during the rising limb of the hydrograph (Miller and Judson 2014).

F.2.2.2 Temperature Effects on the Aquatic Food Base

One of the primary effects of dams, particularly those with hypolimnetic releases, is a change in water temperature, which is primarily responsible for the decline in invertebrate biodiversity. Warmer winter water temperatures can impact invertebrates in a number of ways including loss of physiological signals; disruption of normal growth, fecundity, and emergence; lack of winter chill to break insect egg or larval diapause; and early emergence. Cooler summer water temperatures can also impact invertebrates. For example, water temperatures high enough to complete development may not occur. Other impacts may include decreased fecundity, temporal separation of male and female emergence, delayed emergence, and prolonged emergence. The greater thermal constancy in annual and diel stream water temperatures downstream from dams also tends to decrease food base biodiversity (Vinson 2001).

Seasonal variation in water temperatures decreased gradually from Glen Canyon Dam closure in 1963 until about 1971, when water began to be drawn from the hypolimnion of Lake Powell. Main channel temperatures are now relatively isothermal at 7.2 to 10°C (45 to 50°F), but warm somewhat downstream in summer. There is an estimated maximum warming of the Colorado River mainstem of about 1°C (1.8°F) for every 35 mi, and water released at 10°C (50°F) from Glen Canyon Dam is expected to warm to about 17°C (62.6°F) near Diamond Creek (RM 225) in May or June (Benenati et al. 2002; Valdez 1994). Backwater habitats near the channel margins are one of the few aquatic habitats that warm above these levels. Backwater temperatures tend to warm with distance downstream from the dam (Valdez et al. 1998).

In winter, the mainstem water temperature near Diamond Creek is only about 1°C (1.8°F) higher than at Glen Canyon Dam (Cross et al. 2013). From 1988 to 2005, the average temperature of water released from Glen Canyon Dam was 9°C (48.2°F), and annual high temperatures at Diamond Creek between 1990 and 2002 were about 18°C (64.4°F). A drought that began in 2003 reduced water levels in Lake Powell and resulted in water temperatures that reached an annual high of 21°C (69.8°F) at Diamond Creek in 2005 (Hamill 2009).

In a two-week laboratory study, epiphytic diatom communities from the cold tailwaters of Glen Canyon Dam (12°C [54°F]) were incubated at 18 and 21°C. No change occurred in diatom composition between 18 and 21°C (64 and 70°F), but a significant change occurred between 12 and 18°C (54 and 64°F). At the higher water temperatures, smaller and closely adnate taxa became more important numerically than larger, upright diatoms (Blinn et al. 1989). This shift in diatom species composition may affect macroinvertebrates that feed on diatoms (Lechleitner 1992). Table F-4 provides the distribution, ecological importance, and favorable temperature range for select primary producers in the Colorado River, while Table F-5 provides temperature requirements for common zooplankton taxa.

TABLE F-5 Temperature Requirements for Common Zooplankton

	Temperature, °C (°F)		
Species	Minimum	Maximum	Optimum
Daphnia pulex (cladoceran)	10 (50)	28 (82)	20 (68)
Daphnia galeata (cladoceran)	10 (50)	25 (77)	20 (68)
Daphnia lumholtzi (cladoceran)	10 (50)	30 (86)	25 (77)
Leptodora sp. (cladoceran)	15 (59)	30 (86)	20 (68)
Bosmina sp. (cladoceran)	6 (43)	28 (82)	20 (68)
Diaphanosoma sp. (cladoceran)	10 (50)	30 (86)	25 (77)
Rotifers	15 (59)	30 (86)	25 (77)
Calanoid copepods	10 (50)	30 (86)	25 (77)
Cyclopoid copepods	10 (50)	30 (86)	25 (77)

If stream temperatures are raised by only a few degrees in winter, many aquatic insects that normally emerge in May or June may emerge in February or March and face death by freezing or will be prevented from mating because they are inactivated by low air temperatures. In addition, increases in stream temperatures may exaggerate the separation between the emergence of males and females (e.g., males may emerge and die before females emerge) (Nebeker 1971). Overall, temperatures above or below the optimum can lead to the production of small adults and lower fecundity (Vannote and Sweeney 1980). Slower warming of streams throughout the summer can reduce fecundity of emerging adults, exaggerate the separation of male and female emergence, prolong the emergence period of individual generations (which reduces the number of insects emerging at any given time, which may increase the individual risk of predation by trout or other fish), and reduce the growth rate such that emergence might occur later in the year when air temperatures are suboptimal for mating (Rader et al. 2008; Vinson 2001).

The lack of temperature variability in the Colorado River downstream of Glen Canyon Dam has selected for macroinvertebrates that do not require temperature cues to complete their development. This may at least partially account for the low levels of mayflies and caddisflies and the absence of stoneflies in the mainstem of the Colorado River (Oberlin et al. 1999). Fecundity of *Gammarus* in the tailwaters of Glen Canyon Dam is lower than that reported in other locations, probably due to water temperatures being well below the optimum of 18°C (64°F) for reproduction (Ayers et al. 1998). Table F-6 provides the distribution, importance to higher trophic levels, and temperature range for common benthic macroinvertebrates that occur in the Colorado River.

There is the possibility of an increase in the distribution and prevalence of fish diseases and parasites from river warming (Hoffnagle 2001; Valdez et al. 2000). Warmer, more stable backwaters could provide additional habitats for the Asian tapeworm (*Bothriocephalus acheilognathi)* and anchor worm (*Lernaea cyprinacea*) to substantially increase in abundance,

TABLE F-6 Distribution, Importance to Higher Trophic Levels, and Temperature Range for Common Benthic Macroinvertebrates Downstream of Glen Canyon Dam

Taxa	Distribution in Project Area	Importance to Higher Trophic Levels	Temperature Range in Project Area[a]	Favorable Temperature Range[a]
Gammarus lacustris (amphipod)	Glen Canyon Dam–Paria River (also important component of drift below this reach)	High	7–10 (45–50)	7–29 (45–84)
Simulium (blackfly)	RM 1.0 to Lake Mead and various tributaries	Medium-high	5–31 (41–88)	10–26 (50–79)
Cricotopus (midge)	Glen Canyon Dam–Paria River (also important component of drift below this reach)	Medium	7–10 (45–50)	15–21 (59–70)
Eukiefferiella (midge)	Glen Canyon Dam–Paria River (also important component of drift below this reach)	Medium	7–10 (45–50)	12–18 (54–64)
Orthocladius (midge)	Glen Canyon Dam–Paria River (also important component of drift below this reach)	Medium	7–10 (45–50)	8–18 (46–64)
Chironomus (midge)	RM 1.0 to Lake Mead	Medium	4–23 (39–73)	9–25 (48–77)
Aquatic worms	Glen Canyon Dam–Paria River (also important component of drift below this reach)	Low	4–23 (39–73)	8–25 (46–77)
Aquatic snails	Glen Canyon Dam–Paria River	Low	7–10 (45–50)	7–39 (45–102)
Potamopyrgus antipodarum (New Zealand mudsnail)	Glen Canyon Dam–Paria River	Low	4–23 (39–73)	7–28 (45–82)
Pisidium (pill clam)	Glen Canyon Dam–Paria River	Low	7–10 (45–50)	2–20 (36–68)
Dugesia (planarian)	Glen Canyon Dam–Paria River	Low	7–10 (45–50)	5–16 (41–61)
Baetis (mayfly)	Various tributaries	High	3–31 (37–88)	4–18 (39–86)
Hydropsyche (caddisfly)	Various tributaries	High	3–3 (37–88)	7–30 (45–86)
Megaloptera: Corydalidae (dobsonflies)	Various tributaries	High	5–28 (41–82)	5–30 (41–86)

[a] Temperature in °C (°F).

resulting in their spread along the mainstem and into additional warmwater tributaries. Reported maximum temperature warming above those in the main channel for nearshore habitats ranges from 2.2°C (4.0°F) in eddies to 13°C (23.4°F) in backwaters (Vernieu and Anderson 2013). Warming of nearshore areas is somewhat ephemeral (e.g., decreases at night and during day under windy or cloudy conditions) (Vernieu and Anderson 2013). Temperatures greater than 20°C (68°F) would allow maturation of the Asian tapeworm, while temperatures greater than 15°C (59°F) would allow maturation of the anchor worm (Valdez et al. 1998). Section 4.5.2.4 of the EIS discusses fish parasite and disease incidence for mainstem locations. Table F-7 presents temperature requirements of the Asian tapeworm, anchor worm, and trout nematode. Whirling disease infection prevalence and disease severity reaches its highest levels at 10–15°C (Steinbach Elwell et al. 2009).

As analyzed in Section 4.5.3 of this EIS, temperature differences among alternatives would be minimal. Therefore, no significant changes in the aquatic food base due to elements of the base or condition-dependent operations are expected.

F.2.3 Conclusion

Table 4.5-1 of this EIS summarizes the impacts from the alternatives on the aquatic food base, while Section 4.5.3 presents the impacts of each alternative in more detail. Under Alternative A, existing conditions and trends in the composition, abundance, and distribution of the aquatic food base are expected to persist over the LTEMP period. The cessation of HFEs after 2020 may result in a shift to a food base community not dominated by midges and blackflies (important contributors to the diet of trout). Water temperatures, and their resultant influences on species composition, diversity, and production of the aquatic food base, would be similar to current temperatures in the Colorado River downstream of Glen Canyon Dam.

TABLE F-7 Temperature Requirements for the Asian Tapeworm, Anchor Worm, and Trout Nematode

	Host Activity Temperature Requirements[a]			Infestation Temperature Requirements[a]		
Species	Minimum	Maximum	Optimum	Minimum	Maximum	Optimum
Asian tapeworm	18 (64)	20 (68)	19 (66)	20 (68)	30 (86)	25 (77)
Anchor worm	20 (68)	30 (86)	25 (77)	18 (64)	30 (86)	25 (77)
Trout nematode	16 (61)	20 (68)	18 (64)	16 (61)	20 (68)	18 (64)

[a] Temperature in °C (°F).

Under Alternative B, benthic food base production would be similar to that under Alternative A. HFEs conducted less often than annually may lower the potential to establish a food base adaptable to flood conditions (i.e., one dominated by midges and blackflies). Hydropower improvement flows could decrease benthic food base production, which over the long term may also decrease drift (Kennedy et al. 2014). Over the short term, TMFs could also cause short-term increases in drift rates and slightly decreased primary production compared to Alternative A. Temperature impacts on the aquatic food base under Alternative B would be similar to those under Alternative A.

Under Alternative C, benthic food base productivity may be higher in December through June compared to Alternative A due to higher volumes and larger wetted area, but lower from August through November compared to Alternative A due to lower volumes and smaller wetted area. The more frequent HFEs compared to Alternative A would favor midge and blackfly production. Low summer flows are expected to lower food base production compared to higher flow conditions. Over the short term, TMFs could increase drift rates and slightly decrease primary production compared to Alternative A. Slightly warmer water temperatures for August and September at RM 225 under Alternative C may slightly increase food base production compared to Alternative A, although this could be offset by changes in diatoms from stalked to adnate forms and favoring *Oscillatoria* over *Cladophora*.

The relatively consistent monthly release volumes under Alternative D compared to Alternative A would produce a more consistent and stable aquatic food base. The more frequent HFEs under Alternative D are expected to favor midge and blackfly production compared to Alternative A. Over the short term, TMFs could increase drift rates and slightly decrease primary production compared to Alternative A. Macroinvertebrate production flows in May through August under Alternative D would be tested to determine whether they increase benthic food base production and diversity including the recruitment of mayflies, stoneflies, and caddisflies (important food base organisms currently rare to absent throughout much of the mainstem below Glen Canyon Dam). Low summer flows would provide ideal egg laying conditions for aquatic insects throughout the summer growing season and would therefore be expected to increase food base production; however, the lower magnitude of discharge might lead to lower drift concentrations of invertebrates. Temperature impacts on the aquatic food base under Alternative D would be similar to those under Alternative C.

Under Alternative E, relatively consistent monthly release volumes would favor aquatic food base productivity, but this effect would be offset by larger daily fluctuations. The frequent HFEs under Alternative E will favor midge and blackfly production, although the number of HFEs would be less than under Alternatives C, D, F, and G. Temperature impacts on the aquatic food base for Alternative E would be similar to those under Alternatives C and D.

Because of the comparatively lower flow volumes under Alternative F, food base biomass from July through the following March would be low compared to all other alternatives. Flow stabilization may allow for high benthic densities of New Zealand mudsnails. Over the long term, increased benthic production from flow stabilization may increase drift rates of food base organisms (Kennedy et al. 2014). Higher flow volumes in April through June may increase benthic food base biomass compared to Alternative A. The frequent HFEs will favor blackfly

and midge production. The warmer water temperatures for August and September at RM 225 under Alternative F may slightly increase food base production even more than Alternative D, although this could similarly be offset by changes in diatoms from stalked to adnate forms and favoring *Oscillatoria* over *Cladophora*.

Under Alternative G, consistent and stable aquatic food base conditions would persist throughout the year. Benthic food base biomass would probably be greater under Alternative G, compared to Alternative F, because flows from July through the following February would be higher. However, stable flows may favor dominance by the New Zealand mudsnail. Potentially higher drift rates from spring flows under Alternative F would not occur under Alternative G. However, increased benthic production may increase drift rates over the long term (Kennedy et al. 2014). The frequent HFEs are expected to favor blackfly and midge production. Temperature impacts on the aquatic food base for Alternative G would be similar to those under Alternatives C, D, and E.

F.3 MODELING EFFECTS OF LTEMP ALTERNATIVES ON RAINBOW TROUT AND HUMPBACK CHUB

This section describes the methodology, results, and conclusions from a model developed in support of the LTEMP EIS by Yackulic (Grand Canyon Monitoring and Research Center [GCMRC]), Coggins (U.S. Fish and Wildlife Service [FWS]), and Korman (EcoMetrics) to evaluate effects of alternatives on rainbow trout and humpback chub populations. Although other models were considered for use, the combined rainbow trout-humpback chub model described here was developed to incorporate recent information from the Natal Origins, Juvenile Humpback Chub Monitoring, and Near-Shore Ecology projects being conducted by GCMRC and to utilize newer approaches to modeling humpback chub population demographics. In addition, there was a need to develop the model in a software environment in which batch processing of model runs for multiple hydrologic and sediment input scenarios for each alternative would be feasible and computationally efficient. The model used existing data to inform parameter estimates whenever possible.

F.3.1 Model Overview

The trout-chub model consists of three combined submodels: (1) a model of rainbow trout population dynamics in the Lees Ferry reach, (2) a model of rainbow trout movement and survival downriver from Lees Ferry (trout routing model), and (3) a model of the response of humpback chub population dynamics in the Little Colorado River and Colorado River to monthly mainstem temperatures and monthly trout abundances. The model of the Lees Ferry rainbow trout population dynamics is similar to previous models used for the Glen Canyon reach. The trout movement and humpback chub models, on the other hand, were developed for this application to reflect recent advances, with an emphasis on deriving parameter values from data. The following paragraphs give a brief overview of the three submodels, with more detailed descriptions of each submodel available in subsequent sections (Sections F.3.1.1, F.3.1.2, and F.3.1.3).

Output from a flow model drives the Lees Ferry rainbow trout submodel. This model can be run independently from the trout routing and humpback chub submodels, as it does not include any feedbacks. Simulations include interannual variability in recruitment, outmigration, and growth based both on regression-derived predictions and variation around these predictions. Simulations also include parameter uncertainty, which includes a critical uncertainty related to the effectiveness of TMFs. The parameter associated with the critical uncertainty was fixed at two values (0.10 and 0.50) encompassing a hypothesized range of effectiveness, while all other parameters were drawn from the multivariate distribution estimated from data. Outputs from this submodel include four performance metrics, including simulated outmigration, which was used as input to the trout routing submodel.

The trout routing submodel includes a single biological parameter describing movement, as well as multiple inputs related to implementation of mechanical removal, all of which are fixed. The trout routing submodel model is run a year at a time, after which it passes monthly rainbow trout abundances to the humpback chub submodel.

The humpback chub submodel simulates the impacts of rainbow trout and temperature (forecasted by a temperature model) on humpback chub population dynamics at a monthly time step. It returns the adult population abundance at the end of the year, which is used as one of the performance metrics and is also used by the trout routing model to determine whether mechanical removal would be triggered in the next year. The humpback chub submodel includes parametric uncertainty including levels for a critical uncertainty related to the effect of rainbow trout on humpback chub survival and growth, as well as variation in other parameters. The humpback chub submodel also includes interannual variability in recruitment and outmigration.

More detailed information about each of the submodels is provided in the following sections.

F.3.1.1 Glen Canyon Trout Submodel

An age-structured population dynamics model was used to predict the abundance and growth of rainbow trout in Glen Canyon and the number of those fish that migrate into Marble Canyon. The model makes predictions on an annual time step for ages 1–6 yr. Annual recruitment, which was defined as the number of age-0 fish (i.e., fish hatched in the current year) that enter the population in a given year, is predicted based on flow statistics, and growth is predicted as a decreasing function of overall rainbow trout abundance. Abundance, in combination with age-specific angling vulnerabilities, is used to make predictions of angler catch per hour of effort. Predicted abundance and size distributions are used to compute the number of high-quality fish (trout ≥16 in. total length) potentially available for capture. The number of fish migrating from the Glen Canyon reach into Marble Canyon each year (out-migrants) is predicted as a proportion of the previous year's recruitment, and is used to determine the potential number of fish that eventually migrate down to the confluence of the Little Colorado River (RM 61), where their effects on humpback chub are simulated. Basic simulation parameters and those for key functional relationships were derived or fitted to values from the Korman et al. (2012) stock

synthesis model. This model used 21 years of electrofishing-based catch-per-effort data for Glen and Marble Canyons, in conjunction with length frequencies and other information, to estimate annual recruitment, survival rate, von Bertalanffy growth parameters, and outmigration patterns (numbers, size, and timing). Specifics of the Glen Canyon trout simulation model are provided below.

Recruitment

The annual recruitment of age-0 trout in Glen Canyon was predicted based on a multiple linear regression driven by flow-derived independent variables. The model predicted log annual recruitment as a function of annual Glen Canyon Dam release volume, the range in mean daily flows during the critical early life history rearing period (May–August), and the presence of a spring HFE in each year or in the previous year (Korman et al. 2011c; Avery et al. 2015). The model explained 55% of the annual variation in the recruitment estimates from the Korman et al. (2012) stock synthesis model between 1990 and 2010 (Figure F-1). The flow-dependent regression model predicted that recruitment would be higher in years with greater annual volumes, reduced daily variation in flow between May and August, and when spring HFEs occur. In the simulation model, log recruitment each year is predicted from a random normal distribution, with the mean determined by linear regression parameters and hydrologic statistics, and the extent of error determined by the residual error in the regression model.

Recruitment for a given year was predicted to be higher if a spring HFE occurred in that year or in the previous year, based upon empirical relationships reported by Korman et al. (2011c). However, there is insufficient information to draw a conclusion about whether HFEs that occur in the fall would have a similar effect on recruitment of trout. The model considered this uncertainty about the effect of fall HFEs on recruitment of rainbow trout in the Glen Canyon reach by examining two hypotheses: (1) fall HFEs would have no effect on recruitment and (2) recruitment would increase at the same rate as seen with spring HFEs, but for only one year instead of two.

As described in Section 2.3.3.2 of this EIS, TMFs are a special type of fluctuating flow designed to reduce the recruitment of trout by disadvantaging young-of-the-year (YOY) trout. TMFs have been proposed and developed on the basis of research described in Korman et al. (2005). TMFs are included as elements of some alternatives evaluated in the LTEMP EIS, and the Glen Canyon trout submodel incorporated the ability to consider the effects that occurrence of TMFs could have on trout resources. For alternatives and associated long-term strategies that included TMFs, these flows were triggered in the model during years in which the initial production of YOY rainbow trout (based on hydrologic characteristics) in the Glen Canyon reach was anticipated to be greater than 200,000 individuals. Because there is uncertainty regarding how effective TMFs would be at disadvantaging YOY trout, the model was used to evaluate two different levels of effectiveness by reducing the number of YOY trout surviving to age-1 by either 10% or 50% for each 20-year simulation period.

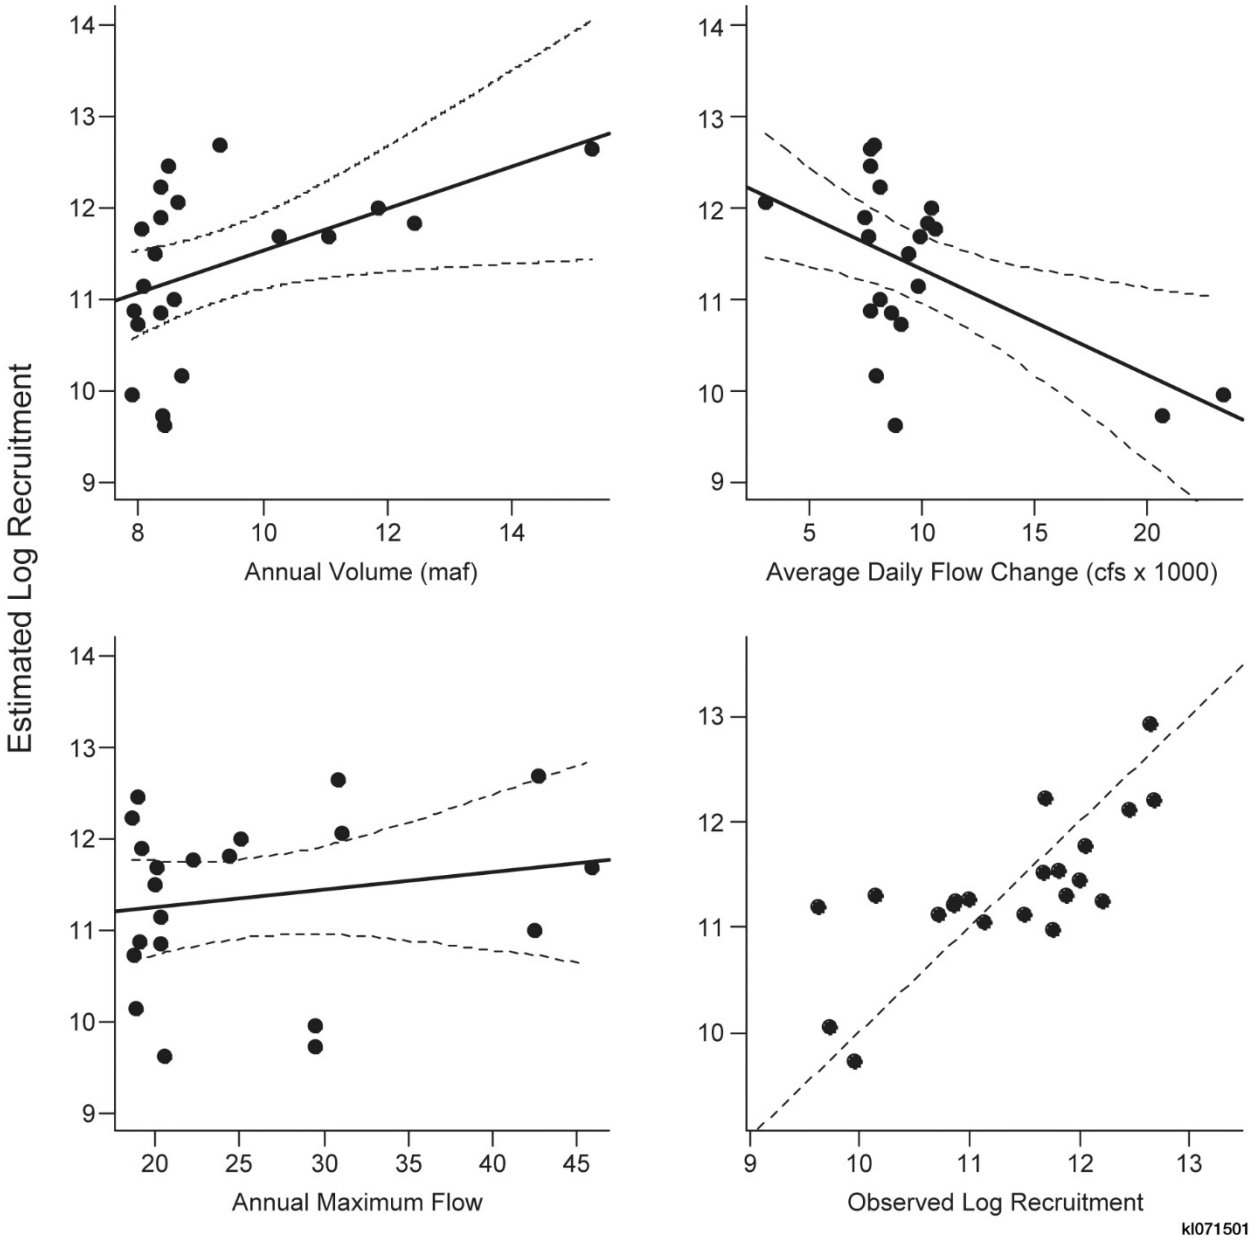

FIGURE F-1 Fit of Regressions Predicting the Log of Recruitment of Rainbow Trout in the Glen Canyon Reach Estimated by the Korman et al. (2012) Stock Synthesis Model as a Function of the Annual Release Volume from Glen Canyon Dam (million acre-feet), the Range of Mean Daily Flows during May–August (thousand cfs), and the Maximum Flow (cfs) Each Year (The bottom-right plot compares the overall fit of a multiple regression model with annual volume and range of mean daily flows during May–August as independent variables, and with the maximum annual flow independent variable replaced with a dummy variable with values of 1 for years prior to or with spring HFEs. The dashed line in the bottom-right graph indicates the 1:1 relationship and the 95% confidence interval in other graphs. The multiple regression model explained 55% of the variation in log recruitment and was statistically significant [p = 0.002].)

Growth

Length-at-age was calculated assuming a von Bertalanffy relationship that depends on the Brody growth coefficient ($vbK = 0.55$), the asymptotic length (L_{inf}, size at the terminal age), the coefficient of variation in length-at-age ($cvLen = 0.1$), and the mean size at age 1 ($L_0 = 130$ mm). Parameter estimates were derived from the stock synthesis model, which was fit to length-frequency and supplemental growth data (Korman et al. 2012, 2011a,b). Annual variation in asymptotic length was predicted as a linear function of the abundance of trout >150 mm. This model predicts only 18% of the annual variation in the annual asymptotic length estimates from the stock synthesis model (Figure F-2). To simulate interannual variation in L_{inf} in the model, annual deviates of L_{inf} in log space were added to a base value (5.89). In the simulation, predicted deviates from the $L_{inf} - N > 150$ regression model were added to the base value, and these formed the mean of a random normal distribution with a standard deviation equal to the residual error of the regression model.

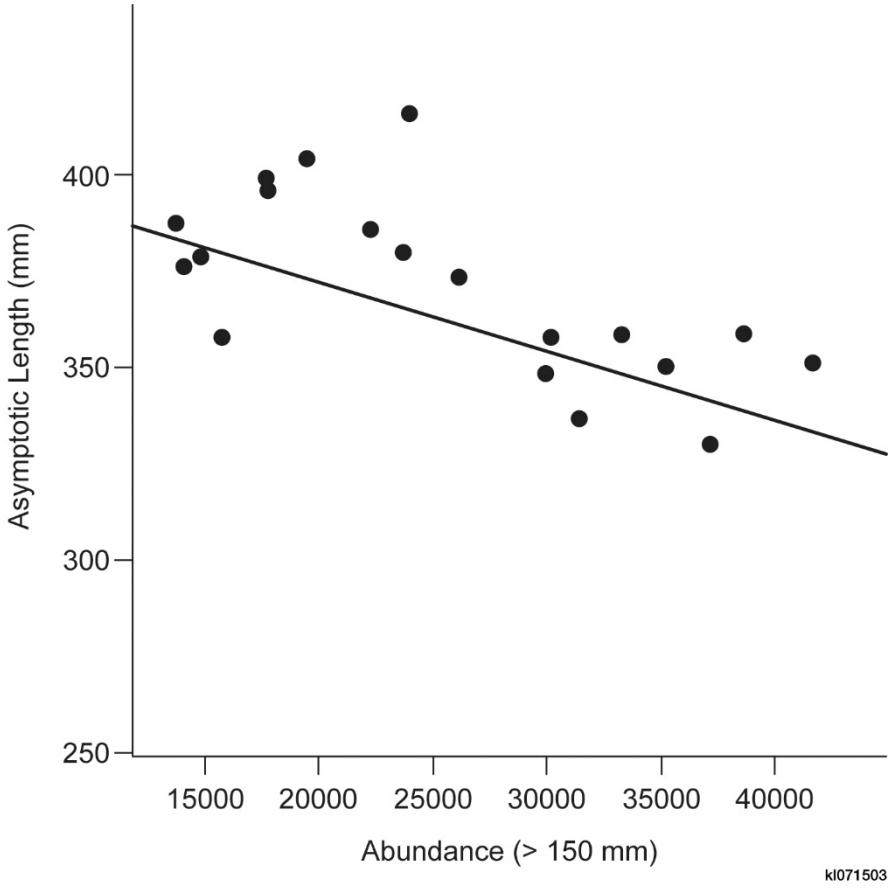

FIGURE F-2 Relationship between Annual Estimates of the Asymptotic Length of Rainbow Trout in Lees Ferry Predicted by the Stock Synthesis Model as a Function of the Estimated Abundance for Fish >150 mm (approximately age-1+) Each Year (The solid line is the best-fit relationship. This relationship explained 18% of the annual variation in asymptotic length and was not statistically significant [p = 0.056].)

Performance Metrics from Glen Canyon Trout Submodel

Four performance metrics were derived from the trout submodel in order to evaluate the relative degree to which the various alternatives would achieve a healthy high-quality recreational trout fishery in Glen Canyon National Recreation Area and reduce or eliminate downstream trout migration consistent with National Park Service fish management and Endangered Species Act (ESA) compliance needs. These four trout performance measures were:

1. Glen Canyon trout abundance index (for age-1+ fish)

2. Catch rate index (number/hr) for age-2+ fish

3. Number of trout >16 in. total length

4. Trout emigration estimate (number of age-0 trout moving into Marble Canyon from Glen Canyon)

The Glen Canyon trout abundance index was calculated as the average of modeled annual abundance of trout that were 1 year of age or older during each 20-year simulation period. The model used an age-structured population dynamics model to calculate the annual abundance for age classes 1 through 6 based upon annual recruitment rates and density-dependent survival rates.

The catch rate index was calculated as the average annual angling catch per unit of effort (number of fish per hour) during the 20-year simulation period. Only fish 2 years of age or older were considered vulnerable to angling. The annual angling catch per effort in the fishery (CPE_{yr}) was predicted as the sum of products of an overall catchability coefficient ($q = 4.25e^{-05}$), age-specific vulnerabilities ($V_1 = 0$, $V_2 = 0.5$, and V_3 *to* $V_6 = 1$), and the predicted age-specific abundance for the year ($N_{yr,a}$):

$$CPE_{yr} = \sum_{a=0}^{6} \left(q \times V_a \times N_{yr,a} \right)$$

To estimate q, the simulation model was run using the recruitment estimates from the stock synthesis model to predict age-specific abundance between 1990 and 2010. The value for q was then calculated from the back-transformed average of the log of the ratio of the observed CPEs to the estimates of the vulnerable population each year. Thus, q represents the average scalar required to convert predicted vulnerable abundance to the observed CPE.

In order to evaluate the potential for large trout to be present in the population under a given alternative, a performance metric was calculated as the average of the annual modeled number of fish equal to or greater than 16 in. that would be present in the Glen Canyon reach. The number of trout in the population with total lengths equal to or greater than 16 in. during a given year was predicted as the sum of the products of the abundance-at-age and the proportion of the age with lengths greater than or equal to 16 in. That proportion meeting the length

criterion is predicted based on a normal distribution (*pnorm*) with a mean predicted by expected length-at-age ($Len_{yr,a}$) determined using the von Bertalanffy relationship and a standard deviation determined by the coefficient of variation in length-at-age (*cvLen*):

$$N_{qual,yr} = \sum_{a=0}^{6} \left[N_{yr,a} \times pnorm\left(16, Len_{yr,a}, cvLen \times Len_{yr,a}\right) \right]$$

The trout emigration performance metric was calculated as the average of the annual modeled number of trout migrating from Glen to Marble Canyon during a 20-year simulation period. The Glen Canyon Trout submodel computes the number of trout migrating to Marble Canyon as a fraction of the recruitment estimate from the previous year (Figure F-3). A linear model with a zero intercept explained about 70% of the estimated outmigration from Korman et al. (2012). The model predicts that on average, the number of out-migrants is 42% of the recruitment value from the previous year; however, there is considerable interannual variation in this percentage (95% of values are between 0 and 91%). A normal distribution (*rnorm*) with a mean equal to the mean of the logit-transformed annual proportions and a standard deviation equal to the standard deviation of the transformed proportions was used to simulate the proportion of fish out-migrating in each year of the simulation. The back-transformed proportions were then multiplied by the previous year's recruitment ($Rec_{\text{yr-1}}$) to calculate the out-migration each year:

$$Out_{yr} = Rec_{yr-1} \times \text{logit}[rnorm(\text{mean} = -0.35, \text{sd} = 1.65)]$$

Parameter estimates for the key linear models (recruitment-flow, out-migration-recruitment, asymptotic length-abundance) were estimated by linear regression. The variance-covariance matrices for these models, which represent the extent of uncertainty in parameter estimates and their covariation, were used to generate 1,000 different parameter values for each relationship. The simulation model integrated over these values to incorporate uncertainty in key functional relationships when making predictions for any long-term strategy and hydrologic trace.

In addition to the performance metrics that were used to evaluate the potential effects of alternatives and long-term strategies on the trout fishery and downstream migration of trout, the trout submodel also kept track of the number of TMFs expected to be triggered during each 20-year simulation period. The number of TMFs during a 20-year period was used as one indicator of how American Indian Tribes—some of which consider lethal actions to fish an adverse effect if there is no beneficial use—could be affected by alternatives and long-term strategies (see Appendix I), rather than as a measure of effects on the trout fishery itself.

Evaluation of Trout Submodel

Annual flow statistics for Glen Canyon Dam were computed from the historical record between 1990 and 2010 and used as input to the Glen Canyon trout model to compare predictions with observations and best estimates of key state variables such as recruitment,

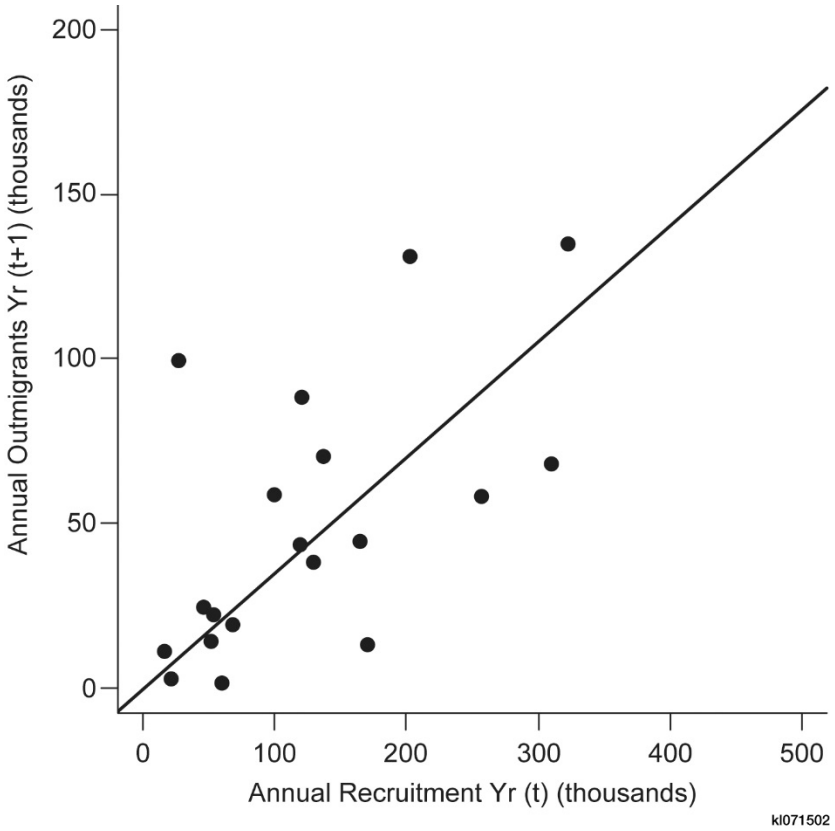

FIGURE F-3 The Relationship between Annual Recruitment of Rainbow Trout in Lees Ferry Estimated by the Korman et al. (2012) Stock Synthesis Model and the Number of Trout That Emigrate from Lees Ferry into Marble Canyon the Following Year (The solid line represents the best-fit relationship, which assumes no out-migration when there is no recruitment in the previous year [i.e., the line is forced through the origin]. This relationship predicted 72% of the annual variation in estimated out-migration and was statistically significant [$p < 0.001$].)

out-migration, and size at the terminal age. Predictions of angler CPE were compared to estimates of annual CPE from the Arizona Game and Fish Department (AZGFD) creel survey (Makinster et al. 2011). Simulations were based on most likely parameter estimates from the key regression models (recruitment-flow, outmigration-recruitment, asymptotic length-abundance) and did not include interannual variation in predictions to facilitate comparisons of predictions and data. Predictions of abundance were compared to the interannual trend in AZGFD electrofishing surveys. Other predictions (recruitment, asymptotic length, and out-migration) were compared to best-fit estimates from the Korman et al. (2012) stock synthesis model.

The historical flow-driven predictions of recruitment made by the simulation model produced an interannual trend quite similar to the estimates produced by Korman et al. (2012; Figure F-4, top-left panel). However, the model substantially over-predicted recruitment in 1996 and under-predicted recruitment in 2007–2009. The effects of high annual volumes and spring

floods on recruitment may be confounded with other variables in the multiple regression model due to the low frequency of these events in the period of record.

The trend in predicted abundance from the model generally matched the trend in electrofishing-based CPE (Figure F-4, middle-left panel). The model over-predicted abundance in 2005–2007, perhaps because it did not account for a number of unusual events in earlier years that likely affected recruitment and adult mortality (e.g., a sudden change in minimum flow due to an emergency shutdown of Glen Canyon Dam generators, very few spawners in 2006, mortality of adults due warm water and low dissolved oxygen in releases during the fall of 2004). The trend in asymptotic length predicted by the model did not provide a good fit to the trend from the Korman et al. (2012) stock synthesis model. This is not surprising, as trout abundance was a relatively poor predictor of asymptotic length (Figure F-3), especially in years when other factors (e.g., low food availability, high mud snail abundance) appeared to have strong effects. Factors such as food availability and quality and long-term trends in reservoir productivity are likely more important drivers of growth than abundance.

The model was only partially able to reproduce the observed trend in angling CPE (Figure F-4, top right). It correctly predicted an increase with abundance between 1992 and 1997. However, observed CPE for the following 3 years was relatively stable, while model predictions indicated that CPE increased by about threefold. As the model provided a relatively good fit to the observed trend in electrofishing CPE over the majority of the historical period, this likely indicates that catchability (q) declined beginning in 1999. Possible mechanisms include a reduction in q at higher trout densities, as a greater fraction of fish use less vulnerable habitats, or reduced q at lower flows (which began in 1999). The predicted number of quality-sized fish in the population (dashed line, top right) has been low over the entire historical period (<1000) and declined from maximum values at the start of the period due to increasing abundance (top left), which reduced asymptotic length (bottom left).

The trend in simulated out-migration estimates was reasonably close to the historic trend estimated by the stock synthesis model (Figure F-4, bottom right). The proportion of recruitment that out-migrates each year is not constant (Figure F-2), and this simplification in the application of the simulation model to historical data leads to some of the error in out-migration estimates. Departures between the best recruitment estimates (Korman et al. 2012) and those derived from the flow regression (Figure F-4, top left) increases the extent of error in out-migration estimates.

F.3.1.2 Trout Movement Submodel

One component of the LTEMP trout/humpback chub simulation model is the movement of rainbow trout from Glen Canyon to near the confluence of the Little Colorado River. The trout movement model predicts the monthly abundance of trout within each mile segment of the Colorado River from RM 0 to RM 150 and reports monthly abundance over broader river reaches as required for the humpback chub population dynamics model. While the LTEMP rainbow trout-humpback chub model is not focused on locations below approximately RM 66, the trout movement model extends below this location to avoid problems with modeling boundary conditions near the Little Colorado River. Key inputs to the trout movement model

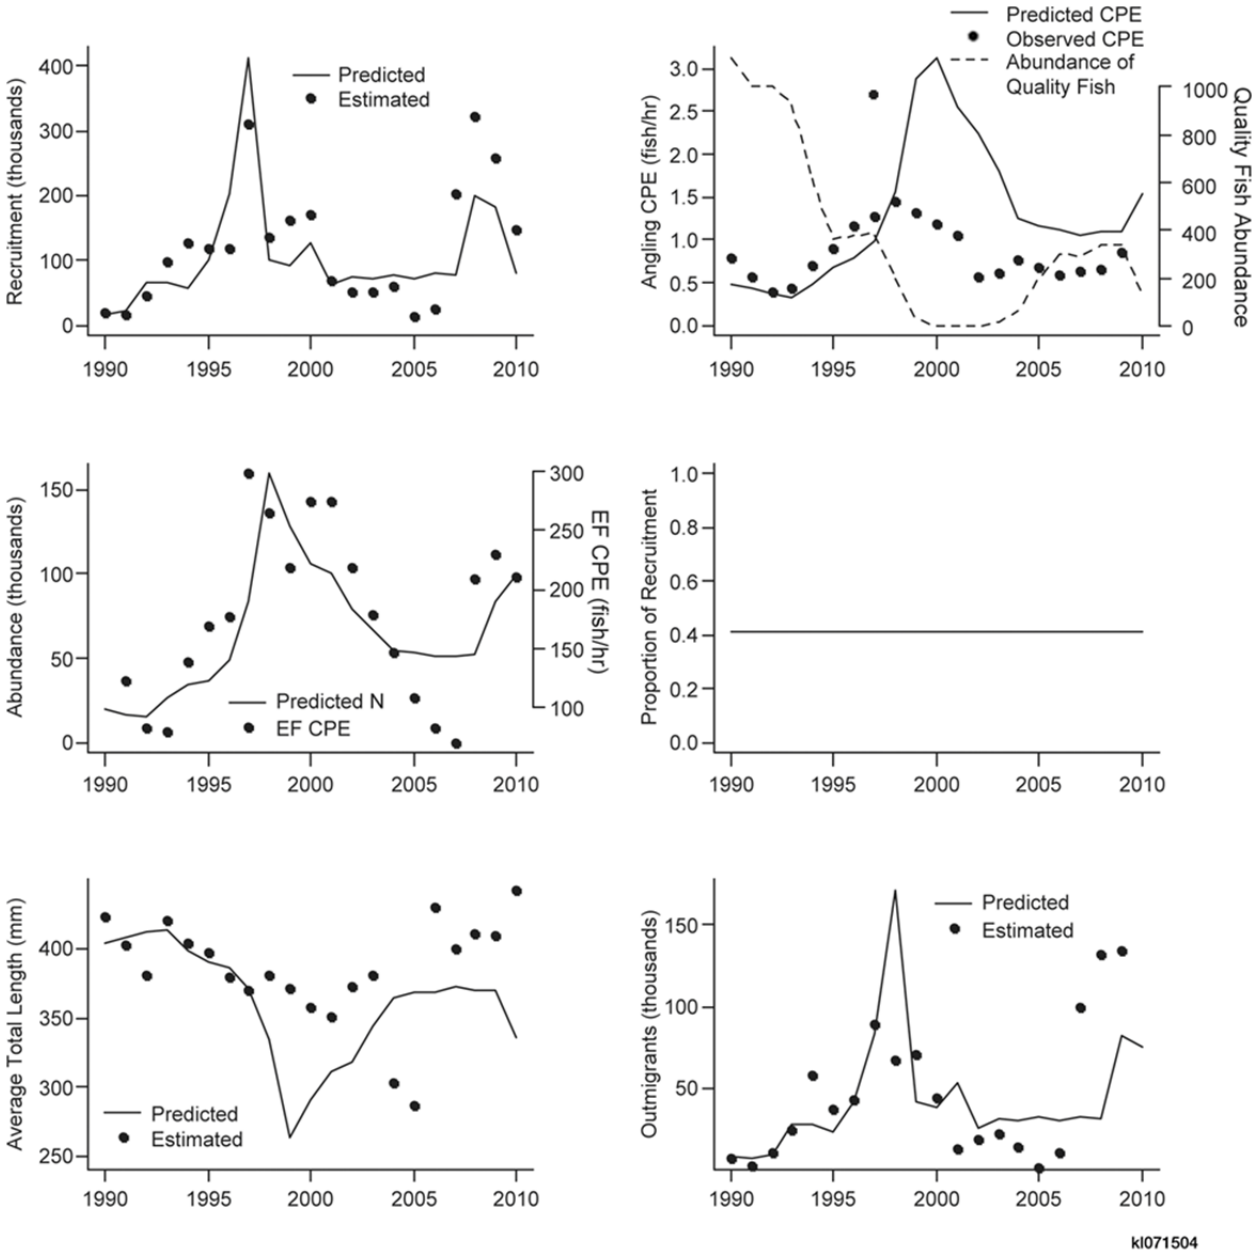

FIGURE F-4 Fit of the Glen Canyon Rainbow Trout Simulation Model to Predictions of Recruitment (top left), Asymptotic Length (bottom left), and the Number of Out-migrants (bottom right) Predicted by the Korman et al. (2012) Stock Synthesis Model (Also shown is the predicted abundance relative to catch per effort [CPE] from AZGFD electrofishing surveys [middle left], the predicted angling CPE compared to AZGFD creel survey estimates [top right], and the average proportion of recruitment that migrates from Glen to Marble Canyon each year [middle right].)

include the monthly number of age-0 trout out-migrating from the Glen Canyon reach, parameters that control the movement and dispersion of rainbow trout in Marble/Grand Canyons, the natural mortality rate of rainbow trout, and the number, intensity, and timing of nonnative mechanical removal trips conducted each year. The rules governing the implementation of

mechanical removal were specified based on the Biological Opinion on nonnative fish control (Reclamation 2011b). Monthly movement and dispersion do not depend on trout density and are modeled as a random process following a Cauchy distribution of movement distances. To allow parameter estimation and to evaluate the ability of the model to reconstruct historic trout abundance patterns, model-predicted catch of rainbow trout from sampling efforts in 2000–2009 was compared to the observed catch.

The trout movement model accounts for the abundance of rainbow trout at a monthly time step and in 1-mi-long river segments (RM segments) from RM 0 to RM 150. The age and size structure of the population was not modeled, although all immigrants from Glen Canyon are assumed to be YOY. At the end of each month, trout within each RM segment are diminished by some survival rate and then distributed to other RM segments according to a RM segment-specific movement distribution. This calculation is accomplished via matrix operations as:

$$n(t+1) = MSn(t),$$

where n is a vector containing the abundance of rainbow trout within each RM segment, M is the movement matrix specifying how the abundance at a particular RM segment is distributed to other segments, S is the survival matrix where the diagonal contains the survival of fish within each RM segment and all other elements are zero, and t is the month of the year.

Number of Trout from the Glen Canyon Reach

The number of fish entering the upstream-most RM segment in the model (RM 1) each month equals the number of annual emigrants calculated by the Glen Canyon trout submodel. The monthly number of trout entering the reach was assumed to be 1/12 of the annual total emigrants, as migration timing was assumed to be uniform across months.

Survival

Instantaneous natural mortality rate (M = 0.49/year) was assumed to be temporally and spatially constant and corresponded to a monthly survival rate of 0.96 based on mark recapture-based methods from the Natal Origins project (Korman et al. 2015). In the RM segments RM 56 to RM 66, monthly survival is also potentially influenced by mechanical removal operations. Survival rate associated with mechanical removal was modeled as:

$$MR_{surv} = (1-p),$$

where MR_{surv} is survival from mechanical removal, p is the electrofishing capture probability, and D is the number of times fish are removed from each RM segment (number of passes). Thus monthly survival rate in RM segments where mechanical removal is not conducted was 0.96, and in RM segments where mechanical removal was conducted, it was $0.96 \times MR_{surv}$. The diagonal elements of the survival matrix S contained these RM segment survival rates and non-diagonal

elements were zero. Capture probability (p) was assumed to be 0.10, based on recent work from the Natal Origins project (Korman et al. 2015).

Mechanical Removal

Mechanical removal in RM 56–66 was triggered in a particular year when three conditions were simultaneously met: (1) mechanical removal was authorized under the alternative being modeled, (2) the estimated abundance of rainbow trout in the trigger reach (RM 63–64.5) during September of the previous year was greater than 760 individuals, and (3) the estimated number of adult humpback chub (from humpback chub submodel, see Section F.3.1.3) was less than 7,000 individuals. When the triggering conditions were met, mechanical removal was implemented as six removal trips that occurred from February through July. Occurrence of removal trips reduced the number of trout in the vicinity of the Little Colorado River during the month, based upon the abundance of trout and electrofishing capture probability estimated from past removal efforts.

Trout Movement

The movement of fish between RM segments was assumed to be a diffusion process in which the probability of a fish moving from each RM segment to every other RM segment followed a truncated Cauchy distribution. The distribution is said to be truncated as movement upstream of the RM 0 segment or downstream of the RM 150 segment was disallowed. The probability distribution for each RM segment was assumed to represent the proportions of fish that would move to every other segment and formed a row vector in a movement matrix.

Performance Metrics from Trout Movement Submodel

The principal purpose of the trout movement submodel was to provide inputs to the humpback chub population submodel pertaining to monthly estimates of the number of rainbow trout that would be present in the vicinity of the Little Colorado River, and to calculate the number of trout that would be removed by mechanical removal efforts. Although no aquatic ecology performance metrics were generated, the trout movement submodel was used to calculate the numbers of years in which mechanical removal trips were triggered for each 20-year simulation, and that calculation was used as an indicator of how Tribal resources could be affected by alternatives and long-term strategies (see Appendix I).

Two factors must coincide to trigger mechanical removal trips in the submodel: (1) there must be more than 760 adult rainbow trout projected for the test reach in the vicinity of the Little Colorado River confluence (RM 63–RM 64.5) and (2) the projected adult humpback chub population must be less than 7,000 individuals. The number of adult humpback chub is calculated by the humpback chub population submodel and provided as input to the trout movement submodel. Once triggered, the model assumes that six mechanical trip passes would occur during the year.

Estimating Model Parameters and Evaluating Model Predictions

Rainbow trout electrofishing catch data from 2000 through 2009 and between RM 0 and RM 65.7 were used to estimate the Cauchy scale distribution parameter and the catchability coefficient (q). These data were composed of the annual electrofishing catch and effort by the 10-mi reaches between RM 0–50 and by the reaches RM 50–61.5 and RM 61.5–65.7 (Makinster et al. 2011). The annual predicted catches (C_i) for each reach (i) were computed as:

$$C_i = n_i \times E_i \times q,$$

where n_i is the model-predicted abundance of rainbow trout within reach *i* during the month of June and E_i is AZGFD electrofishing effort in June.

The observed catch was assumed to be distributed as a Poisson random variable with mean equal to the model-predicted catch. Estimation of the Cauchy scale (γ = 3.38) parameter and the catchability coefficient ($q = 3.4e^{-06}$) was accomplished via the method of maximum likelihood and the function "optim" within R (R Core Team 2013). These estimates provided a reasonably good fit to the data (Figure F-5), providing confidence that the simulation model would accurately portray movement dynamics of rainbow trout. A more complex parameterization of the Cauchy distribution was tested, where the location parameter (which specifies the most probable movement distance) was estimated as a free parameter. The maximum likelihood estimate of the location parameter was approximately $5.0\ e^{-03}$, confirming that most fish do not change location on a monthly basis. A normal distribution also was considered to describe movement distance, but there was a better fit to the data using the Cauchy distribution. In addition, the Cauchy distribution of movement implies a smaller probability of fish moving long distances within a month than the normal distribution (Figure F-6) and is more biologically reasonable, considering the observed movement of tagged trout.

F.3.1.3 Humpback Chub Population Submodel

A size- and location-structured population dynamics model was used to predict the size of the adult population of humpback chub over time. The model assumes five size classes of humpback chub (40–99 mm, 100–149 mm, 150–199 mm, 200–249 mm, and >250 mm, size classes 1–5, respectively) and two locations (Little Colorado River and Colorado River) for a total of 10 "states" (where a state is a unique combination of size and location; for example, a fish in the Little Colorado River that is 40–99 mm is in state 1; Figure F-7). The structure of this model is based on recent modeling work (Yackulic et al. 2014) as well as a new set of candidate models developed specifically to address the effects of temperature and rainbow trout on humpback chub survival (see "Model Selection and Development" below). The model uses a monthly time step and assumes constant survival for all states except for state 6, corresponding to juveniles in the Colorado River. Survival for this state depends on rainbow trout abundance. Growth of size class 1 (40–99 mm) humpback chub depends on both water temperature and rainbow trout abundance. Growth for all other size classes in the Colorado River is temperature-dependent, while Little Colorado River growth is assumed to be constant. Movement between

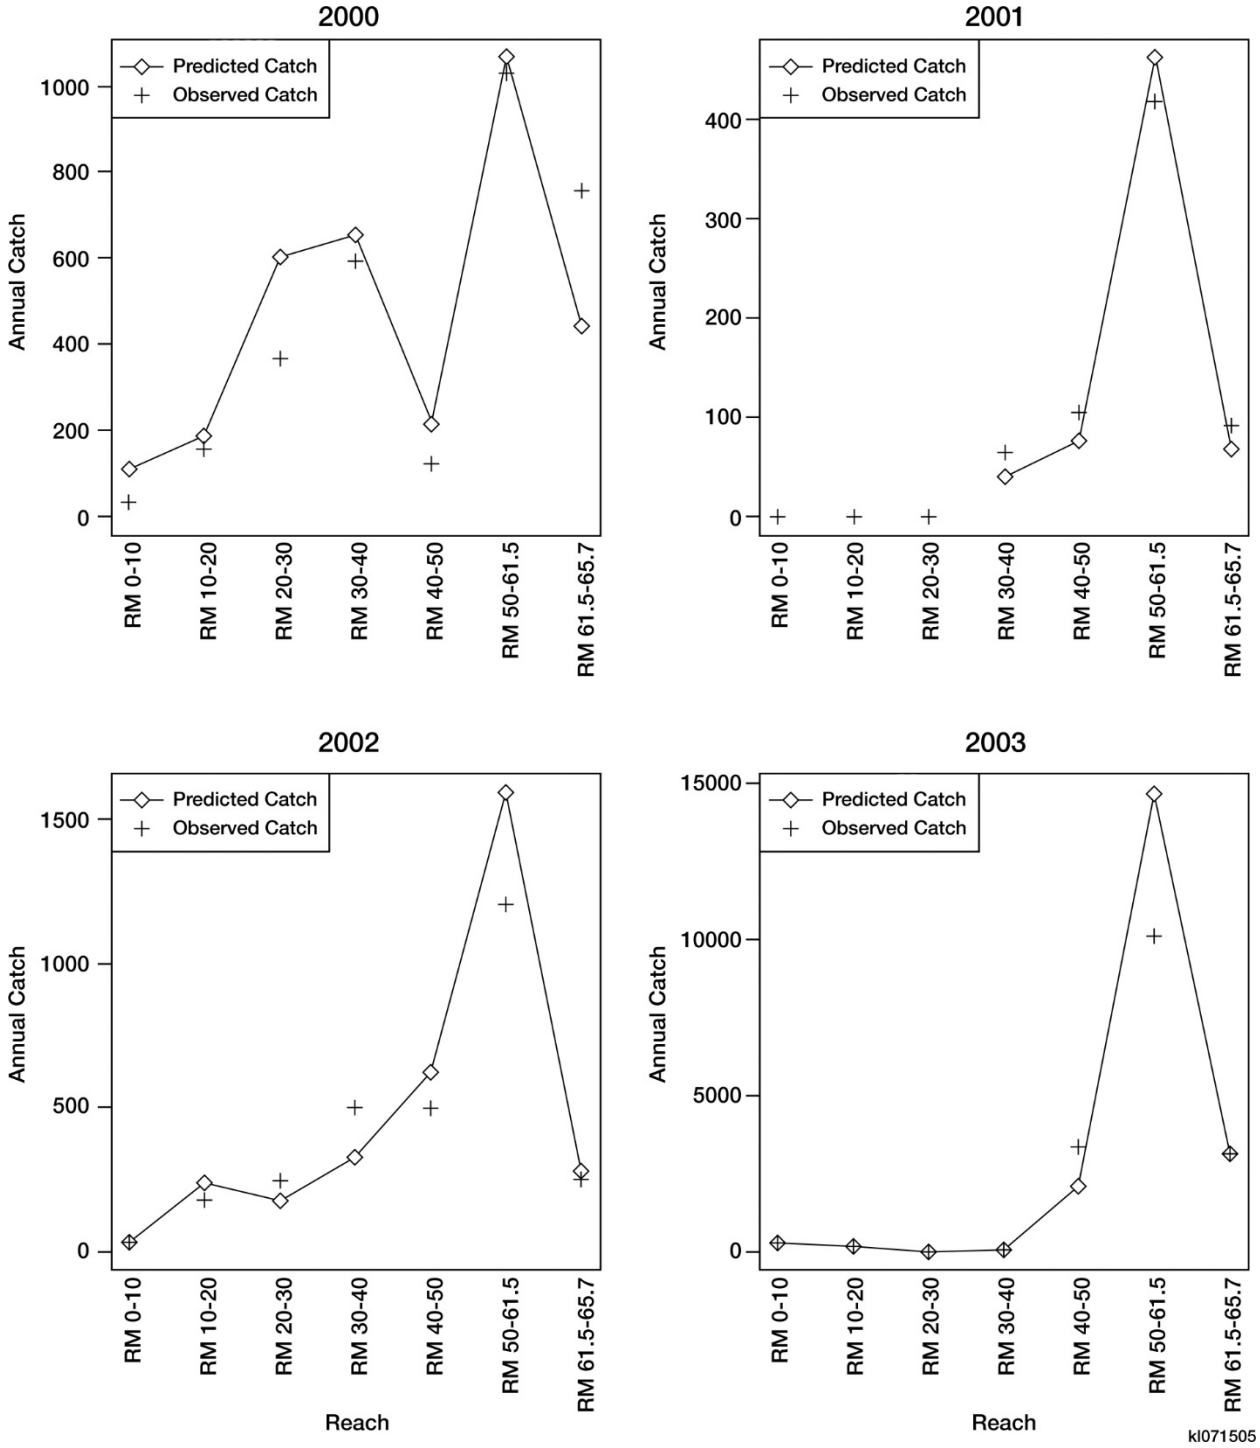

FIGURE F-5 Predicted and Observed Annual Catch of Rainbow Trout by Year and River Reach

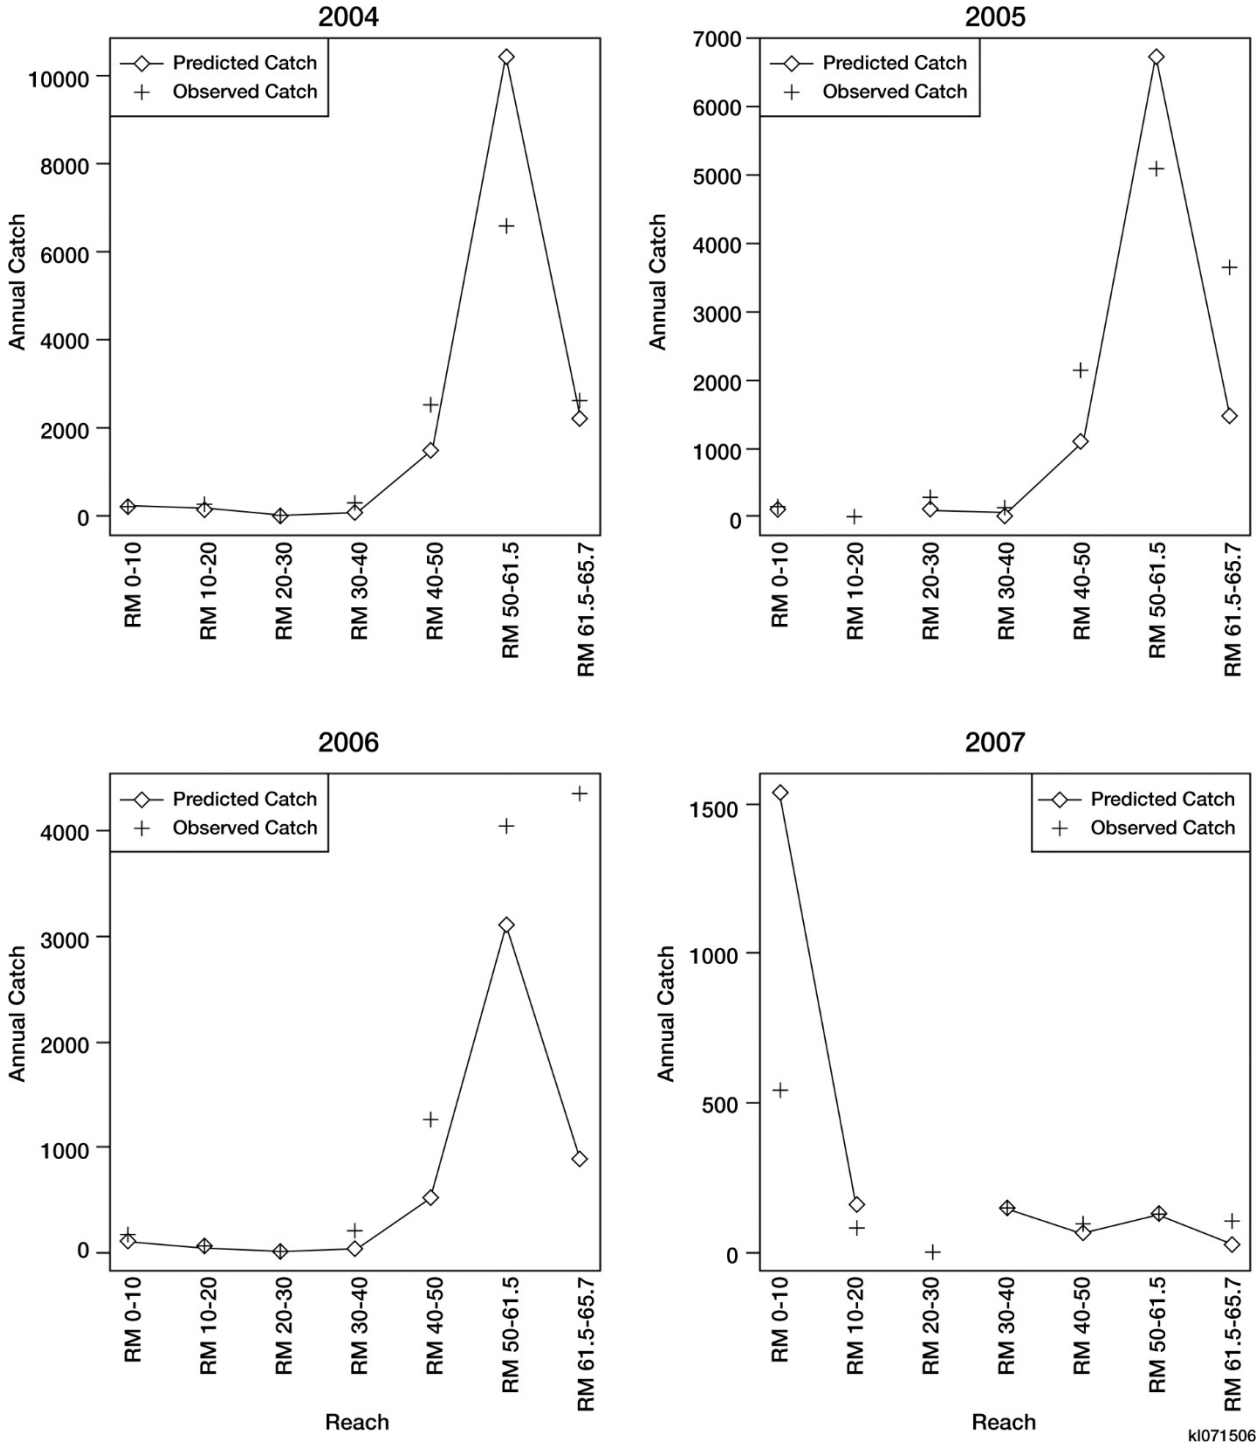

FIGURE F-5 (Cont.)

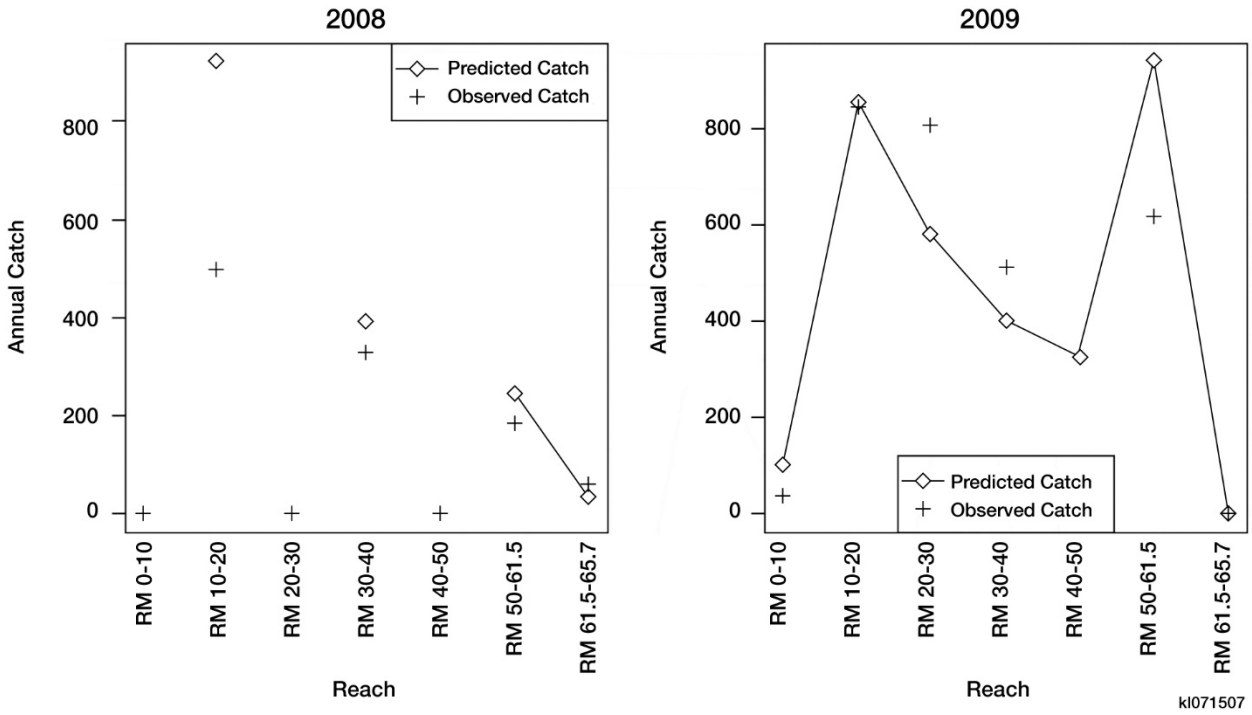

FIGURE F-5 (Cont.)

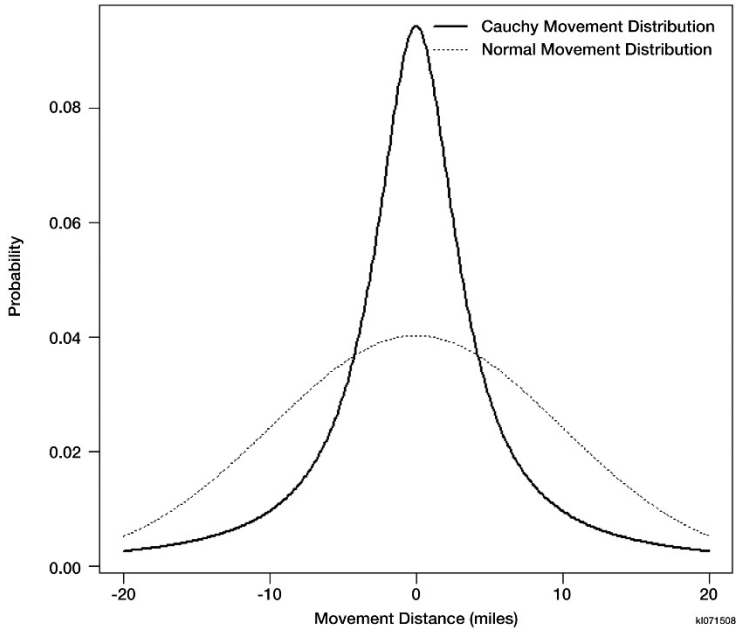

FIGURE F-6 Best-Fitting Distributions Describing Monthly Movement of Rainbow Trout in Marble Canyon Assuming Either a Normal or Cauchy Distribution (The Cauchy distribution implies a lower probability of large monthly movements and agrees better with movement observations from tagging data.)

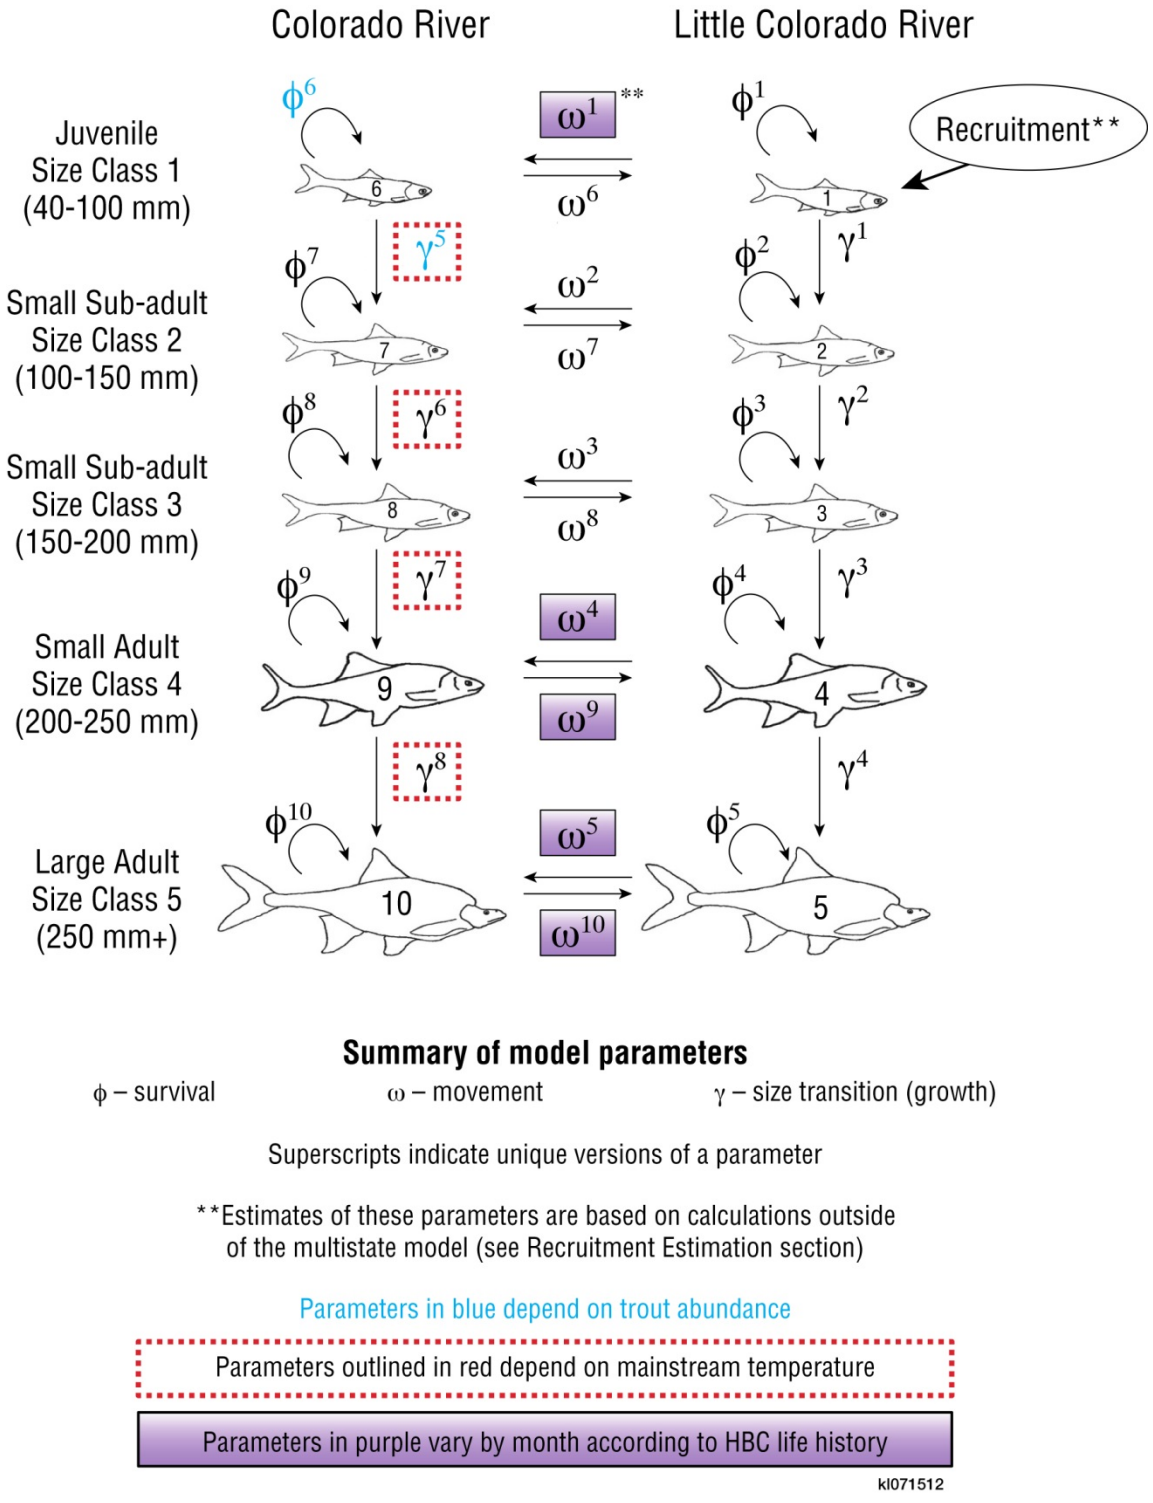

FIGURE F-7 Visual Summary of Humpback Chub Population Model Structure (The number on each fish represents its state number. Modified from Yackulic et al. [2014].)

the Little Colorado River and Colorado River is modeled via movement parameters that vary depending on the month and size class (see Yackulic et al. 2014, for more details regarding movement parameters). In addition to parameters describing survival, movement, and growth, the simulation model also relies on estimates of the starting abundance in each of the 10 states, as well as assumed annual recruit abundance.

All YOY fish recruit to state 1 (i.e., size class 1 fish in the Little Colorado River) in July. Most parameters were estimated directly from data collected during 2009–2013 in the Colorado River and 2009–2012 in the Little Colorado River. Recruitment was approximated by comparing estimated juvenile abundances in the Colorado River and Little Colorado River between 2009 and 2012. This analysis also led to modification of the value for the movement parameter associated with juvenile out-migration from the Little Colorado River (see "Recruitment Estimation" below). Yackulic et al. (2014) had previously speculated that this parameter might be biased, since July marking of juveniles has, until recently, been limited to a small section of the Little Colorado River proximate to the Colorado River that is likely to experience higher overall out-migration than the Little Colorado River as a whole. Recruitment estimates were also influenced by recent research suggesting severely diminished recruitment in years with little winter runoff in the Little Colorado River (Van Haverbeke et al. 2013).

Having estimated the maximum likelihood ("best") values of parameters based mainly on data collected from 2009 to 2013, the simulation model was run using a 20-year sequence of observed temperatures near the Little Colorado River between 1990 and 2009, as well as predictions of rainbow trout abundance for this period from the Glen Canyon and trout movement submodels. These outputs were compared to trends reported in Coggins and Walters (2009), as discussed in "Evaluating Model Predictions," below. Potential uncertainties in model predictions are discussed in "Model Uncertainties" below.

Model Selection and Development

The primary objective for the humpback chub population model was to estimate the effects of mainstem temperature and trout abundance on humpback chub population dynamics (i.e., growth and survival). Six candidate models that represent different a priori hypotheses concerning potential effects were evaluated:

- Model A: Rainbow trout and temperature have no effect on growth and survival.

- Model B: Survival of size class 1 humpback chub in the Colorado River is a logit linear function of rainbow trout abundance. Growth of all size classes in the Colorado River are logit linear functions of temperature with independent intercepts for each size class and a shared slope (a model with different slopes for each size class was considered, a posteriori, but this did not improve the fit considerably). Model B was based on the hypotheses that temperature is a primary control on growth rates and that rainbow trout mainly affect humpback chub by lowering the survival of juvenile humpback chub. This

does not mean that rainbow trout effects are solely predatory, as competition with trout could lead to lowered survival if humpback chub were forced to forage longer or in suboptimal habitat, leading to increased predation risk by species other than rainbow trout.

- Model C: As in Model B, but growth of size class 1 fish is a function of rainbow trout abundance in addition to temperature. Rainbow trout are hypothesized to affect humpback chub growth by forcing them into suboptimal habitats and directly consuming food resources that might otherwise be consumed by young humpback chub. This effect is likely to be greatest in young fish because they are frequently found in the nearshore environments that rainbow trout also prefer.

- Model D: As in Model C, but growth of size class 2 humpback chub is also a logit linear function of rainbow trout abundance in addition to temperature.

- Model E: As in Model B, but survival of size class 1 fish is a function of temperature in addition to rainbow trout abundance. Increased temperature is expected to increase the swimming ability of juvenile humpback chub, which should in turn aid them in avoiding predation by a variety of fish species in the system.

- Model F: A combination of Models C and E.

A general model structure modified from Yackulic et al. (2014) was used to fit a series of mark-recapture multistate models using maximum likelihood. For more technical details, see Yackulic et al. (2014). Yackulic et al. (2014) suggested three important features of humpback chub movement between the Little Colorado River and Colorado River:

1. Juveniles out-migrate from the Little Colorado River at a different and higher rate during July through September compared to the rest of the year,

2. Smaller and larger adults spawn at different rates, and

3. There is evidence for a resident Little Colorado River population.

The models that were considered include the first two of these elements, but ignore the third element. The third element is ignored because it would make simulations more difficult and is likely to only apply to a relatively small portion of the adult population (about 15%). Moreover, since the model only considers those fish that move into the mainstem, the movement dynamics of the system can be well represented without this detail.

Monthly temperatures were calculated using data from U.S. Geological Survey (USGS) gage 09383100 located on the Colorado River above the confluence with the Little Colorado River. Rainbow trout abundance in 2012 and 2013 was calculated by averaging trip estimates from the Natal Origins project within each year. Rainbow trout estimates for 2009–2011 were

back-calculated based on the relationship between the catch between RM 63.4 and RM 64.8 and the estimated abundance in the same area.

Models were fit using general-purpose optimization algorithms provided by "optim" in R (version 3.0.2) using the BFGS (Broyden, Fletcher, Goldfarb and Shanno) method[1] and were run until convergence of all models was obtained. The variance inflation factor (c-hat) was calculated based on model F, and models were compared using the quasi-Akaike's Information Criterion (qAIC) calculation.[2] Model selection based on qAIC favored model C (summarized in Figure F-7), and estimates from this model were used for further steps. Figure F-8 illustrates the estimated relationships between temperature and trout and various survival and growth parameters. The maximum likelihood estimates from these relationships were used for backcasting, while combinations of the draws from the multivariate normal and critical uncertainties were used to characterize these relationships in simulations conducted to compare LTEMP alternatives.

Recruitment Estimation

The one value needed for simulation that was not estimated in the model selection section is the mean annual recruitment, along with the variability around this mean. Annual recruitment is defined here as the number of YOY humpback chub present in the Little Colorado River in July. By July, most YOY are typically above 40 mm in total length. While some YOY will have left the Little Colorado River before this, several lines of evidence suggest that fish that leave the Little Colorado River before July do not contribute appreciably to population growth, given the temperature typically found in the Colorado River during May and June (Robinson and Childs 2001). Unfortunately, direct estimates of July YOY abundance in the Little Colorado River are not available. However, estimates from the Little Colorado River during September–October are available for 2001 through 2012 in Van Haverbeke et al. (2013), and were used here. The parameters estimated in the model should allow back-calculation of July YOY abundance in the Little Colorado River from the September abundance using the following formula:

$$N_J^1 = \frac{N_S^1}{\left[\emptyset^1\left(1-\omega_{JS}^1\right)\right]^2}$$

where N_J^1 is recruitment to state 1 in July, N_S^1 is recruitment to state 1 in September, ϕ^1 is the probability of survival during state 1 in the Little Colorado River, and ω_{JS}^1 is the probability of moving from the Little Colorado River to the mainstem Colorado River during the July-to-September period.

1 For details regarding the "optim" function in the "stats" package for Program R, see http://www.inside-r.org/r-doc/stats/optim.

2 For additional information, refer to http://www.inside-r.org/packages/cran/MuMIn/docs/QAIC.

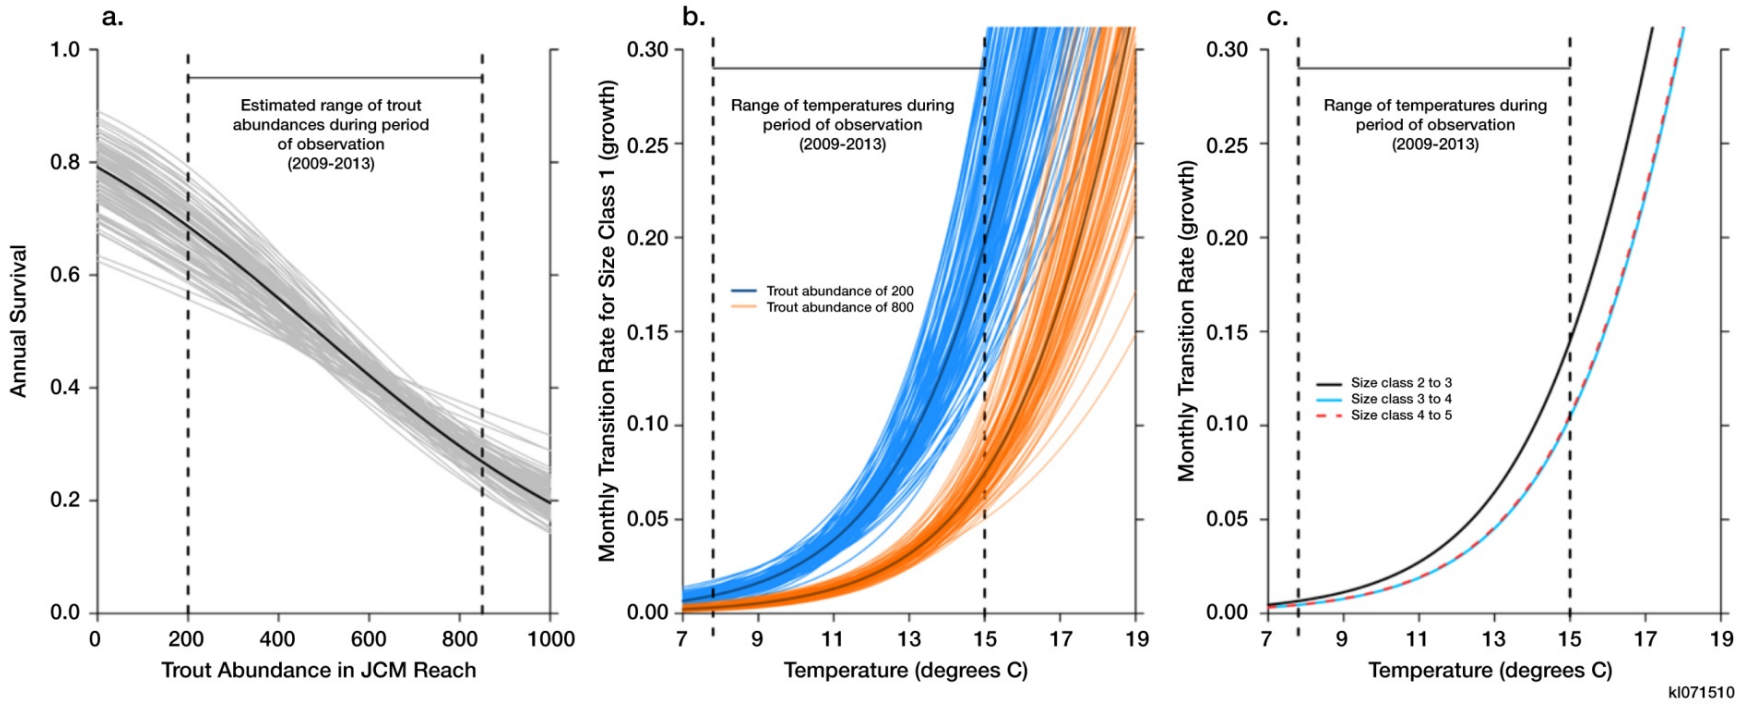

FIGURE F-8 Modeled Effects of Trout Abundance and Temperature on Humpback Chub Survival and Growth ([a] Annual survival of juvenile humpback chub [40–99 mm] declines relative to estimated trout abundance in the Colorado River; gray lines are based on 100 draws from a multivariate normal distribution based on maximum likelihood estimates and associated covariance matrix and give an indication of uncertainty around the maximum likelihood estimates in black. [b] Monthly size transition rates [proportional to growth] as a function of temperature with trout abundance set at either 200 or 800; as in panel [a], dark lines indicate best estimates and lighter lines are draws from a multivariate normal distribution giving an indication of uncertainty. [c] Dependence of size transition rates [growth] for larger fish on temperature. Note that relationships have a common slope but different intercepts. Uncertainty in these rates is comparable to the uncertainty around either of the curves in panel [b], with slightly more uncertainty around the intercept associated with the transition from size class 4 to size class 5.)

However, this approach is based on estimates of the monthly probability of size class fish moving from the Little Colorado River during the July–August and August–September intervals, ω_{JS}^1. Unfortunately, this is the parameter in the multistate model that is most likely to be biased because of details of sampling. In short, until 2013, all July and August marking of humpback chub at the Little Colorado River was limited in its spatial extent to an area near the confluence, which is likely to have a higher rate of export than the Little Colorado River as a whole. Moreover, over two-thirds of the marked fish were marked in 2011 and 2012, years that exhibited large increases in the abundance of size class 1 humpback chub in the juvenile chub monitoring (JCM) reach, thereby suggesting higher export (see Yackulic et al. [2014] for a full discussion). Last, both July recruitment, N_J^1, and movement out of the Little Colorado River, ω_{JS}^1, may exhibit substantial interannual variability (in comparison to, say, adult survival), even though the limited number of marked fish released in July and August into the Little Colorado River in 2009 through 2012 does not allow us to estimate interannual variability in our models.

Therefore, a different approach was taken that is based on the estimated increase in size class 1 abundance in the JCM reach between July and September, as well as the estimated proportion of humpback chub in the JCM reach, τ, and survival rates in both the Little Colorado River, ϕ^1, and Colorado River, ϕ^6. (Note that humpback chub in size class 1 in the Colorado River are frequently 2 or more years old, whereas almost all size class 1 fish caught in the Little Colorado River in the fall are YOY fish). This approach involved solving the following equations for N_J^1 and ω_{JS}^1 for each year:

$$N_J^1 = \frac{N_S^1}{\left[\emptyset^1\left(1-\omega_{JS}^1\right)\right]^2}$$

and

$$N_J^1 = \frac{N_S^6 - N_J^6 \times \emptyset^6 \times \emptyset^6}{\left[\emptyset^1 \times \omega_{JS}^1 \times \emptyset^6 + \emptyset^1 \times \left(1-\omega_{JS}^1\right) \times \emptyset^1 \times \omega_{JS}^1\right] \times \tau}$$

This approach was applied to abundance estimates from 2009 to 2012 and resulted in estimated values of ω_{JS}^1 of 0.15, 0.28, 0.45, and 0.52 (mean, 0.35), with associated values of N_J^1 of 5,000, 17,000, 45,000, and 35,000 (mean, 25,000). Another aspect of recruitment highlighted in Van Haverbeke et al. (2013) is that in years with low runoff between January 1 and May 31, there appears to be weak recruitment, at least in terms of the number of YOY remaining in the Little Colorado River in the fall. Six years between 1990 and 2013 meet this criterion (1990, 1996, 1999, 2000, 2002, and 2006).

When backcasting historical trends, the mean values across years for both ω_{JS}^1 and N_J^1 were used, with the exception of "weak recruitment years" in which recruitment was assumed to be 2,500, based on an examination of estimates in Van Haverbeke et al. (2013). For forecasting, "weak" versus "strong" recruitment years were modeled as a Bernoulli process in which weak years occur with a probability of 0.25 (based on the observed frequency of these hydrologic conditions in the Little Colorado River from 1990 to 2013). For "strong" years, annual

recruitment values were drawn from a uniform distribution between 0 and 50,000. For both "strong" and "weak" years, out-migration was chosen randomly from a uniform distribution between 0.15 and 0.55.

Performance Metrics from Humpback Chub Population Submodel

The resource goal identified for humpback chub is to "meet humpback chub recovery goals including maintaining a self-sustaining population, spawning habitat, and aggregations in the humpback chub's natural range in the Colorado River and its tributaries below the Glen Canyon Dam" (EIS Section 1.4). The humpback chub population submodel was used to calculate an estimate of the number of adult (i.e., >200 mm total length) humpback chub that would be present in the aggregation associated with the Little Colorado River for each year of a 20-year simulation period. In order to evaluate and compare the potential for alternatives and long-term strategies to lead to extinction or improvement of the humpback chub population in the Grand Canyon, the modeled minimum number of adult humpback chub that would occur during each 20-year simulation period was used as the performance metric.

Evaluating Model Predictions

Humpback chub population dynamics were backcasted using maximum likelihood estimates of parameters (see "Model Selection and Development" section), with the exception of the parameters related to recruitment and juvenile out-migration from the Little Colorado River (see "Recruitment Estimation" section) and an initial vector of abundances by state. Initially dynamics were simulated using a monthly time step; however, the time scale was coarsened to 6-month intervals so as to minimize potential issues related to numerical diffusion. This was accomplished by calculating a 6-month transition matrix and then removing any transitions of more than one size class and adding these to the cells corresponding to a one size class transition. The initial structure of the population was based roughly on estimates from 2009 to 2012. For the Little Colorado River, abundance by size classes 1–5 was 4,000, 2,500, 1,800, 1,200, and 800, respectively, while corresponding Colorado River abundances by size were 20,000, 7,000, 5,500, 4,000, and 5,000. The simulation model was also provided a 20-year sequence of observed temperature near the Little Colorado River between 1990 and 2009, as well as predictions of trout abundance for this period that resulted from the Glen Canyon trout and trout movement submodels (Sections F.3.1.1 and F.3.1.1, respectively). While the backcasted simulation (Figure F-9) suggests a later decline than the Age-Structured Mark Recapture (ASMR) estimates (Coggins and Walters 2009), followed by a quicker recovery, the patterns are remarkably similar, given that parameters from the simulation model were derived primarily from a more recent period (2009–2013). Moreover, the ASMR estimation method is known to have some biases (Coggins and Walters 2009), so minor discrepancies are expected.

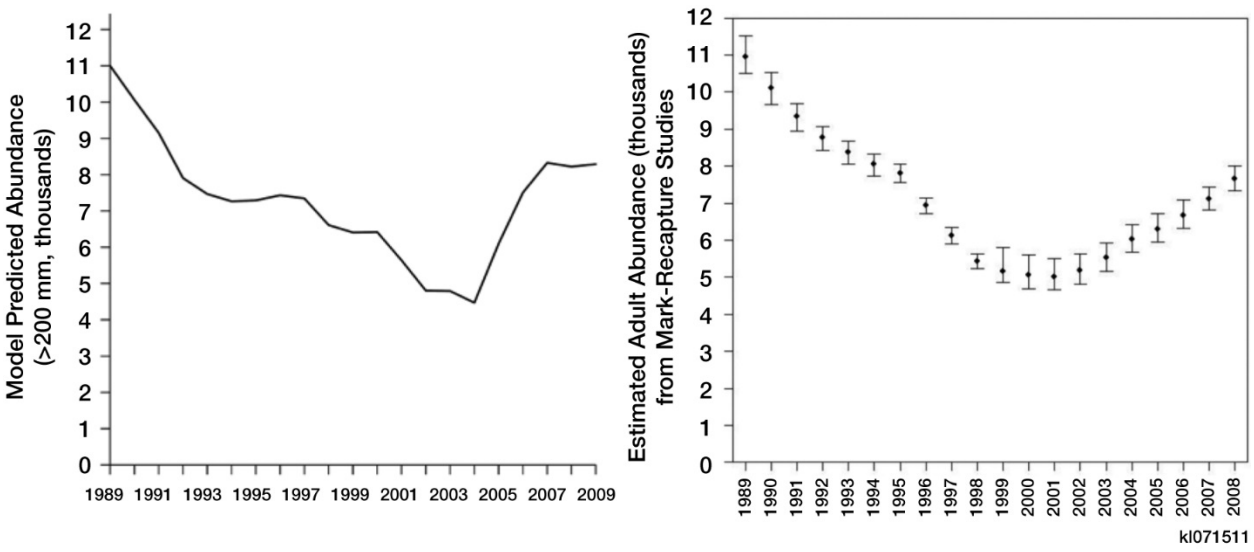

FIGURE F-9 Simulated Adult Abundances from Backcasted Model (left) Compared to Patterns Reported in Coggins and Walters (2009) (right)

Model Uncertainties

The model described here is based on the best available information and does a good job of backcasting the dynamics of humpback chub populations for a period of time (1990–2008) that is separate from the period of time (2009–2012) over which most parameters were estimated. However, like all models, it is only a representation of the actual system it seeks to describe. There are a number of conditions that could lead to dynamics in humpback chub populations that are different from those predicted with the model. Some of these conditions are listed here, in no particular order:

- No portion of this model explicitly models short- or long-term impacts of flows or temperature on the aquatic food base. Flow, particularly an increased frequency of flooding, has the potential to permanently change the composition of the invertebrate assemblage, as has been observed in other regulated rivers (Robinson 2012; also see Section F.2). This shift could be beneficial for both rainbow trout and humpback chub resources, positive for one and negative for the other, or detrimental to both, and initial impacts may differ from long-term consequences. Similar, unpredictable shifts in the invertebrate assemblage could also occur because of long-term changes in release temperatures associated with climate change and lower Lake Powell reservoir elevations.

- Temperature–growth relationships estimated here are based on a relatively short period of record and do not consider seasonal patterns in food availability, light, and turbidity. As such, the humpback chub submodel assumes a temperature of 11°C (52°F) observed in clear water in June during

midge emergence will lead to the same growth as a temperature of 11°C (52°F) in August in turbid water. Moreover, monthly mean temperatures at the Little Colorado River confluence from 2009 to 2013 peaked at roughly 15°C (59°F), suggesting that modeling the effects of substantially warmer temperatures on humpback chub populations represents an extrapolation. On the other hand, the model did a reasonable job of backcasting dynamics during the 1990–2009 era, even though monthly temperatures reached 16.7°C (62°F) in one year (2005).

- The humpback chub model does not consider the potential effects of other fish species besides rainbow trout that are already relatively common in the system and known to eat humpback chub (e.g., brown trout and various catfish species), nor does it attempt to account for the negative effects of other warmwater nonnative fishes that could become prevalent if temperatures above 16°C (61°F) become common. Potential effects of cannibalism by humpback chub are also not directly considered by the model.

- Climate change could lead to increases in the proportion of "weak" recruitment years in the Little Colorado River, particularly if winter precipitation in the Little Colorado River watershed becomes less frequent.

F.3.2 Results for LTEMP Alternatives

The results for the rainbow trout-humpback chub model for each of the alternatives (including associated long-term strategies) are summarized in the following sections. Values for the means of the six metrics resulting from the model are summarized in Table F-8. The magnitude of effects on rainbow trout and humpback chub populations are estimated using the performance metrics identified in Sections F.3.1.1, F.3.1.2, and F.3.1.3.

F.3.2.1 Rainbow Trout Performance Measures

This section summarizes the results for the performance measures for rainbow trout that were derived from the rainbow trout-humpback chub model.

Rainbow Trout Population Estimates

The rainbow trout population estimates for the 19 LTEMP alternatives and associated long-term strategies are summarized in Figure F-10. Among all of the long-term strategies evaluated, the modeled average abundance of age-1 (i.e., individuals that are 1 year old) and older rainbow trout during the simulations of 20-year LTEMP periods ranged from about 48,000 to 242,000 individuals in the Glen Canyon reach. Overall means (i.e., mean abundance for all simulations) for the various long-term strategies ranged from approximately 61,000 individuals under long-term strategy E6 to approximately 160,000 individuals under Alternative F

(Table F-8; Figure F-10). The differences among the modeled population levels for rainbow trout reflect the estimated levels of annual recruitment based on the empirically derived flow-dependent regressions in the model that predict that annual recruitment of rainbow trout will increase as a function of greater annual volumes, reduced daily variation in flow between May and August, the occurrence of spring HFEs, and implementation of management actions (i.e., TMFs) that would decrease annual survival of YOY trout (see "Recruitment" in Section F.3.1.1) in high-recruitment years. Table 4.1-1 identifies the experimental elements included in the various long-term strategies, and Appendix E of this EIS describes the number and duration of HFEs that would be expected under the various long-term strategies.

Although there is a considerable amount of overlap in the ranges of the estimates for some long-term strategies, the overall modeled average rainbow trout abundance in the Glen Canyon reach was greatest under long-term strategies C2, C4, and D3, and Alternatives F and G. With the exception of Alternative G, all of these long-term strategies implement spring HFEs and would have steadier flows (at least for the May–August portion of the year) than Alternative A and would not include implementation of TMFs. Although Alternative G would include implementation of TMFs, the annual production of trout would be expected to be very high due to a high proportion of years with HFEs and the steady pattern of flows that would be

TABLE F-8 Summary of Metrics Values from the Rainbow Trout-Humpback Chub Model[a]

Alternatives and Long-Term Strategies	Trout Abundance	Number of Trout ≥16 in. Total Length	Catch Rates (fish/hr)	Number of Out-migrants (fish/year)	Number of Years with Trout Management Flows	Number of Years with Mechanical Removal	Minimum Humpback Chub Population

[a] Mean values for 63 modeled hydrology–sediment conditions.

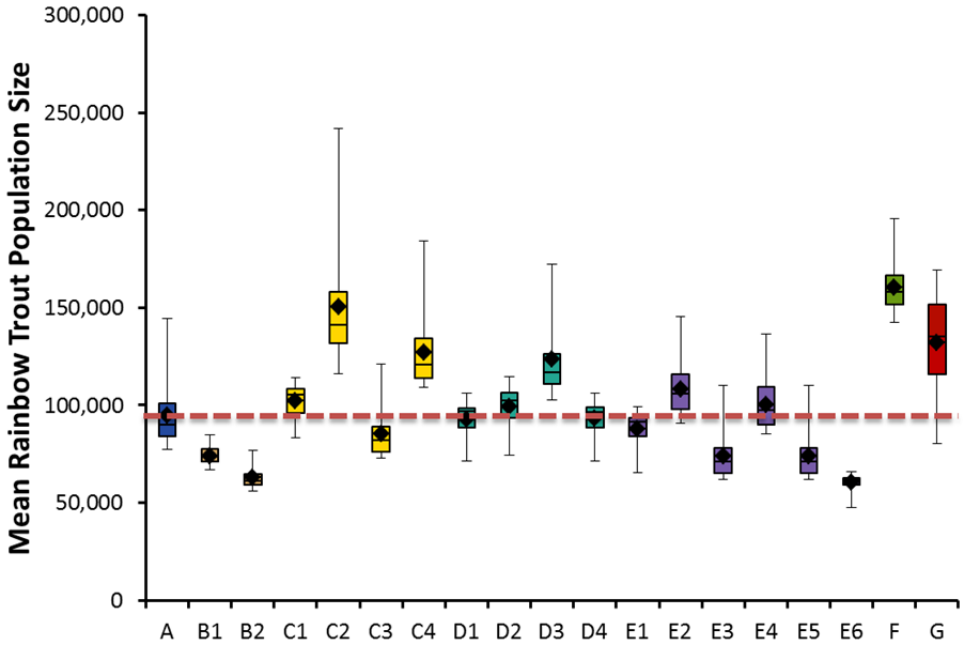

FIGURE F-10 Modeled Average Population Size of Age-1 and Older Rainbow Trout in the Glen Canyon Reach during the 20-year LTEMP Period under LTEMP Alternatives and Long-Term Strategies (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

maintained throughout the year without monthly differences in flow (other than those needed to adjust operations in response to changes in forecast and other operating requirements such as equalization); even at the highest evaluated levels of effectiveness for TMFs (50% reduction in age-0 trout), average annual recruitment would be expected to be quite high under Alternative G.

The overall modeled average rainbow trout abundance in the Glen Canyon reach was lowest under long-term strategies B1, B2, E3, E5, and E6. These long-term strategies generally would not allow spring HFEs (e.g., long-term strategies E3, E5, and E6) or would be expected to have considerably fewer HFEs during the LTEMP period (e.g., long-term strategies B1and B2) than other long-term strategies, would maintain levels of fluctuations in flow similar to or greater than Alternative A, and (with the exception of long-term strategies E3 and E5) would implement TMFs. Thus, average annual recruitment levels would be expected to be lowest under these alternatives.

Modeled levels of trout abundance were intermediate and similar to Alternative A under long-term strategies C1, C3, D1, D2, D4, E1, E2, and E4. These long-term strategies generally included implementation of combinations of flow actions that would be expected to result in intermediate levels of trout recruitment (e.g., no spring HFEs in all or a portion of the LTEMP

period together with higher levels of fluctuation) or included TMFs that would function to control recruitment in years with high levels of trout production (e.g., years with HFEs).

Abundance of Rainbow Trout >16 in. Total Length

The modeled abundance of large rainbow trout in the Glen Canyon reach (i.e., trout that would be larger than 16 in. total length) under LTEMP alternatives are summarized in Figure F-11. Among all the long-term strategies evaluated, the modeled abundance of these larger trout during the simulations of 20-year LTEMP periods ranged from 480 to 1,039 individuals (Figure F-11). Overall modeled means (i.e., mean number of large trout for all simulations) for the various long-term strategies ranged from 592 large fish under Alternative F to 956 large fish under long-term strategy E6 (Table F-8; Figure F-11). Compared to Alternative A, the model suggested that long-term strategies C2, C4, and D3, and Alternatives F and G would have fewer large trout; long-term strategies D1, D4, E1, and E4 would have similar numbers of large trout; and the remaining long-term strategies would have greater numbers of

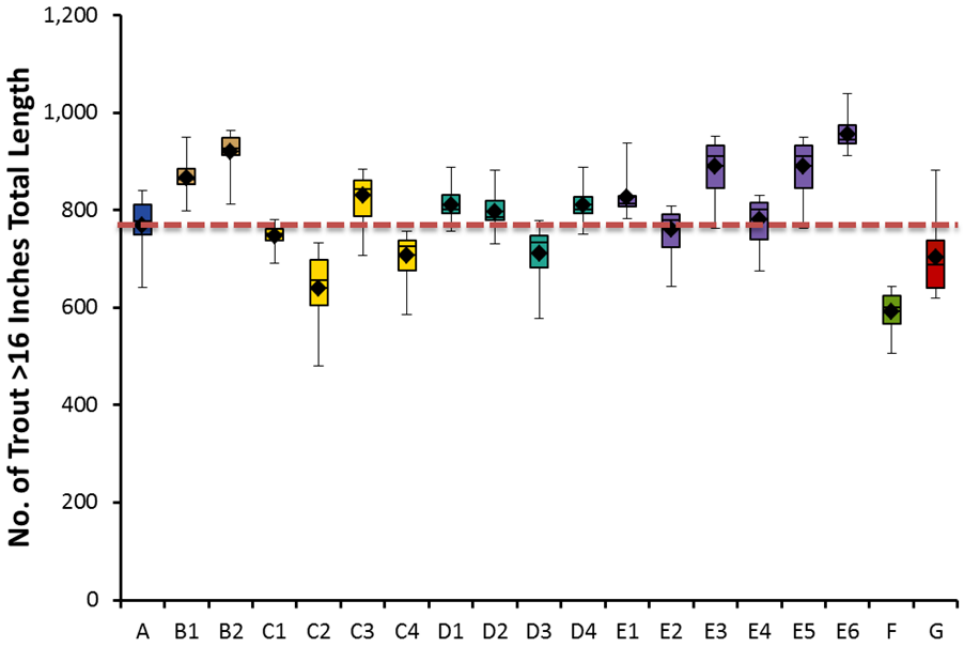

FIGURE F-11 Modeled Mean Annual Number of Rainbow Trout in the Glen Canyon Reach Exceeding 16 in. Total Length during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

large trout (Figure F-11). It is generally expected that the average size of rainbow trout in the population would be inversely proportional to the average population size because of the effects of trout density on growth rates due to competition for food and other resources; this was supported when the modeled results for average number of large trout were compared to the average number of trout in the Glen Canyon reach (Figure F-12). Because of their effect on lowering recruitment levels and population size, long-term strategies (such as long-term strategies B2 and E6) that have fewer HFEs and higher daily fluctuations, and that implement TMFs, are expected to have a greater number of large trout. Table 4.1-1 identifies the experimental elements included in the various long-term strategies, and Appendix E of this EIS describes the number and duration of HFEs that would be expected under the various long-term strategies.

Trout Catch Rates

The modeled angler catch rates for rainbow trout in the Glen Canyon reach under the LTEMP alternatives and long-term strategies are shown in Figure F-13. Modeled average catch rates during the simulations of 20-year LTEMP periods ranged from approximately 1.1 fish/hr to

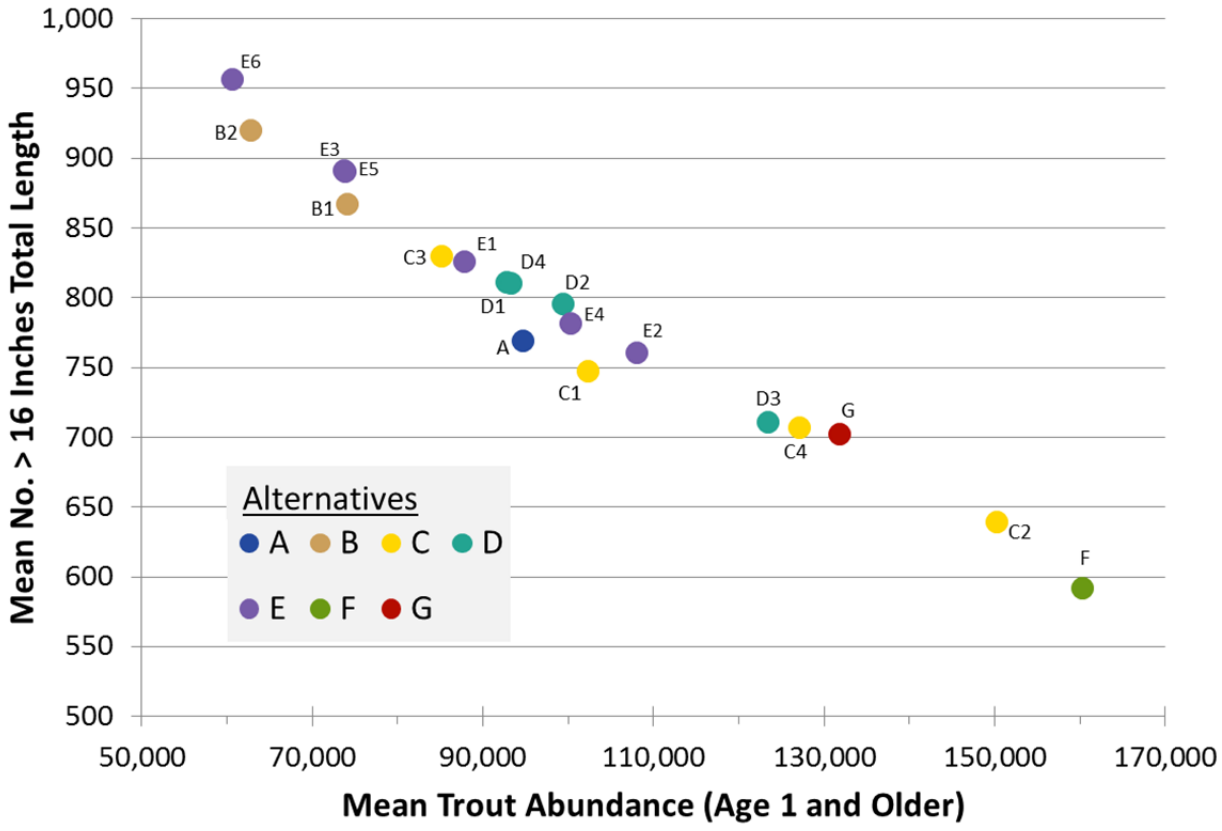

FIGURE F-12 Relationship between Modeled Mean Rainbow Trout Abundance in the Glen Canyon Reach and the Mean Number of Rainbow Trout Exceeding 16 in. Total Length during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies

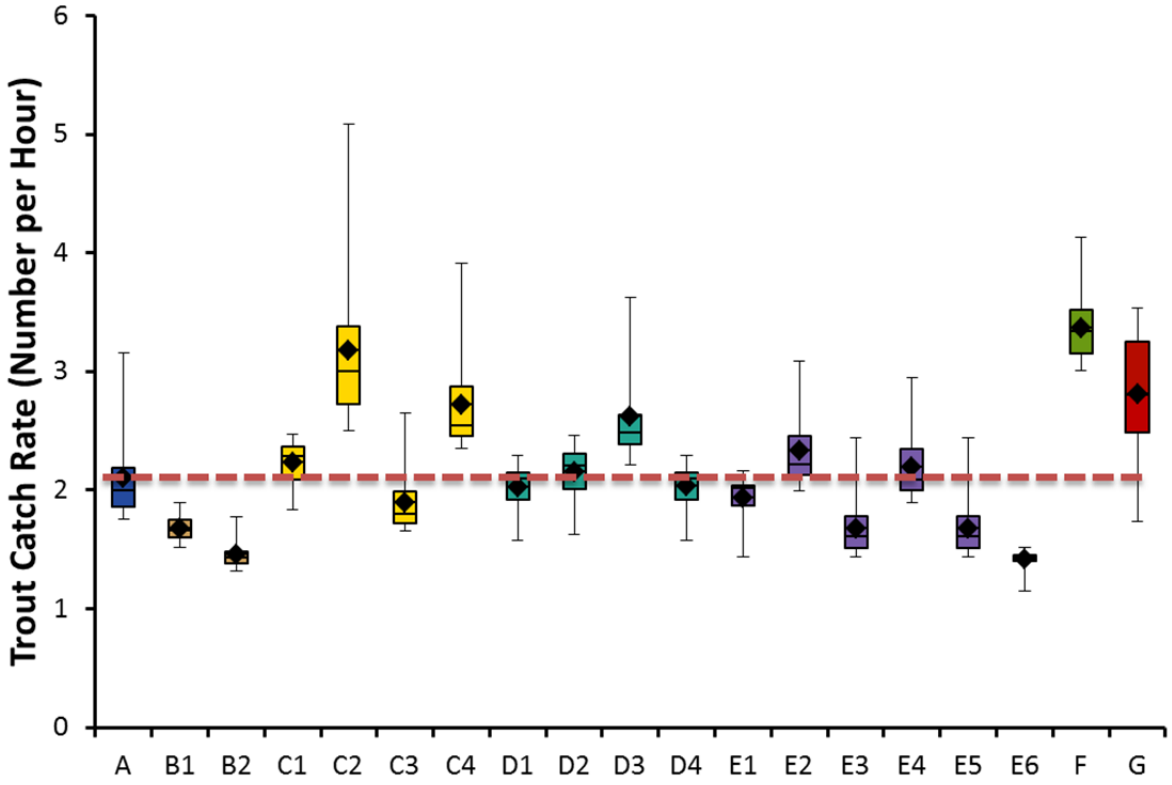

FIGURE F-13 Modeled Mean Annual Angler Catch Rate for Rainbow Trout in the Glen Canyon Reach during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

5.1 fish/hr (Figure F-13). Modeled mean catch rates (i.e., mean catch rates for all simulations) ranged from 1.4 fish/hr under long-term strategy E6 to 3.4 fish/hr under Alternative F (Table F-8; Figure F-13). Compared to Alternative A, the model indicated that long-term strategies B1, B2, C3, E1, E3, E5, and E6 would have lower catch rates; long-term strategies C1, D1, D2, D4, and E4 would have similar catch rates; and long-term strategies C2, C4, D3, and E2, and Alternatives F and G would have higher catch rates (Figure F-13). Although the modeled vulnerability of individual trout to angling varies depending on the age of the trout, modeled average angler catch rates are highly correlated with average population levels of the long-term strategies, as shown in Figure F-14.

For this reason, the same combinations of experimental elements that drive recruitment levels and affect rainbow trout abundance would be expected to drive angler catch rates (see "Recruitment" in Section F.3.1.1 and "Rainbow Trout Population Estimates" in Section F.3.2.1). Thus, long-term strategies that result in more frequent HFEs (especially spring HFEs) have steadier flows and do not include TMFs (e.g., Alternatives F and G and long-term strategies C2

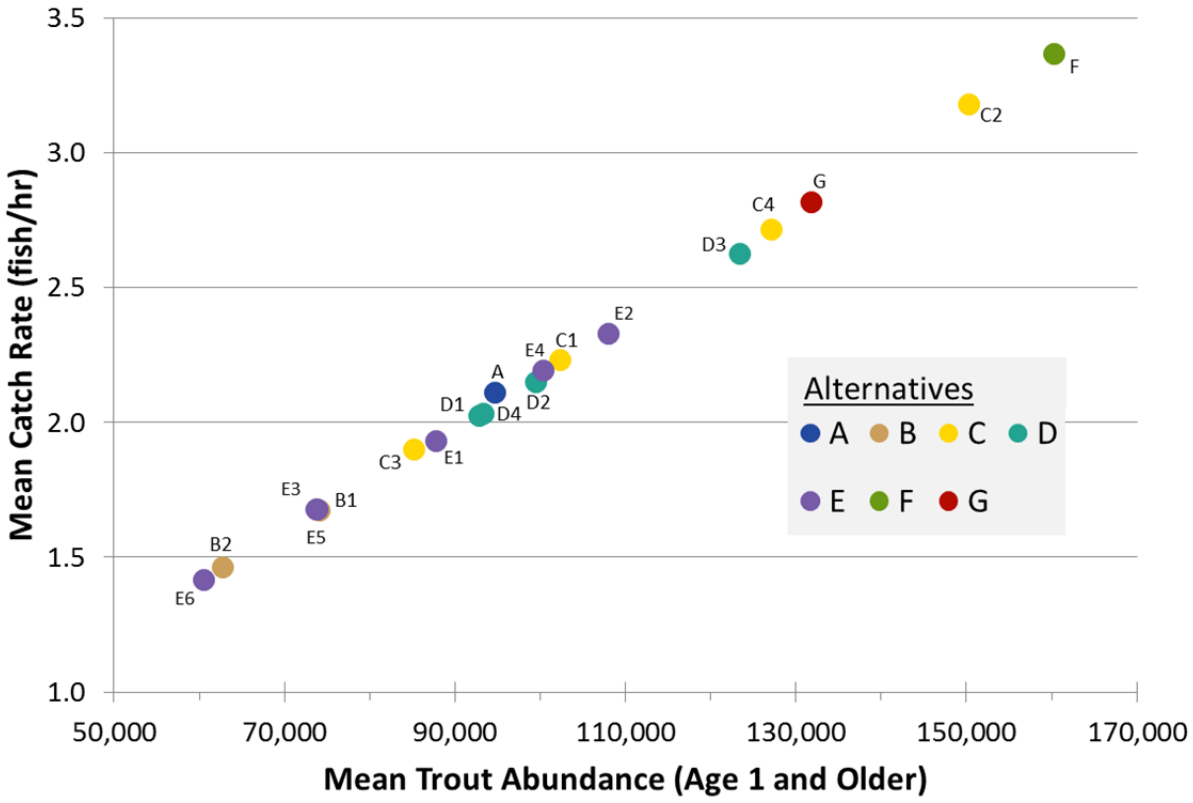

FIGURE F-14 Relationship between Modeled Mean Rainbow Trout Abundance in the Glen Canyon Reach and Mean Angler Catch Rates during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies

and D3) would be expected to have higher trout numbers and would lead to greater angler catch rates for rainbow trout, while long-term strategies that have fewer HFEs, more variable flows, and include TMFs (e.g., long-term strategies B1, B2, and E6) would be expected to have lower trout abundance and lower mean angler catch rates. Table 4.1-1 identifies the experimental elements included in the various long-term strategies, and Appendix E of this EIS describes the number and duration of HFEs for each.

Trout Emigration

The modeled number of trout emigrating (i.e., number of out-migrants) from the Glen Canyon reach into the Marble Canyon reach of the Colorado River under the LTEMP alternatives and long-term strategies are summarized in Figure F-15. Modeled annual number of out-migrants ranged from approximately 18,200 fish/year to 114,900 fish/year (Figure F-15). The modeled mean annual number of out-migrants (i.e., mean number of out-migrants for all simulations) ranged from 22,415 fish/year under long-term strategy E6 to 71,869 fish/year under Alternative F (Table F-8; Figure F-15). Compared to Alternative A, the model indicated that long-term strategies B1, B2, E3, E5, and E6 would have lower numbers of out-migrants; long-term strategies C3 and E1 would have similar numbers of out-migrants; and long-term strategies

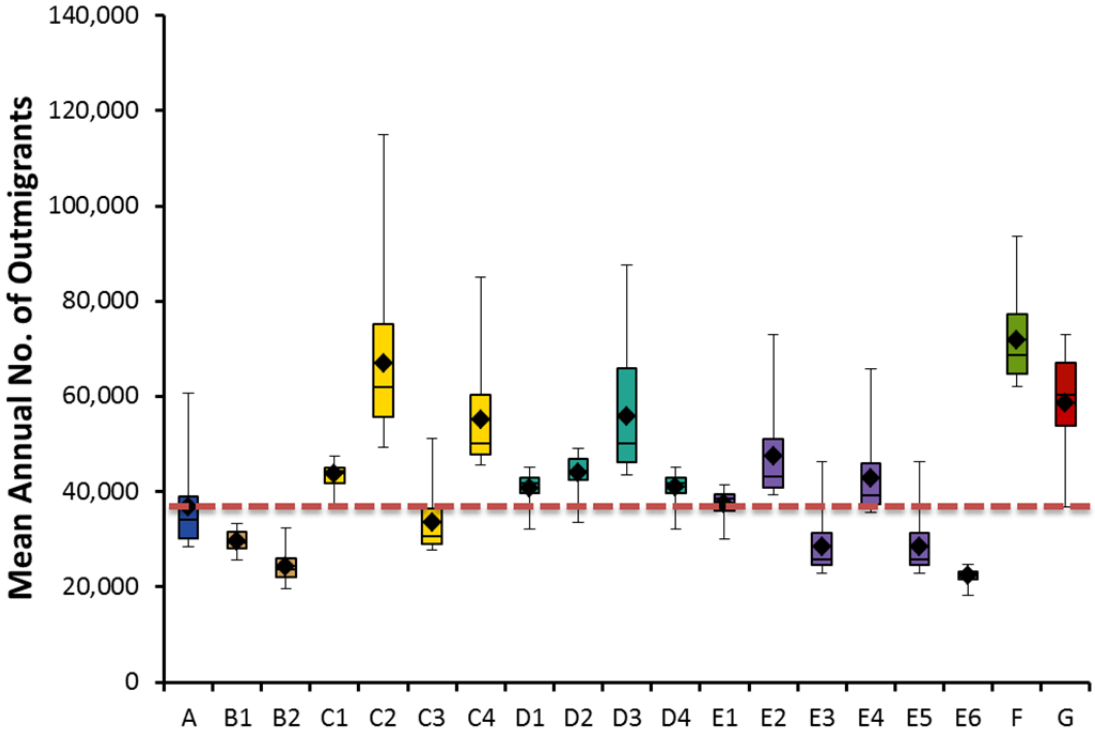

FIGURE F-15 Modeled Annual Average Number of Rainbow Trout Emigrating into the Marble Canyon Reach from the Glen Canyon Reach during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

C1, C2, C4, D1, D2, D3, D4, E2, E4, and Alternatives F and G would have higher numbers of out-migrants (Figure F-13).

As described in Section F.3.1.1, the annual number of trout emigrating from Glen Canyon into Marble Canyon was calculated as a function of the level of trout recruitment during the previous year. Thus, long-term strategies that result in more HFEs (especially spring HFEs), less variability in flows, and do not include TMFs (e.g., Alternatives F and G and long-term strategies C2, C4, D3, and E2) had higher modeled levels of trout emigration than long-term strategies with fewer HFEs, more variable flow regimes, and included TMFs (e.g., long-term strategies B1, B2, and E6). Table 4.1-1 identifies the experimental elements included in the various long-term strategies, and Appendix E of this EIS describes the number and duration of HFEs that would be expected under each.

Mechanical Removal of Trout in the Little Colorado River Reach

The modeled frequency of years in which mechanical removal of trout would be triggered in the Little Colorado River reach under the LTEMP alternatives and long-term strategies is summarized in Figure F-16. Mechanical removal is not included under long-term strategies C1, C2, E1, E2, E5, and E6, and Alternative F. Among the remaining long-term strategies, the average number of years in which mechanical removal was triggered ranged from approximately 0.1 under Alternative A to approximately 3.1 under Alternative G (Table F-8; Figure F-16). The average maximum number of years in which mechanical removal would be triggered is 6.3 out of 20 years under long-term strategy D3. In general, long-term strategies that result in more frequent HFEs (especially spring HFEs), have steadier flows, and do not include TMFs (e.g., Alternatives F and G and long-term strategies C2, C4, and D3) have higher levels of recruitment, increase the number of trout that move downstream to the Little Colorado River reach, and meet conditions in the model that trigger mechanical removal of trout with a greater frequency. Long-term strategies that result in fewer HFEs and more variable flow levels (e.g., long-term strategies B1, B2, and E6) have lower levels of trout recruitment on average; inclusion of TMFs acts to further decrease the potential for large recruitment events. As a consequence, these long-term strategies result in lower numbers of trout entering the Little Colorado River reach and fewer years when mechanical removal is triggered. Table 4.1-1 identifies the experimental elements included in the various long-term strategies, and Appendix E of this EIS describes the number and duration of HFEs that would be expected under each.

F.3.2.2 Humpback Chub Performance Measures

The modeled minimum population sizes for humpback chub adults under the LTEMP alternatives and long-term strategies are summarized in Figure F-17. Modeled minimum adult population sizes ranged from 1,433 to 13,478 fish (refer to upper and lower whiskers in Figure F-17). Overall modeled means (i.e., mean minimum number of adult humpback chub for all simulations) ranged from 4,450 individuals under Alternative F to 5,708 individuals under long-term strategy E6 (Table F-8; refer to diamonds in Figure F-17). The lowest modeled minimum adult population size (1,433 fish) was observed under long-term strategy C2, and the highest modeled minimum adult population size was observed under long-term strategy E6, although the lowest minimum adult population values were relatively similar among all long-term strategies (refer to lower whiskers in Figure F-17). Compared to Alternative A, the model indicated that long-term strategy C2 and Alternative F would have somewhat lower mean minimum adult population sizes; long-term strategies C1, C4, D1, D2, D3, D4, E1, E2, E4 and Alternative G would have similar mean minimum adult population sizes; and long-term strategies B1, B2, C3, E3, E5, and E6 would have higher mean minimum adult population sizes (Figure F-17). These results indicate that although there are small differences among the long-term strategies with regard to the predicted minimum number of adult humpback chub in the Little Colorado River aggregation, all long-term strategies would likely maintain the population above at least 1,000 adults throughout the 20-year LTEMP period.

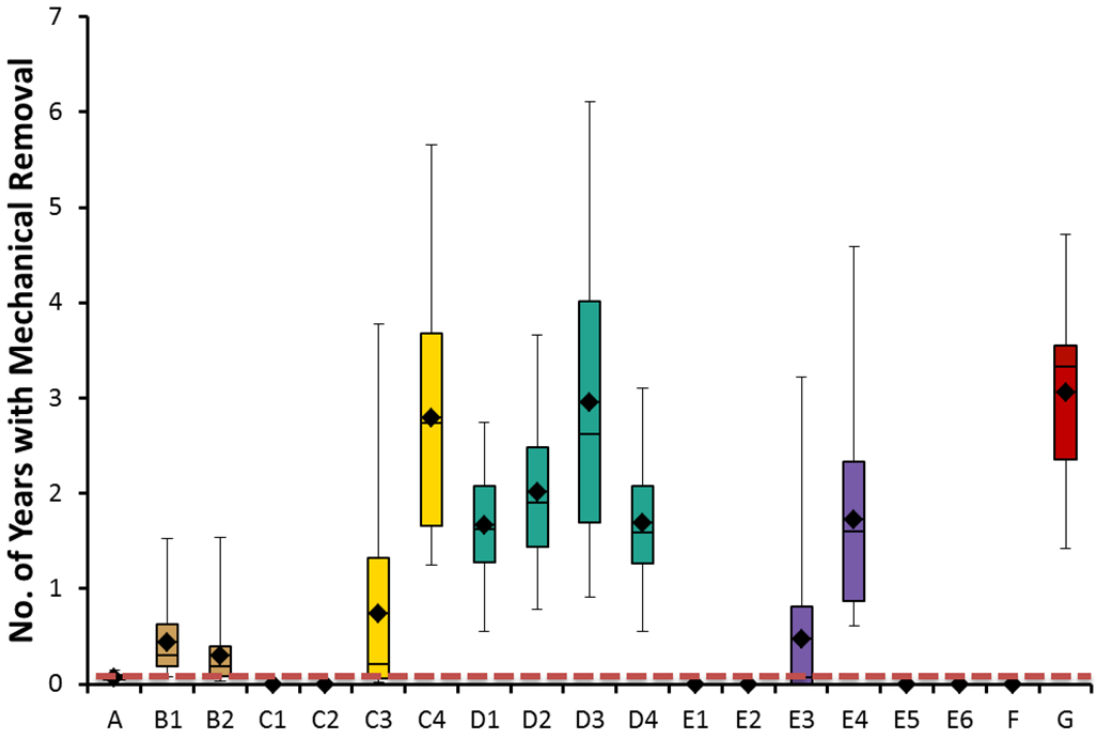

FIGURE F-16 Modeled Frequency of Triggered Mechanical Removal for Rainbow Trout in the Little Colorado River Reach during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

In the humpback chub submodel, the factors that affect annual recruitment and survival of humpback chub are mainstem water temperatures and the number of trout in the Little Colorado River reach (Section F.3.1.3). Because there is little variation among the long-term strategies in modeled mainstem water temperatures at the confluence with the Little Colorado River, the differences in modeled numbers of adult humpback chub among the long-term strategies were primarily affected by the estimated abundance of trout in the Little Colorado River reach where survival of age-0 and juvenile humpback chub and subsequent recruitment of adult humpback chub could be affected by increased competition and predation (e.g., Yard et al. 2011). Because the modeled abundance of trout in the Little Colorado River reach is driven by modeled emigration of rainbow trout from the Glen Canyon reach, there is a strong relationship between the average adult humpback chub population size and the average number of trout emigrating from the Glen Canyon reach for the various long-term strategies (Figure F-18). Refer to the section above entitled "Trout Emigration" for information about the experimental elements of long-term strategies that affect the levels of trout emigration. Although the model predicts that

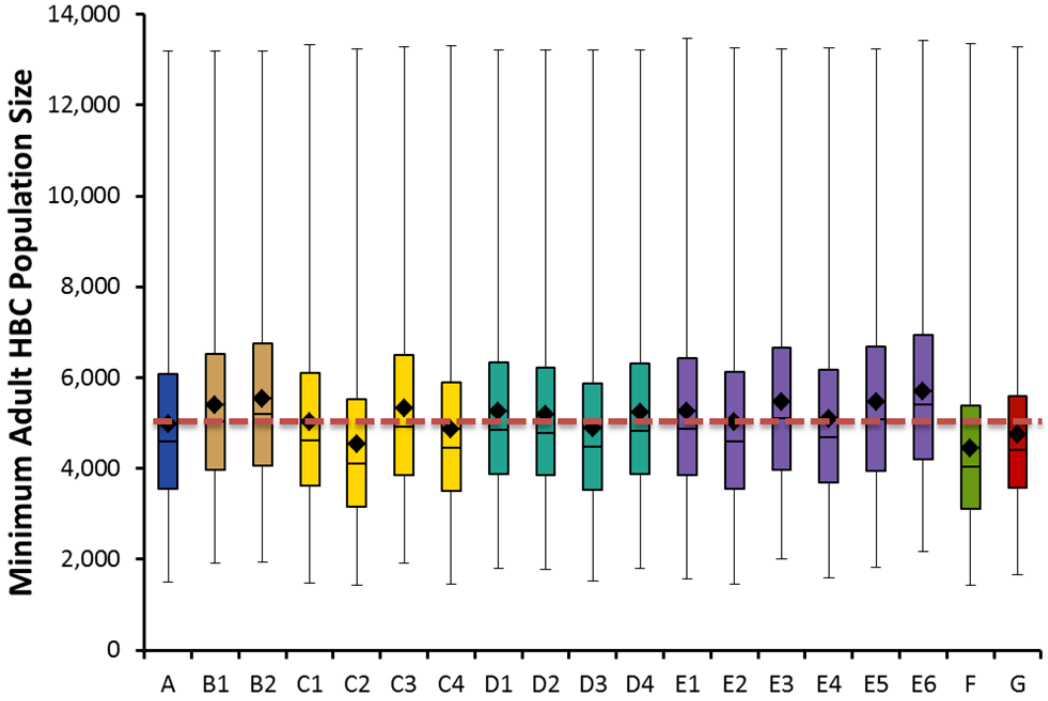

FIGURE F-17 Modeled Minimum Population Size for Humpback Chub (HBC) during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum annual value for all simulations; upper whisker = maximum annual value for all simulations; horizontal dashed line identifies mean value for Alternative A.)

the number of trout at the confluence with the Little Colorado River is related to trout recruitment in the Glen Canyon reach, the actual relationship is unclear and still under investigation.

F.4 MODELING THE EFFECTS OF LTEMP ALTERNATIVES ON TEMPERATURE SUITABILITY

This section describes the modeling approach used to evaluate the effects of LTEMP EIS alternatives on temperature suitability for fishes and invertebrate parasites in the mainstem Colorado River downstream of Glen Canyon Dam. The goal of the temperature suitability modeling was to evaluate the potential for each of the alternatives to result in temperature conditions that would promote maintenance and/or establishment of various fish and invertebrate

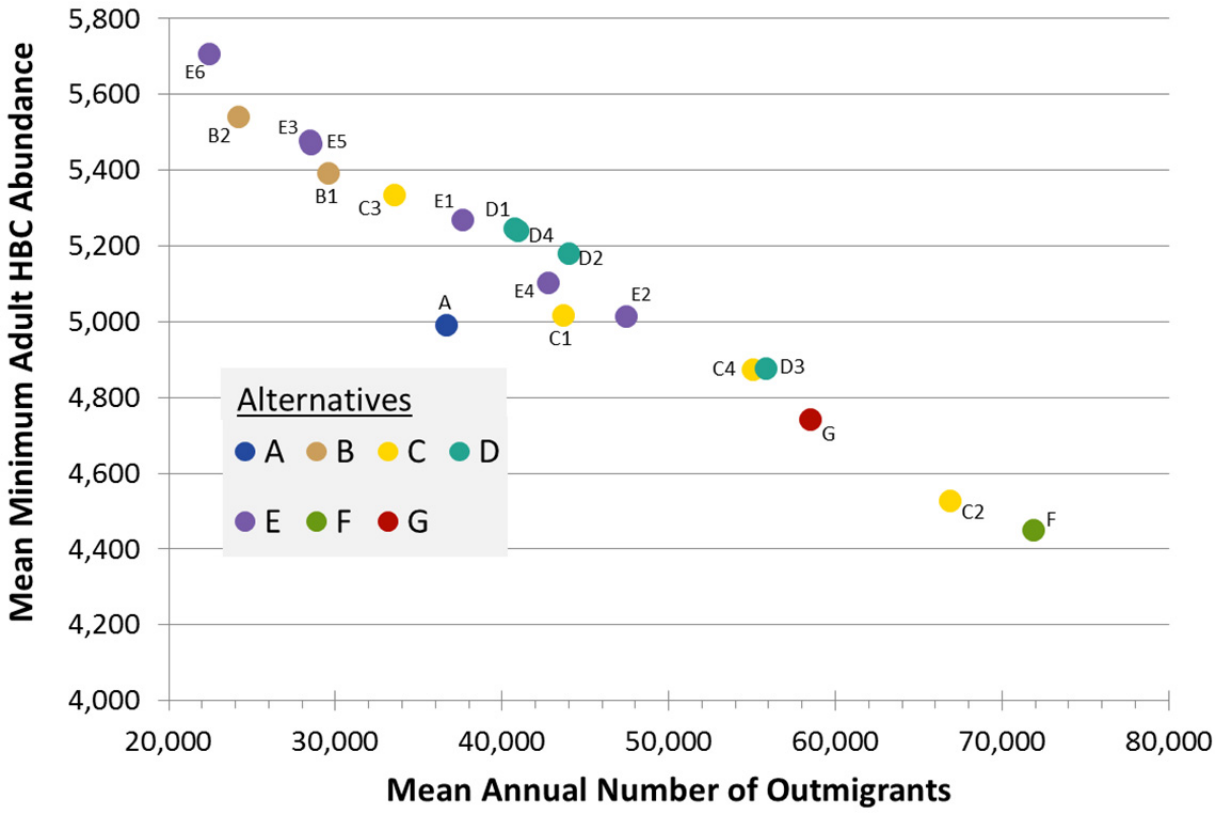

FIGURE F-18 Relationship between Modeled Mean Numbers of Rainbow Trout Out-migrants from the Glen Canyon Reach and the Modeled Mean Minimum Abundance of Adult Humpback Chub during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies

species of management concern. In particular, the temperature suitability modeling is intended to evaluate effects of alternatives on temperature suitability for four species groups:

1. Temperature suitability for establishment and maintenance of self-sustaining aggregations of humpback chub at various river locations in the Colorado River downstream of Glen Canyon Dam;

2. Temperature suitability for establishment and maintenance of self-sustaining populations of native warmwater fish other than humpback chub at various locations in the Colorado River downstream of Glen Canyon Dam;

3. Temperature suitability for establishment and maintenance of self-sustaining populations of nonnative fish species at various locations in the Colorado River downstream of Glen Canyon Dam; and

4. Temperature suitability for establishment and maintenance of self-sustaining populations of parasitic invertebrate species at various locations in the Colorado River downstream of Glen Canyon Dam.

The following sections describe the general modeling approach for evaluating temperature suitability, specific modeling considerations applied in order to implement the modeling approach for each of the species groups to be evaluated, the input data needs and sources for each of the ecological components, and the approach for statistically evaluating the output of the models in order to compare the effects of the various operational alternatives on temperature suitability for each species group.

F.4.1 Model Overview

In general, the temperature suitability modeling considers how well mainstem water temperatures at selected locations downstream of Glen Canyon Dam would meet the temperature requirements for three life history components—spawning, egg incubation, and growth—for each species group evaluated. To accomplish this, monthly water temperature values in a multiyear time series were compared to temperature suitability profiles for life history components of each species group considered. The seasonal timing or period of the year during which the temperature needs for each life history component must be met is taken into account by the model. Possible values for temperature suitability can theoretically range from 0 (completely unsuitable for one or more life history component) to 1 (magnitude and timing of temperatures would be optimal for all life history components). However, since optimal conditions for all life history components cannot be simultaneously met in many cases due to different optimal temperatures during overlapping time frames, the maximum attainable value for a given species would generally be less than one.

The temperature suitability modeling evaluates the potential for all life history components to be met in the mainstem river, even though some species are known to sometimes use tributaries to accomplish particular needs. Thus, the model can predict relatively low temperature suitability for some areas even though species populations appear to be abundant and self-sustaining. In addition, modeled water temperatures used as inputs do not consider the potential for warming near tributary mouths, backwater habitats, or in shallow nearshore areas. Thus, the results of temperature suitability modeling are used to compare relative effects of alternatives on species-specific temperature needs in the mainstem Colorado River, rather than as an exact predictor of the potential for the presence or absence of fish or parasite species at particular locations.

For fish species, the model considers the suitability of each day's water temperature for three life history components (spawning, egg incubation, and growth). The model bases the potential for self-sustaining populations of fish species being successful on the combined temperature suitability scores for spawning, incubation, and growth, and it is assumed that some level of both mainstem spawning and egg incubation would be required to support self-sustaining populations of fish species. The annual potential for successful spawning and egg incubation is assumed to be related to the suitability of the annual temperature regimes for

spawning and egg incubation during the spawning and egg incubation periods. It was assumed that the potential for successful rearing and survival of fish species within the mainstem at each evaluation location was related to the suitability of temperatures throughout the year for growth. The suitability of various temperatures for spawning, egg incubation, and growth needs of fish was calculated using triangular probability functions[3] based upon reported suitable ranges and optimal temperatures for each life history aspect of each species (Valdez and Speas 2007).

For parasite species, the model bases the potential for unacceptable parasite conditions on the temperature suitability scores for host activity and infestation. It is assumed that both elevated host activity and infestation rates would be needed to result in unacceptable infestations of the parasite species and the annual potential for unacceptable infestations is assumed to be related to the suitability of the temperature regimes for host activity and infestation throughout the year. The suitability of various temperatures for host activity and infestation needs of a group of four parasite species was calculated using triangular probability functions based on the reported range of suitable temperatures and the reported optimal temperature for each species (Valdez and Speas 2007). The model calculates daily temperature suitability scores for the life history components based on the triangular suitability relationships and the seasonal time periods during which the temperature needs for each life history component must be met.

Annual temperature suitability for each life history component is calculated as the mean of the daily suitability values that fall within the specified seasonal time period during a given water year. The overall annual temperature suitability for each species is calculated as the geometric mean of the annual temperature suitability scores for the applicable species-specific life history components. Temperature suitability over a 20-year period is based on the mean of the annual temperature suitability values. Evaluations were conducted for each river location to be assessed or using the overall annual means for combinations of downstream locations. The mean of the annual suitability scores for multiple fish or parasite species was used as an indication of the overall suitability of each year's temperature regime for groups of native fish, nonnative fish, or parasite species.

The LTEMP temperature suitability model requires inputs pertaining to daily water temperatures for each of the downstream locations to be assessed, and it requires identification of temperature requirements for the life history aspects of each species to be evaluated. Species-specific temperature requirement information includes the minimum, optimal, and maximum suitable temperatures for important life history components and information describing the appropriate months of the year during which conditions for each life history component should be met. Table F-9 summarizes the input data needs and the anticipated sources of the input values. The model is formulated to consider daily water temperatures for multiyear periods. The daily water temperature input values were derived from external modeling (i.e., not calculated within the LTEMP temperature suitability model) following formulas developed by Wright et al. (2009) to predict mean monthly water temperatures at various locations downstream of Glen

[3] With the triangular functions used, the temperature suitability value rises linearly from 0 at the minimum suitable temperature to 1 at the optimum temperature, then falls linearly from 1 at the optimum to 0 at the maximum suitable temperature). Each of these functions was based on species-specific temperature requirements as reported by Valdez and Speas (2007). See Figure F-19 for example functions.

TABLE F-9 Description of Input Parameters for the LTEMP Temperature Suitability Model

Input Parameter	Description of Input Data	Comments
$TW_{x,y}$	Mean daily water temperature (°C) for a specific day (*x*) in a given year (*y*)	Provided by water temperature modeling. Although daily water temperatures are used as inputs into the model, modeled mean monthly water temperatures were used to provide the mean daily temperatures to be used within the months for each year. The model is formulated to accommodate multiyear traces of daily temperature data. A water temperature time series covering the same time period was developed for each downstream location.
$T_{Min(s,l)}$	The minimum suitable temperature (°C) to meet a given life history need (*l*) for a given species (*s*)	Values obtained from Valdez and Speas (2007).
$T_{Max(s,l)}$	The maximum suitable temperature (°C) to meet a given life history need (*l*) for a given species (*s*)	Values obtained from Valdez and Speas (2007).
$T_{Opt(s,l)}$	The optimum suitable temperature (°C) to meet a given life history need (*l*) for a given species (*s*)	Values obtained from Valdez and Speas (2007).
$MonthStart_{(s,l)}$	The beginning month of the water year during which a given life history need (*l*) for a given species (*s*) should be met	Used to identify the beginning of the appropriate time period for meeting each species–life history component combination.
$MonthEnd_{(s,l)}$	The ending month of the water year during which a given life history need (*l*) for a given species (*s*) should be met	Used to identify the end of the appropriate time period for meeting each species–life history component combination.

Canyon Dam based on assumed meteorological conditions, the expected magnitude of water releases, and the temperature of the water being released from Lake Powell for each of the LTEMP alternatives. The temperature suitability for each alternative/long-term strategy was evaluated using a total of 63, 20-year temperature input scenarios generated from conditions expected during operations for a range of hydrology–sediment trace combinations. The temperature suitability model was implemented using R (R Core Team 2013; see http://www.r-project.org/about.html).

The following sections provide specific information regarding implementations and results of the temperature suitability modeling approach to evaluate suitability for (1) self-sustaining aggregations of humpback chub; (2) self-sustaining populations of native warmwater fish species other than humpback chub; (3) self-sustaining populations of coldwater and warmwater nonnative fish species; and (4) establishment and maintenance of invasive parasitic invertebrate species.

F.4.2 Humpback Chub Aggregations

The temperature suitability model evaluates how well alternatives would provide mainstem water temperatures suitable for spawning, egg incubation, and growth of humpback chub at reported aggregation locations. The model based the potential for a self-sustaining aggregation of humpback chub becoming successfully established at each location on the combined potential for successful spawning, successful incubation, and successful growth of humpback chub. The time series of water temperatures was based upon estimated water temperatures for eight mainstem Colorado River locations (Table F-10) where humpback chub aggregations have been reported to occur. As described in Section F.4.1, the water temperatures used as inputs for these locations were modeled using a water temperature model developed by Wright et al. (2009).

It was assumed that mainstem spawning would be required to support self-sustaining aggregations at all locations except for the aggregation at the confluence of the mainstem and the Little Colorado River (RM 61), where successful tributary spawning is known to occur. Thus, except for the Little Colorado River aggregation, the annual potential for successful spawning is assumed to be related to the suitability of temperature regimes in the mainstem Colorado River for spawning. The potential for successful spawning at various temperatures was calculated using a triangular probability function based upon the reported range of suitable spawning temperatures (16–22°C) (61–72°F) and the reported optimal spawning temperature (18°C) (64°F) for humpback chub (Valdez and Speas 2007). The calculated suitability of various water temperatures for successful humpback chub spawning is shown in Figure F-19.

April, May, and June were identified as encompassing the possible spawning period for humpback chub aggregations (Figure F-20), based on observations of fish in spawning condition reported by Valdez and Ryel (1995) for aggregations and by Gorman and Stone (1999) for spawning in the Little Colorado River. The annual suitability values for spawning were set to a value of 1 for the Little Colorado River aggregation, since water temperature in the Little

Colorado River is known to support spawning needs for this aggregation. The potential for successful spawning for each aggregation during a given water year was calculated as the average of the estimated suitability scores during April through June (Figure F-20).

It was assumed that mainstem egg incubation would be required to support self-sustaining aggregations at all locations except for the aggregation at the confluence of the mainstem and the Little Colorado River (RM 61), where successful tributary spawning is known to occur. The suitability for incubation in the Little Colorado River (RM 61) aggregation was assumed to be 1. At other aggregation locations, the annual potential for successful egg incubation was assumed to be related to the suitability of mainstem temperature regimes for incubation during the spawning period, because incubation of humpback chub eggs may require as little as 3 days at optimal temperatures. Thus, it was assumed that the spawning period of April, May, and June also encompassed the egg incubation period for aggregations (Figure F-20). The suitability of various temperatures for egg incubation was calculated using a triangular probability function based upon the reported range of suitable egg incubation temperatures (16–27°C) (61–81°F) and the reported optimal egg incubation temperature (19°C) (66°F) for humpback chub (Valdez and Speas 2007; Figure F-19).

It was assumed that the potential for successful rearing of humpback chub within the mainstem at each aggregation location is related to the suitability of temperatures throughout the year for humpback chub growth. The suitability of various temperatures for growth of humpback chub was calculated using a triangular probability function based upon the reported range of suitable temperatures (16–22°C) (61–72°F) and the reported optimal temperature (18°C) (64°F) for growth (Valdez and Speas 2007; Figure F-19). The annual suitability of daily temperatures for growth was calculated as the mean of daily suitability values during the entire water year (Figure F-20).

The geometric mean of the annual temperature suitability values for spawning, egg incubation, and growth was used as an indicator of the annual potential for an aggregation to be successful (and self-sustaining) at a particular location. The arithmetic mean of the annual suitability scores for each of the eight aggregation locations was used as an indication of the overall relative suitability of each year's temperature regime for supporting humpback chub aggregations in the mainstem Colorado River downstream of Glen Canyon Dam.

F.4.2.1 Historic Temperature Suitability for Humpback Chub

Historic temperature suitability of mainstem water temperatures for humpback chub aggregations was examined using modeled water historic temperatures at the aggregation locations for a 23-year period from October 1, 1989, through September 30, 2012 (water years 1990–2012), as the temperature inputs (Figure F-21). The annual values of the modeled historic temperature suitability for the various aggregation locations are summarized in Figure F-22.

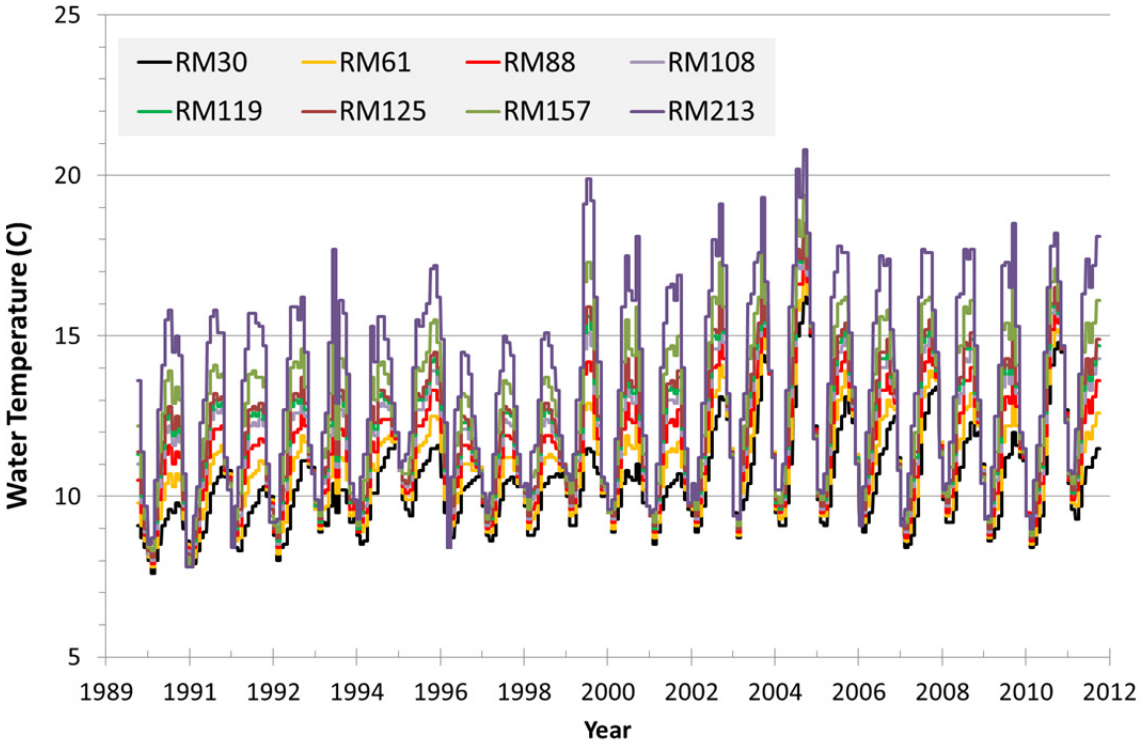

FIGURE F-21 Modeled Historic Water Temperatures in the Colorado River at Humpback Chub Aggregation Locations, Water Years 1990–2012 (Source: Williams 2013)

F.4.2.2 Results for LTEMP Alternatives

Figure F-23 summarizes the temperature suitability for humpback chub at aggregation locations under the LTEMP alternatives and long-term strategies. Modeled main channel water temperature suitability for humpback chub was relatively low and similar to Alternative A under all the long-term strategies for most aggregation locations. Modeled mean annual main channel temperature suitability for humpback chub at RM 61 (the Little Colorado River confluence) was slightly higher under Alternative F than under the other long-term strategies (Figure F-23), because the lower summer and fall flows of this alternative resulted in warmer water that would benefit growth during those seasons; note that the overall suitability score for RM 61 reflects temperature suitability for growth in the main channel, and optimal spawning and egg incubation temperatures in the Little Colorado River where the species spawns. Because the water warms as it travels downstream from the dam (for spring through fall months), temperature suitability improves with increasing distance. At RM 213, mean annual temperature suitability for humpback chub was similar to Alternative A under all long-term strategies except for C1, C2, C3, and C4, and Alternative F. Compared to Alternative A, long-term strategies C1, C2, C3, and C4 were slightly lower, although differences were small (Figure-F-23). Modeled temperature suitability at RM 213 was lowest under Alternative F (Figure F-23), reflecting the higher, colder flows expected to occur under this alternative during spawning and egg incubation periods (April through June). Based on these results, the combined suitability of mainstem temperatures for spawning, egg incubation, and growth by humpback

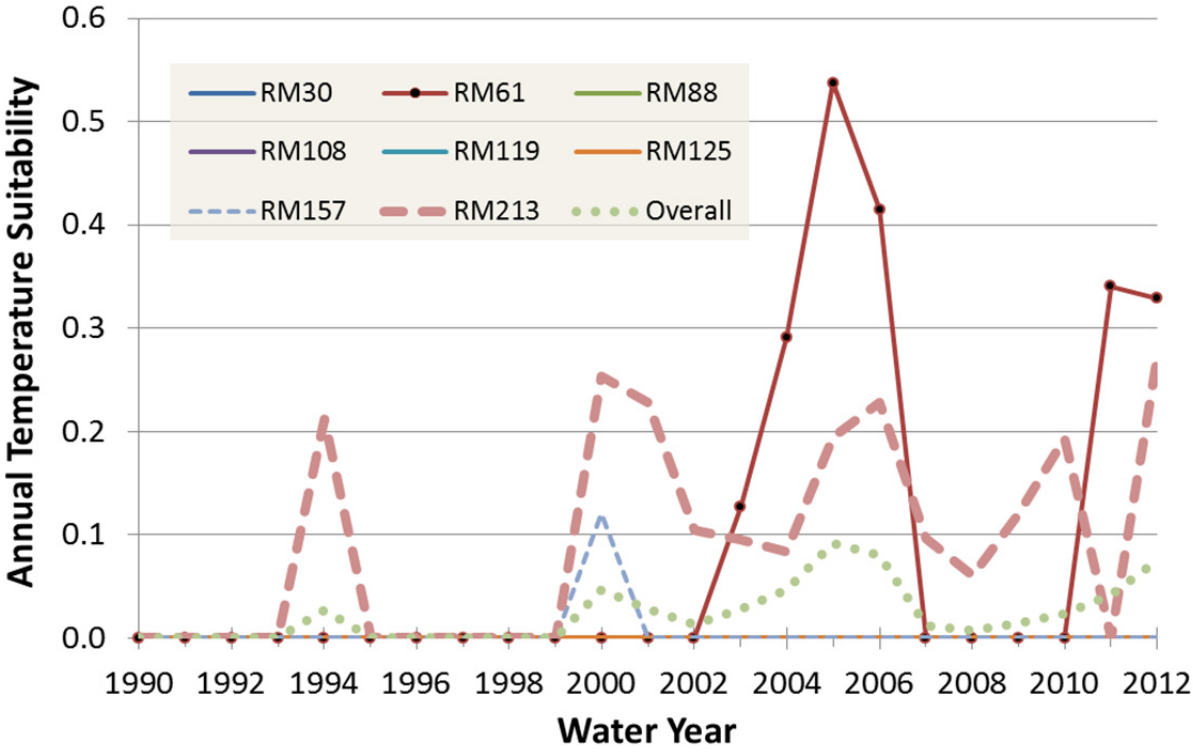

FIGURE F-22 Output from the Temperature Suitability Model for Humpback Chub Aggregation Locations Based on Modeled Water Temperatures for Water Years 1990–2012

chub in the downstream-most aggregation sites is anticipated to be negatively affected compared to current conditions under Alternative F; however, for the other long-term strategies, suitability would remain similar to the low historic levels, as represented by the suitability under Alternative A (the no-action alternative). It should be noted that, historically, there have been years where the magnitude and timing of mainstem water temperatures have likely coincided to allow spawning and egg incubation to occur in some of the downstream aggregation areas; however, the overall average suitability has likely been low (Figure F-22).

F.4.3 Other Native Fish

The temperature suitability model for native fish evaluates how well alternatives provide mainstem water temperatures suitable for spawning, egg incubation, and growth of four species of warmwater native fish other than humpback chub (speckled dace [*Rhinichthys osculus*], razorback sucker [*Xyrauchen texanus*], flannelmouth sucker [*Catostomus latipinnis*], and bluehead sucker [*C. discobolus*]). In order to account for changes in water temperatures as water released from Glen Canyon Dam travels downstream, evaluations of temperature suitability were conducted for five mainstem Colorado River locations (Table F-11). As described in Section F.4.1, the time series of water temperatures used as inputs for these locations are generated using a water temperature model developed by Wright et al. (2009).

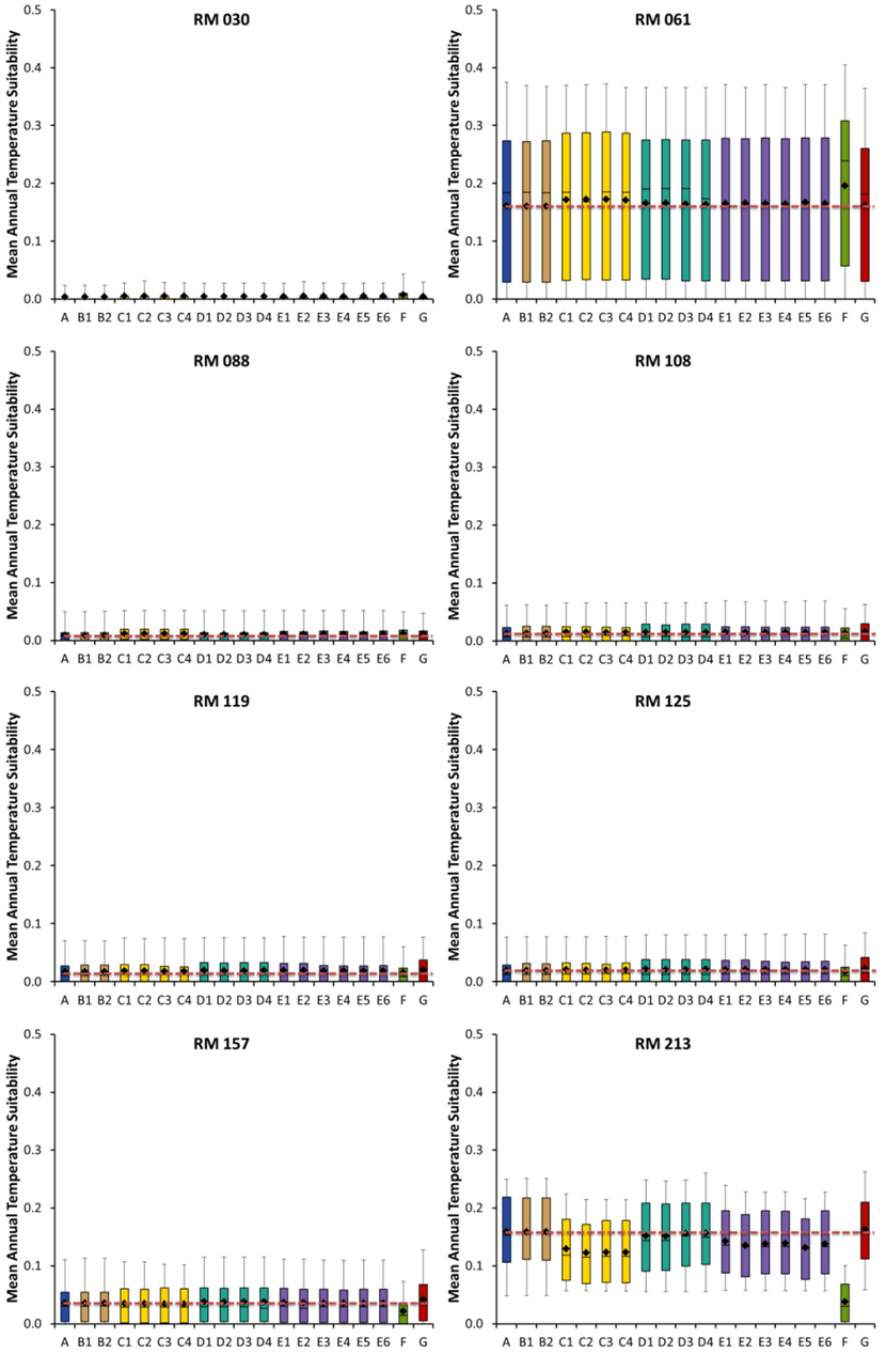

FIGURE F-23 Mainstem Temperature Suitability for Humpback Chub Aggregation Locations under LTEMP Alternatives and Long-Term Strategies (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

TABLE F-11 Locations Used for Temperature Suitability Modeling of Native Fish, Nonnative Fish, and Parasites

Aggregation Location	River Mile (RM)[a]
Glen Canyon Dam	RM –15
Paria River/Lee Ferry	RM 0
Little Colorado River confluence	RM 61
Havasu Creek	RM 157
Diamond Creek	RM 225

[a] River mile distances are calculated as the distance downstream from the Lee Ferry Gage. Glen Canyon Dam is indicated as being at RM –15, since it is located upstream of Lee Ferry.

The calculated suitability of various water temperatures for successful spawning, egg incubation, and growth of the four native species is depicted in Figure F-24. The months encompassing the spawning, egg incubation, and growth periods for each of the four native fish species are indicated in Figure F-25.These time periods were identified by reviewing the scientific literature pertaining to each of the species.

F.4.3.1 Historic Temperature Suitability for Native Fish

Historic temperature suitability of mainstem water temperatures for the four native fish species was examined using modeled water historic temperatures at five evaluation locations for a 23-year period from October 1, 1989, through September 30, 2012 (water years 1990–2012) as the temperature inputs (Figure F-26). Figure F-27 presents the annual temperature suitability scores for spawning, incubation, and growth of the four native fish species based upon the modeled historic temperatures for water years 1990–2012 at RM 225 (Diamond Creek). Figure F-28 presents the annual temperature suitability scores for the five river locations and a combined overall score for all locations based on the modeled historic temperature suitability for the various assessment locations. The overall means of annual suitability scores at each river location for native fish over the 1990–2012 water years are presented in Figure F-29.

F.4.3.2 Results for LTEMP Alternatives

The temperature suitability for the four native fish at multiple downstream locations under the LTEMP alternatives and long-term strategies is summarized in Figure F-30. Modeled main channel water temperature suitability for native fish species was relatively low and similar to Alternative A under all long-term strategies at RM 61, reflecting the prevalence of coldwater releases from Glen Canyon Dam throughout the year and the limited effect that the long-term strategies would have on mainstem water temperature regimes at RM 61. Because the water

FIGURE F-26 Modeled Historic Water Temperatures in the Colorado River Downstream of Glen Canyon Dam, Water Years 1990–2012 (Source: Williams 2013)

warms as it travels downstream from the dam (for spring through fall months), temperature suitability improves with increasing downstream distance, and differences in suitability among the long-term strategies begin to appear. Whereas suitability for most long-term strategies remain similar to, or lower than, the modeled suitability under Alternative A at these downstream locations, temperature suitability for native fish improves somewhat under long-term strategies D1, D2, D3, and D4 (Figure F-30). It should be noted that there is little difference in temperature suitability among the long-term strategies specific to Alternatives B, C, D, and E, suggesting that experimental elements identified in Table 4.1-1 such as HFEs, low summer flows, TMFs, and hydropower improvement flows would have little effect on mainstem water temperature regimes during periods of the year considered most important for spawning and egg incubation by native species. Rather, differences in temperature suitability for native fish under the various long-term strategies appear to be more related to differences in the seasonal patterns of releases and the effects of those patterns on seasonal temperatures. Thus, the reduction in modeled temperature suitability under Alternative F at RM 225 reflects the higher flows expected to occur under this alternative during spring and early summer months when native fish are expected to spawn; those higher flows would result in temperatures less suitable for spawning and egg incubation.

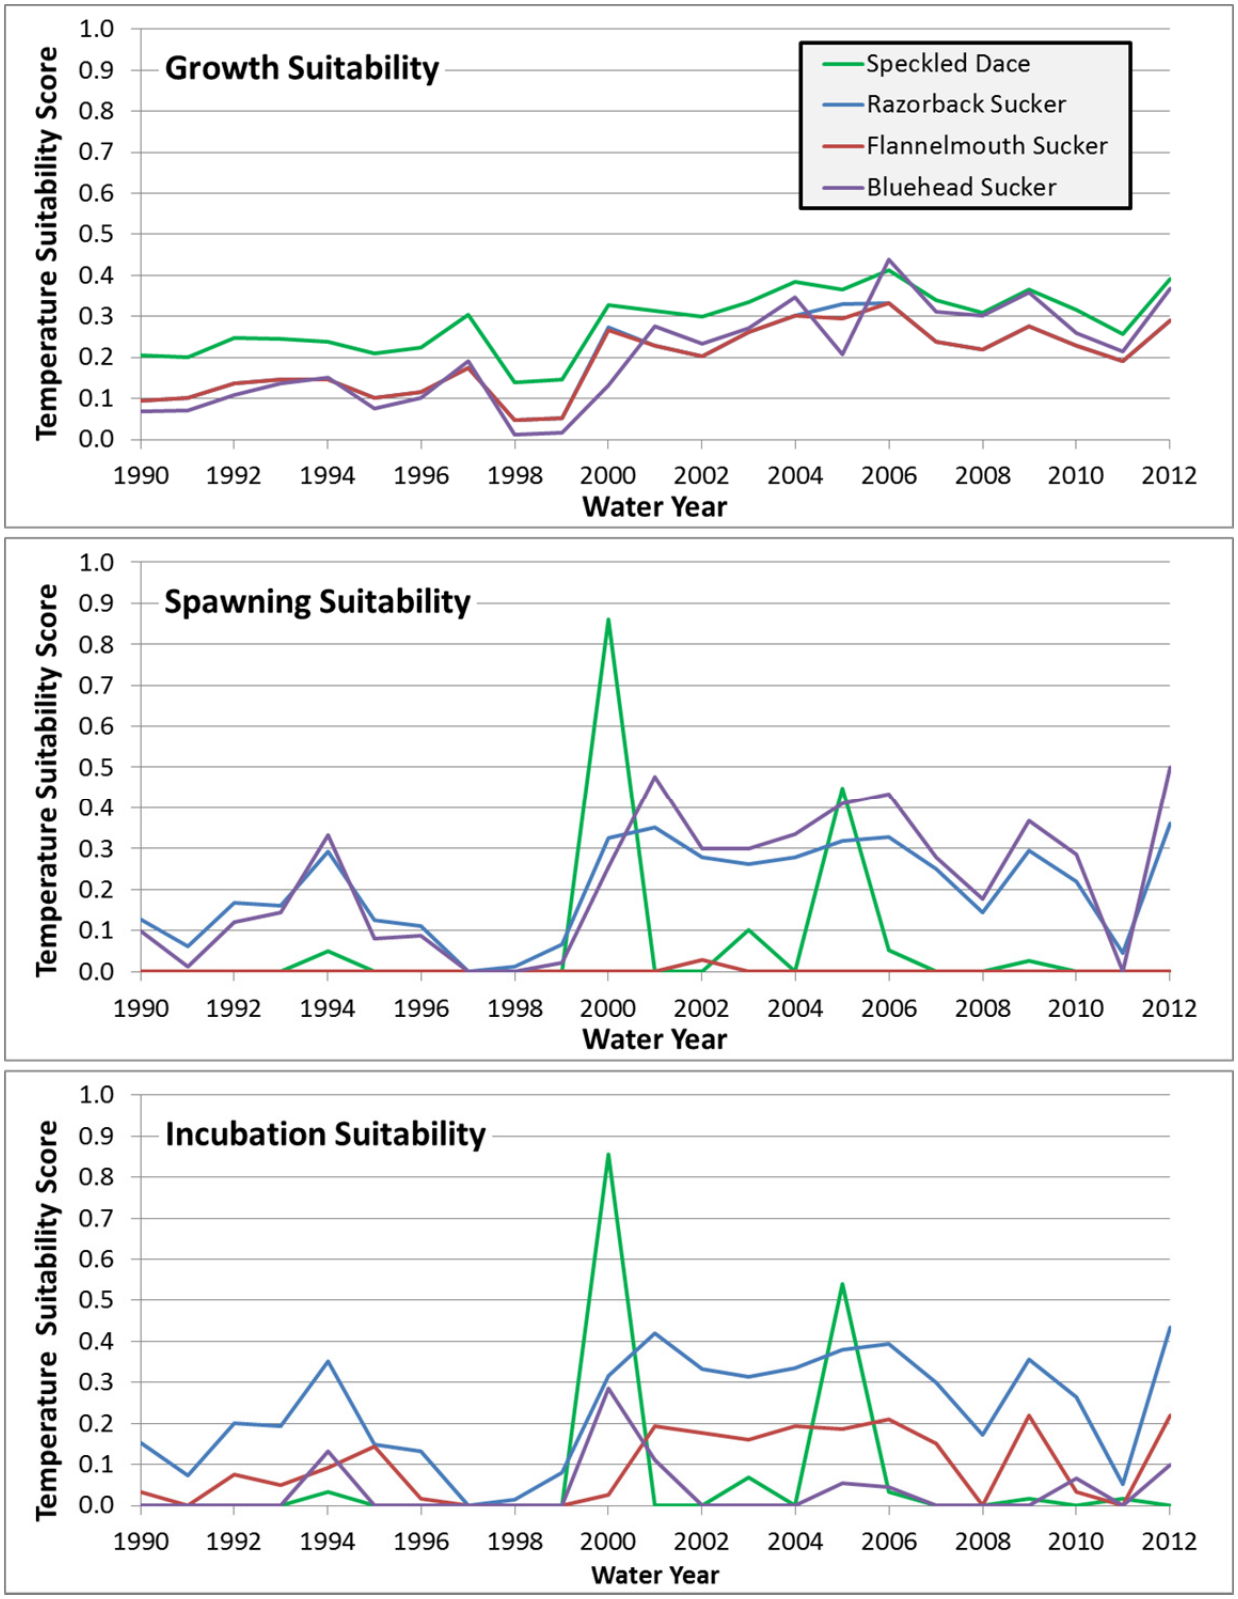

FIGURE F-27 Annual Temperature Suitability Scores for Growth, Spawning, and Egg Incubation of Native Fish Species at RM 225 Based on Modeled Water Temperatures for Water Years 1990–2012

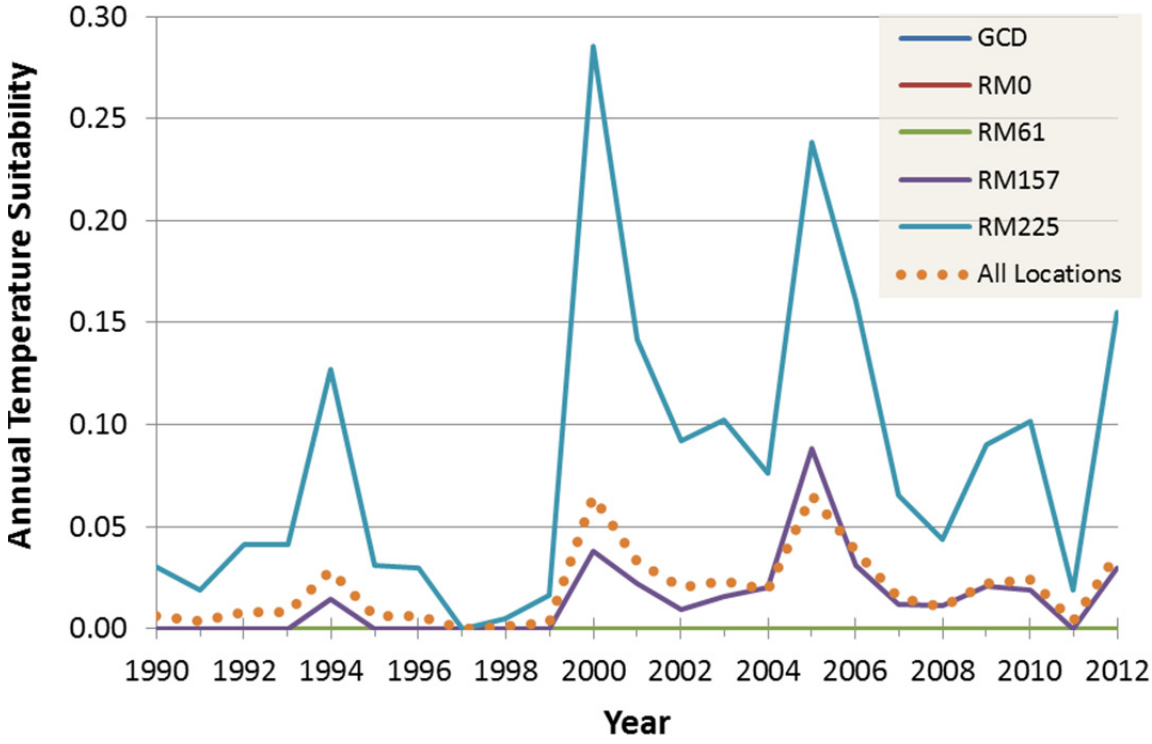

FIGURE F-28 Annual Temperature Suitability Scores for Native Fish by Assessment Location Based on Modeled Water Temperatures for Water Years 1990–2012

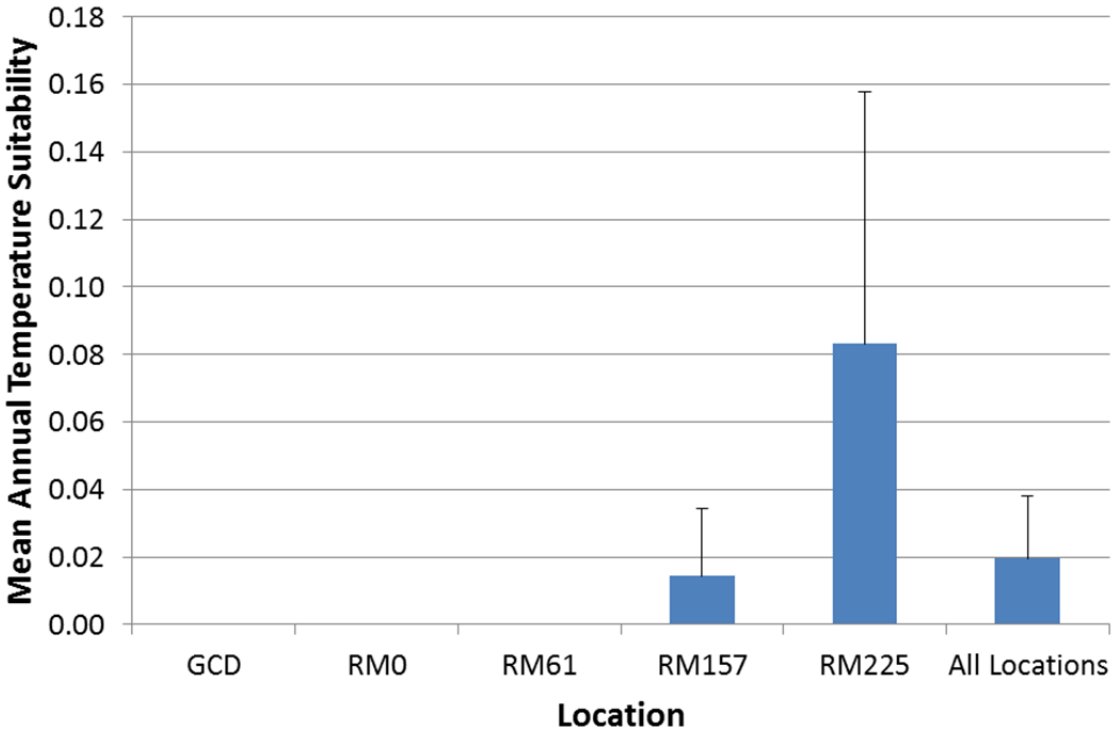

FIGURE F-29 Mean (±SD) Annual Overall Temperature Suitability for Native Fish by Assessment Location Based on Modeled Water Temperatures for Water Years 1990–2012

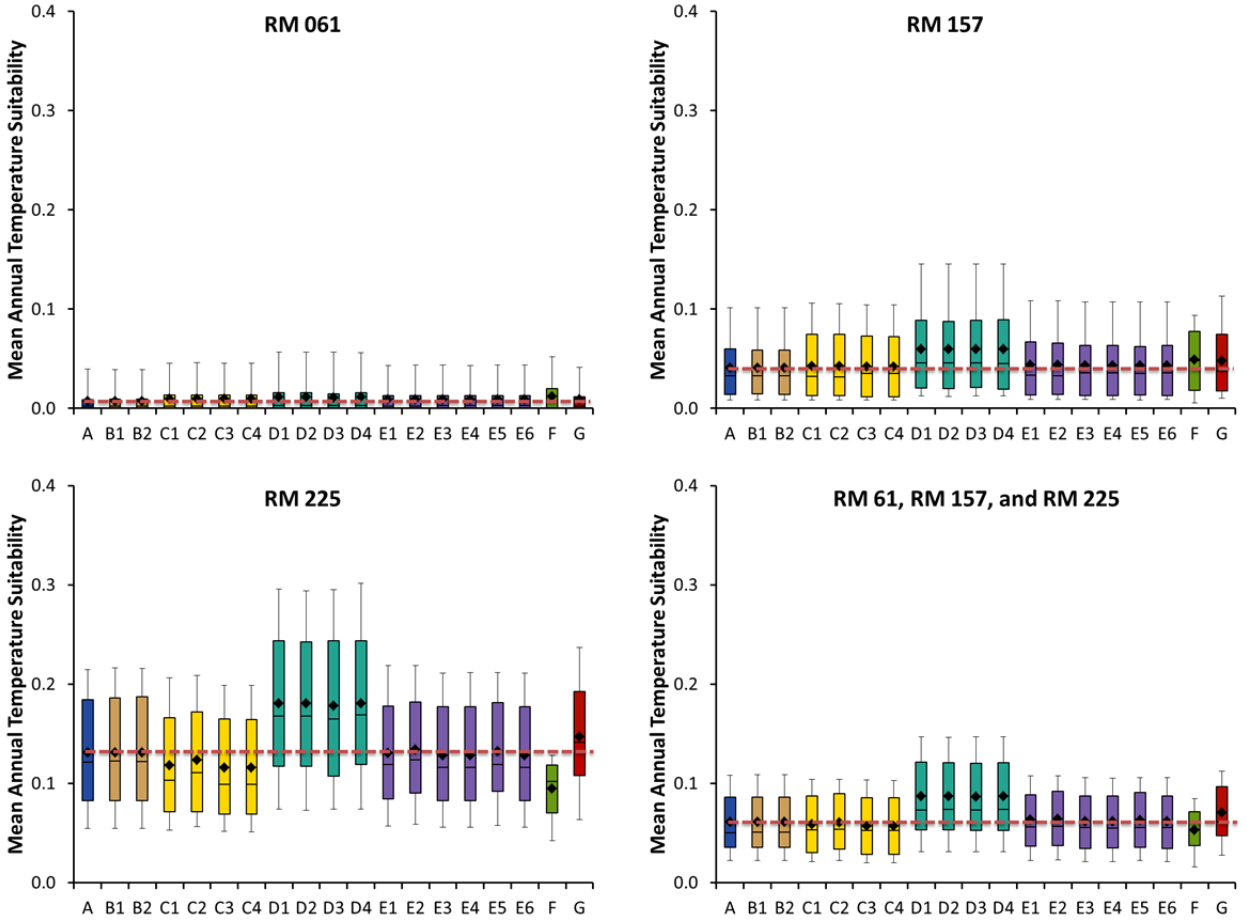

FIGURE F-30 Mean Annual Mainstem Temperature Suitability for Native Fish under LTEMP Alternatives and Long-Term Strategies at RM 61, RM 157, and RM 225, and Overall Mean for RM 61–225 (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

F.4.4 Nonnative Fish

The temperature suitability model for nonnative fish evaluates how well alternatives provide mainstem water temperatures suitable for spawning, egg incubation, and growth of six species of coldwater (brown trout [*Salmo trutta*], rainbow trout) and warmwater (channel catfish [*Ictalurus punctatus*], green sunfish [*Lepomis cyanellus*], smallmouth bass [*Micropterus dolomieu*], and striped bass [*Morone saxatilis*]) nonnative fish. In order to account for changes in water temperatures as water released from Glen Canyon Dam travels downstream, evaluations of temperature suitability were conducted for the five mainstem Colorado River locations identified in Table F-11. As described in Section F.4.1, the time series of water temperatures used as inputs for these locations were generated using a water temperature model developed by Wright et al.

(2009). The calculated suitability values for various water temperatures for successful spawning, egg incubation, and growth of the six nonnative fish species are depicted in Figure F-31. The months encompassing the spawning and egg incubation periods for each of the six nonnative fish species are indicated in Figure F-32. The annual suitability of daily temperatures for growth is calculated as the mean of daily suitability values for the entire water year (October through September). The overall means of temperature suitability values for the coldwater and warmwater nonnative species groups were examined separately.

F.4.4.1 Historic Temperature Suitability for Nonnative Fish

Historic suitability of mainstem water temperatures for the six nonnative fish species was examined using modeled water historic temperatures at the five evaluation locations for a 23-year period from October 1, 1989, through September 30, 2012 (water years 1990–2012), as the temperature inputs (Figure F-26). Figure F-33 presents the annual temperature suitability scores for spawning, incubation, and growth of the six nonnative fish species based upon the modeled historic temperatures for water years 1990–2012 at RM 225 (Diamond Creek). The mean annual temperature suitability scores for each species and temperature group for the five river locations are presented in Figure F-34. The overall means of annual suitability scores for the coldwater and warmwater nonnative fish species across all river locations during the 1990–2012 water years are presented in Figure F-35.

F.4.4.2 Results for LTEMP Alternatives

In general, temperature suitability for coldwater nonnative species (i.e., brown and rainbow trout) would be similar among most of the long-term strategies at most locations downstream of Glen Canyon Dam and would be remain similar to current conditions based on comparisons to Alternative A (Figure F-36). Because of the effects of the timing and magnitude of peak and base flow releases on water temperatures, temperature suitability would be slightly greater under Alternative F than under the other long-term strategies at the confluence with the Little Colorado River (RM 61), and lower under Alternative F than under the other long-term strategies for locations farther downstream; however, those differences are very small and may not be biologically significant. Although main channel temperature regimes at and downstream of RM 61 appear to become more suitable for trout species than at locations closer to the dam (Figure F-36), the abundance of trout is known to be lower at those locations (based on sampling), suggesting that other habitat characteristics (e.g., substrate composition and water clarity) may be less suitable at these downstream locations. Because inclusion of flow actions—such as HFEs, TMFs, and low summer flows—had only minor influences on modeled monthly mainstem water temperatures during periods of the year considered most important for spawning and egg incubation by trout, these flow actions have little effect on modeled mainstem temperature suitability and would not alter relative suitability for coldwater nonnative species among the long-term strategies (Figure F-36).

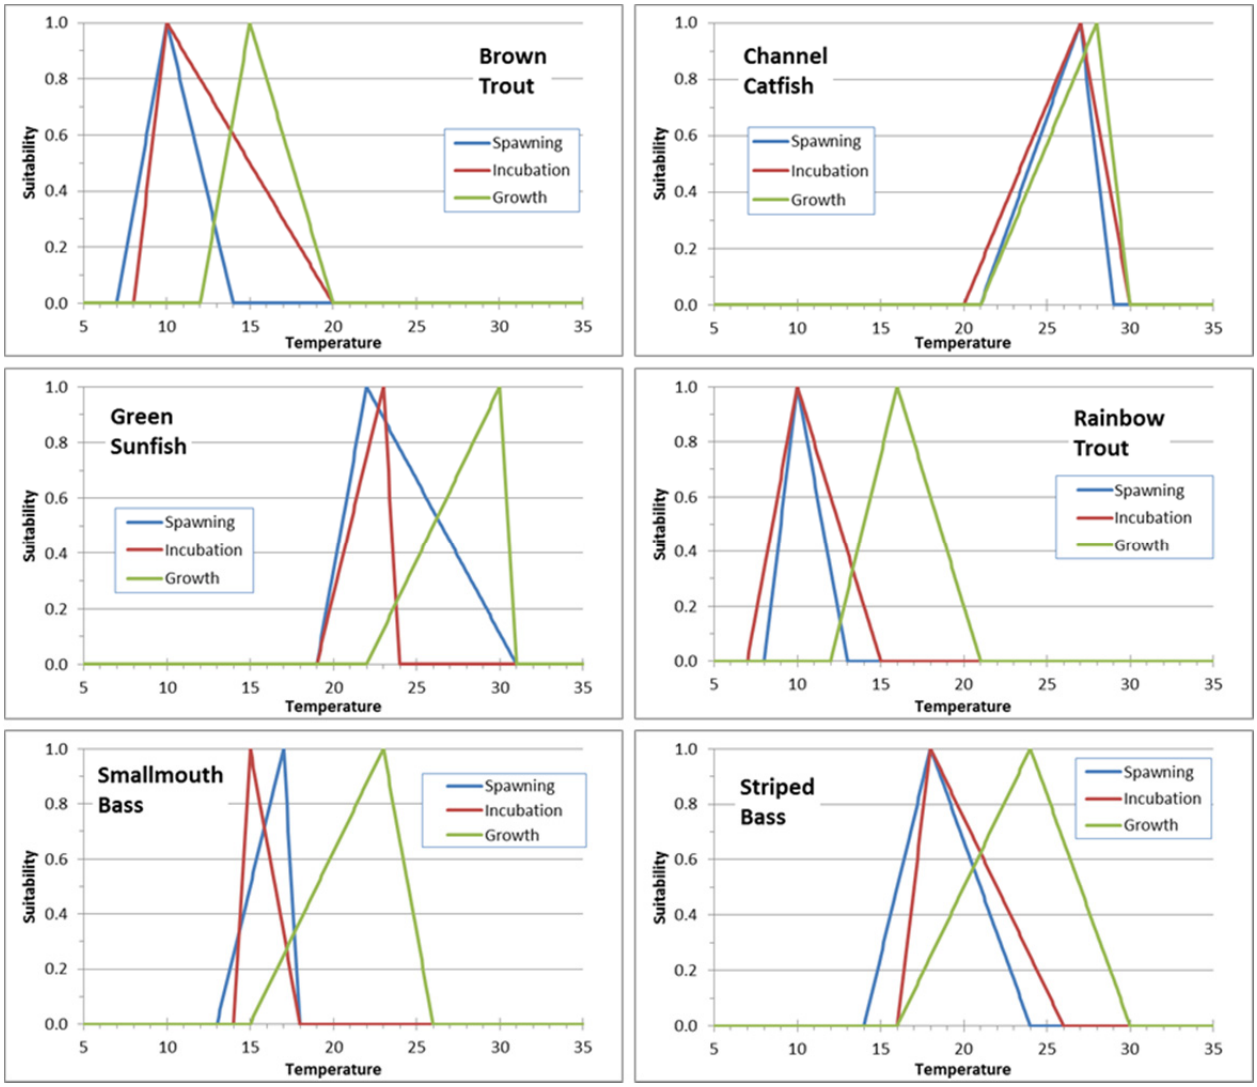

FIGURE F-31 Suitability of Water Temperatures (°C) for Spawning, Egg Incubation, and Growth of Nonnative Fish Species (Source: Valdez and Speas 2007)

Temperature suitability at the various main channel locations was modeled for the four nonnative warmwater species considered to be representative of the warmwater nonnative fish community (smallmouth bass, green sunfish, channel catfish, and striped bass). In general, the estimated average main-channel temperature suitability for these nonnative fish did not differ greatly among the long-term strategies, and was low under all long-term strategies (Figure F-37). The modeled temperature suitability indicated that temperature conditions would be most suitable for warmwater nonnative species at locations farther downstream from Glen Canyon Dam (e.g., RM 157 and RM 225) compared to upstream locations (e.g., RM 0 and RM 61); this agrees with past surveys that have found more warmwater nonnative fish species in those areas. Relative to current conditions (as exemplified by Alternative A), the temperature suitability model indicated that the long-term strategies for Alternative C (i.e., long-term strategies C1, C2, C3, and C4) and Alternative F have the greatest potential to improve conditions for warmwater nonnative fish at locations downstream of RM 157, which could result in increased numbers

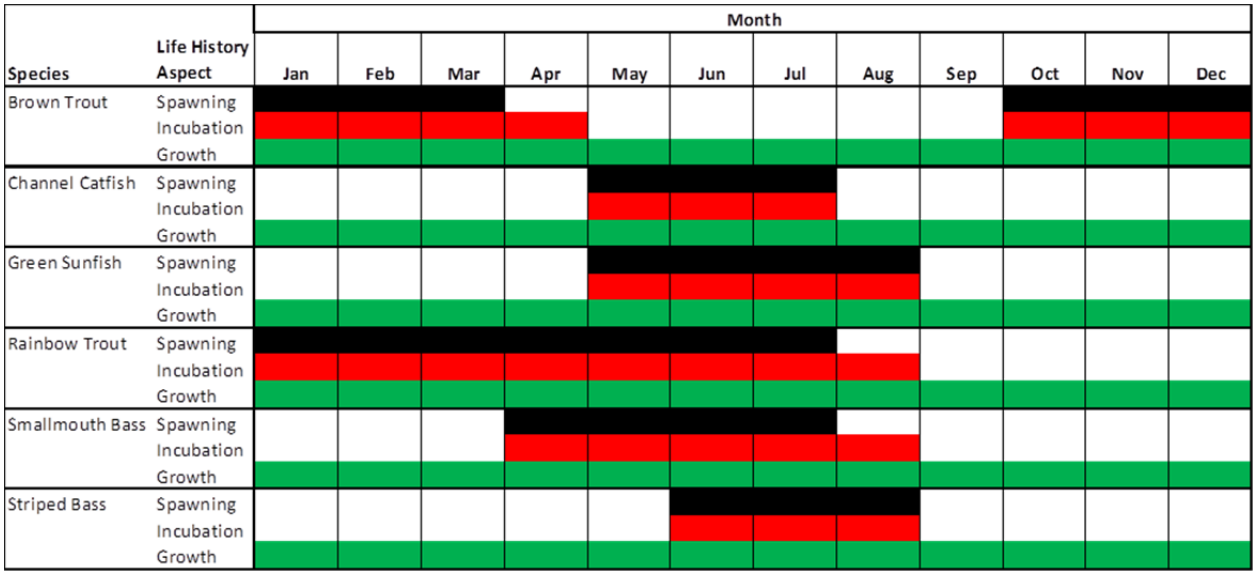

FIGURE F-32 Months during Which Temperature Suitability for Specific Life History Aspects Were Calculated for Nonnative Fish Species

and a greater potential for upstream spread of warmwater nonnative fish species. As described above for coldwater fish species, inclusion of flow actions such as HFEs, TMFs, and low summer flows had only minor influences on modeled monthly mainstem water temperatures during periods of the year considered most important for spawning and egg incubation by nonnative warmwater species. As a consequence, the various experimental elements associated with the long-term strategies (Table 4.1-1) would be expected to have little effect on mainstem temperature suitability for warmwater nonnative species (Figure F-37). Rather, as identified for native fish in Section F.4.3.2, differences among alternatives appear to be more related to differences in the seasonal patterns of releases and the effects of those patterns on seasonal temperatures.

F.4.5 Aquatic Parasites

The temperature suitability model for aquatic parasite species evaluates how well alternatives provide mainstem water temperatures suitable for host activity for and infestation by four species (Asian tapeworm [*Bothriocephalus acheilognathi*], anchor worm [*Lernaea cyprinacea*], trout nematode [*Truttaedacnitis truttae*], and whirling disease [*Myxobolus cerebralis*]) that could parasitize fish in the Colorado River downstream of Glen Canyon Dam. In order to account for changes in water temperatures as water released from Glen Canyon Dam travels downstream, evaluations of temperature suitability were conducted for the mainstem Colorado River locations identified in Table F-11. As described in Section F.4.1, the time series of water temperatures used as inputs for these locations were generated using a water temperature model developed by Wright et al. (2009).

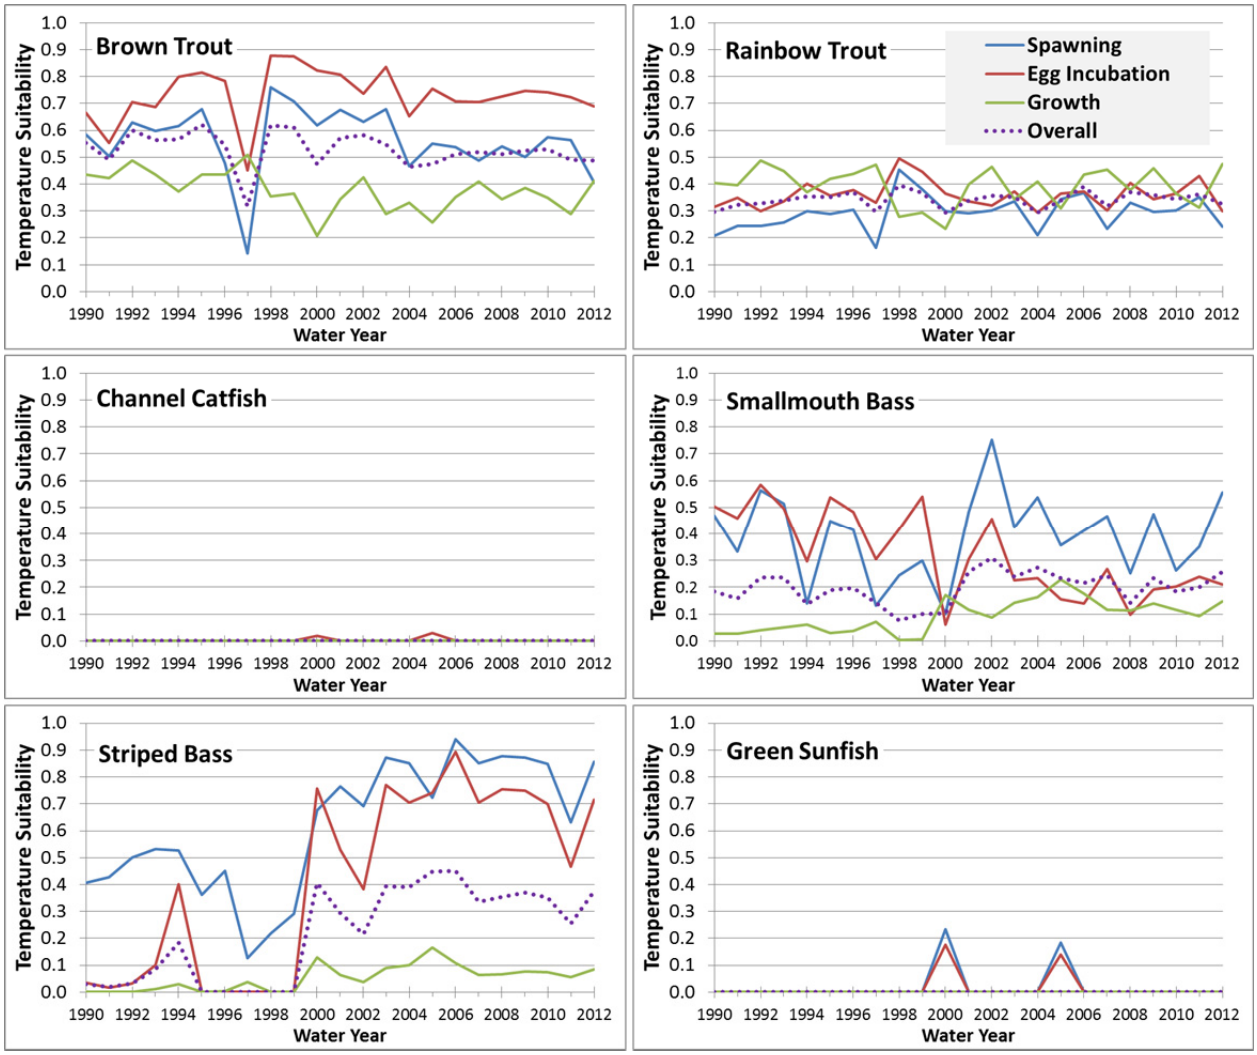

FIGURE F-33 Annual Temperature Suitability Scores for Spawning, Incubation, and Growth of Nonnative Fish Species at RM 225 (Diamond Creek) Based on Modeled Temperatures for Water Years 1990 to 2012

The calculated suitability values at various water temperatures for host activity and infestation rates of the four parasite species is depicted in Figure F-38. It was assumed that evaluation of temperature suitability across the entire water year (rather than just a portion of the year) was relevant for both of the parasite life history components. The geometric mean of the annual temperature suitability values for host activity and infestation was used as an indicator of the annual overall suitability for each parasite species and served as the indicator of the potential for each of the parasite species to become problematic at a particular downstream location. The combined mean of the annual suitability scores for all four parasite species was used as an indication of the overall suitability of each year's temperature regime for the group of parasite species at each downstream location. The mean of the group means for all of the downstream locations was calculated as an indication of overall relative suitability of the temperature regime

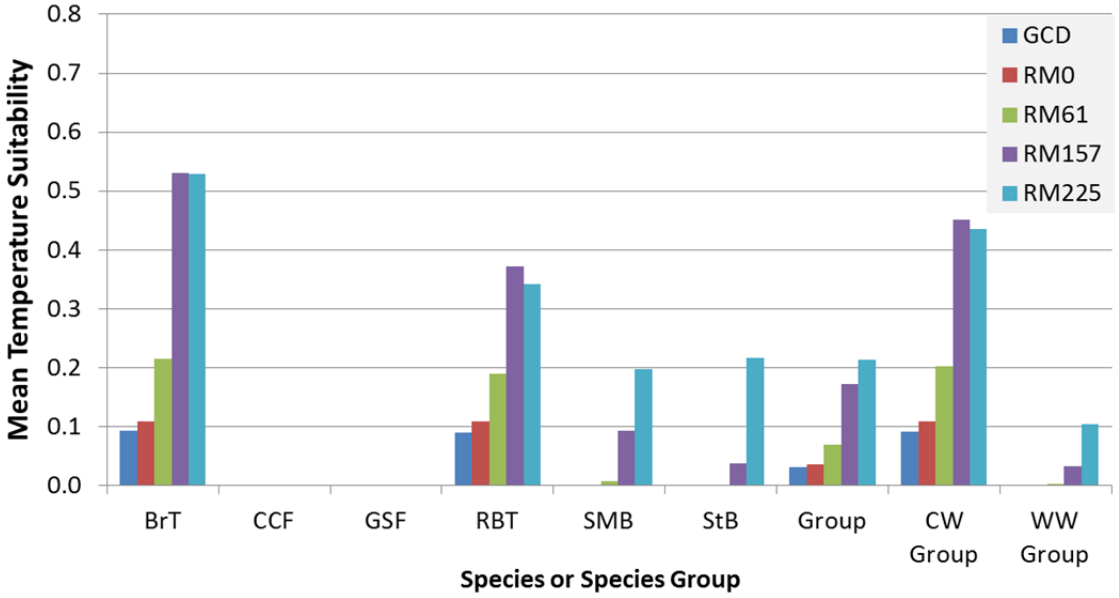

FIGURE F-34 Mean Annual Temperature Suitability Scores for Nonnative Fish Species and for Temperature Groups by River Location Based on Modeled Water Temperatures for Water Years 1990–2012 (BrT = brown trout; CCF = channel catfish; GSF = green sunfish; RBT = rainbow trout; SMB = smallmouth bass; StB = striped bass; Group = combined coldwater and warmwater; CW = coldwater; WW = warmwater)

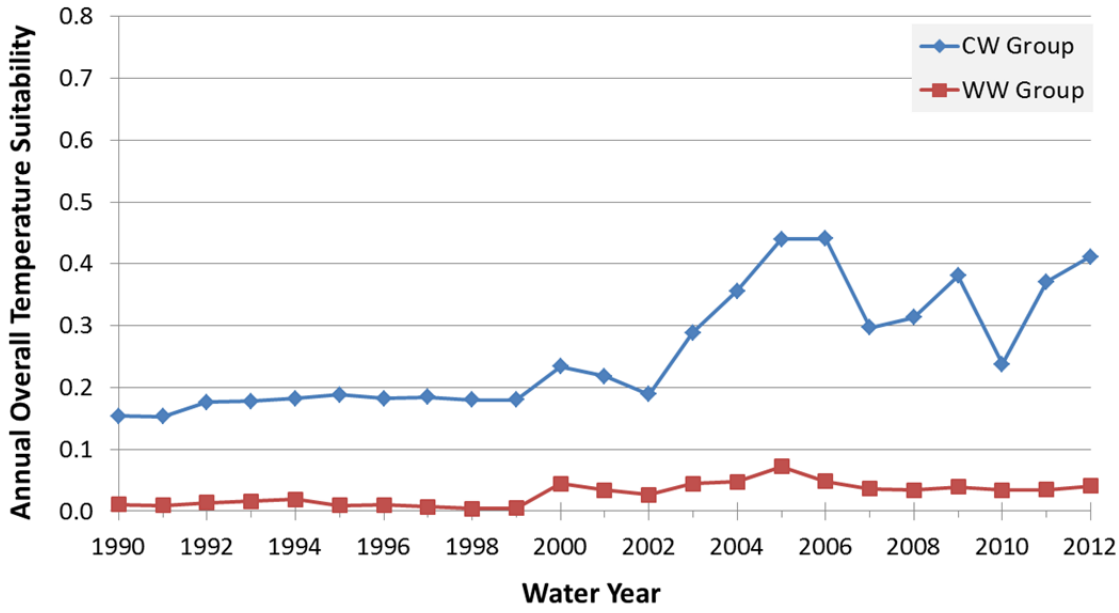

FIGURE F-35 Mean Annual Overall Temperature Suitability Scores for Coldwater (CW) and Warmwater (WW) Nonnative Fish Species Groups Based on Modeled Historic Temperatures for Water Years 1990–2012

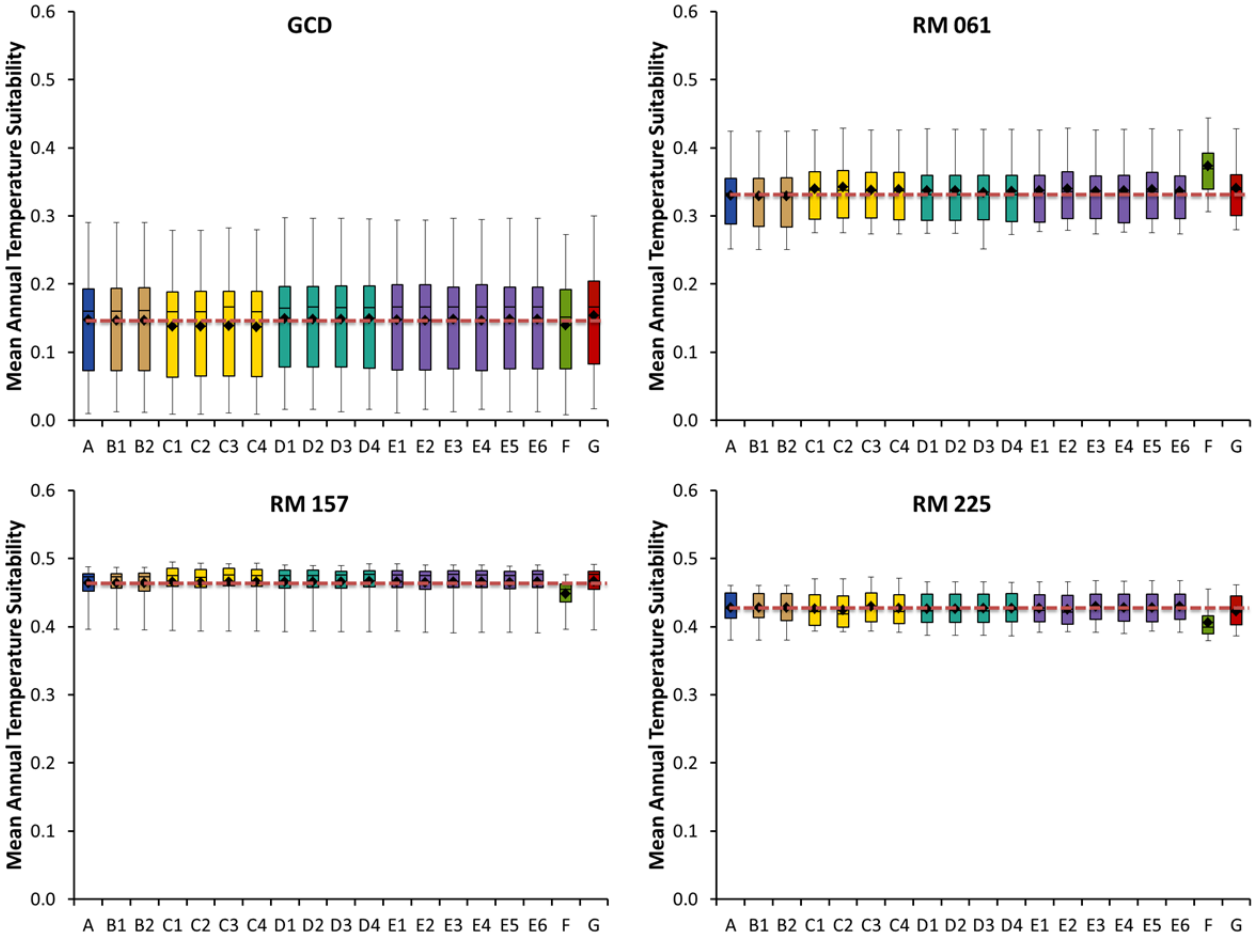

FIGURE F-36 Mean Annual Mainstem Temperature Suitability for Coldwater Nonnative Fish (brown trout and rainbow trout) under LTEMP Alternatives and Long-Term Strategies at RM 15 (Glen Canyon Dam, GCD), RM 61, RM 157, and RM 225 (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

within a particular year for parasite species in the mainstem Colorado River downstream of Glen Canyon Dam.

F.4.5.1 Historic Temperature Suitability for Aquatic Parasites

Historic suitability of mainstem water temperatures for the four aquatic parasite species was examined using modeled water historic temperatures at the five evaluation locations for a 23-year period from October 1, 1989, through September 30, 2012 (water years 1990–2012), as the temperature inputs (Figure F-26). Figure F-39 presents the annual temperature suitability

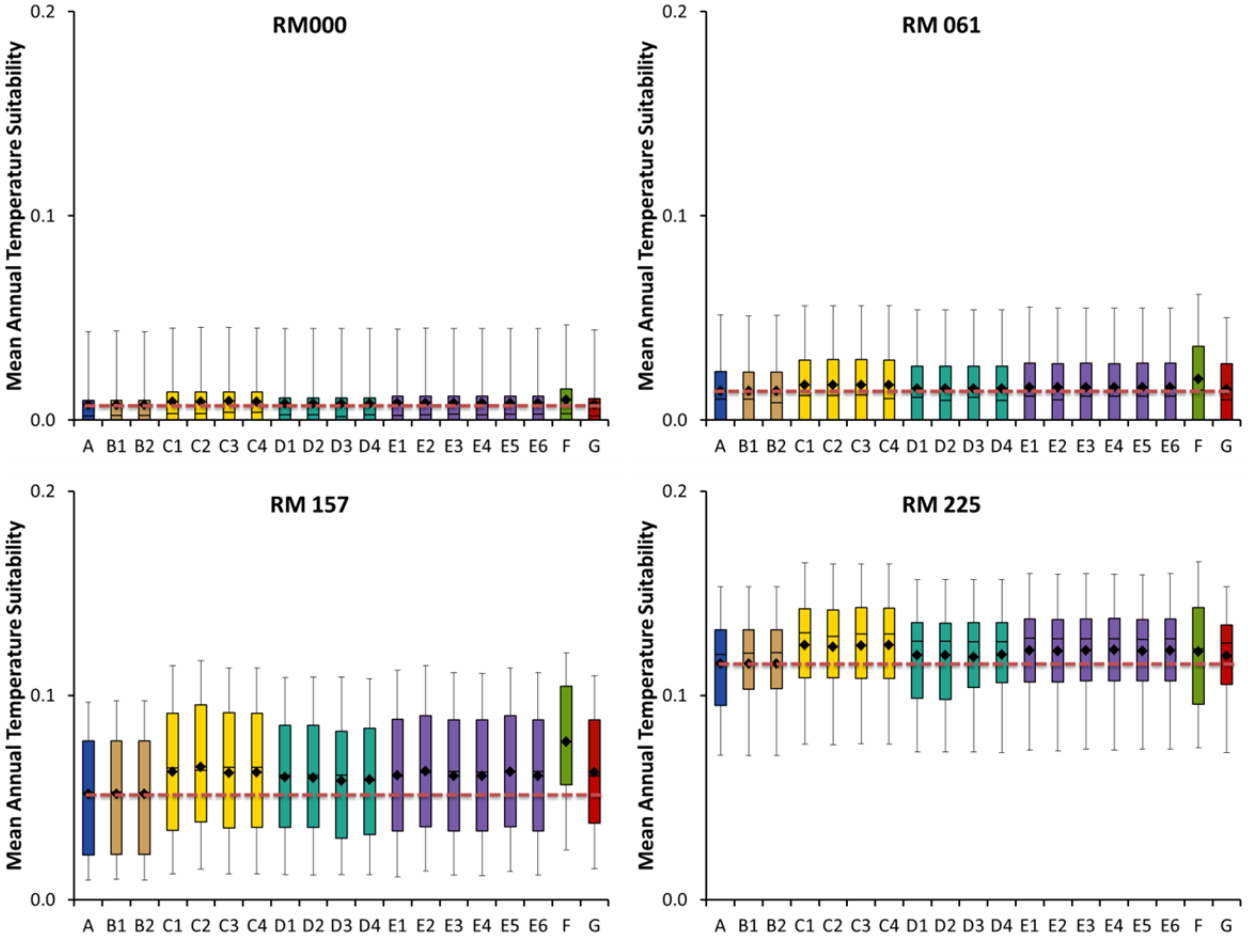

FIGURE F-37 Mean Annual Mainstem Temperature Suitability for Warmwater Nonnative Fish (channel catfish, green sunfish, smallmouth bass, and striped bass) under LTEMP Alternatives and Long-Term Strategies at RM 0, RM 61, RM 157, and RM 225 (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

scores for host activity and infestation rates of the parasite species based upon the modeled historic temperatures for water years 1990–2012 at RM 225 (Diamond Creek). The mean annual temperature suitability scores for each species and temperature group for the five river locations are presented in Figure F-40. The overall means of modeled annual suitability scores for the coldwater and warmwater nonnative fish species groups across all river locations during the 1990–2012 water years are presented in Figure F-41.

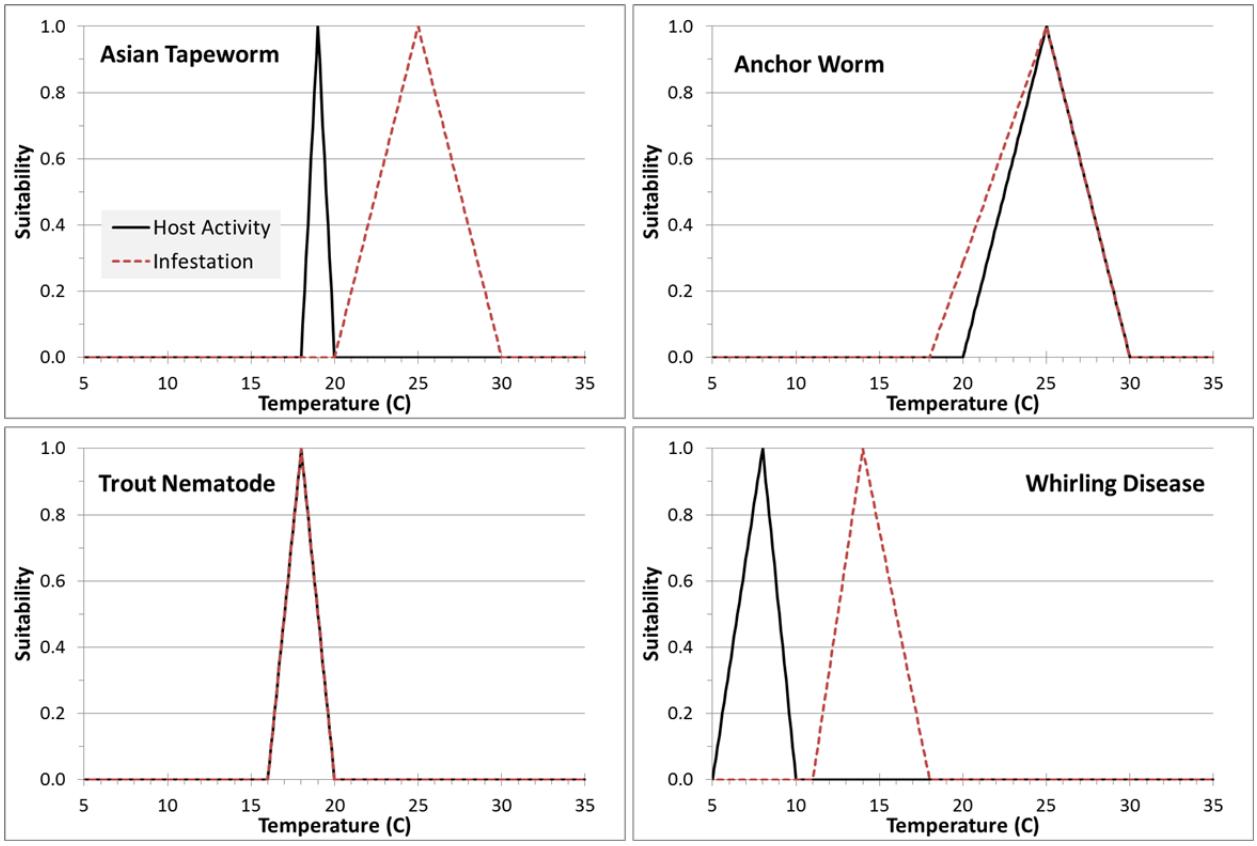

FIGURE F-38 Suitability of Various Water Temperatures for Host Activity and Infestation Rates of Parasite Species (Source: Valdez and Speas 2007)

F.4.5.2 Results for LTEMP Alternatives

Temperature suitability for the four aquatic parasite species (Asian tapeworm, anchor worm, trout nematode, and whirling disease) under the LTEMP alternatives and long-term strategies was modeled for various locations downstream from Glen Canyon Dam. Modeling indicated that temperature suitability for the aquatic parasite species would generally be very low under all long-term strategies and would be comparable to the suitability under current operations as represented by Alternative A (no-action alternative; Figure F-42). As a consequence, the relative distributions of aquatic parasites or the effects of aquatic parasites on survival and growth of native fish or trout species would not be expected to change relative to current conditions under any of the long-term strategies. Under current conditions, population-level effects of parasites on survival and growth of native fish or trout have not been observed. Inclusion of flow actions such as HFEs, TMFs, and low summer flows had only minor influences on modeled monthly mainstem water temperatures during periods of the year considered most important for spawning and egg incubation by native fish. As a consequence, these flow actions are expected to have minor effects on temperature suitability for the parasite species group and would not alter the relative suitability among the long-term strategies.

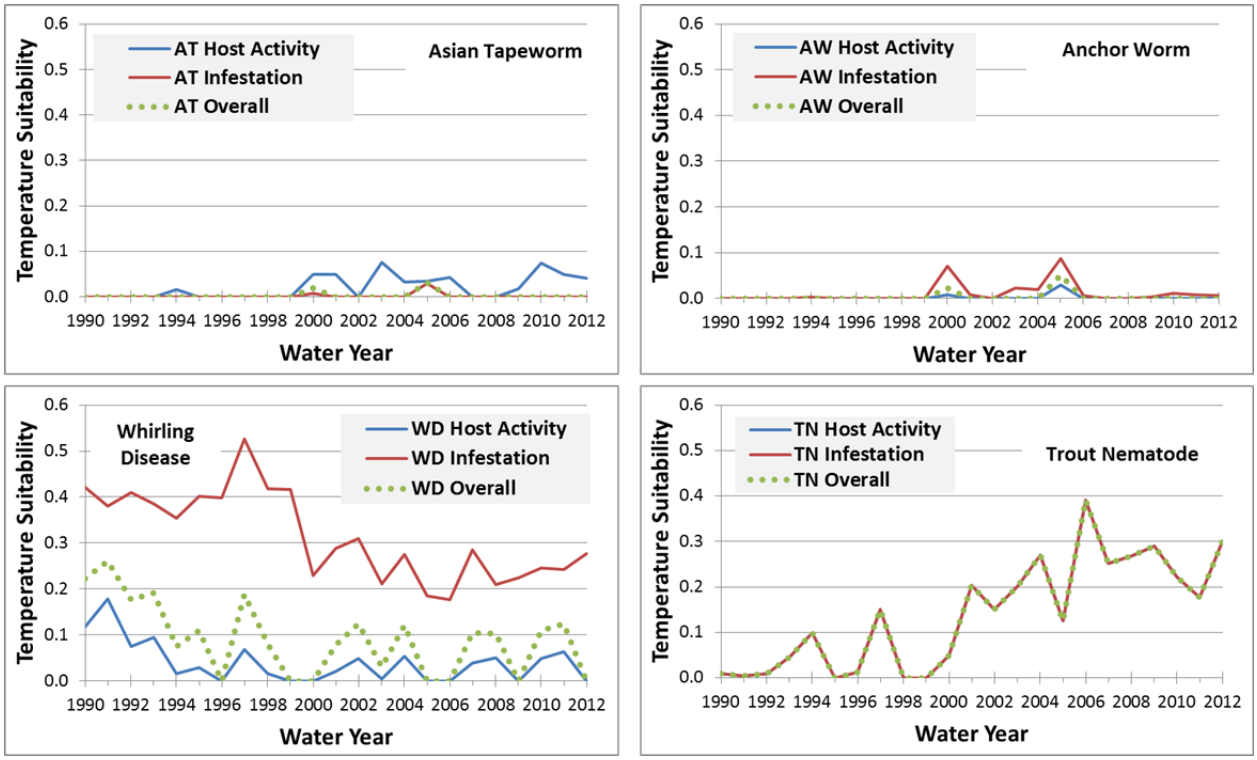

FIGURE F-39 Annual Temperature Suitability Scores for Parasite Species at RM 225 (Diamond Creek) Based on Modeled Water Temperatures for Water Years 1990–2012 (AT = Asian tapeworm; AW = anchor worm; TN = trout nematode; and WD = whirling disease)

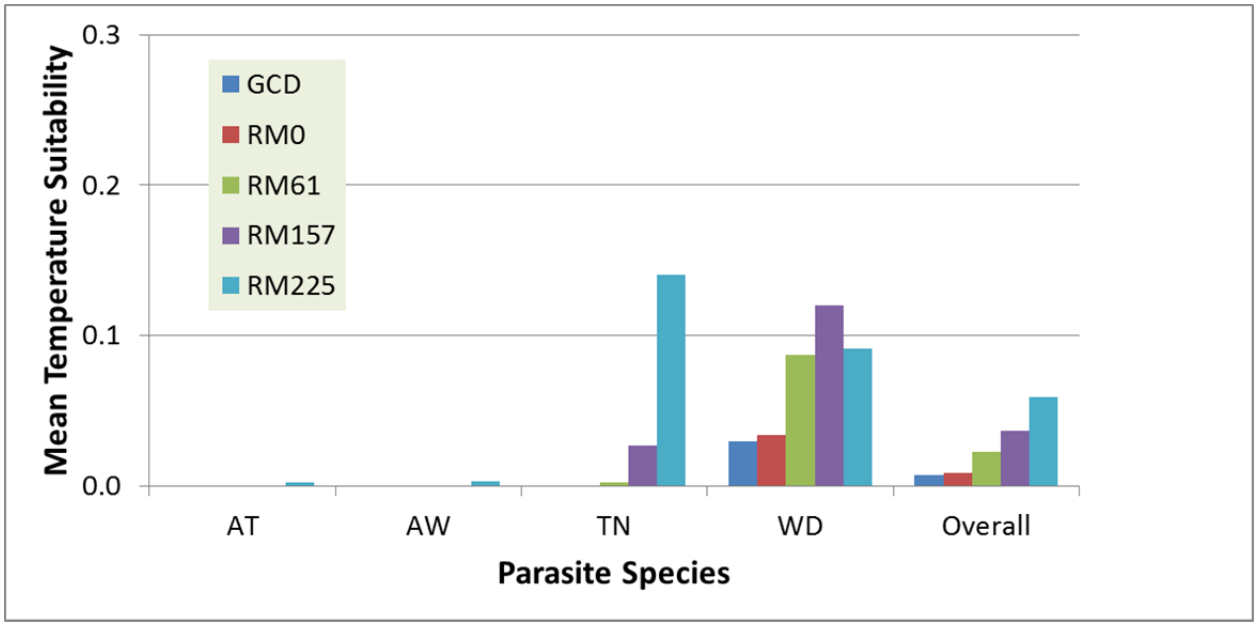

FIGURE F-40 Mean Annual Temperature Suitability Scores for Parasite Species by River Location Based on Modeled Water Temperatures for Water Years 1990–2012 (AT = Asian tapeworm; AW = anchor worm; TN = trout nematode; and WD = whirling disease)

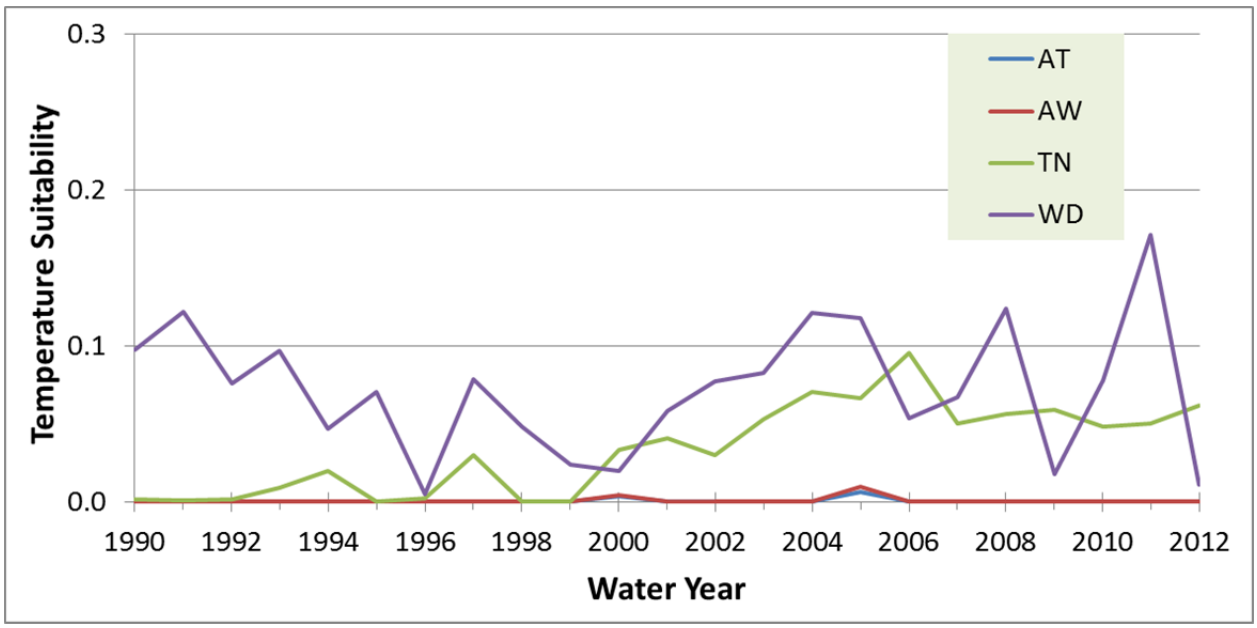

FIGURE F-41 Overall Means of Annual Suitability Scores for Parasite Species across All River Locations during the 1990–2012 Water Years (AT = Asian tapeworm; AW = anchor worm; TN = trout nematode; and WD = whirling disease)

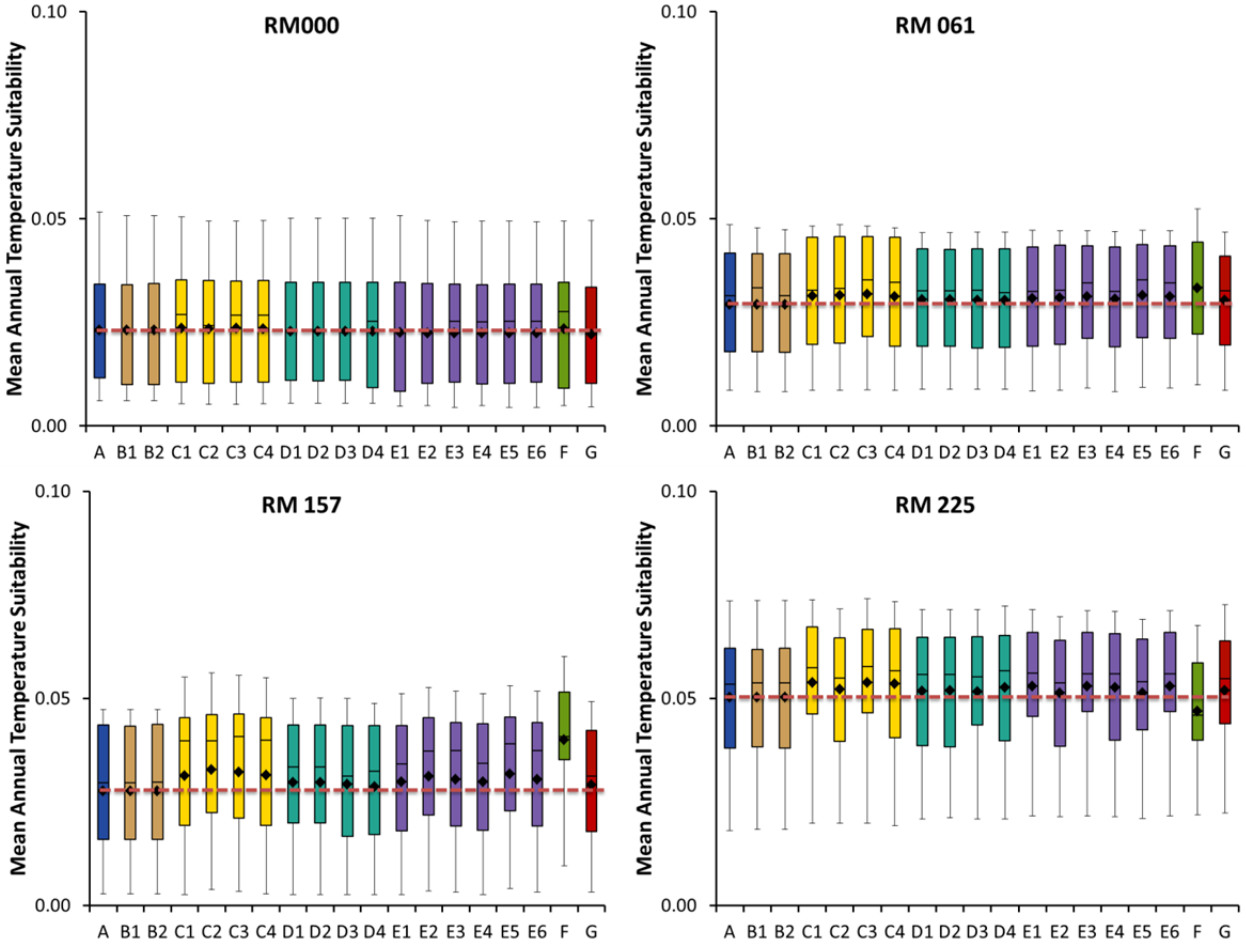

FIGURE F-42 Overall Modeled Mean Annual Temperature Suitability under LTEMP Alternatives and Long-Term Strategies for Aquatic Fish Parasites (Asian tapeworm, anchor worm, trout nematode, and whirling disease) at Four Locations Downstream of Glen Canyon Dam (The graph shows the mean, median, 75th percentile, 25th percentile, minimum, and maximum values for 21 hydrology scenarios and three sediment scenarios. Means were calculated as the average for all years within each of the 21 hydrology runs. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum; horizontal dashed line identifies mean value for Alternative A.)

VEGETATION TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX G:

VEGETATION TECHNICAL INFORMATION AND ANALYSIS

G.1 ANALYSIS METHODS

The analysis of impacts on plant communities is primarily based on the evaluation of four performance metrics that were developed for the Long-Term Experimental and Management Plan (LTEMP) assessment process. The metrics are calculated using the results of an existing state and transition model for Colorado River riparian vegetation downstream from Glen Canyon Dam. Model details are described in Ralston et al. (2014). The four metrics are as follows:

- *Native Cover metric*. Relative change in cover of native vegetation community types (other than arrowweed[1]) on sandbars and channel margins using the total percentage increase in native states (change in native cover = $cover_{final}/cover_{initial}$).

- *Native Diversity metric*. Relative change in diversity of native vegetation community types (other than arrowweed) on sandbars and channel margins using the Shannon-Weiner Index for richness/evenness (change in diversity = $diversity_{final}/diversity_{initial}$).

- *Native/Nonnative Ratio metric*. Relative change in the ratio of native- (other than arrowweed) to nonnative-dominated vegetation community types on sandbars and channel margins (change in native/nonnative ratio = $ratio_{final}/ratio_{initial}$).

- *Arrowweed metric.* Relative change in the arrowweed state on sandbars and channel margins using the total percentage decrease in arrowweed states (change in arrowweed = $arrowweed_{initial}/arrowweed_{final}$).

These performance metrics were developed from the resource goal for riparian vegetation downstream from Glen Canyon Dam: *Maintain native vegetation and wildlife habitat, in various stages of maturity, that is diverse, healthy, productive, self-sustaining, and ecologically appropriate*.

The state and transition model was developed to compare the effects of various flow regimes on Colorado River riparian vegetation. Seven vegetation states are used in the model to represent plant community types found along the river on sandbars and channel margins in the new high-water zone and fluctuation zone. Species associated with a state respond similarly to Colorado River hydrologic factors, such as depth, timing, and duration of inundation. These

[1] This species was selected to be excluded from the native species metrics and to be a fourth metric. It is managed differently from other native species because of its tendency to rapidly establish on sandbars to the exclusion of other species.

states and the plant species associated with each are given in Table G-1. The model and data used to calculate performance metrics are based on vegetation studies conducted within Grand Canyon National Park and may have limited application to riparian vegetation communities within Glen Canyon. The model consists of six submodels based on landforms: lower separation bar, upper separation bar, lower reattachment bar, upper reattachment bar, lower channel margin, and upper channel margin. Upper and lower bars are divided at the 25,000-cfs flow stage.

The model uses the daily maximum flow from the GTMax-Lite 2 hydrograph (GTMax-Lite 2 includes hourly flows for the entire 20-yr flow period); it does not include daily fluctuations (the range in flows within a day). A total of 63 hydrology-sentiment trace combinations were included in the analysis of each alternative and long-term strategy. Within each run of each alternative, the model identifies the occurrence of hydrologic events, such as spill flows, spring and fall high-flow experiments (HFEs), extended low flows, extended high flows, and growing or nongrowing seasons without extended high or low flows, occurring during the growing season (May–September) or nongrowing season (October–March) (see Table G-2). The model then records transitions between vegetation states, based on a set of rules developed for each submodel, driven by these hydrologic events. The model includes a subset of states and transition rules for each bar type and channel margin type. The transition rules for the upper portions of the bars and channel margins are the same because of the similarity of plant community types and responses to flow characteristics. The transition rules are based on the effects of scouring, drowning, desiccation, and sediment deposition on riparian plant species. The interrelationships among vegetation states were developed primarily from published vegetation studies based on data collected in Grand Canyon National Park (see Ralston et al. 2014 and citations therein). A subject matter expert team refined the transitions based on extensive field experience in the Colorado River riparian system. Transition rules for the submodels are given in Table G-3. Although the model is a simplification of the complexities of the riparian ecosystem, it is a valuable tool for estimating the changes in riparian vegetation under a variety of flow regimes.

Model results include the total number of years each state occurs for the 20-yr period of the model run, according to each potential starting state in each submodel (i.e., the number of years each feature is in each state, based on the transition rules). Each model run starts with each potential state of each submodel, shown in Table G-1. For example, the lower reattachment bar submodel uses five different starting states for each hydrologic trace: bare sand, *Phragmites australis* Temperate Herbaceous Vegetation, *Equisetum hyemale* Herbaceous Vegetation, Tamarisk Temporarily Flooded Shrubland, and *Pluchea sericea* Seasonally Flooded Shrubland. Therefore, five model runs, each with a different starting state, are made with the reattachment bar submodel for each trace.

G.1.1 Old High-Water Zone Analysis

Plant communities of the old high-water zone are not included in the riparian state and transition model. Therefore, a qualitative assessment was conducted to evaluate impacts of alternatives. The old high-water zone vegetation is located at high-flow stage elevations (above 60,000 cfs, but primarily from about 100,000 to approximately 200,000 cfs), well above the level

of current dam operations. Dam operations, other than HFEs, are limited to 31,500-cfs flows (generally will not exceed 25,000 cfs), and HFEs do not exceed 45,000 cfs.

None of the alternatives considered would include flows sufficient to maintain these pre-dam plant communities. HFEs could potentially provide occasional soil moisture to some older deep-rooted plants located in the old high-water zone that are at the lower edge, close to the new high-water zone. Dam releases can affect water availability for plants at elevations up to approximately 15,000 cfs above discharge levels (Melis et al. 2006; Ralston 2005). Alternatives with more frequent spring HFEs—such as Alternative F, with annual spring HFEs, or Alternative G; Alternative C, long-term strategies C1 and C2; and Alternative D, long-term strategies D1–D4, all with considerably more spring HFEs than Alternative A—may result in higher survival rates of plants at lower elevations of the old high-water zone than under Alternative A because of increased moisture within the root zone. The differences between alternatives in effects on the lower margin of the old high-water zone are expected to be minor. Spill flows (between 45,000 and 85,000 cfs) would provide soil moisture to old high-water zone plants; however, these have not occurred since the mid-1980s. Periodic spill flows could occur within the 20-yr period of this evaluation, but would likely be infrequent and would occur equally under all alternatives. Because of a lack of sufficiently high flows and nutrient-rich sediment, mortality of pre-dam plants within this zone has been occurring for decades, along with a lack of seedling establishment for some species, such as mesquite and hackberry (Kearsley et al. 2006; Anderson and Ruffner 1987; Webb et al. 2011). Because of generally continued low soil moisture and lack of recruitment opportunities under all alternatives, the upper margins of this zone would be expected to continue moving downslope, with a continued narrowing of this zone. Desert species occurring on the pre-dam flood terraces and aeolian deposits above the old high-water zone would increasingly establish within this zone. Therefore, the narrowing of the old high-water zone is outside the scope of the LTEMP impact analysis.

G.1.2 New High-Water Zone

The four metrics—(1) relative change in cover of native vegetation community types, (2) relative change in diversity of native vegetation community types, (3) relative change in the ratio of native- to nonnative-dominated vegetation community types, and (4) relative change in the arrowweed state—were calculated from the model results for each alternative and long-term strategy. The four native-dominated states are *Phragmites australis* Temperate Herbaceous Vegetation, *Salix exigua-Baccharis emoryi* Shrubland/*Equisetum laevigatum* Herbaceous Vegetation, *Populus fremontii*/*Salix exigua* Forest, and *Prosopis glandulosa* var. *torreyana* Shrubland. Two of these states, both of which represent wetland community types, are further discussed below. Although arrowweed is a native species, because of its invasive characteristics and tendency to form monocultures, the *Pluchea sericea* Seasonally Flooded Shrubland state is excluded from the native states in the performance metrics.

Model results were used to calculate the performance metrics for each alternative/long-term strategy using the sum of years of each of the states for all six models. This value was then compared to the number of years each state would have accumulated if the current condition was maintained (i.e., if no transitions occurred and each of the seven states remained the same for the

full 20 yr of the model run). This proportion was then multiplied by the acreage of mapped cover types from the National Park Service Vegetation Map of Grand Canyon National Park (Table G-4) corresponding to the seven model states (Table G-5). This final acreage and the initial mapped acreage were then used to calculate the performance metrics.

The results for the four metrics were then summed to derive a final score for each alternative long-term strategy. Alternatives with higher scores were considered to have come closer to achieving the resource goal.

The 63 hydrology-sediment trace combinations used in the model runs were developed from the historical record (see Section 4.2 of the EIS for a detailed description). Twenty-one potential Lake Powell inflow scenarios for the 20-yr LTEMP period were sampled from the 105-yr historic record (water years 1906–2010), producing 21 hydrology traces for analysis. In addition, three 20-yr sequences of sediment input from the Paria River sediment record (water years 1964–2013) were analyzed. In combination, the analysis considered 63 possible hydrology-sediment scenarios. An assumption underlying the model results is that future river flows will be similar to past flows. To examine the effect of potential climate change, each of the traces used in the model runs was then differentially weighted (see Section 4.17.1.2). Weights were developed based on climate change projections of the 2012 Colorado River Basin Water Supply and Demand Study (Reclamation 2012). These assigned weights thus reflect the likelihood of occurrence of each hydrology trace under potential future climate change, emphasizing the drier scenarios. The model result for each trace was then multiplied by the assigned weight.

G.1.2.1 Native Cover Metric

The first metric is the relative change in cover of native vegetation community types (other than arrowweed) on sandbars and channel margins, calculated by using the total percentage increase in native states (change in native cover = $cover_{final}/cover_{initial}$).

The results for the Native Cover metric based on historical flows are shown in Figure G-1. The two highest scoring long-term strategies, E6 and E3, are significantly different from the others (differences between means of the 63 traces based on a three-factor ANOVA followed by Tukey's Studentized Range [HSD] Test) but not from each other. Results under projected climate change are similar to those for historical flows (all alternatives score slightly higher) and are shown in Figure G-2. Thus the relative performance of each alternative under climate change would be similar to that modeled under historical conditions.

To illustrate the relative change in native cover, the modeled acreage changes for several alternatives/long-term strategies are shown in Table G-6.

Native states tend to increase with growing and nongrowing seasons without extended high or low flows. Bare Sand, Tamarisk Temporarily Flooded Shrubland, and *Pluchea sericea* Seasonally Flooded Shrubland tend to increase with extended high and extended low flows. The

effect of differences between hydrologic traces is greater than the effect of differences between alternatives.

G.1.2.2 Native Diversity Metric

The second metric is the relative change in diversity of native vegetation community types (other than arrowweed) on sandbars and channel margins, calculated by using the Shannon-Weiner Index for richness/evenness (change in diversity = $\text{diversity}_{final}/\text{diversity}_{initial}$).

The Native Diversity metric is calculated using the Shannon-Weiner Index for richness/evenness: $-\Sigma(p_i)(\log_2 p_i)$, where p_i is the proportion of the i-th state of the total native cover. The calculations use the initial mapped cover and final (modeled) cover of each of the four native-dominated states. The results for the Native Diversity metric based on historical flows are shown in Figure G-3. the two highest scoring alternatives—Alternative E, long-term strategy E4, and Alternative B, long-term strategy B1—are not significantly different from each other (differences between means based on a three-factor ANOVA followed by Tukey's Studentized Range [HSD] Test); long-term strategy B1 is not significantly different from long-term strategies D3 and D2. Results under projected climate change are similar to those for historical flows, with 11 alternatives showing a slight increase and 8 a slight decrease, and are shown in Figure G-4. thus the performance of each alternative under climate change would be similar to that modeled under historical conditions. The results for all alternatives include all states. Therefore, there is no difference in the number of states between alternatives; diversity is increased by the evenness of states. For example, long-term strategy B2 and Alternative F, which are somewhat lower scoring, have a low representation of the *Phragmites australis* Temperate Herbaceous Vegetation state, while long-term strategies B1 and E4, somewhat higher scoring, have a relatively high representation of that state. The transition to the *Phragmites australis* Temperate Herbaceous Vegetation state from the bare sand state in the lower reattachment bar is slowed by growing-season extended high flows, and growing-season extended low or high flows contribute to transitions of the *Phragmites australis* Temperate Herbaceous Vegetation state to other states. The effect of differences between alternatives is greater than the effect of differences between hydrologic traces.

G.1.2.3 Native/Nonnative Ratio Metric

The third metric is the relative change in the ratio of native- (other than arrowweed) to nonnative-dominated vegetation community types on sandbars and channel margins (change in native/nonnative ratio = $\text{ratio}_{final}/\text{ratio}_{initial}$).

The Native/Nonnative Ratio metric is calculated using the ratio of the cover of each of the four native-dominated states to the cover of the tamarisk state. The ratio of the final (modeled) cover is then divided by the ratio of the initial mapped cover. The results for the Native/Nonnative Ratio metric based on historical flows are shown in Figure G-5. the three highest-scoring long-term strategies, E6, E3, and E5, are not significantly different from each other (between means based on a three-factor ANOVA followed by Tukey's Studentized

Range [HSD] Test); long-term strategy E5 is not significantly different from long-term strategy B1. Results under projected climate change are similar to those for historical flows (all alternatives score slightly higher) and are shown in Figure G-6. Thus the performance of each alternative under climate change would be similar to that modeled under historical conditions.

Native states tend to increase with growing and nongrowing seasons without extended high or low flows. The tamarisk state tends to increase with extended high flows followed by extended low flows, as well as spring HFEs with an extended low or high flow. Under Alternative C, long-term strategy C1, and Alternative F, high flows shift all states to sand, which then shifts to tamarisk (e.g., lower reattachment bar, growing-season extended low).

G.1.2.4 Arrowweed Metric

The fourth metric is the relative change in the arrowweed state on sandbars and channel margins, calculated by using the total percentage decrease in arrowweed states (change in arrowweed = $\text{arrowweed}_{initial}/\text{arrowweed}_{final}$).

The results for the Arrowweed metric based on historical flows are shown in Figure G-7. The two highest scoring long-term strategies, C1 and C2, are not significantly different from each other (between means based on a three-factor ANOVA followed by Tukey's Studentized Range [HSD] Test); long-term strategy C2 is not significantly different from Alternatives F and G. Results under projected climate change are similar to those for historical flows (all alternatives score slightly lower) and are shown in Figure G-8. Thus the performance of each alternative under climate change would be similar to that modeled under historical conditions (Alternative F would be the highest scoring, however).

To illustrate the relative change in arrowweed, acreage changes for several alternatives/long-term strategies are shown in Table G-7.

The arrowweed state tends to increase with extended high and extended low flows, but this increase can be slowed by fall HFEs. The effect of differences between hydrologic traces is greater than the effect of differences between alternatives.

G.1.2.5 Overall Score

The results for the overall score based on historical flows are shown in Figure G-9. The six highest scoring long-term strategies, D4, E4, E6, E3, E5, and B1, are not significantly different from each other (between means based on a three-factor ANOVA followed by Tukey's Studentized Range [HSD] Test); long-term strategies E5 and B1 are not significantly different from long-term strategy E2. These alternatives included the five highest scores in the Native Cover metric and Native/Nonnative Ratio metric. The lowest scoring is long-term strategy C3, which is the lowest in the Arrowweed metric and consistently low scoring in the other metrics. Results under projected climate change are similar to those for historical flows, with four alternatives showing a slight decrease and all others a slight increase, and are shown in

Figure G-10. thus the performance of each alternative under climate change would be similar to that modeled under historical conditions.

For the overall score, the effects of the differences between alternatives are greater than the effects of differences between hydrologic traces; sediment traces 1 and 2 are significantly different.

The following is a review of the components of the overall score:

- *Native Cover metric*. Long-term strategies E6 and E3 are the highest scoring; native states tend to increase with growing and nongrowing seasons without extended high or low flows.

- *Native Diversity metric*. Long-term strategies E4 and B1 are the highest scoring. The transition to the *Phragmites australis* Temperate Herbaceous Vegetation state from the bare sand state in the lower reattachment bar is slowed by growing-season extended high flows, reducing diversity, and growing-season extended low or high flows contribute to transitions of the *Phragmites australis* Temperate Herbaceous Vegetation state to other states.

- *Native/Nonnative Ratio metric*. Long-term strategies E6, E3, and E5 are the highest scoring; the tamarisk state tends to increase with extended high flows followed by extended low flows, as well as spring HFEs with an extended low or high flow.

- *Arrowweed metric*. Long-term strategies C1and C2 are the highest scoring; the arrowweed state tends to increase with extended high and extended low flows.

G.1.3 Wetlands

Two of the model states discussed above represent wetland community types: *Phragmites australis* Temperate Herbaceous Vegetation, a marsh community, and *Salix exigua-Baccharis emoryi* Shrubland/*Equisetum laevigatum* Herbaceous Vegetation, a shrub wetland community. These occur on the lower reattachment bar and lower channel margin (as well as lower reattachment bar) (Table G-1) and occupy 4.4 and 0.2 ac, respectively (Table G-5). The relative change in cover of these wetland community types was calculated from the model results using the method described for the Native Cover metric. The results for the 19 alternatives/long-term strategies are presented in Table G-27 and Figure G-11 (a score of 1.0 means no change from initial conditions). Only Alternative E long-term strategies E3, E5, and E6 show an increase in wetland community cover (based on mean scores); all others show a decrease. Decreases of greater than 50% occur under Alternative B, long-term strategy B2; Alternative C; Alternative F; and Alternative G. Results under projected climate change are similar to those for historical flows (all alternatives score slightly higher; however, Alternative F shows only a minimal

increase) and are shown in Figure G-12. Thus the performance of each alternative under climate change would be similar to that modeled under historical conditions.

G.2 ALTERNATIVE-SPECIFIC IMPACTS

This section provides additional information on the impacts of alternatives, specifically the impacts associated with the long-term strategies that were analyzed for condition-dependent alternatives (Alternatives B, C, D, and E). This analysis supplements the information presented in Section 4.6 of the EIS.

G.2.1 Alternative A (No Action Alternative)

Alternative A includes sediment-triggered spring and fall HFEs through 2020 (no spring HFEs until 2015). Alternative A has higher monthly volumes in the high-electricity-demand months of December, January, July, and August. This alternative has fewer spring and fall HFEs than other alternatives, occasional extended low flows, and more frequent extended high flows than most other alternatives, the last being particularly frequent in the growing season. The model results for each of the metrics as well as the overall score for Alternative A are presented in Table G-8.

G.2.2 Alternative B

Alternative B includes spring and fall HFEs (the number of HFEs not to exceed one every other year). This alternative lacks low summer flows and has higher monthly volumes December–January and July–August. Alternative B has few spring HFEs, similar to Alternative A, but more fall HFEs than Alternative A. The expected number of HFEs would be lower under this alternative than under any other. Alternative B has the same monthly pattern in release volume as Alternative A; however, Alterative B has no extended low flows; long-term strategy B1 has a slightly greater frequency of extended high flows compared to Alternative A; and long-term strategy B2 has considerably more extended high flows than long-term strategy B1—far more than any other alternative long-term strategy. The results for Alternative B are presented in Table G-9 for long-term strategy B1 and in Table G-10 for long-term strategy B2.

G.2.3 Alternative C

Alternative C includes spring and fall HFEs in long-term strategies C1 and C2, fall HFEs only in long-term strategy C4, and no HFEs in long-term strategy C3; proactive spring HFEs are tested in April, May, or June in high-volume years. This alternative features low summer flows in some years in long-term strategy C2 and has highest monthly release volumes December–January and July, and lower volumes August–November. Long-term strategies C1–C4 have more extended low flows and fewer growing-season extended high flows than

Alternative A (although long-term strategies C2–C4 have more growing-season extended high flows than long-term strategy C1); long-term strategy C3 has slightly more nongrowing-season extended high flows than the other Alternative C long-term strategies. Long-term strategies C1 and C2 have considerably more spring and fall HFEs than Alternative A; the number of long-term strategy C4 fall HFEs is similar to those of long-term strategies C1 and C2. The model results for each of the metrics, as well as the overall score for Alternative C, are presented in Table G-11 for long-term strategy C1; in Table G-11 in Table G-12 for C2, in Table G-13 for C3, and in Table G-14 for C4.

G.2.4 Alternative D (Preferred Alternative)

Alternative D includes spring (March–April) and fall (October–November) HFEs; proactive spring HFEs (24 hr, 45,000 cfs) would be tested (April, May, or June) in high-volume years; no spring HFEs the first 2 yr; and extended-duration fall HFEs (up to 250-hr duration, up to 45,000 cfs), up to four in a 20-yr period. As a result, Alternative D has a greater frequency of fall and spring HFEs compared to Alternative A. Monthly water volumes would be similar to Alternative E, but August and September would have higher volumes and January–July would have slightly lower volumes than Alternative E. A 2- or 3-yr test for invertebrate production would reduce flows to the minimum for the month on Saturdays and Sundays in May–August starting the third year of the LTEMP period. If successful, these flows would be implemented for the remainder of the LTEMP period (up to 18 yr total), resulting in few, if any, growing-season extended high flows during those years. Low summer flows (July–September) would be tested in two or three of the second 10 yr. This alternative has very few growing-season extended low flows, as well as slightly fewer nongrowing-season extended low or high flows, because of the monthly pattern of flows as well as the amount of daily fluctuations. Alternative D has frequent growing-season extended high flows but not as many as Alternative A. Seasons, especially nongrowing seasons, without extended low or high flows are frequent. The model results for each of the metrics as well as the overall score for Alternative D are presented in Table G-15 for long-term strategy D1, in Table G-16 for D2, in Table G-17 for D3, and in Table G-18 for D4.

G.2.5 Alternative E

Alternative E includes spring and fall HFEs; no spring HFEs in the first 10 yr; rapid response tested every fourth HFE matching Paria flood; spring and fall HFEs in long-term strategies E1 and E2; fall HFEs only in long-term strategy E4; and no HFEs in long-term strategies E3, E5, and E6. This alternative has lower monthly water volumes in August, September, and October. Low summer flows occur in some years (triggered) of the second 10 yr in long-term strategies E2 and E5. Long-term strategies E1–E6 have fewer growing-season extended high flows than Alternative A (long-term strategies E2 and E5 have slightly more than the other Alternative E long-term strategies) and more HFEs than Alternative A. Long-term strategies E1 and E2 have similar numbers of HFEs; the number of fall HFEs for long-term strategy E4 is similar to those for long-term strategies E1 and E2. The model results for each of the metrics as well as the overall score for Alternative E are presented in Table G-19 for long-

term strategy E1, in Table G-20 for E2, in Table G-21 for E3, in Table G-22 for E4, in Table G-23 for E5, and in Table G-24 for E6.

G.2.6 Alternative F

Alternative F includes spring and fall HFEs; peak flows in May and June; base flows July–January; and a 168-hr (7-day) 25,000-cfs flow at the end of June. This alternative also features higher volumes than Alternative A April–June and lower volumes than Alternative A in the other months. This alternative has more extended low flows, slightly fewer extended high flows, and considerably more HFEs than Alternative A (more than any other alternative). The model results for each of the metrics as well as the overall score for Alternative F are presented in Table G-25.

G.2.7 Alternative G

Alternative G includes spring and fall HFEs; HFEs for up to 336 hr (2 weeks); proactive spring HFEs tested in high-volume years; and monthly volumes varying only in response to runoff forecast and other requirements. This alternative has more extended low flows and fewer extended high flows than Alternative A. The model results for each of the metrics, as well as the overall score for Alternative G, are presented in Table G-26.

G.3 SUMMARY

Transitions between plant community types, or to bare sand, are driven by specific flow events that vary among the alternatives. Spring HFEs, fall HFEs, spill flows, extended low flows, extended high flows, and seasons without extended high or low flows occurring during the growing or nongrowing season result in changes in the distribution and cover of new high-water zone plant communities.

HFEs result in sediment deposition, but scouring is minor and limited to low-elevation wetland species. HFEs transport seeds of nonnative as well as native species. Repeated extended high flows result in removal of vegetation by drowning and scouring, primarily on lower elevation surfaces. Increased soil moisture at upper elevations from extended high flows can increase vegetation growth and seedling establishment. The germination of seeds transported by HFEs or extended high flows is promoted by extended low flows (e.g., elevated base flows) that reduce disturbance, expose lower elevation surfaces, and maintain soil moisture at lower elevations, all of which are conducive to seedling growth. Extended low flows also can result in the lowering of groundwater levels, thus increasing the depth to groundwater and reducing soil moisture, creating conditions that favor the growth of more drought-tolerant species.

Repeated seasons of extended high flows, extended high flows above 50,000 cfs, or spill flows transition native communities to bare sand through the processes of drowning, scouring, and burial. All the alternatives would result in a decrease in native plant community cover.

Wetland communities generally transition only from bare sand or other wetlands; they can transition back to bare sand or to arrowweed, tamarisk, or cottonwood-willow communities. Alternatives that include frequent extended low flows, such as annually for Alternative F, or extended high flows followed by extended low flows tend to result in transitions of wetlands to other plant community types. All the alternatives are expected to result in a decrease in wetland cover, with particularly large decreases for Alternative F.

The overall cover of tamarisk-dominated communities would be expected to increase under Alternatives C, F, and G, each of which is expected to produce frequent transitions to tamarisk communities, in large part because they frequently have extended high flows, extended low flows, and spring HFEs. This combination of flows encourages transitions to tamarisk because tamarisk increases when high flows coincide with seed release during spring and early summer, followed by lower flows, all of which results in establishment of seedlings above the elevation of subsequent floods. Also, under these alternatives, various community types frequently shift to bare sand, which then shifts to tamarisk. Each of these alternatives has more extended low flows and more spring HFEs than the other alternatives. The overall cover of the tamarisk is expected to decrease under Alternatives A, B, D, and E. Each of these alternatives has frequent extended high flows, which result in consecutive seasons and consecutive years of extended high flows. Two or more years of extended high flows are required for tamarisk to be removed by drowning, leaving a bare sand lower reattachment bar, or two consecutive seasons on a lower separation bar.

The overall cover of the arrowweed community would be expected to increase under Alternatives A, B, and E; under these alternatives, bare sand would transition to arrowweed rather than tamarisk because there are few spring HFEs and/or few growing-season extended high flows, both of which promote the establishment of tamarisk on bare sand, and, except in Alternative B, arrowweed would transition from marsh because of growing-season extended low flows. Once established, arrowweed would tend to remain for many years under these alternatives. HFEs alone are not effective at reducing arrowweed as burial typically results in resprouting from roots, buried stems, and rhizomes, and subsequent vegetative growth occurs. Arrowweed would decrease under Alternatives C, D, F, and G, usually by transitioning to bare sand with repeated extended high flows, but often by transitioning to tamarisk.

TABLE G-2 Hydrologic Events Considered in the Riparian Vegetation Model

Event	Flow Range	Timing
Spill flow[a]	>45,000 cfs one day or more	Any month
Spring HFE	>31,500 cfs to ≤45,000 cfs, less than 30 days[b]	March–June
Fall HFE	>31,500 cfs to ≤45,000 cfs, less than 30 days[b]	October–December
Extended low flow	≤10,000 cfs for at least 30 consecutive days	Growing season; nongrowing season
Extended high flow	≥20,000 cfs to ≤45,000 cfs for at least 30 consecutive days	Growing season; nongrowing season
Growing or nongrowing seasons without extended high or low flows	Flows that can fluctuate up to 25,000 cfs (i.e., the absence of spill flows or extended high or extended low flows)	Growing season; nongrowing season

[a] Spill flows (i.e., flows that include releases through the spillway and total >45,000 cfs) are not a function of the alternatives, but rather a function of annual hydrology. These do not differ among the alternatives.

[b] A peak or spike in flow between 31,500 and 45,000 cfs that begins or ends below 31,500 cfs is considered an HFE.

TABLE G-3 Riparian Vegetation Model Transition Rules

Transition	From	To	Trigger	Notes
Upper Separation Bar				
T1	Bare Sand	*Pluchea sericea* Seasonally Flooded Shrubland	*Pluchea* cover[a] = 30%	*Pluchea* growth variable (before T1 transition): cover starts at 1% in bare sand frame; nongrowing-season extended low flow or season without extended high or low flow + growing-season extended low flow or season without extended high or low flow same year = 5%; nongrowing-season extended low flow or season without extended high or low flow + growing-season extended high flow same year = 7.5%; nongrowing-season extended high flow + growing-season extended low flow or season without extended high or low flow same year = 7.5%; nongrowing-season extended high flow + growing-season extended high flow same year = 10%; fall HFE same year = increase × 0.5.
T2	Bare Sand	Tamarisk Temporarily Flooded Shrubland	Spring HFE + growing-season extended high flow same year	*Pluchea* cover must be ≤10%.
T3	Tamarisk Temporarily Flooded Shrubland	*Prosopis glandulosa* var. torreyana Shrubland	*Prosopis* cover = 25%	*Prosopis* growth variable (before T3 transition): cover starts at 0% in tamarisk frame; spring HFE + growing season without extended high or low flow same year = +2%; spring HFE + growing-season extended high flow same year = +2%; growing-season extended low flow = −0.5%.
T4	Tamarisk Temporarily Flooded Shrubland, *Pluchea sericea* Seasonally Flooded Shrubland, or *Prosopis glandulosa* var. *torreyana* Shrubland	Bare Sand	Spill flow; *or* any season extended high flow >50K cfs	Extended high flow must be >50K cfs.

TABLE G-3 (Cont.)

Transition	From	To	Trigger	Notes
Lower Separation Bar				
T1	Bare Sand	*Populus fremontii/Salix exigua* forest	*Populus/Salix* cover = 20%	*Populus/Salix* growth variable (before T1 transition): cover starts at 1% in S1 frame; nongrowing season without extended high or low flow + growing season without extended high or low flow same year = +3%; nongrowing-season extended high flow + growing season without extended high or low flow same year = cover × 0.5.
T2	Bare Sand	Tamarisk Temporarily Flooded Shrubland	Nongrowing-season extended high flow + growing-season extended low flow same year; *or* spring HFE + growing-season extended low flow same year	
T3	Tamarisk Temporarily Flooded Shrubland or *Populus fremontii*/*Salix exigua* Forest	Bare Sand	Nongrowing-season or growing-season spill flow; *or* nongrowing-season extended high flow + growing-season extended high flow same year; *or* growing-season extended high flow + nongrowing-season extended high flow next year	
Lower Reattachment Bar				
T1	Bare Sand	*Phragmites australis* Temperate Herbaceous Vegetation	*Phragmites* cover = 20%	*Phragmites* growth variable (before T1 transition): growing season without extended high or low flow = +10%; growing-season extended high flow set to 0.

TABLE G-3 (Cont.)

Transition	From	To	Trigger	Notes
Lower Reattachment Bar (Cont.)				
T2	*Phragmites australis* Temperate Herbaceous Vegetation	*Salix exigua-Baccharis emoryi* shrubland/*Equisetum laevigatum* Herbaceous Vegetation	Growth variable = 4 (see "Notes" column of this table for growth variable calculation)	*Salix-Baccharis/Equisetum* growth variable (before T2 transition): nongrowing season without extended high or low flow + growing season without extended high or low flow same year = +1; fall HFE or spring HFE = −1; any season extended high flow sets to 0. Values are not additive within a year; e.g., fall HFE + spring HFE in same year is still −1. Nongrowing-season extended low flow = season without extended high or low flow.
T3	*Salix exigua-Baccharis emoryi* Shrubland/*Equisetum laevigatum* Herbaceous Vegetation	Tamarisk Temporarily Flooded Shrubland	Nongrowing-season extended high flow + growing-season extended low flow same year; *or* growing-season extended high flow + next year growing-season extended low flow	
T4	*Phragmites australis* Temperate Herbaceous Vegetation, or *Salix exigua-Baccharis emoryi* Shrubland/*Equisetum laevigatum* Herbaceous Vegetation, or *Pluchea sericea* Seasonally Flooded Shrubland	Bare Sand	Nongrowing-season extended high flow + growing-season extended high flow same year; *or* growing-season extended high flow + nongrowing-season extended high flow next year; *or* growing-season extended high flow + growing-season extended high flow next year; *or* any spill flow	
T5	*Phragmites australis* Temperate Herbaceous Vegetation	Tamarisk Temporarily Flooded Shrubland	Nongrowing-season extended high flow + growing-season extended low flow same year *or* growing-season extended high flow + growing-season extended low flow next year	

TABLE G-3 (Cont.)

Transition	From	To	Trigger	Notes
Lower Reattachment Bar (Cont.)				
T6	Tamarisk Temporarily Flooded Shrubland	Bare Sand	Growing-season extended high flow + nongrowing-season extended high flow in sequence of 4; *or* growing-season extended high flow in sequence of 4; *or* any season spill flow	Does not have to be same year.
T7	Bare Sand	Tamarisk Temporarily Flooded Shrubland	Growing-season extended low flow	
T8	*Pluchea sericea* Seasonally Flooded Shrubland	Tamarisk Temporarily Flooded Shrubland	Growing-season extended high flow + growing-season extended low flow the next year *or* nongrowing-season extended high flow + growing-season extended low flow same year	
T9	*Phragmites australis* Temperate Herbaceous Vegetation	*Pluchea sericea* Seasonally Flooded Shrubland	Growing-season extended low flow	*Not* if nongrowing-season extended high flow same year (then *Phragmites* transitions to tamarisk).
Lower Channel Margin				
T1	Bare Sand	*Salix exigua-Baccharis emoryi* Shrubland/*Equisetum laevigatum* Herbaceous Vegetation	Growth variable = 4 (see *Notes* for growth variable calculation)	*Salix-Baccharis/Equisetum* growth variable (before T1 transition): nongrowing season without extended high or low flow + growing season without extended high or low flow same year = +1; growing-season extended low flow = −1; fall HFE or spring HFE = −1; any season extended high flow sets to 0. Values are not additive within a year; e.g., fall HFE + growing-season extended low flow in same year is still −1.

TABLE G-3 (Cont.)

Transition	From	To	Trigger	Notes

TABLE G-7 Example Results for the Arrowweed Metric[a]

Alternative/ Long-Term Strategy	Final Area (ac)	Change
C1, C2	152	−25
D4	160	−17
A	222	45
C3	235	58

[a] Initial area: 177 a\c (based on Kearsley et al. 2015).

TABLE G-8 Results for Alternative A

Parameter	Metric 1: Native Cover (Final Cover/ Initial Cover)	Metric 2: Native Diversity (Final Diversity/ Initial Diversity)	Metric 3: Native/ Nonnative Ratio (Final Ratio/ Initial Ratio)	Metric 4: Arrowweed (Initial Arrowweed/ Final Arrowweed)	Overall Score
Mean score (weighted mean for all sediment traces)	0.827	0.983	1.051	0.799	3.661
Modeled values	263.8 ac, all four native states (initial cover 319.0 ac)	Modeled diversity 1.065, all four native states (initial diversity 1.083)	Modeled ratio 1.226 (initial ratio 1.166)	221.8 ac arrowweed state (initial cover 177.3 ac)	NA
Change in cover (ac)	Native states decrease of 55.2 ac	NA	Tamarisk state decrease of 58.4 ac[b]	Arrowweed state increase of 44.5 ac	NA
Percentage change in cover	17.3% reduction in cover of native states	1.7% reduction in diversity of native states[a]	5.1% increase in the native/ nonnative ratio	25.1% increase in the arrowweed state cover	Overall movement away from the resource goal

[a] Because the results for each modeled run include the same number of states (each state is a different starting condition for model runs), a reduction in diversity indicates a reduction in evenness among the vegetation states.

[b] A relative increase in native cover or decrease in nonnative cover can increase the ratio.

TABLE G-9 Results for Alternative B, Long-Term Strategy B1

Parameter	Metric 1: Native Cover (Final Cover/ Initial Cover)	Metric 2: Native Diversity (Final Diversity/ Initial Diversity)	Metric 3: Native/ Nonnative Ratio (Final Ratio/ Initial Ratio)	Metric 4: Arrowweed (Initial Arrowweed/ Final Arrowweed)	Overall Score
Mean score (weighted mean for all sediment traces)	0.849	1.027	1.148	0.842	3.865
Modeled values	270.7 ac, all four native states (initial cover 319 ac)	Modeled diversity 1.113, all four native states (initial diversity 1.083)	Modeled ratio 1.338 (initial ratio 1.166)	210.6 ac arrowweed state (initial cover 177.3 ac)	NA
Change in cover (ac)	Native states decrease of 48.3 ac	NA	Tamarisk state decrease of 71.4 ac[b]	Arrowweed state increase of 33.3 ac	NA
Percentage change in cover	15.1% reduction in cover of native states	2.7% increase in diversity of native states[a]	14.8% increase in the native/ nonnative ratio	18.8% increase in the arrowweed state cover	Movement away from the resource goal

[a] Because the results for each modeled run include the same number of states (each state is a different starting condition for model runs), a reduction in diversity indicates a reduction in evenness among the vegetation states.

[b] A relative increase in native cover or decrease in nonnative cover can increase the ratio.

TABLE G-10 Results for Alternative B, Long-Term Strategy B2

Parameter	Metric 1: Native Cover (Final Cover/ Initial Cover)	Metric 2: Native Diversity (Final Diversity/ Initial Diversity)	Metric 3: Native/ Nonnative Ratio (Final Ratio/ Initial Ratio)	Metric 4: Arrowweed (Initial Arrowweed/ Final Arrowweed)	Overall Score
Mean score (weighted mean for all sediment traces)	0. 529	0.913	0. 869	0. 809	3.120
Modeled values	168.9 ac, all four native states (initial cover 319 ac)	Modeled diversity 0.988, all four native states (initial diversity 1.083)	Modeled ratio 1.013 (initial ratio 1.166)	219.2 ac arrowweed state (initial cover 177.3 ac)	NA
Change in cover (ac)	Native states decrease of 150.1 ac	NA	Tamarisk state decrease of 107.0 ac[b]	Arrowweed state increase of 41.9 ac	NA
Percentage change in cover	47.1% reduction in cover of native states	8.7% decrease in diversity of native states[a]	13.1% decrease in the native/ nonnative ratio	23.6% increase in the arrowweed state cover	Movement away from the resource goal

[a] Because the results for each modeled run include the same number of states (each state is a different starting condition for model runs), a reduction in diversity indicates a reduction in evenness among the vegetation states.

[b] A relative increase in native cover or decrease in nonnative cover can increase the ratio.

TABLE G-11 Results for Alternative C, Long-Term Strategy C1

Parameter	Metric 1: Native Cover (Final Cover/ Initial Cover)	Metric 2: Native Diversity (Final Diversity/ Initial Diversity)	Metric 3: Native/ Nonnative Ratio (Final Ratio/ Initial Ratio)	Metric 4: Arrowweed (Initial Arrowweed/ Final Arrowweed)	Overall Score
Mean score (weighted mean for all sediment traces)	0.631	0.924	0.457	1.165	3.177
Modeled values	201.3 ac, all four native states (initial cover 319 ac)	Modeled diversity 1.001, all four native states (initial diversity 1.083)	Modeled ratio 0.533 (initial ratio 1.166)	152.2 ac arrowweed state (initial cover 177.3 ac)	NA
Change in cover (ac)	Native states decrease of 117.7 ac	NA	Tamarisk state increase of 104.0 ac[b]	Arrowweed state decrease of 25.1 ac	NA
Percentage change in cover	36.9% reduction in cover of native states	7.6% decrease in diversity of native states[a]	54.3% decrease in the native/ nonnative ratio	14.2% decrease in the arrowweed state cover	Movement away from the resource goal

[a] Because the results for each modeled run include the same number of states (each state is a different starting condition for model runs), a reduction in diversity indicates a reduction in evenness among the vegetation states.

[b] A relative increase in native cover or decrease in nonnative cover can increase the ratio.

TABLE G-12 Results for Alternative C, Long-Term Strategy C2

Parameter	Metric 1: Native Cover (Final Cover/ Initial Cover)	Metric 2: Native Diversity (Final Diversity/ Initial Diversity)	Metric 3: Native/ Nonnative Ratio (Final Ratio/ Initial Ratio)	Metric 4: Arrowweed (Initial Arrowweed/ Final Arrowweed)	Overall Score
Mean score (weighted mean for all sediment traces)	0.632	0.925	0.463	1.163	3.183
Modeled values	201.5 ac, all four native states (initial cover 319 ac)	Modeled diversity 1.001, all four native states (initial diversity 1.083)	Modeled ratio 0.540 (initial ratio 1.166)	152.4 ac arrowweed state (initial cover 177.3 ac)	NA
Change in cover (ac)	Native states decrease of 117.5 ac	NA	Tamarisk state increase of 99.3 ac[b]	Arrowweed state decrease of 24.9 ac	NA
Percentage change in cover	36.8% reduction in cover of native states	7.5% decrease in diversity of native states[a]	53.7% decrease in the native/ nonnative ratio	14.0% decrease in the arrowweed state cover	Movement away from the resource goal

[a] Because the results for each modeled run include the same number of states (each state is a different starting condition for model runs), a reduction in diversity indicates a reduction in evenness among the vegetation states.

[b] A relative increase in native cover or decrease in nonnative cover can increase the ratio.

TABLE G-13 Results for Alternative C, Long-Term Strategy C3

Parameter	Metric 1: Native Cover (Final Cover/ Initial Cover)	Metric 2: Native Diversity (Final Diversity/ Initial Diversity)	Metric 3: Native/ Nonnative Ratio (Final Ratio/ Initial Ratio)	Metric 4: Arrowweed (Initial Arrowweed/ Final Arrowweed)	Overall Score
Mean score (weighted mean for all sediment traces)	0.626	0.923	0.529	0.755	2.834
Modeled values	199.8 ac, all four native states (initial cover 319 ac)	Modeled diversity 1.000, all four native states (initial diversity 1.083)	Modeled ratio 0.617 (initial ratio 1.166)	234.9 ac arrowweed state (initial cover 177.3 ac)	NA
Change in cover (ac)	Native states decrease of 119.2 ac	NA	Tamarisk state increase of 50.1 ac[b]	Arrowweed state increase of 57.6 ac	NA
Percentage change in cover	37.4% reduction in cover of native states; 74.8% reduction in wetland cover	7.7% decrease in diversity of native states[a]	47.1% decrease in the native/ nonnative ratio	32.5% increase in the arrowweed state cover	Movement away from the resource goal

[a] Because the results for each modeled run include the same number of states (each state is a different starting condition for model runs), a reduction in diversity indicates a reduction in evenness among the vegetation states.

[b] A relative increase in native cover or decrease in nonnative cover can increase the ratio.

TABLE G-14 Results for Alternative C, Long-Term Strategy C4

Parameter	Metric 1: Native Cover (Final Cover/ Initial Cover)	Metric 2: Native Diversity (Final Diversity/ Initial Diversity)	Metric 3: Native/ Nonnative Ratio (Final Ratio/ Initial Ratio)	Metric 4: Arrowweed (Initial Arrowweed/ Final Arrowweed)	Overall Score
Mean score (weighted mean for all sediment traces)	0.632	0.925	0.533	0.892	2.981
Modeled values	201.5 ac, all four native states (initial cover 319 ac)	Modeled diversity 1.001, all four native states (initial diversity 1.083)	Modeled ratio 0.621 (initial ratio 1.166)	198.8 ac arrowweed state (initial cover 177.3 ac)	NA
Change in cover (ac)	Native states decrease of 117.5 ac	NA	Tamarisk state increase of 50.9 ac[b]	Arrowweed state increase of 21.5 ac	NA
Percentage change in cover	36.8% reduction in cover of native states	7.5% decrease in diversity of native states[a]	46.7% decrease in the native/ nonnative ratio	12.1% increase in the arrowweed state cover	Movement away from the resource goal

[a] Because the results for each modeled run include the same number of states (each state is a different starting condition for model runs), a reduction in diversity indicates a reduction in evenness among the vegetation states.

[b] A relative increase in native cover or decrease in nonnative cover can increase the ratio.

TABLE G-15 Results for Alternative D, Long-Term Strategy D1

G	2.0	0.425	−2.6	−57.5%

[a] Weighted mean for all sediment traces. Relative change in wetland cover was calculated as *final wetland area*/*initial wetland area* using the initial and final total areas of the two wetland community types: *Phragmites australis* Temperate Herbaceous Vegetation (marsh community) and *Salix exigua-Baccharis emoryi* Shrubland/*Equisetum laevigatum* Herbaceous Vegetation, (shrub wetland community).

[b] Initial wetland area = 4.6 ac.

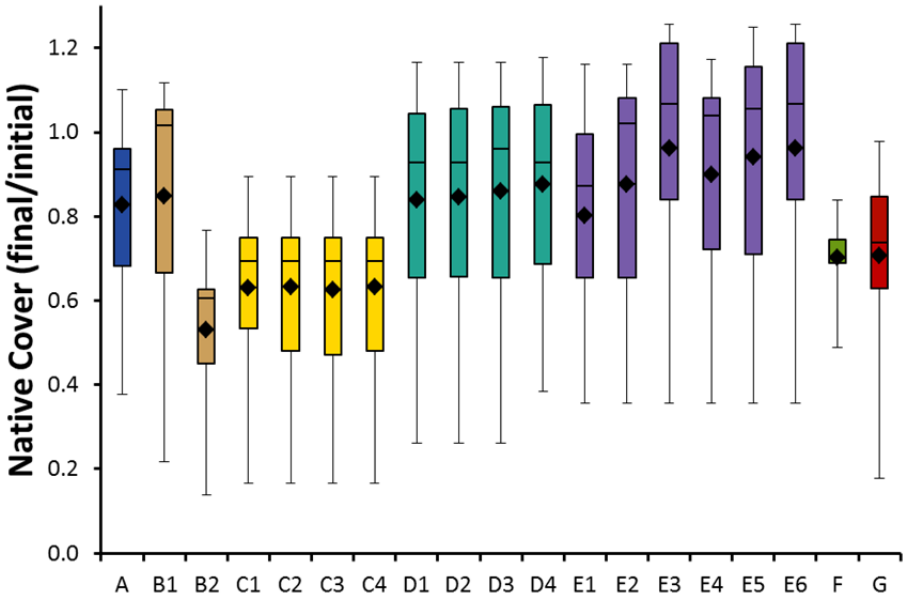

FIGURE G-1 Native Cover Metric for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers) (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)

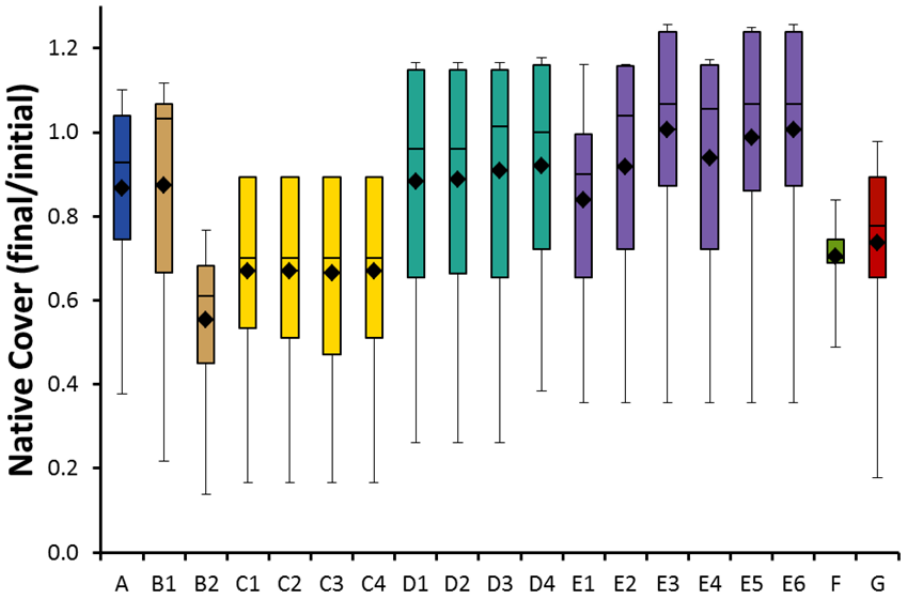

FIGURE G-2 Native Cover Metric under Climate Change for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers) (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)

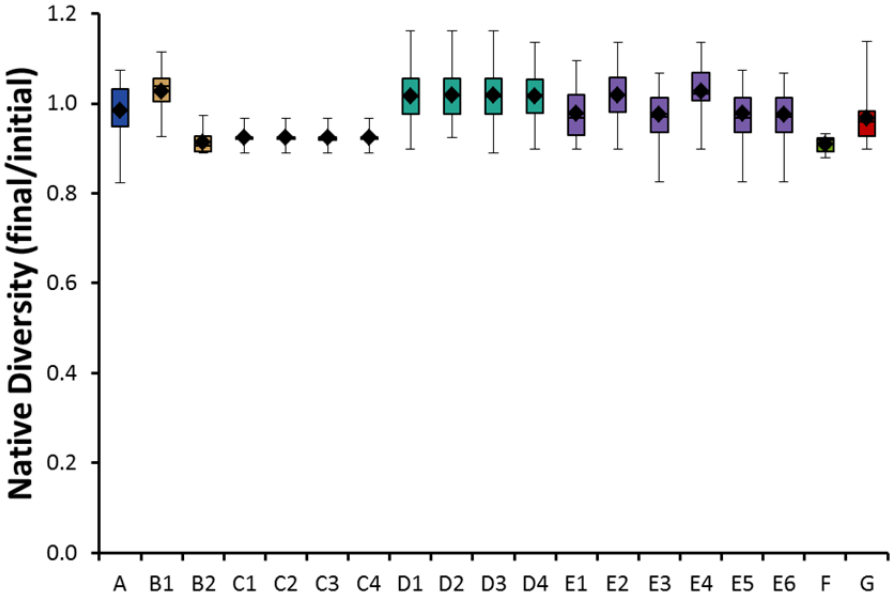

FIGURE G-3 Native Diversity Metric for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers) (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)

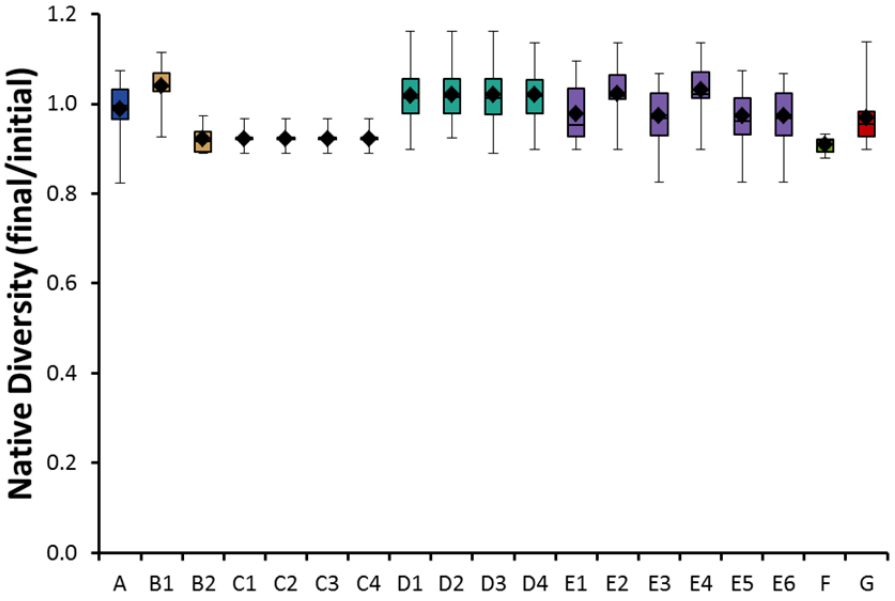

FIGURE G-4 Native Diversity Metric under Climate Change for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers) (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)

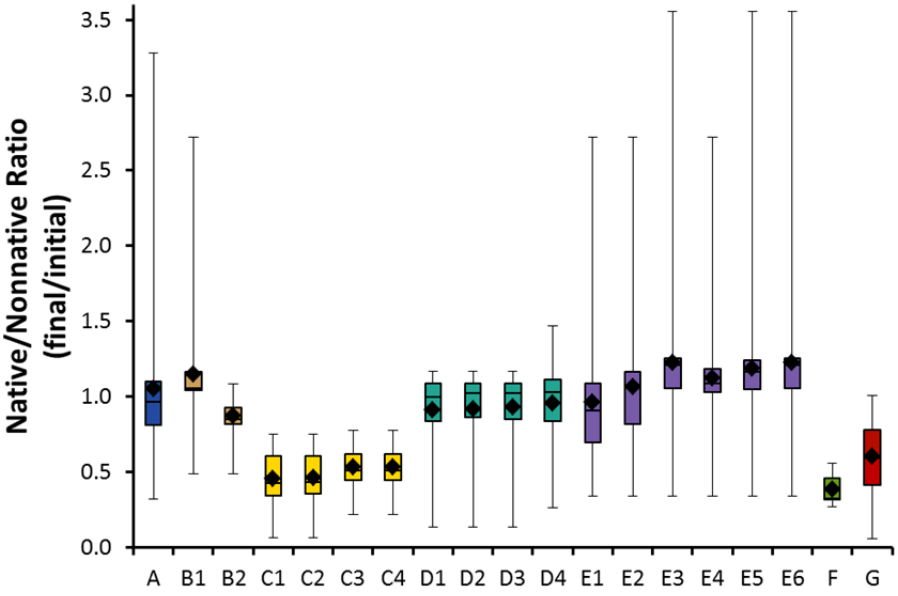

FIGURE G-5 Native/Nonnative Ratio Metric for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers) (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)

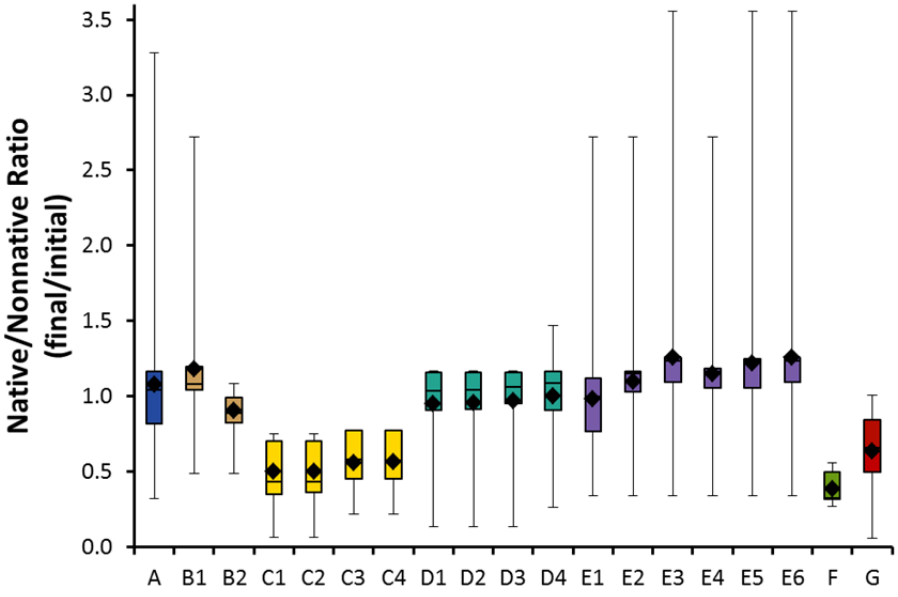

FIGURE G-6 Native/Nonnative Ratio Metric under Climate Change for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers) (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)

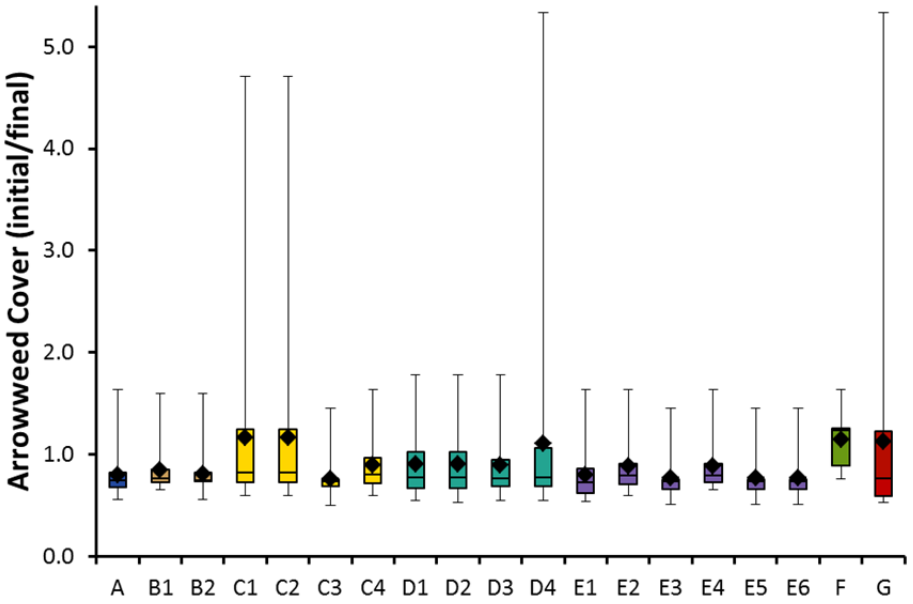

FIGURE G-7 Arrowweed Metric for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers); Higher Values Indicate Less Arrowweed (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)

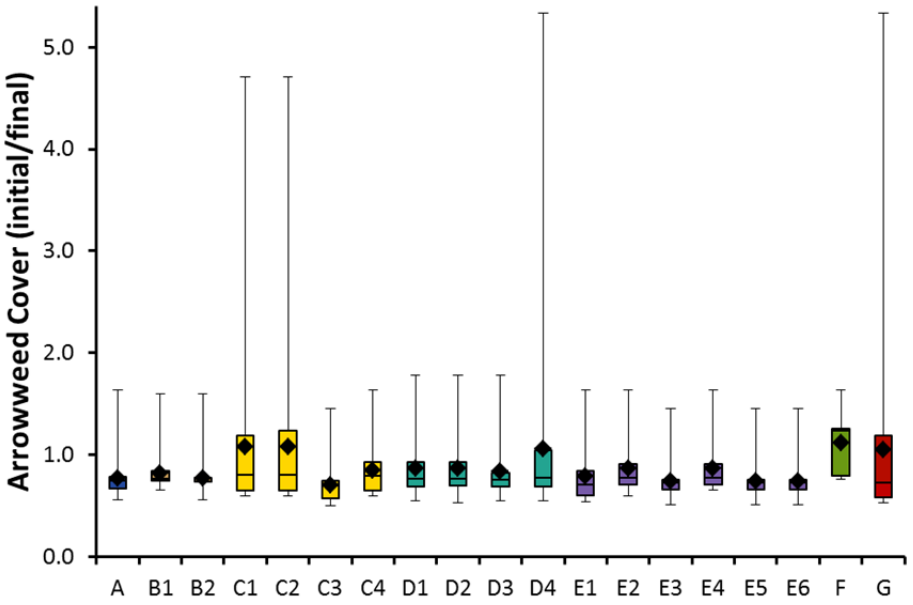

FIGURE G-8 Arrowweed Metric under Climate Change for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers); Higher Values Indicate Less Arrowweed (Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum of the values for the 63 traces analyzed.)
