APPENDIX H:

CULTURAL RESOURCES TECHNICAL INFORMATION AND ANALYSIS

The assessment of potential impacts on cultural resources relied on three factors identified during the Long-Term Experimental and Management Plan (LTEMP) assessment process as the primary factors affecting the stability of historic resources in the canyons: (1) erosion (Thompson and Potochnik 2000; Damp et al. 2007; Spurr and Collette 2007), (2) inundation (Baker 2013), and (3) visitor effects (Bulletts et al. 2008, 2012; Jackson-Kelly et al. 2013). Metrics were formulated for these factors to quantitatively analyze the effects on cultural resources of the LTEMP alternatives based on modeling of discharge and sediment loads. The metrics are:

- Wind Transport of Sediment Index
- Flow Effects on Cultural Resources in Glen Canyon Index
- Time Off River Index

This appendix discusses the modeling of each metric and presents a detailed discussion of the modeling results. The metrics were developed through consultation with subject matter experts, findings in published papers and reports, and consideration of comments from cooperating agencies. See Section 3.8 for a more detailed description of Grand Canyon cultural resources and Chapter 2 for a detailed description of the LTEMP alternatives.

H.1 WIND TRANSPORT OF SEDIMENT

Prior to the construction of Glen Canyon Dam, periodic large-magnitude storm events would flood the Colorado River and deposit fluvial sediment onto high-elevation terraces. Wind also transported sediment from the active river channel onto the high-elevation terraces and helped to maintain the sediment deposits (Draut 2012). The deposited sediment buried and protected evidence of past human activity within the floodplain of the river. However, the dam's closure in 1963 trapped most of the sand that would have been transported into the Glen Canyon and Grand Canyon reaches of the Colorado River, and operations reduced the magnitudes of annual peak flows and increased the magnitudes and durations of low flows (baseflows). The decrease in magnitude of sediment-rich peak flows has lowered the elevation of the area scoured by high flows and at which new sand can be deposited. The increase in elevation and duration of low flows has promoted the expansion of riparian vegetation onto bare sand (Sankey et al. 2015) and has limited the duration of time sand is dry and subaerially exposed, both of which reduce the wind's ability to transport sediment (East et al. 2016; Draut 2012; Draut and Rubin 2008). These changes decreased the renewal of sediment to high-elevation terraces downstream of the dam (East et al. 2016). With limited rejuvenation of sand, landscapes and archaeological sites are more prone to erosion, which can expose sites found along the riparian zone of the river (East et al. 2016; Collins et al. 2016; Sankey and Draut 2014).

Sediment deposited along the riverbank above the elevation of normal operational flows and below the elevation of peak operational flows can be transported by the wind and deposited onto high-elevation terraces, many of which contain archaeological sites (East et al. 2016). This windblown sediment can make the landscape less vulnerable to erosion from rainfall-runoff processes and can potentially increase the preservation potential of archaeological sites on these high-elevation terraces (East et al. 2016). It has been observed that the optimal annual timeframe for this transfer of sediment is in the spring months, when a reduced amount of rainfall and strong winds create conditions for windblown sediment transport (Draut and Rubin 2008). A wind transport metric was developed based on principles identified by Draut and Rubin (2008) to address the possibility of systemwide benefits to archaeological sites located on these higher terraces.

H.1.1 Wind Transport of Sediment—Methods

The Wind Transport of Sediment Index (WTSI) evaluates the availability of fine sediment for wind transport to cover cultural resources at higher elevations (i.e., those properties located at stages above 31,500 cfs). Optimal conditions for wind transport of sediment occur when (1) fine sediment is deposited by flows above the stage of normal operations and (2) low flows occur during the windy season, which exposes more sand for redistribution by the wind. These two conditions are accounted for by the Wind Transport of Sediment Index (WTSI) using the following equation (Eq. H.1), where SLI is the Sand Load Index and FF is the flow factor*:*

$$WTSI = SLI \times Average(FF)_{2014-2033} \quad \text{(H.1)}$$

Both of the inputs for the metric (SLI and FF) are indices ranging from 0 to 1. The resulting Wind Transport of Sediment Index is a value from 0 to 1, where a value of 1 corresponds to the most potential movement of sediment by the wind, and therefore has the highest likelihood to contribute to the preservation of cultural resources. Both elements of the equation (SLI and FF) are limiting factors in the sense that the highest value between the two is the highest possible output. This mirrors the occurring environmental limitations—no more sediment can be transported than available, while, regardless of availability, wet sand is not likely to be easily transported by the wind.

The WTSI is calculated for a total of 63 scenarios representing different hydrologic (20 traces) and sediment conditions (3 traces), and weighted by the historical exceedance percentage of the sediment traces included in the scenario. Because of modeling limitations, environmental factors—such as sandbar erosion due to fluctuations in water level, rainstorm events that may further saturate soil, and vegetation barriers that could prevent sediment transport by the wind—were not incorporated into the metric. Complex parameters like these would require more assumptions, which could result in less confidence in the model.

The SLI is an index of the potential sand deposited on sandbars along the river channel in Marble and Grand Canyons above normal stage elevations (31,500 cfs). The SLI is calculated as the ratio of the cumulative sand load at flows greater than 31,500 cfs relative to the total cumulative sand load at all flows. The sand load, or the mass of sand in transport by the river, is

calculated at RM 30 and is computed by a version of the Sand Budget Model (Wright et al. 2010) for the 20-year LTEMP modeling period. A larger SLI (on a scale of 0 to 1) indicates a greater potential for sediment deposition. The SLI is described in more detail in Appendix E. The SLI was calculated using Equation H.2:

$$SLI = \frac{\sum_{2014-2033} Sand\ Load\ at\ dam\ discharges > 31{,}500\ cfs}{\sum_{2014-2033} Sand\ Load\ at\ all\ dam\ discharges} \quad \text{(H.2)}$$

The FF represents the relative exposure of dry, fluvial sand along the banks of the river available for wind transport. An increase or decrease in dam discharge will increase or decrease the downstream river elevation, respectively. Therefore, a lower discharge will expose a greater amount of sediment. For this metric, maximum daily flows above normal river stage (8,000 cfs) are considered increasingly worse for sediment exposure. The maximum daily discharge (Q_{max}) modeled by GTMax-Lite represents the maximum discharge released from Glen Canyon Dam in cubic feet per second (cfs) and thus the extent of dry sand for each day. The yearly FF is the average of FF_{Daily} (Eq. H.3) for the spring months of March through June.

$$FF_{Daily} = \begin{cases} \text{if } Q_{max} \leq 8{,}000; & 1 \\ \text{if } 8{,}000 < Q_{max} < 31{,}500; & 1.34 - 0.0000425 \times Q_{max} \\ \text{if } Q_{max} \geq 31{,}500; & 0 \end{cases} \quad \text{(H.3)}$$

Note that although the FF only takes into account the months of March through June, the SLI incorporates the entire year. This is because the exposure of sand is most prominent during the windy season, but the sediment transported during those months is continuously built up throughout the year.

H.1.2 Wind Transport of Sediment—Results

WTSI values calculated for the LTEMP alternatives under historical flow and sediment inputs are shown in Figure H-1. The metric values represent the *potential* for sand to be transported to cultural sites rather than the actual transport that would occur or the level of protection that transport may provide to cultural sites. This results in some uncertainty with regard to actual differences in impact among the alternatives based on this metric. Our conclusions on relative impact are based on comparisons of the metric values calculated for Alternatives B, C, D, E, F, and G, and their long-term strategies against Alternative A (the no-action alternative), which has the same basic operational discharge pattern as current operations under Modified Low Fluctuation Flows (MLFF). Research done to date on the effects of windblown sand and archaeological sites has examined operations since the closure of Glen Canyon Dam including MLFF conditions. This research has shown that the number of archaeological sites ideally situated to receive aeolian sand supply from the river has decreased since the completion of the dam and most recently under MLFF conditions (East et al. 2016). When sites are no longer ideally situated to receive sand supply, they are at elevated risk from erosion (East et al. 2016). These changes in sand supply and erosion risk can be attributed to several specific characteristics and effects of MLFF, including the absence of sediment-rich

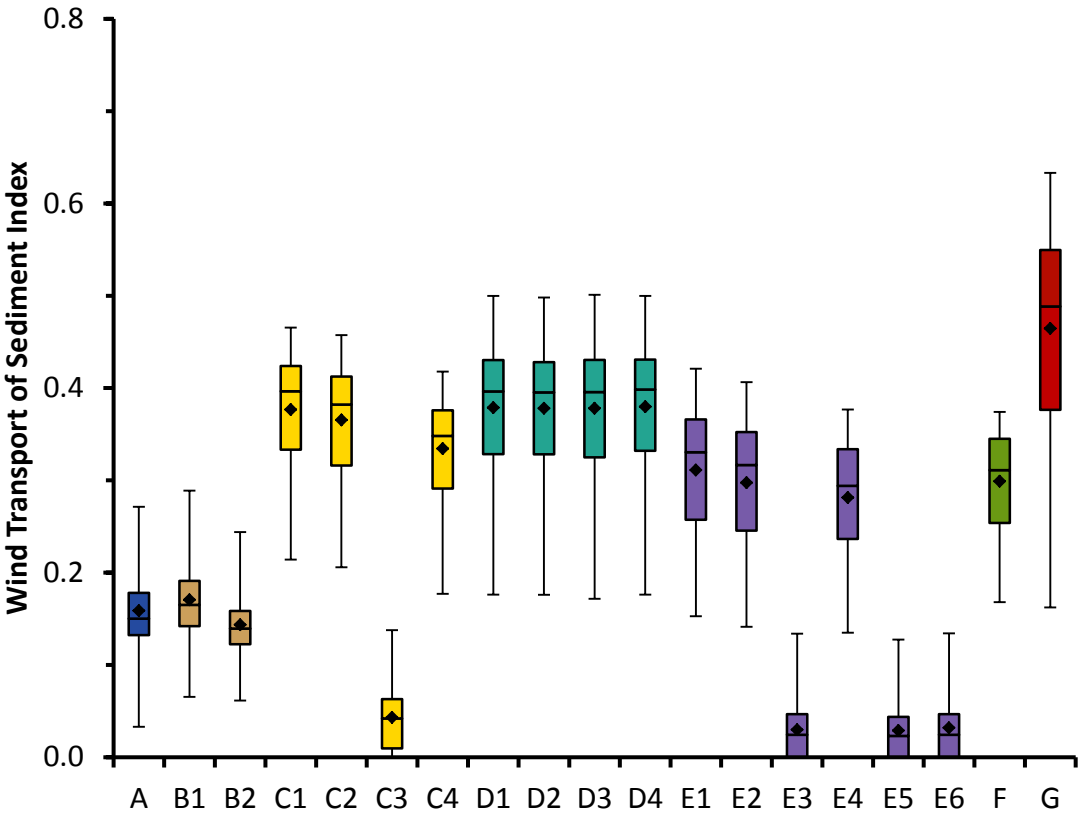

FIGURE H-1 Wind Transport of Sediment Index Values for the LTEMP Alternatives (letters) and Associated Long-Term Strategies (numbers) (Index values of 1 are considered optimal. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

floods above 45,000 cfs, increases in riparian vegetation, and decreases in open, dry sand area that is available for aeolian transport within the active river channel (East et al. 2016).

Of the long-term strategies analyzed, one for each alternative was selected as most representative of the alternative as fully implemented. These representative long-term strategies were B1, C1, D4, and E1, and Alternatives A, F, and G. All of the representative long-term strategies B1, C1, D4, and E1, as well as Alternatives F and G, scored greater than Alternative A because they have more frequent high-flow experiments (HFEs). Long-term strategies B2, C3, E3, E5, and E6 rank below Alternative A. With the exception of long-term strategy B2, HFEs are not conducted for these strategies, and flows above 31,500 cfs would occur rarely, if at all. Recall that one of the primary assumptions for this metric is that flows above 31,500 cfs are the primary mechanism for sediment deposition at higher elevations. If there are no high flows to deposit sand at higher elevations along the banks of the river, there is no new sediment to be moved by the wind. Increased flow fluctuations in long-term strategy B2 cause it to rank below Alternative A.

Alternative G scores the highest of all the alternatives, with an average WTSI nearly three times greater than Alternative A. With the highest number of HFEs and the lowest maximum daily flows during the windy months (Figure H-2), this alternative has parameters ideal for wind-transport of fluvial sediment to high-elevation terraces that contain cultural resources. The second highest scoring long-term strategy, D4, is not significantly different from long-term strategies D1, D2, D3, and C1 (statistical differences between means based on a three-factor analysis of variance [ANOVA] followed by Tukey's Studentized Range Test).

On the whole, the WTSI is highly correlated with the number of HFEs and the corresponding SLI. The relationship between SLI and HFEs is discussed in Appendix E. The similarity between WTSI and HFEs can be seen by comparing Figure H-1 with the average number of HFEs in Figure H-2. The WTSI is highly correlated with the SLI because the average maximum discharge between March and June for each of the alternatives is within 5,000 cfs (standard deviation of 0.05). With minimal difference in flow, the amount of sediment for distribution becomes the determining factor for the index. The exception to this is Alternative F. Figure H-3 shows a sample trace of the typical 8.23 million acre-feet (maf) release year. In April, May, and June, the discharge of Alternative F is higher than that of all other alternatives. Although Alternative F was determined to have the second highest potential sand deposition (highest SLI), it ultimately has an average WTSI value lower than Alternatives C, D, E, and G, as larger discharges of water create less ideal conditions for wind transport.

Long-term strategies C2 and E2 feature low summer flows and trout management flows (TMFs) when conditions trigger them. Reallocation of water volume from low summer flows can cause increased discharge in other portions of the water year. This reallocation combined with

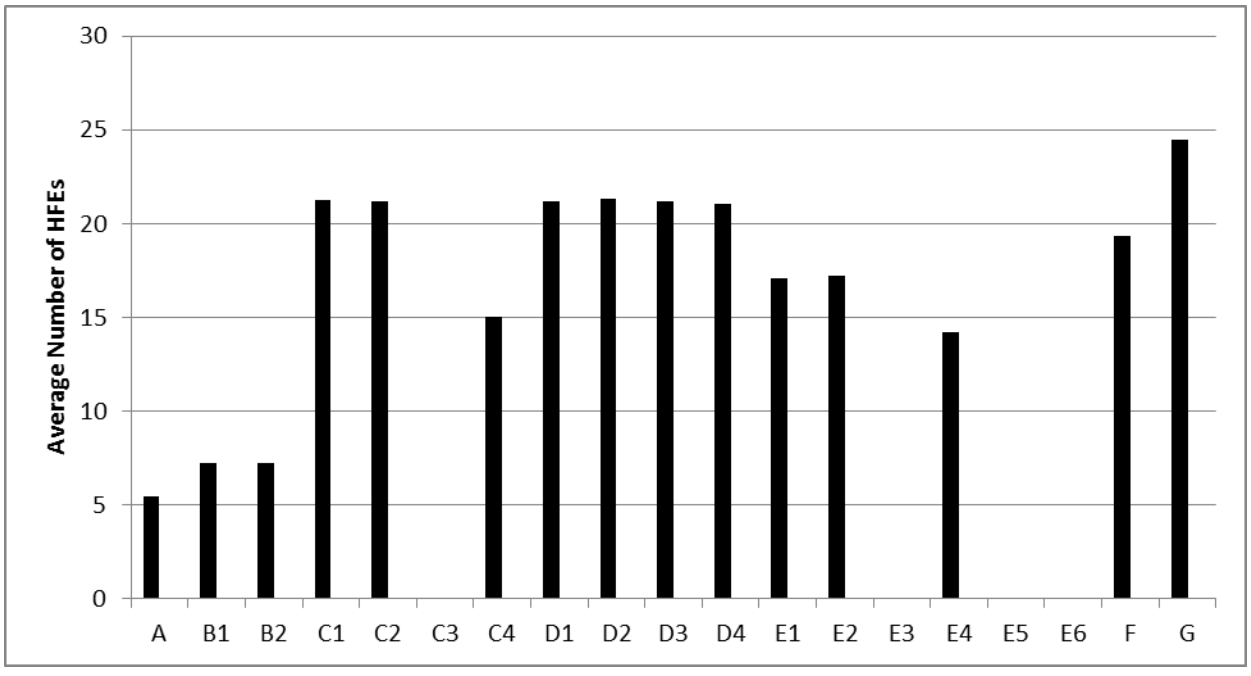

FIGURE H-2 Average Number of HFEs in the 20-Year LTEMP Period

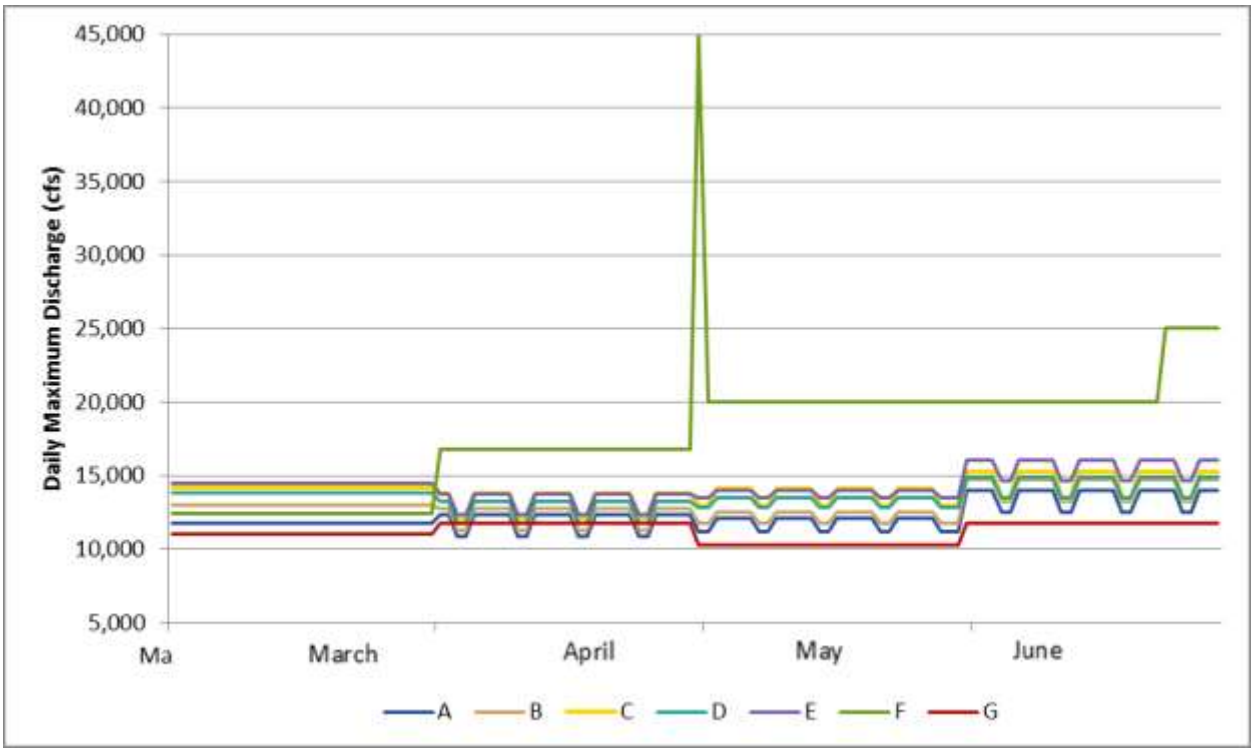

FIGURE H-3 Daily Maximum Discharge in a Typical 8.23-maf Water Volume Release Year from the Glen Canyon Dam during the Windy Season of March–June

the high-flow portion of TMFs causes long-term strategies C2 and E2 to rank lower than their base alternatives. Similarly, the exclusion of spring HFEs in long-term strategies C4 and E4 decrease their WTSI in comparison to long-term strategies C1 and E1.

The WTSI is useful for understanding the interplay between the components of the alternatives. Alternatives that incorporate strategies for enhancing sediment retention (i.e., Alternatives C, D, E, and G, which have reduced fluctuations or more even monthly volumes) have higher WTSI values. The metric also illustrates through Alternative F the effect that flow operations can have on wind transport. Index values are lower for Alternative F because the alternative features higher flows in the windier periods of the spring and summer, which negates some of the benefits of the higher sediment retention indicated in the SLI. Although the metric is beneficial for comparative and theoretical purposes, it reflects idealized conditions for wind transport of sediment that cannot be easily translated into actual site preservation. The extent to which wind transport of sediment can mitigate the erosion occurring in cultural sites on high-elevation terraces remains unknown.

H.2 FLOW EFFECTS ON CULTURAL RESOURCES IN GLEN CANYON

The construction of Glen Canyon Dam significantly scoured the immediate downstream Glen Canyon reach of the Colorado River and cut off nearly all of the sediment supply from

upstream. Unlike further downstream sections of the river, a lack of significant tributaries in Glen Canyon results in very little sediment deposition on river banks of the canyon. In fact, high flows meant to distribute sediment have been shown to degrade terraces in the Glen Canyon reach (Grams et al. 2007). Archaeological sites located in Glen Canyon are also not associated with significant wind deposition of sediment (Anderson 2006). Without the rejuvenation of sediment, higher flows can increase erosion within the Glen Canyon, which is a concern for significant archeological sites.

Anderson (2006) identified 14 archaeological sites within Glen Canyon that were being affected by river-based arroyos or gullies. However, only one of these sites, commonly referred to as Ninemile Terrace, was determined to have erosional features that are unequivocally related to direct impacts of river operations. Bank stability at Ninemile Terrace, and at other terraces with the potential to contain cultural resources, is partially dependent on the accumulation of material at the base of the slope. Removal of this protective material through erosion leaves the lower-bank material prone to a continuing cycle of undercutting, collapse, and removal. This, in turn, contributes to slumping of the upper-bank material, whether dry or saturated. The flow at which the base of the slope begins to erode serves as the "flow elevation threshold." Flows at or above this threshold have the potential to adversely affect cultural resources through bank erosion and destabilization (Baker 2013). Time-lapse photography from the November 2012 HFE shows that the inundation of the existing base of the slope at Ninemile Terrace occurs at a flow of 23,200 cfs.

Ninemile Terrace reflects many characteristics of other sites in Glen Canyon and was considered representative of other Glen Canyon terrace sites for determining the effects of water flow on high-elevation terraces. In the absence of direct field measurements to further clarify a flow elevation threshold, the flow rate of 23,200 cfs was identified by Glen Canyon National Recreation Area staff as an approximate measure to represent the flow elevation above which erosional processes could contribute to impacts that have the potential to adversely affect cultural resources.

H.2.1 Flow Effects on Cultural Resources in Glen Canyon—Methods

Impacts on cultural resources in the Glen Canyon reach were determined by calculating the number of days per year that the maximum daily flow would be >23,200 cfs. A higher number represents the increased potential for erosion of terraces that contain cultural resources. The maximum daily flow is used to capture all instances where flow is high enough to contribute to erosional processes. As with the WTSI, a total of 63 scenarios of different hydrologic and sediment conditions were analyzed.

This metric determines the relative difference among alternatives for the potential impacts of flow on cultural resources. Research would be needed to determine the number of days of high flow that would produce noticeable or extensive impacts on cultural sites.

H.2.2 Flow Effects on Cultural Resources in Glen Canyon—Results

Figure H-4 shows the number of days per year during which flows would be >23,200 cfs for each alternative. The average number of days flows would be >23,200 cfs ranges from 18 to 36 among the alternatives. High maximum values of 50–77 days would occur under all alternatives (as noted by the upper whisker) and would occur in years with high water volumes released from Glen Canyon Dam (e.g., annual average release volume for the trace was 11.5 maf or higher).

Alternative A has the highest number of days per year during which flows would be >23,200 cfs. Alternative A most closely represents the current conditions of MLFF. Long-term strategies C3, E3, E5, and E6 (long-term strategies with no HFEs) have average values that are lower than under Alternative A, but they differ from that number by no more than 3 days. Alternative F would have the highest number of days per year during which flows would be >23,200 cfs; it averages 14 days per year more than under Alternative A. Alternative F, therefore, has the highest potential for impacts on terraces that contain cultural resources in

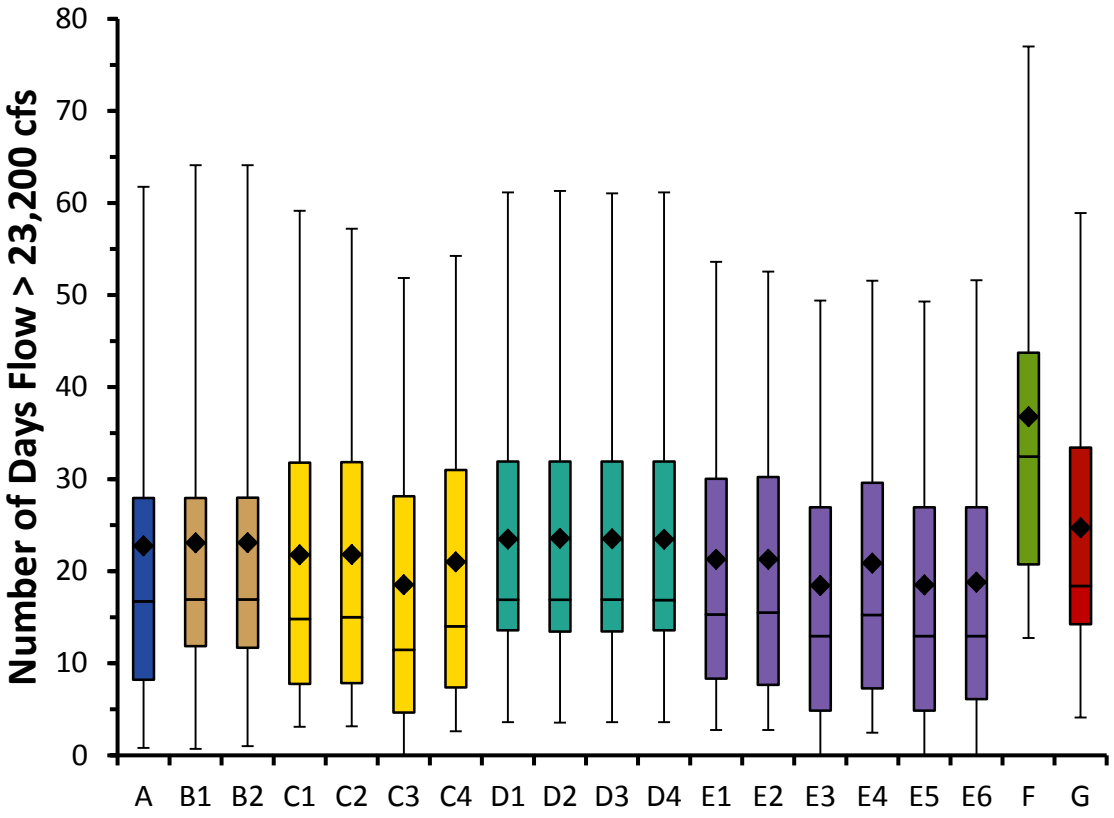

FIGURE H-4 Number of Days per Year Flows Would Be >23,200 cfs under LTEMP Alternatives (Letters) and Long-Term Strategies (Numbers) (Flows of this magnitude have the potential to affect cultural resources in Glen Canyon. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

Glen Canyon. The higher number of high-flow days under Alternative F results from the relatively high spring flows between May and June (see Section 2.2.6). For the remaining alternatives, average number of days per year during which flows would be >23,200 cfs are within 4 days of those under Alternative A.

Besides the high spring flows of Alternative F and HFEs under all alternatives, operational changes within long-term strategies seem to have minimal effect on the number of days per year during which flows would be >23,200 cfs. Long-term strategy B2 includes tests of hydropower improvement flows (i.e., operations with wider water release fluctuations in high electrical demand months than the base operations of long-term strategy B1). Although hydropower improvement flows increase within-day flow fluctuations, in most cases, the altered maximum flow does not exceed 22,000 cfs. Therefore, long-term strategies B1 and B2 have nearly identical values and are not significantly different. Long-term strategies C2, D3, E2, and E5 all have low summer flows. Low summer flows result in higher flows at other times of year, but do not affect the number of days per year during which flows would be >23,200 cfs, and these long-term strategies will not have any effect on this metric. TMFs would also have minimal effect on this metric.

Although the number of HFEs (Figure H-2) in the alternatives differ, these differences have little effect on the number of days per year during which flows would be >23,200 cfs. This occurs because HFEs are relatively short (Figure H-5), and the large volume released under the HFE must be compensated for by releasing less water at other times of the year (Figure H-6). Because all alternatives must release the same annual volume of water, alternatives with HFEs may have lower releases at other times of years than those without. The effect on the metric

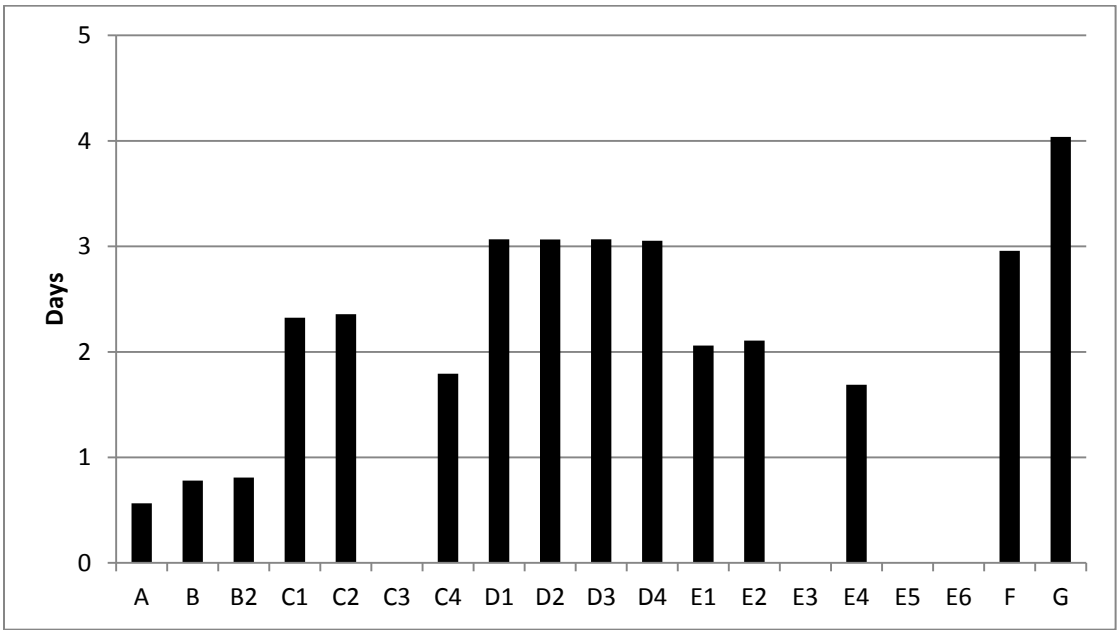

FIGURE H-5 Average Number of Days of an HFE Event per Year

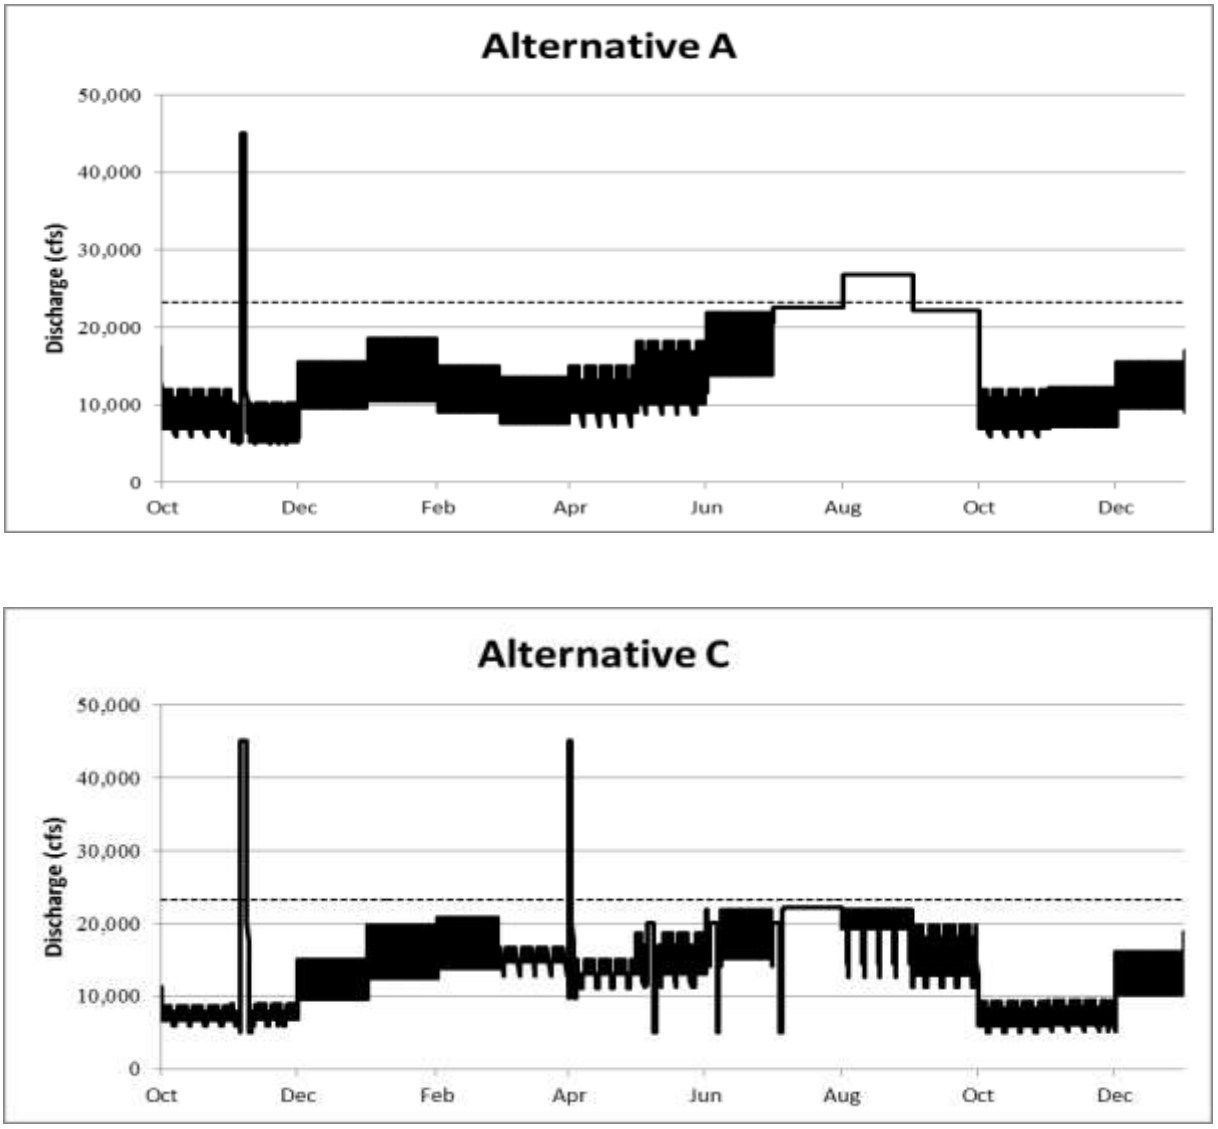

FIGURE H-6 Modeled Glen Canyon Dam Discharge for the Same Year (the line represents 23,200 cfs)

would be greater in years of high volume (≥10 maf) when equalization flows would be implemented according to the Interim Guidelines (Reclamation 2007).

This explains why Alternatives A and B, with minimal HFE events, have nearly the same metric value as alternatives like Alternative C with more than four times the number of HFEs (Figure H-2). Although Alternative C has two HFEs (Figure H-6) and Alternative A has only one, Alternative A must release more water in August to compensate. Historically, precipitation was higher than conditions in recent years; therefore, equalization flows may be triggered less frequently and days above 23,200 cfs might be less than for those based on historical flows. The 50th and 25th percentile values are more applicable to recent climate conditions seen in the Glen Canyon region. In addition, the variability (noted by the length of box) in the value is a result of

the variability in the release volume between water years, HFEs, and the interaction between the two for a particular alternative.

H.3 TIME OFF RIVER

Greater discretionary time for whitewater rafters to explore the canyons downstream of Glen Canyon Dam increases the likelihood that they could have an impact on archaeological sites by creating trails to sites or looting or vandalizing sites. When the river is moving at a faster pace and boat travelers arrive at their destination earlier, their discretionary time off river increases. It is therefore hypothesized that higher flows may increase the potential for adverse human contact with archeological sites.

H.3.1 Time Off River—Methods

The Time Off River Index (TORI) represents the degree to which flows could affect visitor potential to interact and disturb cultural sites. Grand Canyon visitor numbers vary depending on the time of the year. Recreational activity is more common in the warmer summer months, less so in the spring and fall months, and even less in the colder winter months. The yearly TORI (Eq. H.4) is the ratio of the sum of seasonal ratios that designate flows ideal for minimal visitor-site interaction. Summer has the highest weight (0.54), while winter has the lowest (0.15) and spring and fall are in between (0.31). The TORI is a 0–1 value, where 1 equals the least discretionary time for visitors to access archaeological sites, and, therefore, the lowest potential for impacts on cultural sites.

$$TORI = \left[0.15 \left(\frac{\sum_{winter} ORFF}{\sum Days_{winter}} \right) + 0.31 \left(\frac{\sum_{\frac{spring}{fall}} ORFF}{\sum Days_{\frac{spring}{fall}}} \right) + 0.54 \left(\frac{\sum_{summer} ORFF}{\sum Days_{summer}} \right) \right] \quad \text{(H.4)}$$

An overall annual mean TORI value for the 20-year modeling period was developed for each alternative and used as the performance metric (Eq. H.5).

$$TORI = Average\ (TOR_{annual})_{2014-2033} \quad \text{(H.5)}$$

The Off River Flow Factor (ORFF) represents the potential for discretionary time off river. The discharge level at which boats begin to exceed typical river travel times is 10,000 cfs. However, once flows reach more than 31,500 cfs, visitors are more likely to stay at campsite areas rather than travel in a turbulent river. Daily average flows (Q_{avg}) represent the average release from Glen Canyon dam in cubic feet per second. Average daily discharge from the dam was modeled in GTMax-Lite. The ORFF is a 0–1 value, where 1 indicates the lowest potential for discretionary time off river and therefore the lowest potential for increased visitation of archaeological sites. Specifically, the average daily ORFF is assigned as follows (Eq. H.6), where the value within the brackets in the right column is assigned to $ORFF_{Daily}$ if the equation in the left column is satisfied:

$$ORFF_{Daily} = \begin{cases} \text{if } Q_{avg} \leq 10{,}000; & 1 \\ \text{if } 10{,}000 < Q_{avg} < 31{,}500; & 1.465 - 0.0000465 \times Q_{avg} \\ \text{if } Q_{avg} \geq 31{,}500; & 0 \end{cases} \quad \text{(H.6)}$$

As with the WTSI, a total of 63 scenarios of different hydrologic and sediment conditions were analyzed.

H.3.2 Time Off River—Results

TORI does not specify how much additional discretionary time off river a visitor may experience. Instead, TORI is intended to determine the potential for visitors to spend more time off of the river exploring—which could result in more cultural resources being visited and possibly affected—by examining the flows under the various alternatives as compared to Alternative A.

A summary of TORI results is provided in Figure H-7. Except Alternative F, all of the alternatives and their long-term strategies performed relatively similarly for this metric. Values

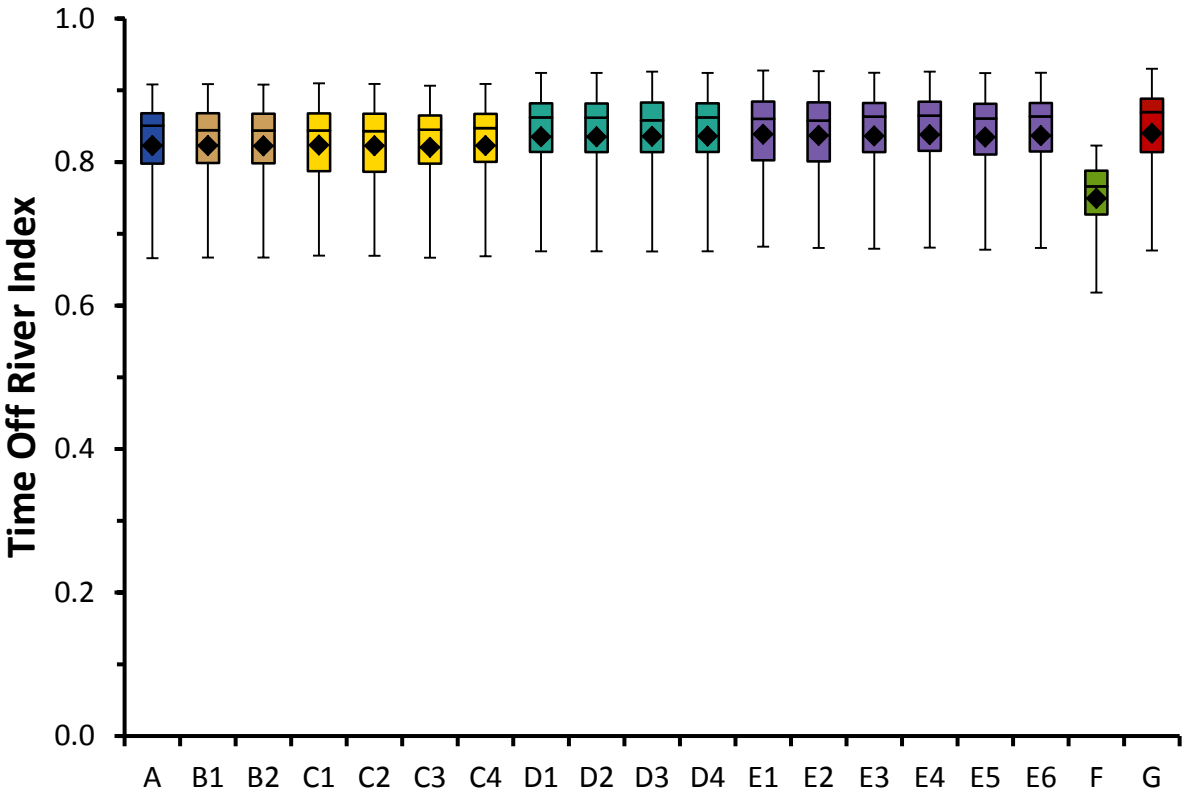

FIGURE H-7 Time Off River Index Values for All LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers) (Index values of 1 are considered optimal. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

of TORI under long-term strategies B1, B2, C2, and C4 were not significantly different than those under Alternative A. Although Alternatives D, E, and G rank the highest with regard to this value (and thus would be expected to have the lowest impact), the minimal differences in the metric values from Alternative A likely indicate that they would not have noticeable impacts on visitor-site interactions.

The difference between the TORI for Alternative F and the other alternatives is largely due to flows during the spring and early summer that are generally at or above 20,000 cfs, while all other alternatives have daily flows that average between 8,000 and 12,000 cfs. Figure H-8 shows the difference in average discharge between Alternative F and the other alternatives. Although Alternative F has very low flows in December and January, the alternative has flows that are more than 7,000 cfs higher than those under other alternatives in spring and early summer months.

TORI values would be higher in years of high volume (>10 maf) when relatively high equalization flows would be implemented according to the Interim Guidelines (Reclamation 2007). However, these relatively high releases result from high inflow volumes in wet years, are unavoidable, and differ little among alternatives.

APPENDIX I:

TRIBAL RESOURCES TECHNICAL INFORMATION AND ANALYSIS

Section 4.9 of the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS) assesses and compares the potential impacts of LTEMP alternatives on resources important to federally recognized Tribes. Indian Tribes have been recognized by the courts as "domestic dependent nations." They were sovereign entities before the arrival of Euro-American colonizers and continue to exercise that sovereignty within their reserved lands. Consultation between Tribes and the federal government is consultation between sovereign entities. Even when they have been removed from their ancestral lands, Tribes often retain strong ties to culturally important resources in their traditional homelands. When those resources are located on federal lands or could be affected by federal or federally licensed undertakings, federal agencies are required to take into account those potential impacts in their decision-making (see Table I-1).

The nature and degree of impacts that an undertaking could have on resources important to Tribes are best evaluated with significant input from the Tribes themselves. To this end, the Bureau of Reclamation (Reclamation) and National Park Service (NPS) have sought to include input from all federally recognized Tribes that have traditional, historical, cultural, or religious ties to the canyons. Forty-three Tribes with potential ties to the canyons were notified of the LTEMP EIS project by mail with telephone follow-up and invited to participate. Of these, six chose to become Cooperating Agencies; two Tribes chose to consult, but not as Cooperating Agencies; and nine chose not to actively consult, but to be kept informed of project developments. Thirteen Tribes chose not to participate. There was no response from the remaining twelve Tribes (see Appendix N).

Assessing the comparative impacts of the LTEMP alternatives on Tribal resources presents a challenge both (1) because of the holistic view of the canyons that Tribal members tend to take, in which all elements of the environment are interconnected, so that effects on one part of the environment affects the whole, because there is no single "Tribal view" held by all members of all Tribes, and (2) because knowledge of the location of some of the most sacred places is not shared with outsiders. Not all Tribes agree with each other on all issues, but some common themes and issues did emerge from discussions with Tribal representatives, review of canyon monitoring reports produced by the Tribes, and ethnographic sources produced by or for

the Tribes. For many Tribes, environmental features considered inanimate in Western cultures are seen as imbued with life; in some cases, such as with the Colorado River and the Little Colorado River, they are considered deities. Various Tribes regard the canyons as sacred space, the place where their people emerged into this world, the home of their ancestors, the residence of the spirits of their dead, and the source of many culturally important plant, animal, and mineral resources. Many Tribes view themselves as connected to the Colorado River and its canyons and as stewards over the living world around them, including water, earth, plant life, and animal life. This holistic view encompasses subject areas considered in this EIS, and Tribal perspectives on these resources are found throughout the document. The values the Tribes place on the river and its canyons are significant and real, but often intangible; therefore, they are not easily or are only partially quantifiable. In addition, many of the values and resources that are most important to the Tribes are not directly affected by differences in the patterns of release of water from the Glen Canyon Dam.

Knowledge of some of the most sacred and sensitive places and resources in the canyons is esoteric, known chiefly by elders and initiated religious practitioners. Only they can provide information on what is most sacred and what can be revealed in a public format such as an EIS. Funding was provided to support Tribes in obtaining and providing these important perspectives on the river and the canyons. Appendix N details the efforts undertaken to obtain Tribal input regarding resources important to Tribes that could be affected by the operation of Glen Canyon Dam and proposed associated actions. These efforts included face-to-face meetings, webinars, and conference calls. The Tribes that chose to act as Cooperating Agencies also were afforded the opportunity to provide text for the EIS, and to review and comment on the draft document before it was released to the public.

Although many aspects of the effects on Tribal resources are not quantifiable, quantifiable measures of effects on the canyon environment were found that reflect important Tribal values and could stand as proxies for those values. These include effects on the diversity of riparian vegetation, effects on marshes and other wetlands, effects of large-scale taking of nonnative fish for fish management purposes, effects on Tribal water rights, and factors that could affect Tribal economics. Tribes are concerned with natural resources beyond plant and aquatic life in the canyons. Bighorn sheep, songbirds, and butterflies are among the indicators of canyon health mentioned by Tribal members. Many of these resources are considered qualitatively in the wildlife section of the EIS (Sections 3.7 and 4.7) and can be reviewed and considered by Tribal specialists and representatives.

I.1 QUANTIFIABLE MEASURES USED TO ASSESS IMPACTS ON TRIBAL RESOURCES

I.1.1 Riparian Diversity

Among the quantifiable projected impacts are those on riparian vegetation, the plant life likely to be most directly affected by flow management at the Glen Canyon Dam. The Western concept of "ecosystem" comes close to Tribal views of interconnectedness. Plant life is a

fundamental part of most ecosystems. The state of riparian vegetation is a good indicator of the state of the canyon ecosystem as a whole. Thriving, diverse vegetation communities indicate a healthy ecosystem. Models of future plant diversity along the river provide a quantitative indicator of ecosystem health. Many Tribes give native species and nonnative plant species equal value as forms of life to be respected. Therefore the measure presented here includes plant communities dominated by both native and nonnative plants. For a discussion of diversity in native plant communities, see the Native Diversity Index in Appendix G.

A metric for vegetation community diversity in the riparian zone has been developed based on the results of a state and transition model for Colorado River riparian vegetation downstream of Glen Canyon Dam. This model has been developed to compare the effects of alternative flow regimes on Colorado River riparian vegetation. The model is discussed in Section 4.6.1. For a more detailed discussion of the model, see Ralston et al. (2014) and Appendix G. The model uses characteristics of annual dam operations to predict transitions from one plant community type to another on sandbars and channel margins in the riparian zone. The model projects transitions over a 20-year period for each alternative and long-term strategy analyzed. Relative change in the diversity of vegetation community types on sandbars and in channel margins is projected using the Shannon-Weiner Index for richness/evenness[1] and a diversity score calculated by comparing the final (modeled) diversity to the initial diversity (change in diversity = $\text{diversity}_{final}/\text{diversity}_{initial}$). A healthy ecosystem is characterized by a high degree of species diversity, represented here by diversity in vegetation community types. A total diversity score was calculated that included nonnative (primarily tamarisk) as well as native communities including the invasive arrowweed. Table I-2 shows the seven vegetation states, or plant community types, that were considered. The species associated with a state all respond similarly to Colorado River hydrologic factors such as depth, timing, and duration of inundation.

The model consists of six submodels based on the following landforms: lower separation bars, upper separation bars, lower reattachment bars, upper reattachment bars, lower channel margins, and upper channel margins. Upper and lower landforms are divided at the 25,000 cfs

TABLE I-2 Vegetation States

Vegetation States
Bare Sand
Marsh (Common Reed Temperate Herbaceous Vegetation)
Shrub Wetland (Coyote Willow-Emory Seep Willow Shrubland/Horsetail Herbaceous Vegetation)
Tamarisk (Tamarisk Temporarily Flooded Shrubland)
Cottonwood-Willow (Fremont Cottonwood/Coyote Willow Forest)
Arrowweed (Arrowweed Seasonally Flooded Shrubland)
Mesquite (Mesquite Shrubland)

1 For a discussion of the Shannon-Weiner Index, see Appendix G.

flow stage (see Section 3.3.1.1 for a description of these landforms). The model projects transitions between vegetation states, based on a set of rules developed for each submodel, driven by hydrologic events. The model includes a subset of states and transition rules for each submodel. The states and transition rules for the upper portions of the bars and channel margin are the same because of the similarity of plant community types and responses to flow characteristics. The transition rules are based on the effects of scouring, drowning, desiccation, and sediment deposition on riparian plant species. Transition rules are presented in Table G-3 in Appendix G.

Figure I-1 shows the weighted diversity scores for the seven LTEMP alternatives and their associated long-term strategies (described in Appendix C). The higher the score, the greater the diversity of plant community types. A score of 1.0 indicates that the current degree of plant community diversity is projected to be maintained. A score greater than 1.0 indicates increased diversity, less than 1.0 a loss of diversity. The mean scores for each alternative fall into a somewhat wider range than the Native Diversity scores presented in Appendix G. They range from 0.70 under Alternative F to 0.97 under long-term strategy B1. Alternative A (no action alternative) scored 0.95. Alternatives D and E scored above 0.90 under all of their associated long-term strategies.

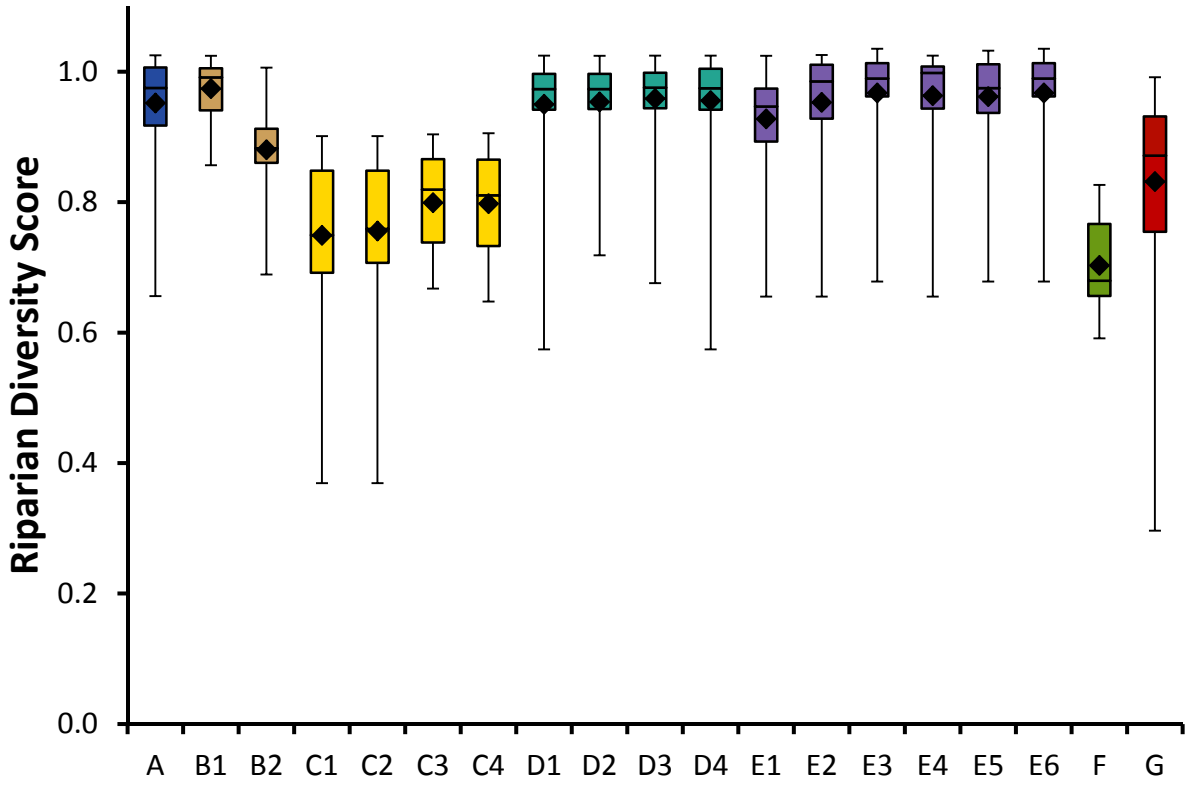

FIGURE I-1 Riparian Diversity for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

The results indicate that on average all alternatives would result in a small decrease in total vegetation state diversity over the 20-year LTEMP modeling period. The loss in diversity would be greatest under those long-term strategies where there is an increase in the area covered by the tamarisk community type (see Table 4.8-3). Alternatives where tamarisk[2] would increase are characterized by high flows (high-flow experiments [HFEs] or ≥30 days with flows >20,000 cfs), which serve to distribute seed, and/or low flows in the growing season (May–September) that allow seedlings to establish themselves. Once established, tamarisk is tenacious. When it does transition, it is most often to bare sand.

Under climate change assumptions, the modeled pattern shows very little difference from the historical-based assumptions (Figure I-2). There is a minimal overall increase in mean diversity scores, suggesting that the difference would be barely perceptible on the ground.

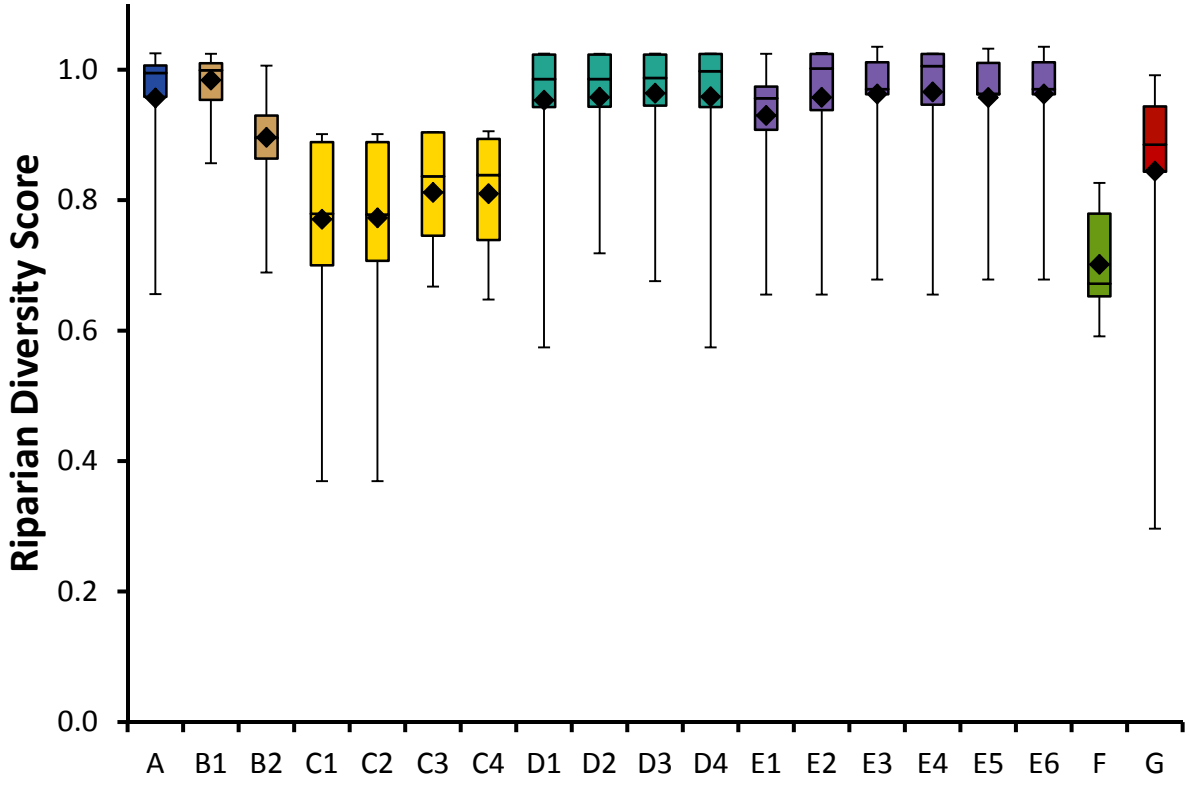

FIGURE I-2 Riparian Diversity under Climate Change Assumptions for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

2 The model takes into account the effects of scouring, drowning, desiccation, and sediment deposition, but does not account for the effects of the tamarisk leaf beetle or tamarisk weevil. These two insect species may result in a reduction in the amount of live tamarisk in the river corridor.

I.1.2 Wetland Abundance

Some Tribes (e.g., the Hopi) see the health of canyon wetlands as an indicator of canyon health (Yeatts and Huisinga 2013). Assessments of the projected state of wetland cover over the next 20 years can be derived from the state and transition model discussed above. Two of the model states listed in Table I-2 are wetland community types: Common Reed Temperate Herbaceous Vegetation, a marsh community; and Coyote Willow-Emory Seep Willow/Horsetail Herbaceous Vegetation, a shrub wetland community.

Wet marsh communities of flood-tolerant herbaceous species that occur on low-elevation areas of reattachment bars have developed in response to frequent inundation. Wet marsh communities (with common reed and cattail the dominant species) occur on fine-grained silty loam soils in low-velocity environments on lower areas of eddy complex sandbars; although they are easily scoured by high flows, they can redevelop quickly. Shrub wetland communities (with coyote willow, Emory seep willow, and horsetail the dominant species) occur on sandy soils of reattachment bars and channel margins, below the 25,000 cfs stage, that are less frequently inundated.

Wetland communities generally transition only from bare sand or other wetlands; they can transition back to bare sand or to arrowweed, tamarisk, or cottonwood-willow communities. An increased occurrence of transitions from bare sand to wetlands and/or maintenance of wetlands (lack of transitions to other community types) would result in greater wetland cover. Large daily fluctuations increase the area of saturated soil and thus the sandbar area available for wetland species establishment. The reduction of daily fluctuations may increase the establishment of wet marsh species at lower elevations and promote the transition of higher elevation marshes to woody species such as tamarisk or arrowweed. Periodic flooding and drying tend to increase diversity and productivity in wetland communities. Although low-elevation plants in marshes in Marble Canyon and Grand Canyon, such as cattail, common reed, and willow, may become buried with coarse sediment, recovery generally occurs within 6 to 8 months. Low steady flows can cause some wetland patches to dry out, resulting in considerable plant loss. Sustained high releases reduce wetland vegetation cover to less than 20% on lower reattachment bars. Extended high flows typically scour herbaceous vegetation; however, most woody plants often remain. Thus, extended high flows followed by extended low flows in the following growing season result in a transition from shrub wetland to a cottonwood-willow community on channel margins. A transition from marsh to shrub wetland occurs on lower reattachment bars with 4 years of consecutive seasons of low fluctuating flows or non-growing season sustained low flows (Ralston et al. 2014).

The relative change in cover of these wetland community types was calculated from the state and transition model results. The number of years each of the wetland states occur in each submodel is projected for the 20-year LTEMP modeling period. The results for the seven alternatives and their long-term strategies are presented in Figure I-3. A mean score of 1.0 indicates no change from initial conditions is expected. A score greater than 1.0 indicates an increase in wetland cover; a score of less than 1.0 indicates a loss in wetlands. Alternative F scored the lowest (0.14), and long-term strategy E6 scored the highest (1.10). Alternative A scored 0.72.

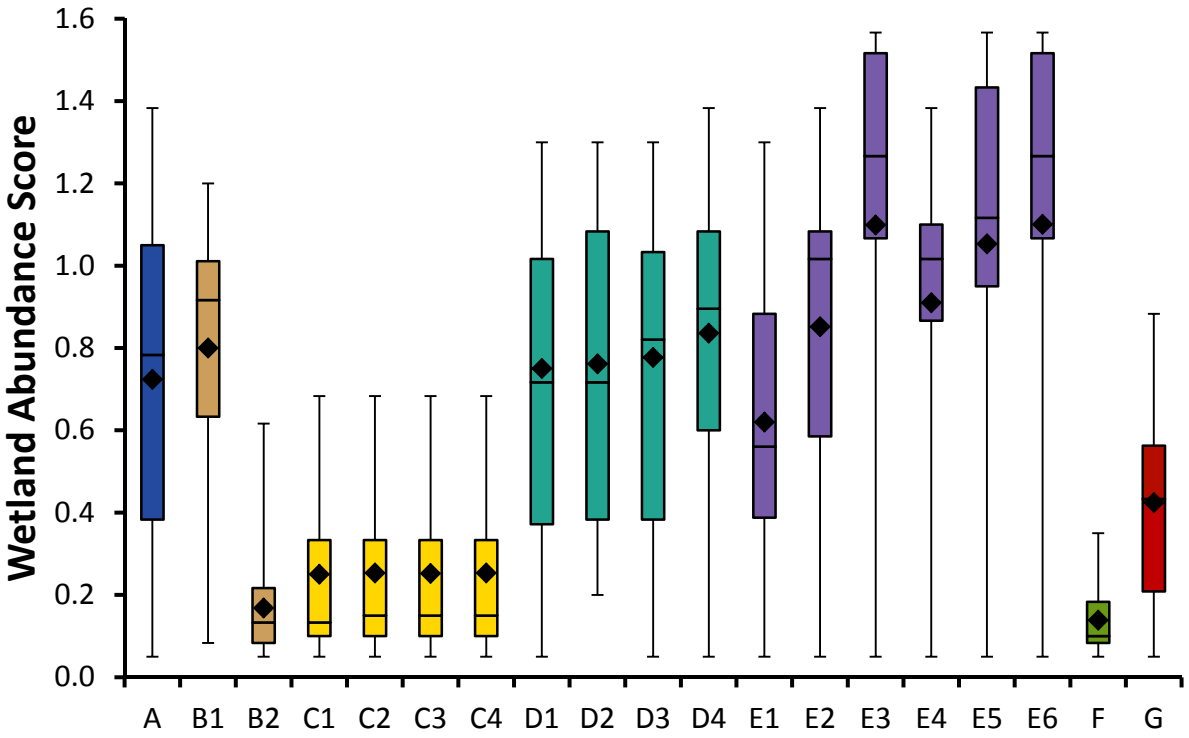

FIGURE I-3 Wetland Abundance for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

Only Alternative E, long-term strategies E3, E5, and E6—none of which have HFEs—show an increase in wetland cover (based on mean scores); all others show a decrease. However, long-term strategies B1, D1, D2, D3, D4, E2, E3, E4, E5, and E6 all scored higher than Alternative A. The alternatives with high scores are characterized by fewer extended high flows (greater than 20,000 cfs) and fewer extended low flows (less than 10,000 cfs) than Alternative A. There is enough water to sustain wetlands, but not too much inundation to support them over time. A large decrease in wetland community cover occurs under B2, all Alternative C long-term strategies, Alternative F, and to a lesser extent Alternative G. Frequent extended low flows or extended high flows followed by extended low flows tend to result in the transition of wetlands to other plant community types. Repeated seasons of extended high flows, or sufficiently high flows during one season, can remove wetlands, resulting in bare sand landforms.

Under climate change assumptions, the overall pattern remains the same for all alternatives, except that the Alternative F score increases slightly, as seen in Figure I-4. On average, scores increased by 0.08, with Alternative F showing only a negligible increase in the mean score (0.0017).

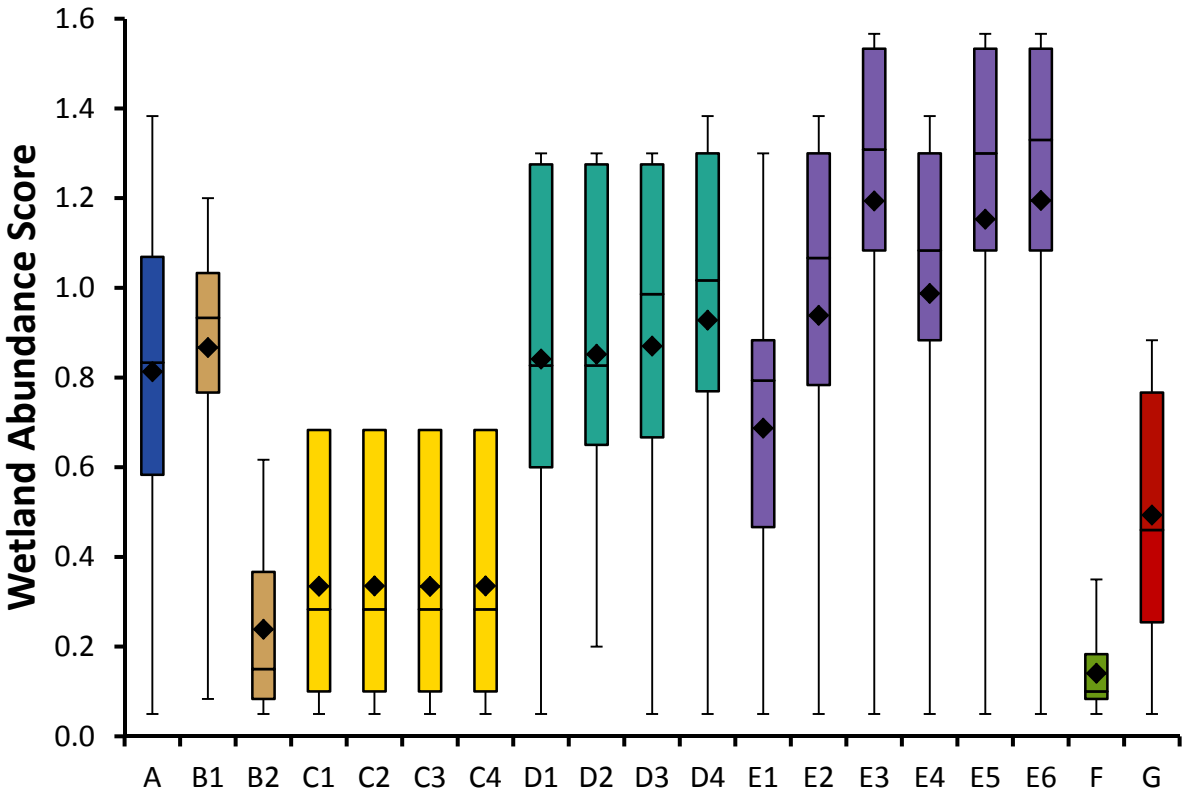

FIGURE I-4 Wetland Abundance under Climate Change Assumptions for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

I.1.3 Trout Management Flows

Reclamation and NPS are required under the U.S. Fish and Wildlife Service (FWS) biological opinion related to the *Non-native Fish Control Downstream from Glen Canyon Dam Environmental Assessment* (Reclamation 2011) to take steps to protect and encourage the recovery of endangered humpback chub (*Gila cypha*) populations in the canyons. The Little Colorado River is the home of a significant population of chub, which interact with rainbow trout at the confluence of the Colorado River and the Little Colorado River. Past and proposed methods for encouraging chub population growth involve reducing the number of nonnative trout, which prey on and compete with the chub. Large-scale killing of trout brings Reclamation and NPS into conflict with the value placed on all forms of life held by some Tribes. Although Tribes differ as to whether they consider the removal of nonnative fish species positively or negatively, many Tribes place a high value on the sanctity of life throughout the ecosystem and see themselves as its stewards. For them life, including fish and animal life, must not be wasted and must not be taken except to sustain human life. The Zuni in particular have important cultural ties to aquatic life in the canyons. The confluence of the Colorado River and the Little Colorado River is particularly sacred.

Aquatic resources models allow the comparison of the number of years trout management flows designed to strand trout larvae and fry would be triggered, and the number of years in which mechanical removal of trout would be triggered across the alternatives and their associated long-term strategies. Details of the models are presented in Appendix F.

A trout management flow is a highly variable flow pattern of water releases at Glen Canyon Dam intended to control the number of young-of-the-year trout in the Glen Canyon reach of the Colorado River. Reducing the number of trout in the Glen Canyon reach would reduce the number of trout emigrating downstream to the confluence with the Little Colorado River and other downstream areas. A typical trout management flow would consist of several days of a relatively high sustained flow (e.g., 20,000 cfs) that would prompt young fish to move into the shallows along the channel margins and, depending on the time of year, would prompt spawning fish to construct redds and lay eggs in nearshore shallow areas. The high flows would be followed by a rapid drop to a low flow (e.g., 5,000 cfs), stranding and killing young-of-the-year trout and, depending on the time of year, possibly exposing eggs in shallow redds, thus preventing them from hatching. Management flows would be triggered during years in which the production of young-of-the-year rainbow trout in the Glen Canyon reach is anticipated to be high (more than 200,000 individuals).

Figure I-5 shows the projected number of years in which trout management flows would be triggered under each alternative and long-term strategy. Trout management flows are not elements of all alternatives and may not occur in many years, even under alternatives that allow them. Under each of the alternatives and long-term strategies in which trout management flows are included, they would first be conducted as tests and then implemented only if they prove to be effective in reducing the trout population in the Glen Canyon reach and emigration to downstream sections of the Colorado River. Trout management flows are not included as elements of nine alternatives/strategies: Alternative C long-term strategies C2, C3, and C4; Alternative D long-term strategy D3; Alternative E long-term strategies E2, E3, E4, and E5; and Alternative F. They would be only tested under Alternative A. In long-term strategies D1, D2, and D4, trout management flow experiments would be implemented without triggers during the first 5 years of the LTEMP period. Figure I-5 assumes experiments in the first 5 years of the LTEMP period. In general, trout management flows would most likely be triggered when spring HFEs, which stimulate the food base, are followed by relatively steady summer flows (May–August). These factors are associated with higher production of young-of-the-year trout and would result in conditions that would trigger trout management flows more often. Where the number of HFEs is limited, as in Alternative B, it is expected that there would be fewer years in which trout management flows would be triggered. Modeling indicates trout management flows would be triggered most often under Alternative G and long-term strategy D2. The mean number of years in which trout management flows would occur are relatively high under long-term strategies D1, D2, and D4 because of the experimental flows that would be implemented, whether trout management flows are triggered or not. If trout management flows prove successful, they would reduce the number of times mechanical removal near the Little Colorado River confluence would be triggered.

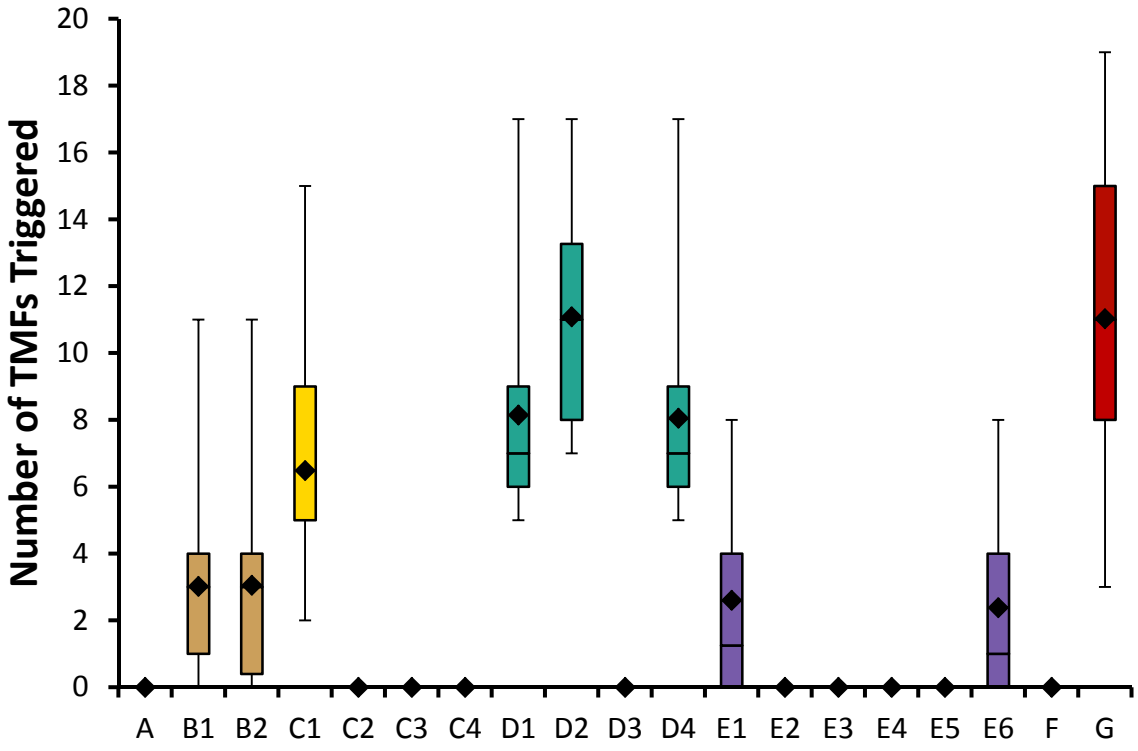

FIGURE I-5 Frequency of Trout Management Flows for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

As shown in Figure I-5, trout management flows would be triggered in just under half the alternative long-term strategies. Among the alternative long-term strategies that include trout management flows, the mean number of years during the 20-year LTEMP period in which trout management flows would occur ranges from 2.4 under E6 to 11.0 under Alternative G; the average number ranges between 2 and 4 years under six out of the nine alternative/long-term strategies where trout management flows are allowed.

Figure I-6 shows the frequency of trout management flows under climate change assumptions. A comparison of Figures I-5 and I-6 shows that the frequency distribution pattern is virtually the same for historical and climate change assumptions. On average, the mean value for each alternative/long-term strategy is 0.49 years less under climate change assumptions; this suggests that there would be somewhat fewer trout in the Glen Canyon reach, perhaps a reflection of a drier, warmer future climate.

I.1.4 Mechanical Removal of Trout

Mechanical removal would be implemented by using electrofishing to stun and remove nonnative fish.

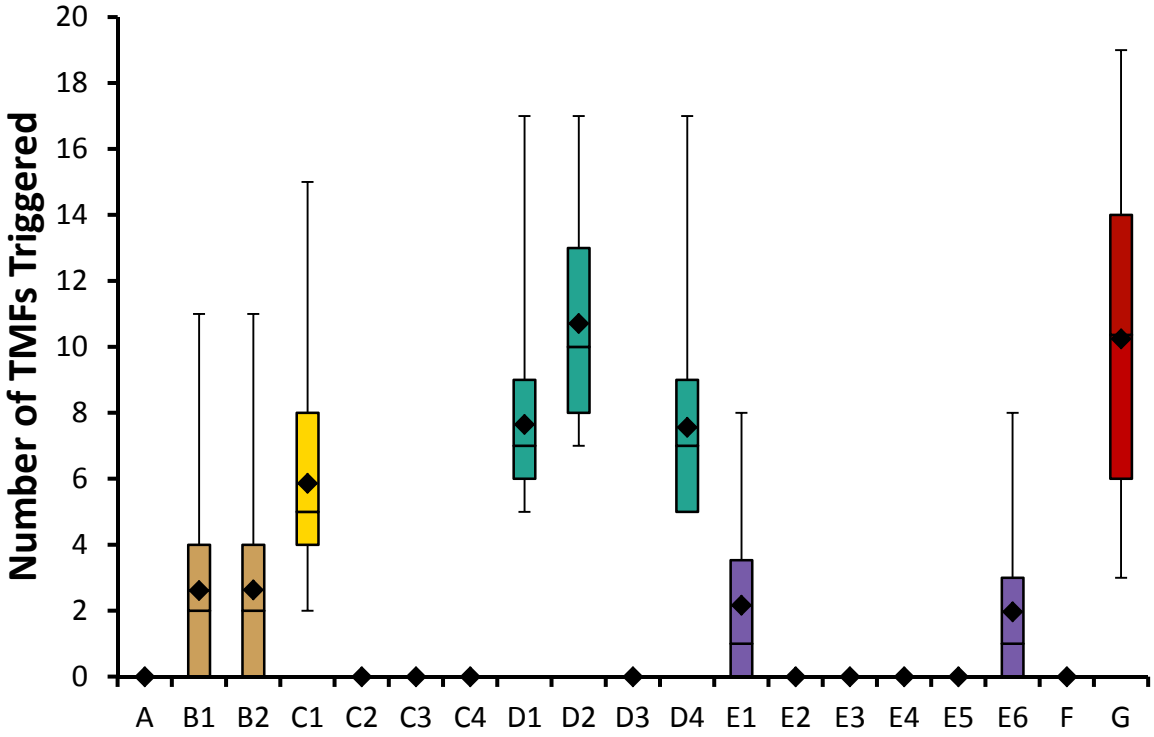

FIGURE I-6 Frequency of Trout Management Flows under Climate Change Assumptions for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

Although this does not kill the fish, usually the removed fish would be euthanized (killed) and put to some beneficial use. For example, in one mechanical removal test, the trout were emulsified and used as fertilizer in the Hualapai tribal gardens (Reclamation 2011). Grand Canyon Monitoring and Research Center (GCMRC) has modeled the number of years in which mechanical removal would be triggered under various alternatives. In the model two factors must coincide to trigger mechanical removal trips: (1) there must be more than 760 adult rainbow trout projected for the test reach in the vicinity of the Little Colorado River confluence (RM 63–RM 64.5), and (2) the projected adult humpback chub population for the canyons must be less than 7,000 individuals.

Figure I-7 shows the projected number of years in which mechanical removal from the Little Colorado River reach would be undertaken. Mechanical removal is not an allowed element of seven alternatives/strategies: Alternative C long-term strategies C1 and C2; Alternative E long-term strategies E1, E2, E5, and E6; and Alternative F. The mean number of years in which mechanical removal is modeled to occur ranges from 0.07 under Alternative A to 3.05 under Alternative G. In general, mechanical removal would be triggered in far fewer years than trout management flows. Modeling indicates that the average maximum number of years in which mechanical removal would be triggered is 6.3 out of 20, the projected maximum under D3. The overall pattern of mechanical removal events would be similar to the pattern of trout management flow occurrences and for similar reasons. Conditions that favor trout production

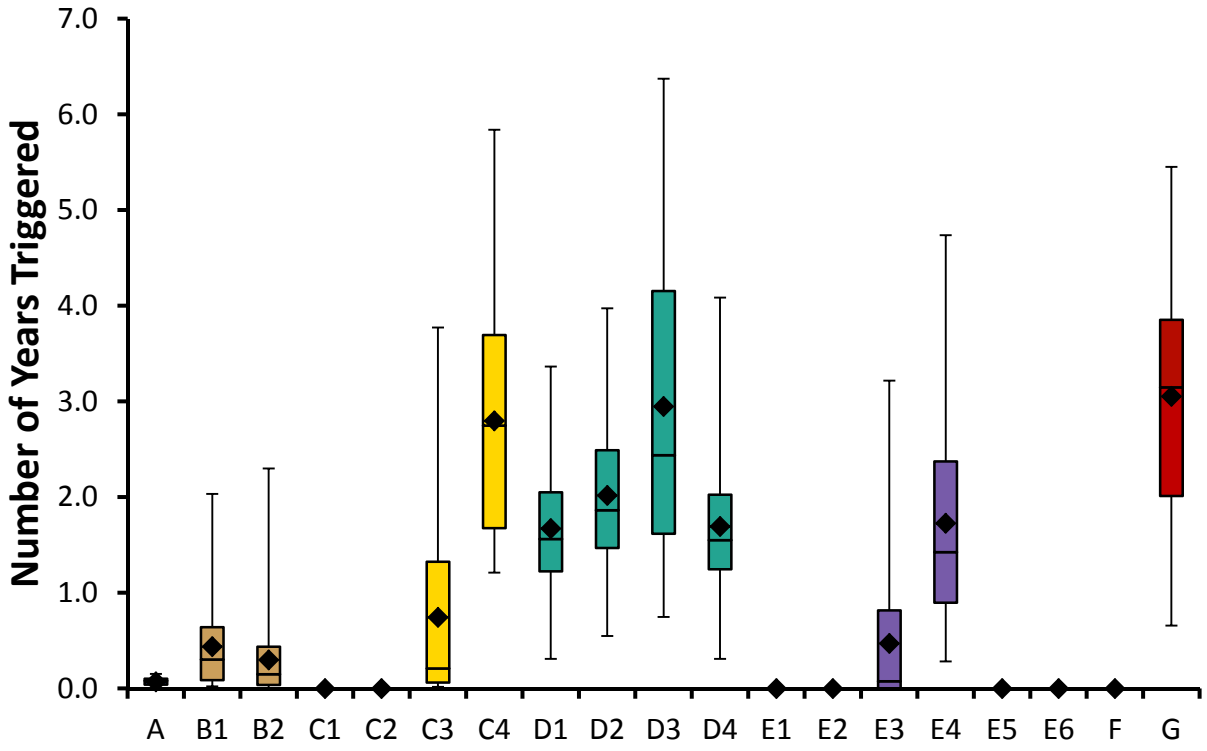

FIGURE I-7 Frequency of Mechanical Removal for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

(spring HFEs and steady summer flows) result in trout population increases in the Glen Canyon reach, thereby increasing the number of trout that move downstream to the Little Colorado River reach and triggering mechanical removal more often.

Figure I-8 shows the frequency of mechanical removal under climate change assumptions. As with trout management flows, the distribution pattern varies very little between the two plots. In all cases except Alternative G there is a slight decline in the mean number of years in which mechanical removal would be triggered. On average, those that score lower under climate change assumptions score 0.13 years less, while Alternative G scores 0.06 years more. This suggests that with the exception of Alternative G, river conditions would be slightly less favorable for trout production under climate change conditions.

I.1.5 Water Levels at Lake Powell

The domestic water supply for the LeChee Chapter of the Navajo Nation is obtained from Lake Powell through pumping and conveyance facilities that were first constructed at the time Glen Canyon Dam was built between 1957 and 1964 (NPS 2009). The current system relies on either an intake on the face of the dam at 3,480 ft above mean sea level (AMSL), or an intake off the penstocks, which are at an elevation of 3,470 ft AMSL at Lake Powell. Therefore, 3,470 ft

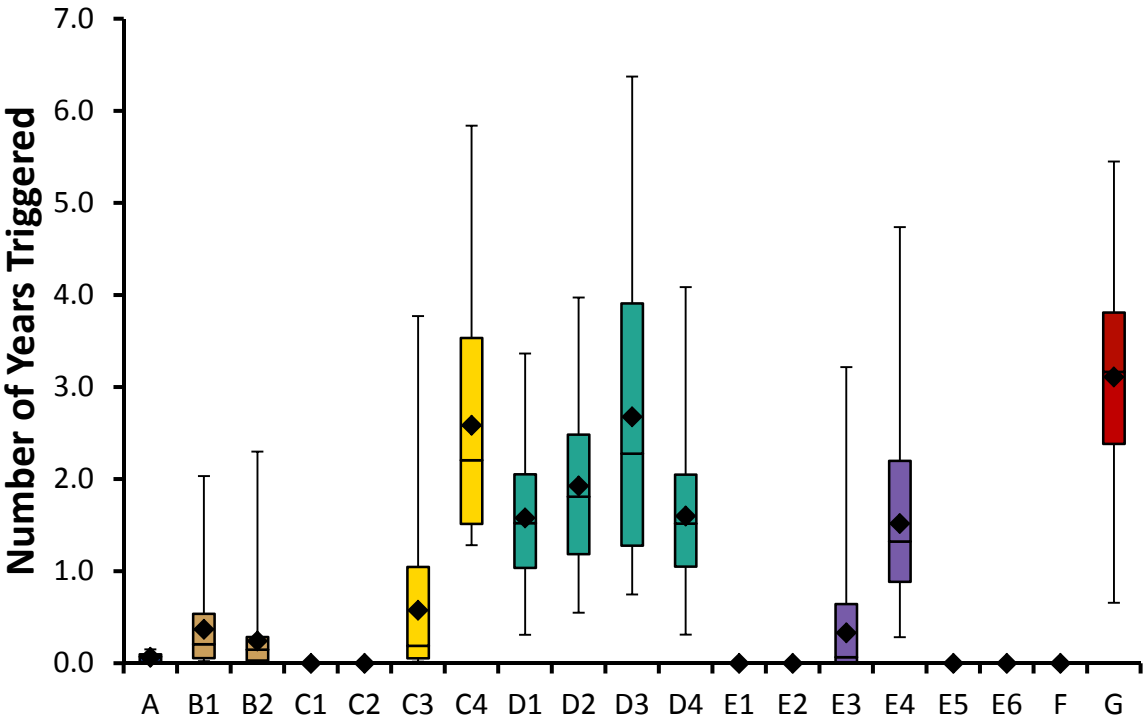

FIGURE I-8 Frequency of Mechanical Removal under Climate Change Assumptions for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

AMSL is the minimum elevation necessary for the LeChee Chapter to draw water from Lake Powell, even while penstock units are down or are undergoing maintenance.

An environmental assessment (EA) done in 2009 addresses possible future construction to provide a backup water supply to the area (NPS 2009). Three designs for new water supply systems from Lake Powell for the City of Page and the LeChee Chapter were evaluated. The EA eliminated two of the designs and narrowed the options to either no action or an entirely new pumping system which calls for six 48-in. intake pipes reaching the lake at an elevation of 3,373 ft AMSL.

The Colorado River Simulation System (CRSS) model was used for the LTEMP process to project future river and reservoir system conditions on a monthly time-step.

Because there are no known restrictions within the model for the intake pipes, an analysis was conducted to identify modeled minimum Lake Powell elevations in order to address concern regarding the LeChee Chapter's ability to draw water under LTEMP. End-of-the-month Lake Powell elevations were created as part of the LTEMP analysis (see Appendix E) for all the different hydrologic and sediment inputs (see Section 4.1 for a presentation of the overall modeling approach). A script within the MATLAB® scripting program was created to retrieve the minimum elevation possible within each alternative.

As shown in Figure I-9, there is little variation projected for Lake Powell water levels among the LTEMP alternatives. The mean water level for Lake Powell under all alternatives and long-term assumptions falls between 3,540 ft AMSL and 3,560 ft AMSL, well above intake elevations. More importantly, the minimum elevation of the lake modeled for all different input combinations and alternatives was 3,480 ft AMSL. This is the same elevation as the intake on the dam face and 10 ft above the elevation of the penstock intakes and well above elevations for any planned future intakes. Although there is always potential for modification of dam operations based on circumstantial conditions, the LeChee Chapter is projected to retain its water supply from Lake Powell under all LTEMP alternatives, with average levels slightly higher under Alternative F than the other alternatives.

As seen in Figure I-10, with the exception of Alternative F, climate change assumptions mean lake elevations are projected to fall just below 3,540 ft AMSL. Mean lake levels under Alternative F would be just above 3,540 ft AMSL. Even under climate change assumptions, minimum lake elevations are never projected to fall below 3,480 ft AMSL and are project to remain at least 10 ft above the minimum required to supply the LeChee Chapter with water. Only under Alternative F would the minimum projected Lake Powell elevation be above 3,490 ft AMSL.

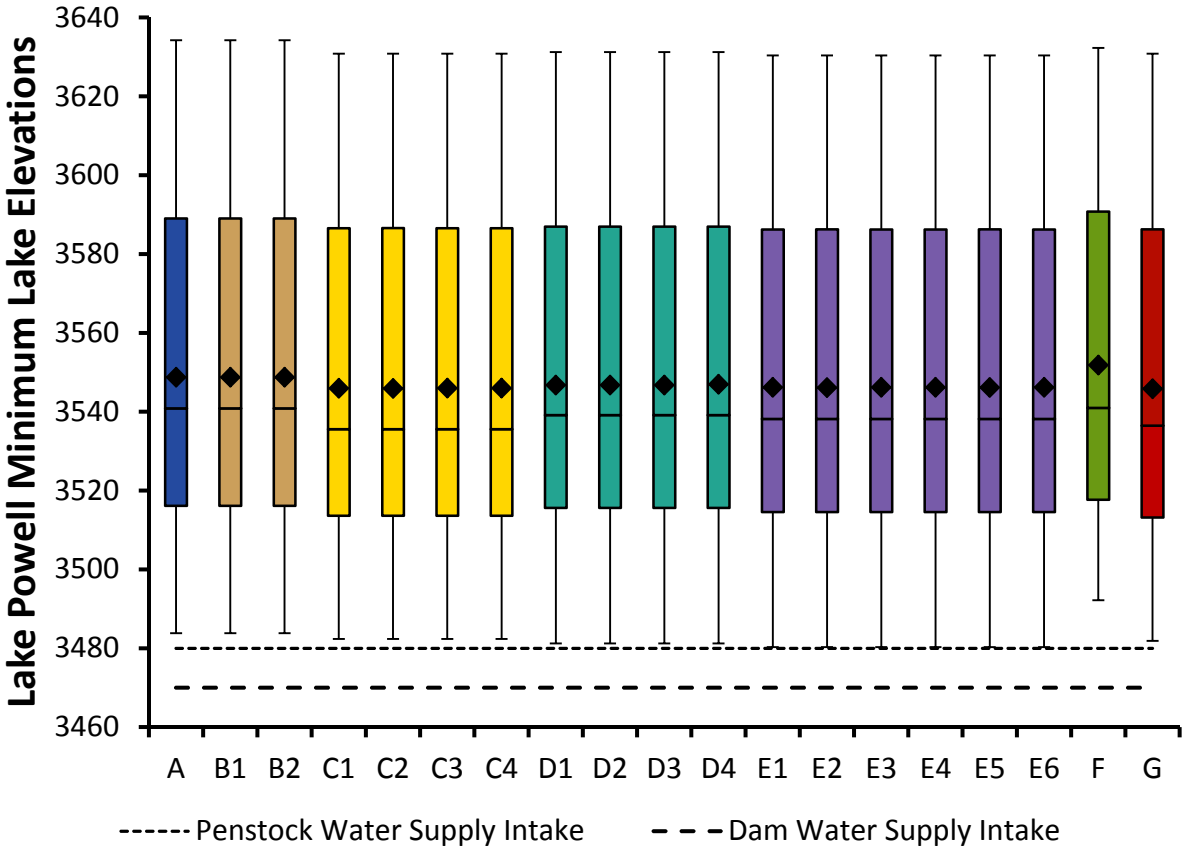

FIGURE I-9 Lake Powell Water Levels for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

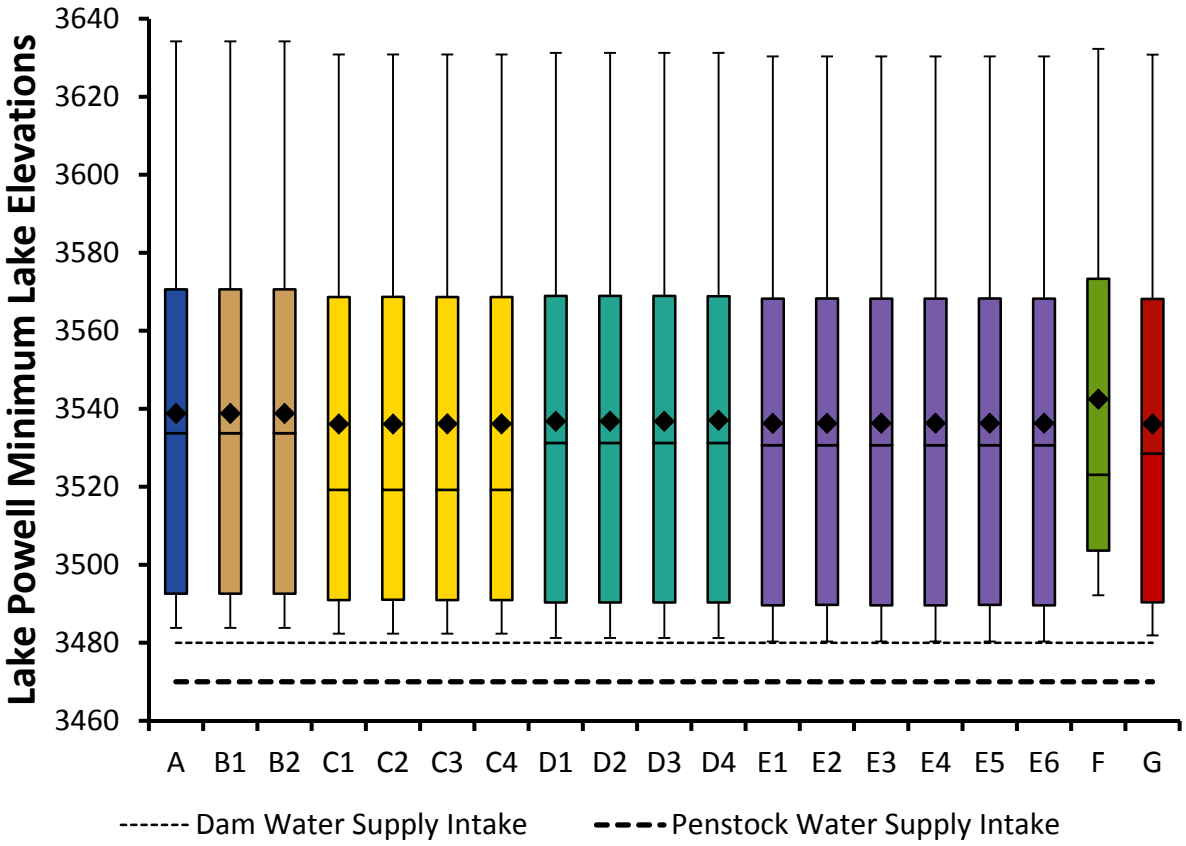

FIGURE I-10 Lake Powell Water Levels under Climate Change Assumptions for the LTEMP Alternatives (Letters) and Associated Long-Term Strategies (Numbers)

I.1.6 Access to Resources

Access to culturally important sites and resources has the potential to be a significant factor in assessing impacts from the alternatives. Resources important to the Tribes include plant resources important for food, medicinal, and ritual purposes; minerals including salt and pigments that are ritually important; and sacred places including springs and offering sites. Potential access interruption is tied to the frequency of HFEs. HFEs could cause temporary loss of access to culturally important resources through inundation of the resources or trails leading to them. These temporary interruptions can be mitigated by communication between Reclamation and the Tribes so that Tribes have notice of impending HFEs. Of the LTEMP alternatives, Alternative F and Alternative G have the most HFEs. Under the latter alternative, there are HFEs that last as long as 2 weeks. Alternative C long-term strategies C1 and C2 have a similar number of HFEs as the steady flow alternatives. Alternative C long-term strategy C4 and Alternative E long-term strategies E1, E2, and E4 have a moderate number of HFEs. Alternative A and Alternative B long-term strategies are projected to have a small number of HFEs (seven or fewer over 20 years). No HFEs are projected for Alternative C long-term strategy C3 or Alternative E long-term strategies E3, E5, and E6.

Potential impacts on archeological sites important to Tribes are discussed in Appendix H of this EIS.

RECREATION, VISITOR USE, AND EXPERIENCE TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX J:

RECREATION, VISITOR USE, AND EXPERIENCE TECHNICAL INFORMATION AND ANALYSIS

The Glen and Grand Canyons of northern Arizona provide a unique experience of extraordinary geologic landscapes, diverse wildlife and vegetation, and over 12,000 years of human history for visitors from across the globe. The area offers a variety of recreational activities including flatwater and whitewater boating, hiking, and angling. This Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS), developed by the Bureau of Reclamation (Reclamation) and the National Park Service (NPS), has identified the recreational experience goal as being to "maintain and improve the quality of recreational experiences for the users of the Colorado River ecosystem. Recreation includes, but is not limited to, flatwater and whitewater boating, river corridor camping, and angling in Glen Canyon" (Section 1.4). Past recreational studies have shown that Glen Canyon Dam operations can affect the experience of recreationalists in the downstream Glen and Grand Canyons (Bishop et al. 1987; Hall and Shelby 2000; Stewart et al. 2000; Roberts and Bieri 2001). In an effort to quantitatively assess the downstream impacts on recreational activities of the LTEMP alternatives, six performance metrics were created to address recreational concerns. This appendix explains the metrics and compares the performance of the LTEMP alternatives as indicated by the metrics.

The alternatives encompass 19 long-term strategies, which include various combinations of experimental components (Appendix C). A full range of potential hydrologic and sediment conditions were modeled for the 20-year LTEMP period. Twenty-one potential Lake Powell in-flow scenarios (known as hydrology traces) for the 20-year LTEMP period were used to generate twenty-one 20-year hourly release patterns for each alternative and long-term strategy. In addition to these twenty-one hydrology traces, three 20-year sequences of sediment inputs from the Paria River sediment record were analyzed that represented low, medium, and high sediment conditions. In combination, the twenty-one hydrology traces and three sediment traces resulted in an analysis that considered sixty-three possible hydrology-sediment conditions.

In the presentation of results below, LTEMP alternatives are identified by the alternative letter designation (Alternatives A through G) and, if the alternative includes multiple long-term strategies, a number designation (1 through 6, depending on the number of long-term strategies for an alternative) that denotes a particular long-term strategy within an alternative. See Appendix C for descriptions of the long-term strategies.

J.1 RECREATIONAL EXPERIENCE METRICS

The analysis of potential impacts on recreational experience is based primarily on the evaluation of six quantitative metrics that were developed for the assessment, but also on more qualitative information and experience of GCNRA and GCNP staff and on the studies that served as the basis for quantitative metrics. The metrics were developed through consultation with

subject matter experts, findings in published papers and reports, and with consideration of comments from the Cooperating Agencies.

J.1.1 Grand Canyon Metrics

Of the six evaluation metrics, four address issues important to visitor use and experience in Grand Canyon National Park (GCNP) downstream of Lees Ferry, while the remaining two metrics address the Glen Canyon reach between the dam and Lees Ferry. The metrics are:

- *Camping Area Index (CAI):* Accounts for optimal campsite area building and maintenance flows and sediment load (also used as input to the assessment of campsite crowding).

- *Navigational Risk Index (NRI):* Measure of navigation difficulty based on the number of days during which the daily minimum flow was less than 8,000 cfs (also used as input to the assessment of campsite crowding and encounters with other groups).

- *Fluctuation Index (FI):* Measures the degree to which combinations of flows and fluctuations are within a range identified as preferable by experienced boat guides.

- *Time Off River Index (TORI):* Relates the level of flows to visitors being able to spend time ashore visiting attractions.

J.1.2 Glen Canyon Metrics

- *Glen Canyon Rafting Metric (GCRM):* Estimates the number of visitors unable to participate in day rafting in Glen Canyon due to high flows.

- *Glen Canyon Inundation Metric (GCIM):* Accounts for flows that impact recreational sites and recreational uses within the Glen Canyon reach.

Some of the metrics evaluate non-tangible, qualitative aspects of the recreational experience. Such metrics may be based on results of recreational surveys of visitor experience under various flow and fluctuation conditions, which overlap dam operations under LTEMP alternatives (Hjerpe and Kim 2001). These and other metrics used in the analyses and described elsewhere in this EIS (see Appendices B and C) based on relative performance are expressed as an index having values from 0 to 1, where increasing values indicate increasing performance with respect to the associated resource goal. Metrics employing an index include the CAI, NRI, FI, TORI, and GCIM. The GCRM is the only metric that uses an absolute scale. It is the number of potential lost visitor trips for day-use rafts in Glen Canyon due to high flows during high-flow experiments (HFEs).

The metrics all rely on the hourly Glen Canyon Dam discharge computed by the GTMax-Lite model (Reclamation 2007) with the incorporation of a sediment analysis (Russell and Huang 2010) to account for HFE implementation (Appendix E). GTMax-Lite produces a trace (20 years of hourly discharge) for each combination of hydrology and tributary sediment traces input into the model. For each metric, all 7 alternatives and any associated long-term strategies were analyzed for all 63 traces (see Section 4.1 for more detail). The following sections explain the calculation of recreation metrics for an individual trace.

In all metrics but the GCRM, the index value is weighted to emphasize seasons with greater recreational use over the course of a year. Percent of annual recreation use was determined to be 15% in the winter months of November, December, January, and February; 31% in the spring and fall months of March, April, September, and October; and 54% in the summer months of May, June, July, and August (based on monthly visitation statistics presented in https://irma.nps.gov/Stats/Reports/Park/GRCA).

J.2 METRIC DEFINITIONS, ANALYSIS METHODS, AND RESULTS

J.2.1 Camping Area Index

Campsites are primarily located on sandbars along the shoreline of the river, and they provide open, flat areas ideal for camping. Crucial for multi-day trips, campsites can limit the visiting capacity (the number of people to maintain a desired natural visitor experience) for high-demand downstream rafting trips (Kearsley et al. 1994). The management of campsites is therefore of particular concern to river managers (NPS 2006). To meet the visitor capacities established in the NPS Colorado River Management Plan, it is necessary to develop and retain medium (16–25 people) and large (>25 people) campsites, which maintain and potentially improve visitor experience based on preferences expressed in surveys of visitors. Commercial and private trip leaders preferred large beaches for camping compared to smaller beaches (Stewart et al. 2000). A study by Kaplinski and others monitoring campsites from 1998 to 2012 reported a decrease of average campsite area by 36% with any decrease in area noted at 29 out of the 37 study sites (Kaplinski et al. 2014).

Dam operations have been shown to have significant effects on campsite area. HFEs have proven to temporarily increase campsite area due to sandbar deposition (Grams et al. 2010; Hazel et al. 2010). In the Grand Canyon Monitoring and Research Center (GCMRC) *Fiscal Year 2014 Annual Project Report* (GCMRC 2015), Kaplinski and others concluded, “sandbar deposition associated with high flows results in increases in campsite area, while post-HFE erosion causes decreases in campsite area.” Currently, it is perceived that lower discharge reduces erosion to campsites, while also exposing campsites that are covered at higher discharges. A decrease of discharge from 25,000 cfs to 15,000 cfs during normal flows increased campable area by 73%; a further increase of 46% in campable area was seen when discharges further decreased to 8,000 cfs (Kearsley and Warren 1993).

J.2.1.1 Camping Area Index—Methods

The CAI evaluates the conditions conducive to increased camping area in the Grand Canyon, which is a function of the amount of sand deposited and retained and campsite area exposure as a function of river level (flow rate). The output from the sand load index (SLI), which simulates sediment conditions between RM 0 and 30 provides a proxy for indicating whether the alternatives are likely to create the conditions conducive to creating/retaining campsite area (Appendix E). The CAI is the product of the SLI and a Seasonally Weighted Flow Factor (SWFF):

$$CAI = Average(SWFF)_{2014-2033} \times SLI$$

Both the SLI and SWFF are indices ranging from 0 to 1, as is the resulting CAI, where a value of 1 indicates the greatest potential to increase camping area. As the metric output is a generalization of sediment conditions throughout the canyon, it does not predict conditions at any particular site. Erosion is not taken into account in the CAI. Daily flow level is accounted for in the SWFF, as discussed below. Lower flows provide more camping area (i.e., there is more camping area at 8,000 cfs than at 25,000 cfs because more sand is exposed at lower flows [Kearsley and Warren 1993]). The minimum flow within the daytime period (7 am to 7 pm) is 8,000 cfs under most LTEMP alternatives.

The SLI is an index of the potential sand deposited on sandbars along the river channel in Marble and Grand Canyons above normal stage elevations (31,500 cfs). The SLI is calculated as the ratio of the cumulative sand load at flows greater than 31,500 cfs relative to the total cumulative sand load at all flows modeled (Appendix E). The sand load, or the mass of sand in transport by the river, is calculated at RM 30 and is computed by a version of the Sand Budget Model (Wright et al. 2010) for the 20-year LTEMP period. A larger SLI (on a scale of 0–1), indicates a greater potential for sediment deposition. The SLI was calculated using the following equation:

$$SLI = \frac{\sum_{2014-2033} Sand\ Load\ at\ dam\ discharges > 31{,}500\ cfs}{\sum_{2014-2033} Sand\ Load\ at\ all\ dam\ discharges}$$

The SWFF is a yearly value representing the relative amount of river bank exposure available for camping areas dependent on the Glen Canyon discharge. Low river flows will expose more campsite area while higher flows will submerge campsite area and potentially cause erosion (Kearsley and Warren 1993). Flows above 8,000 cfs are considered to increasingly reduce camping area and to submerge most campsite areas at 31,500 cfs. Camps above 25,000 cfs are considered high campsites in Kaplinski (2014). With no data on the exact location of all campsites relative to the river, an informed assumption is made here. The daily maximum flow is used to evaluate the extent to which flows may cover campsites at any point in the day.

Modeled daily flows are assigned a 0–1 index value, referred to as the daily flow factor (FF_{Daily}):

$$FF_{Daily} = \begin{cases} \text{if } Q_{max} \leq 8{,}000 \text{ cfs}; & 1 \\ \text{if } 8{,}000 < Q_{max} < 31{,}500\ cfs; & 1.34 - 0.0000425 \times Q_{max} \\ \text{if } Q_{max} \geq 31{,}500 \text{ cfs}; & 0 \end{cases}$$

where Q_{max} refers to the daily maximum discharge released from the Glen Canyon Dam in cfs and FF_{Daily} is equal to the value in the right column if the equation in the left column is satisfied.

The yearly index value (SWFF) is the ratio of the index values for each season:

$$\text{SWFF} = \left\{0.15\left(\frac{\sum_{\text{winter}} FF_{daily}}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{\text{spring\&}fall} FF_{daily}}{\sum Days_{spring\&fall}}\right) + 0.54\left(\frac{\sum_{\text{summer}} FF_{daily}}{\sum Days_{summer}}\right)\right\}$$

J.2.1.2 Camping Area Index—Results

CAI values for all 19 LTEMP long-term strategies are shown in Figure J-1. All of these have higher CAI values than Alternative A (no-action alternative). Long-term strategies B2, C3, E3, E5, and E6 rank below Alternative A. With the exception of B2, HFEs are not conducted for these long-term strategies, and therefore flows above 31,500 cfs, the primary mechanism for sediment deposition, occur rarely, if at all. Experimentally increased flow fluctuations (hydropower improvement flows) under B2 cause it to rank below Alternative A.

The CAI is fairly insensitive to SWFF because SWFF values typically range only between 0.55 and 0.77. Consequently, the CAI is strongly dependent on the SLI, and therefore to the number of HFEs under a given alternative or long-term strategy (see Appendix E). The strong dependence of CAI on SLI can be seen by comparing Figure J-1 and Figure J-2.

Alternative G has the highest CAI, a value 3.2 times that of Alternative A. This result is attributed to the highest number of HFEs and relatively even year-round daily flows under Alternative G, conditions conducive to conserving sediment and increasing camping area through deposition and retention of sediment. Ranking second-highest, Alternative F, with a CAI 2.9 times that of Alternative A, has low flows in non-summer months and more 96-hour HFEs than other long-term strategies.

Long-term strategy B2 has a slightly reduced CAI compared to B1 attributable to testing of hydropower improvement flows under B2, which reduces CAI through reductions in both SLI and SWFF. The CAI for long-term strategy C4 is reduced relative to that for C1 and C2 due to the absence of spring HFEs and proactive spring HFEs under C4, which reduces its SLI value. C3 is much reduced owing to the absence of spring or fall HFEs, as noted above.

The CAI for long-term strategy D4 is not significantly different from D1, D2, D3, or C1, based on a test of differences between means using a three-factor analysis of variation (ANOVA)

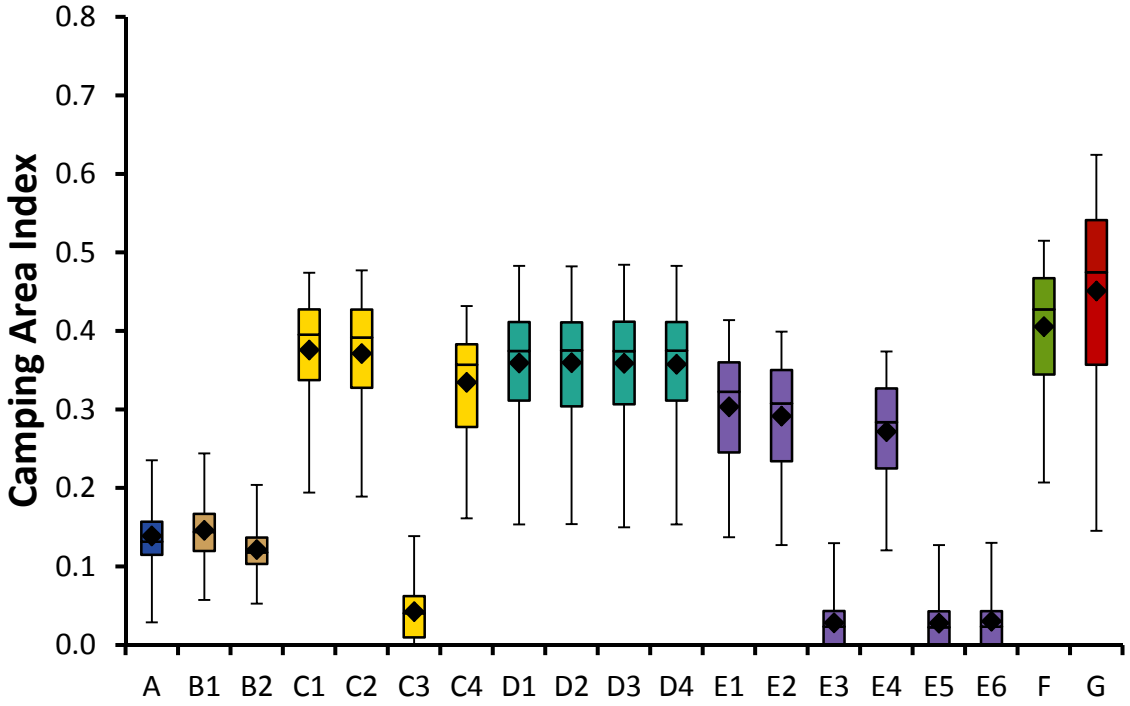

FIGURE J-1 Camping Area Index for LTEMP Long-Term Strategies (Increasing values indicate increasing camping area. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

followed by Tukey's Studentized Range Test. This indicates that low summer flows under D1, D2, and D3 have no effect on CAI, nor does sustained low flows for benthic invertebrate production under D2 or the absence of trout management flows under D3.

The CAI for long-term strategy E4 is slightly lower than that for E1 and E2, indicating a small reduction in sediment retention for E4 due to the absence of spring HFEs in the second 10 years of the LTEMP period, which are conducted under E1 and E2. As noted above, E3, E5, and E6 do not include spring or fall HFEs, explaining their low CAI values.

J.2.2 Navigational Risk Index

Navigating the Colorado River downstream of Glen Canyon Dam at low flows, especially at rapids, can cause difficulties for oar and motor trips. A survey conducted by Bishop et al. (1987) of commercial oar and motor guides indicated that flow levels below 9,200 cfs and 8,400 cfs, respectively, began to compromise boater safety. In the Bishop et al. (1987) study, guides were simply asked for minimum levels of flow for running safely with passengers. Survey respondents noted that at these flows, boat accidents related to exposed rocks are much more probable. A similar survey by Shelby et al. (1992) reported nearly the same

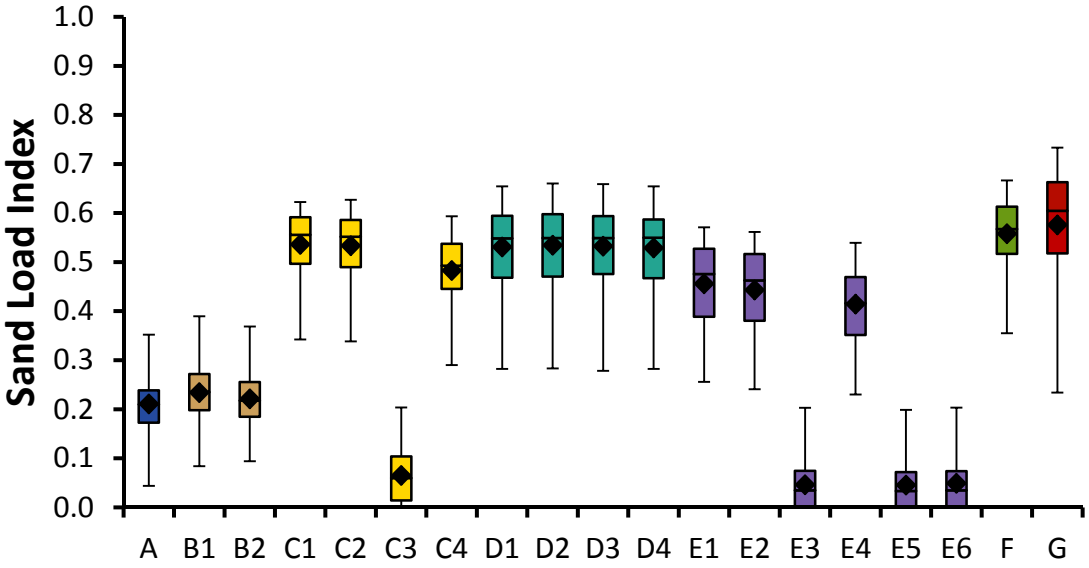

FIGURE J-2 Sand Load Index (see Appendix E) for LTEMP Long-Term Strategies (Increasing values indicate more sediment deposited along river banks. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

values as Bishop et al. (1987), and a more recent survey by Stewart et al. (2000) had similar findings with oar and motor river guides identifying approximately 8,100 cfs and 7,800 cfs, respectively, as minimum flows for what they considered safe river trips. Exposures to experimental low flows of 8,000 cfs in the summer of 2000 further supported the guides' perceptions of potentially dangerous flows, with double the number of boating accidents reported than the previous year, mostly associated with hitting exposed rocks (Ralston 2011).

J.2.2.1 Navigational Risk Index—Methods

To assess the risk due to difficulties of motor rigs navigating rapids at lower flows, the risk (frequency) of daily minimum discharges that are ≤8,000 cfs was determined for each season. To account for the variance in use between the seasons, the yearly value is averaged with weights corresponding to recreational use as used above for SWFF in calculating the CAI. The annual risk was calculated as:

$$Risk = \left\{ 0.15 \left(\frac{\sum_{\text{winter}} Days_{min}}{\sum Days_{winter}} \right) + 0.31 \left(\frac{\sum_{\frac{\text{spring}}{\text{fall}}} Days_{min}}{\sum Days_{\frac{spring}{fall}}} \right) + 0.54 \left(\frac{\sum_{\text{summer}} Days_{min}}{\sum Days_{summer}} \right) \right\}$$

where $Days_{min}$ is the number of days when flows were <8,000 cfs, $Days_{winter}$ is the number of days in the winter, $Days_{spring/fall}$ is the number of days in the spring and fall, and $Days_{summer}$ is the number of days in the summer.

The index is the complement of the risk, where 1 indicates 100% of minimum daily flow above 8,000 cfs and is therefore the least risk to river navigators. Thus, the NRI for a single input trace for the LTEMP period of 2014–2033 is as follows:

$$NRI = Average(1 - Risk)_{2014-2033}$$

While Alternatives A through E restrict minimum flows to 8,000 cfs during day hours (7 am to 7 pm), flows during night hours (7 pm to 7 am) can drop to 5,000 cfs, and these low flows can affect downstream boaters during daylight hours well after the change in discharge rate occurs at the dam due to the transit time required for the change to reach downstream locations. The calculation of daily minimum flow was therefore inclusive of the entire 24-hour period.

J.2.2.2 Navigational Risk Index—Results

NRI values for each alternative are shown in Figure J-3. Long-term strategies C1–C4, D2, F, and G have higher values than Alternative A, while D1, D3, and D4 are only slightly lower than Alternative A. Long-term strategy B2 has the lowest NRI value owing to high flow fluctuations and low minimum flows, while B1 and E1–E6 are also lower than Alternative A.

Alternative G has year-round steady flows of approximately 11,000 to 13,000 cfs, rarely dipping below 8,000 cfs, resulting in an NRI approaching 1 (lowest risk). Alternative F, which also has steady daily flows, has high flows in the months of February through June and lower flows running near or below 8,000 cfs in July through January. However, for the historic water volumes modeled (typically greater than 8.23 maf), higher releases would sometimes occur for equalization purposes at the end of the water year. Primarily for this reason, the average days with flows above 8,000 cfs actually outnumber the days below it for Alternative F. On average, Alternative F has an NRI almost 1.5 times that of Alternative A.

For alternatives with fluctuating flows, the size of daily fluctuations generally differentiates between alternatives, while experimental features drive differences between long-term strategies within alternatives. Daily fluctuations under Alternative C are lower than those under Alternatives A, D, E, and B, resulting in fewest occurrences of flows less than 8,000 cfs and the highest NRI value (lowest risk) of the fluctuating-flow alternatives. The relative ranking of these alternatives in Figure J-3 generally reflects the size of daily fluctuations, which determines the frequency of flows less than 8,000 cfs.

Within alternatives, long-term strategy B2 has a lower NRI (higher risk) than B1 due to high fluctuations and flows less than 8,000 cfs associated with experimental hydropower improvement flows not included in B1. For the same reasons, B2 has the lowest NRI (highest risk) of all long-term strategies. C2 has a slightly lower NRI than C1, C3, and C4 due to the

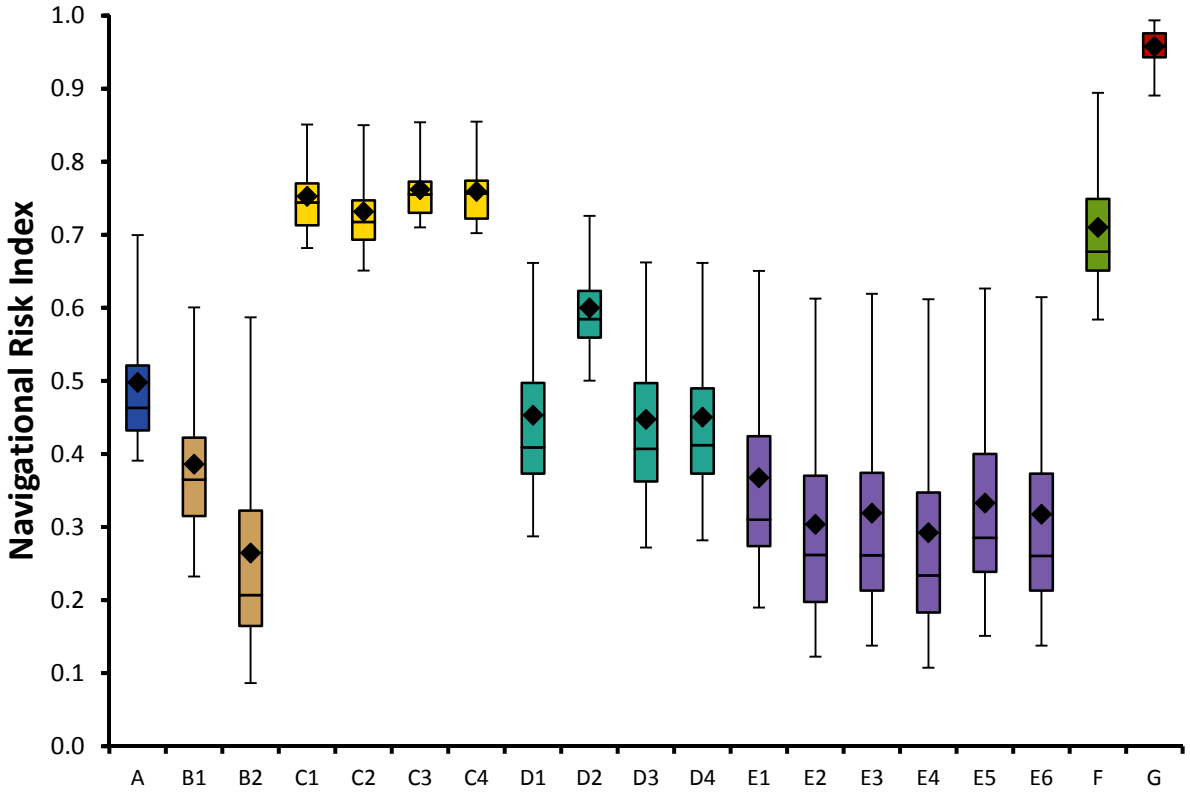

FIGURE J-3 Navigational Risk Index Values for the LTEMP Long-Term Strategies (Increasing values indicate improving navigation conditions. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

inclusion of low summer flows, which allows minimum daily flows as low as 5,000 cfs. Low weekend flows to promote benthic invertebrate production during May–August under long-term strategy D2 increase the overall minimum flow during those months, elevating the NRI relative to D1, D3, and D4. Absence of low summer flows under E1, E3, E4, and E6 elevates the NRI for these long-term strategies slightly compared to E2 and E5.

J.2.3 Fluctuation Index

Whitewater rafting guides surveyed by Bishop et al. (1987) indicated that moderate (8,000–25,000 cfs) and severe (1,000–33,500 cfs) daily fluctuations are potentially problematic for rafting trips. Fluctuations can complicate mooring at campsites, and running rapids, and can increase the unpredictability of flows. Bishop et al. surveyed guides and private trip leaders with experiences of both large fluctuations (greater than 15,000 cfs) and steady flows and documented the ranges of tolerable fluctuations at various river flow levels, as shown in Table J-1.

TABLE J-1 Reported Mean Tolerable Daily Changes in Flow Levels for Commercial Motor Guides, Commercial Oar Guides, and Private Trip Leaders Who Have Experienced Daily Fluctuations of at Least 15,000 cfs in the Grand Canyon[a,b]

River flow (cfs)	Commercial Motor Guides	Commercial Oar Guides	Private Trip Leaders
5,000–9,000 cfs			
Mean daily change (cfs)	3,231	*3,412*	*2,428*
Standard deviation (cfs)	2,320	3,180	2,233
Sample size	52	34	45
9,000–16,000 cfs			
Mean daily change (cfs)	4,706	*4,786*	*3,936*
Standard deviation (cfs)	2,094	2,311	2,693
Sample size	52	35	47
16,000–32,000 cfs			
Mean daily change (cfs)	*7,192*	6,708	*6,410*
Standard deviation (cfs)	3,404	2,812	3,679
Sample size	52	36	50
32,000 cfs and above			
Mean daily change (cfs)	*9,760*	*7,903*	8,612
Standard deviation (cfs)	5,375	2,917	6,470
Sample size	52	36	49

[a] Table taken from Table 4-7 of Bishop et al. (1987).

[b] Italicized values indicate the maximum tolerable fluctuation threshold range used in the FI after rounding to the nearest hundred cfs.

J.2.3.1 Fluctuation Index—Methods

Table J-1 is the basis for the FI. It is assumed that (1) the river flow ranges shown in the left-hand column of Table J-1 are based on the mean daily flow and that (2) the maximum tolerable fluctuation threshold (italicized flow values in Table J-1) serves as the level above which fluctuations become increasingly more unacceptable to river users.

A daily flow factor (FF) value of 0–1 was computed using Table J-1 and the mean flow for a given day. The daily flow factor is 1 if the fluctuations are within the acceptable range. Above the threshold, daily FF goes linearly to zero as the fluctuation increases to 10,000 cfs. Daily fluctuation levels greater than 10,000 cfs are clearly noticeable by river users (Bishop et al. 1987). The daily FF is computed as follows, where Q_{avg} is the daily mean flow, Q_{range} is the daily fluctuation, and Q_{tol} is the tolerable fluctuation threshold:

$$FF_{daily} = \begin{cases} \text{if } Q_{range} \leq Q_{tol} & 1 \\ \text{if } Q_{range} > Q_{tol} & \\ \quad where\ 5{,}000 < Q_{avg} < 8{,}999 & 1.515 - (0.00015 \times Q_{range}) \\ \quad where\ 9{,}000 < Q_{avg} < 15{,}999 & 1.923 - (0.00019 \times Q_{range}) \\ \quad where\ 16{,}000 < Q_{avg} < 31{,}999 & 3.571 - (0.00036 \times Q_{range}) \\ \quad where\ Q_{avg} > 32{,}000 & 50 - (0.005 \times Q_{range}) \end{cases}$$

The annual FI is the sum of daily FFs weighted by season according to recreational use, with seasonal weights being the same as for the NRI:

$$FI_{annual} = \left\{0.15\left(\frac{\sum_{winter} FF_{Daily}}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{spring/fall} FF_{Daily}}{\sum Days_{spring/fall}}\right) + 0.54\left(\frac{\sum_{summer} FF_{Daily}}{\sum Days_{summer}}\right)\right\}$$

An overall annual mean index value for the 20-year modeling period was calculated as follows:

$$FI = Average\ (FI_{annual})_{2014-2033}$$

J.2.3.2 Fluctuation Index—Results

The results of the FI are shown in Figure J-4. Differences between alternatives reflect differences in levels of daily flow fluctuations under the respective operational regimes. Alternatives F and G have FIs approaching 1 due to the absence of daily fluctuations; G is slightly lower, as it includes trout management flows in years when trout recruitment is high. Alternatives C, A, D, E, and B have rankings in order of increasing levels of daily fluctuations.

Alternative A and all long-term strategies under Alternatives C, D, and E have average index values above 0.5, indicating a high proportion of daily fluctuations that are within the tolerable range. Long-term strategy B1 has an annual FI value roughly half that of Alternative A, while B2 has a value roughly a third of Alternative A. Tests of hydropower improvement flows, particularly during highly weighted summer months, reduce B2 relative to B1, while high fluctuation levels overall contribute to low FI values for B1 and B2. Steady, low weekend flows to promote benthic invertebrate production during May through August elevate the FI for D2 relative to D1, D3, and D4. The slightly higher FI values for long-term strategies E1 and E2 relative to E3–E6 can be attributed to the inclusion of both spring and fall HFEs in EI and E2. Water released for HFEs is not available for load following, thus reducing fluctuations and raising the FI. Likewise, E4, which includes fall but no spring HFEs, has a slightly elevated FI compared to E3, E5, and E6, which have no HFEs.

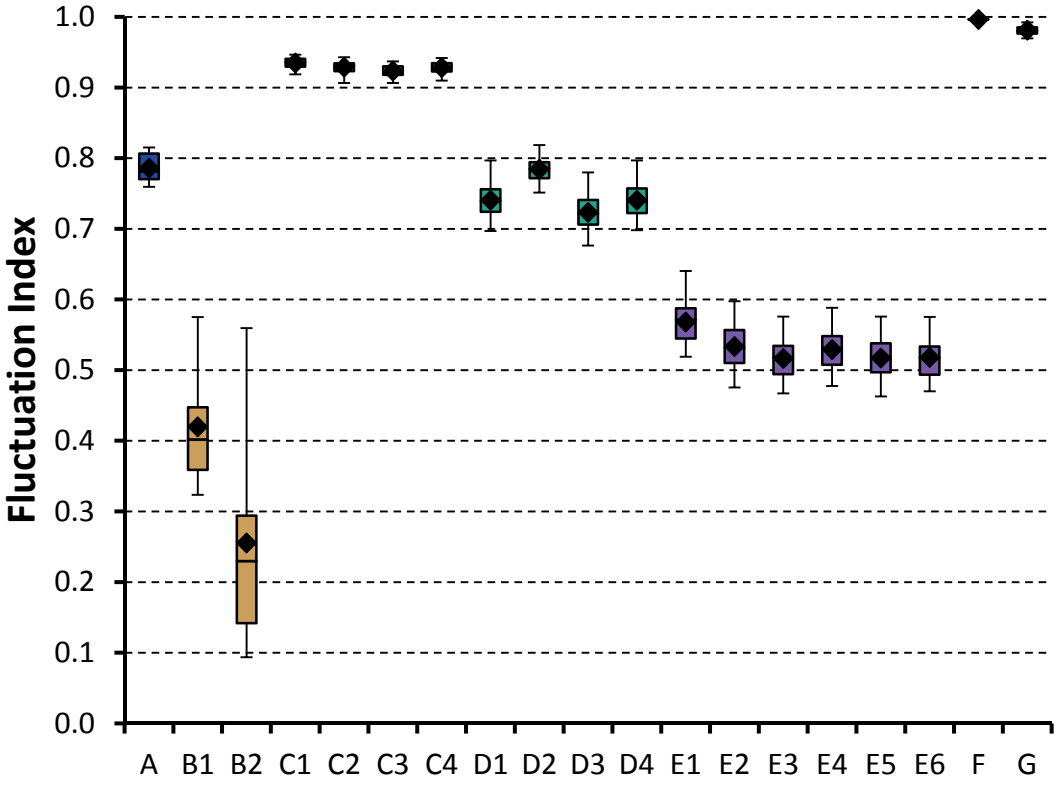

FIGURE J-4 Fluctuation Index for LTEMP Long-Term Strategies (Increasing values indicate more days have tolerable fluctuation levels. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

J.2.4 Time Off River

For rafting visitors, time off river to visit attractions and for other activities is important to the recreational experience (Stewart et al. 2000). Low river flows reduce travel speed for boats. Below a flow of about 10,000 cfs, there may be problems getting to camp on time and not enough time for stops at scheduled locations (Shelby et al. 1992).

J.2.4.1 Time Off River Index—Methods

The TORI is computed using a daily flow factor (FF), which is an index from 0 to 1 that uses a flow threshold of 10,000 cfs. The daily FF is computed as follows, where the value within the brackets in the right column is assigned to the FF if the equation in the left column is satisfied, and where Q_{avg} is the average daily discharge:

$$FF_{Daily} = \begin{cases} \text{if } Q_{avg} \leq 10{,}000; & 0 \\ \text{if } 10{,}000 < Q_{avg} < 31{,}500; & 0.0000465 \times Q_{avg} - 0.465 \\ \text{if } Q_{avg} \geq 31{,}500; & 1 \end{cases}$$

The annual TORI is the sum of the weighted seasonal index values. The seasonal index is the mean of the FF for all days within a given season, as above for NRI and FI:

$$TORI_{annual} = \{0.15\left(\frac{\sum_{winter} FF_{Daily}}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{spring/fall} FF_{Daily}}{\sum Days_{\frac{spring}{fall}}}\right) + 0.54\left(\frac{\sum_{\text{summer}} \text{FF}_{\text{daily}}}{\sum Days_{summer}}\right)\}$$

An overall annual mean index value for the 20-year modeling period was calculated as follows:

$$TORI = Average\ (TORI_{annual})_{2014-2033}$$

J.2.4.2 Time Off River Index—Results

Figure J-5 shows the TORI results for all long-term strategies. TORI values for all of the long-term strategies have similar mean and quartile values, due to similar average flows among the alternatives. The exception is the TORI for Alternative F, which is notably higher than for other alternatives. This difference is largely due to elevated flows during March–June under Alternative F, which falls within moderately to highly weighted seasons in the annual TORI computation. Figure J-6 shows elevated average daily discharge rates during March–June for Alternative F relative to the other alternatives. For all other long-term strategies, there would be negligible differences in time off river from current conditions.

J.2.5 Glen Canyon Rafting Use

Day-rafting trips in Glen Canyon are a popular visitor attraction of Glen Canyon National Recreation Area. These day-rafting trips regularly run as full-day, half-day, and rowed trips during March 1 to December 1. Glen Canyon rafting trips are not sensitive to flow levels (Bishop et al. 1987) and can generally operate during all releases up to powerplant capacity

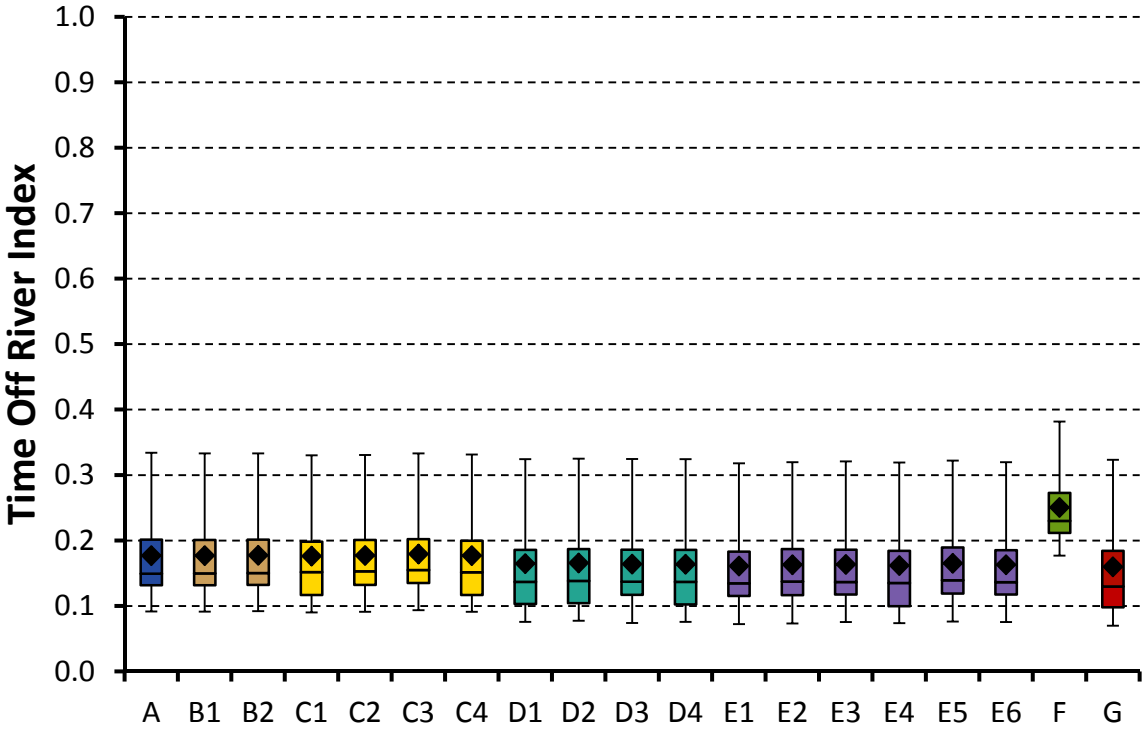

FIGURE J-5 Time Off River Index for LTEMP Long-Term Strategies (Increasing values indicate more time off river. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

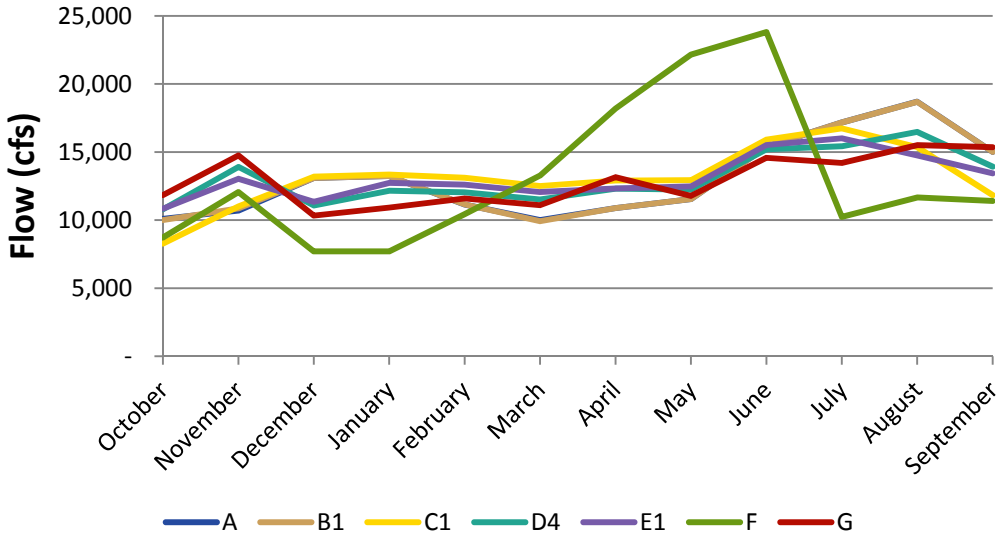

FIGURE J-6 Average Daily Discharge for All Modeled Traces and Years under LTEMP Alternatives

(31,500 cfs). However, when HFEs are run and the bypass tubes are activated, the turbulence at the loading dock is too great to safely load passengers and the commercial operator, Colorado River Discovery, ceases day-use rafting operations (Grim 2012).

J.2.5.1 Glen Canyon Rafting Use Metric—Methods

The Glen Canyon Rafting Use Metric (GCRM) represents the number of visitors unable to take day-rafting trips due to HFEs. Monthly passenger logs for Colorado River Discovery from 2011 to 2012 (Blais 2014) were used to estimate the number of daily passengers (*ADV*) for the months in which HFEs occur (March, April, May, October, and November). Data from 2013 was available but was not included because roadway closures that year potentially impacted visitor numbers. HFEs in spring and fall are possible each year. Estimates of the average daily rafting visitor count for lost trips from spring and fall HFEs are approximately 155 and 68, respectively. Thus, spring HFEs would have a much greater impact than fall HFEs due to higher rafting use in spring (more than double the passengers affected for a given HFE duration).

HFEs require day-raft concessioners to pull the boats from the water or relocate them. Therefore, the number of days lost for Glen Canyon rafting because of an HFE (*D*) is equal to the HFE duration plus 2 days prior and 2 days post HFE ($D = T_{HFE} + 4$ days) required to de-mobilize and re-mobilize rafting operations. The total number of lost rafting days (*D*) is multiplied by the estimated visitors per day (*ADV*) to calculate the number of passengers unable to raft due to an HFE. Note that, unlike the other recreation metrics in this appendix, the Glen Canyon Rafting Use Metric (GCRM) is a measure of an absolute effect, the actual number of annual lost visitor trips, as opposed to a relative index.

The operational 24-hr, 45,000 cfs spring high flow under Alternative F is taken into account in this analysis. No other high flows, such as equalization flows, except those distinctly defined as HFEs are considered. For each modeled year, there is the potential for a spring HFE, a fall HFE, or both to occur. The GCRM is calculated as follows for each HFE event.

$$GCRM_{HFE} = ADV\left[\frac{visitors}{day}\right] \times D\ [days]$$

If there are two HFEs within a single year, the number of passengers unable to raft is summed as in the following equation:

$$GCRM_{annual} = \sum_{yearly} GCRM_{HFE}$$

The final metric value is the average number of passengers unable to raft the Glen Canyon reach for the 20-year LTEMP modeling period (2014 to 2033) due to HFEs:

$$GCRM = Average\ (GCRM_{annual})_{2014-2033}$$

J.2.5.2 Glen Canyon Rafting Use Metric—Results

Figure J-7 shows GCRM values for LTEMP alternatives and long-term strategies. As the metric is based on the number of HFEs, the GCRM closely resembles the pattern of HFEs under each alternative. This can be seen by comparing the GCRM values in Figure J-7 with the average HFE count in Figure J-8. Not shown for Alternative F is the annual 24-hr high flow that occurs in years without a spring HFE. This further contributes to increases the GCRM, resulting in the highest number of lost visitor trips for Alternative F. As spring trips have a higher number of passengers than fall trips, spring HFEs have a larger impact on lost visitor trips than do fall HFEs.

As they do not include HFEs, long-term strategies C3, E3, E5, and E6 incur no lost visitor rafting trips. With few HFEs and mostly fall HFEs, long-term strategies A and B1 and B2 have the next fewest lost trips on average, while C4 and E4 have only slightly more, due mainly to the absence of spring HFEs under these long-term strategies. E1 and E2 have more lost trips than E4 due to spring HFEs in the second 10 years of the LTEMP period that do not occur under E4. Long-term strategies C1–C2 and D1–D2 have similar numbers of lost visitor trips owing to similar numbers and durations of HFEs. Alternative G has the second highest number of lost trips at roughly 500 annually, due to a high number of HFEs, an estimated 24.5 over the 20-year LTEMP period, including HFEs of 96 hr or longer duration. Finally, Alternative F has the highest number of lost visitor trips, on average over 900 annually, due to the highest number of HFEs, an estimated 38.1 over the 20-year LTEMP period, including the annual 24-hr release in all summers of years without a spring HFE. In addition, roughly two-thirds of HFEs under Alternative F are of 96-hr duration, representing a large number of days closed to rafting.

J.2.6 Glen Canyon Inundation Metric

The 15-mi stretch of Glen Canyon, from the Glen Canyon Dam to Lees Ferry, along the Colorado River is a hub for recreation within Glen Canyon National Recreation Area. Due to its unique geography, Lees Ferry is the only place directly accessible by car to visitors in hundreds of miles of canyon country. It is therefore an ideal location for boating, fishing, swimming, kayaking, camping, and hiking activities by visitors. However, these activities are directly downstream of the Glen Canyon Dam, and can be impacted by dam operation.

Surveys of users have indicated that the most ideal recreational conditions for Glen Canyon are flows from 8,000 to 20,000 cfs. Bishop et al. (1987) and Stewart et al. (2000) reported that anglers preferred a constant flow of about 10,000 cfs, while more recent information indicated Lees Ferry anglers preferred constant flows from 8,000 to 16,000 cfs (Gunn 2012). Flows within the 8,000 to 20,000 cfs range are ideal for shoreline access for boaters, who primarily only report poor conditions or water level issues with extremely high or low flows. For example, the Colorado River Discovery day rafting service reported operating issues with flows below 3,000 cfs and inoperable conditions when bypass tubes are in operation (above 31,500 cfs), as they create too much turbulence below the dam (Grim 2012). Flows at or

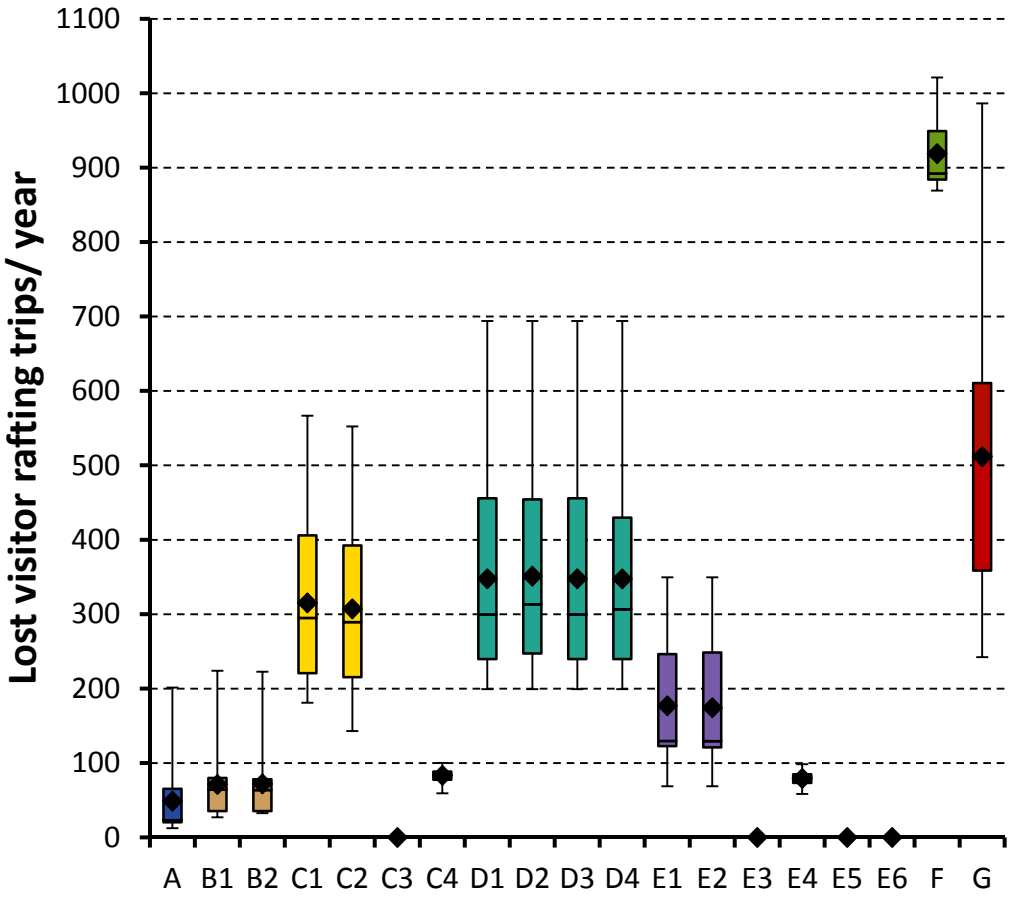

FIGURE J-7 Glen Canyon Rafting Metric for All LTEMP Long-Term Strategies (Values are estimated annual lost visitor rafting trips. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

below 8,000 cfs may allow tamarisk tree growth and, as observed in the low summer flows of 2000 (Hjerpe and Kim 2001), may make prime angling spots impenetrable. At flows above 20,000 cfs, reduced participation in upstream fishing has been observed (McGinnis 2014).

J.2.6.1 Glen Canyon Inundation Metric—Methods

The Glen Canyon Inundation Metric (GCIM) represents the percentage of time that flow is at preferred levels for recreational experiences within the canyon, 8,000 to 20,000 cfs. Table J-2 presents a summary of recreational response to various discharge rates. This information was used in the computation of the Glen Canyon Inundation Metric as follows. A flow factor (FF) value from 0 to 1 is computed as a function of daily maximum discharge and

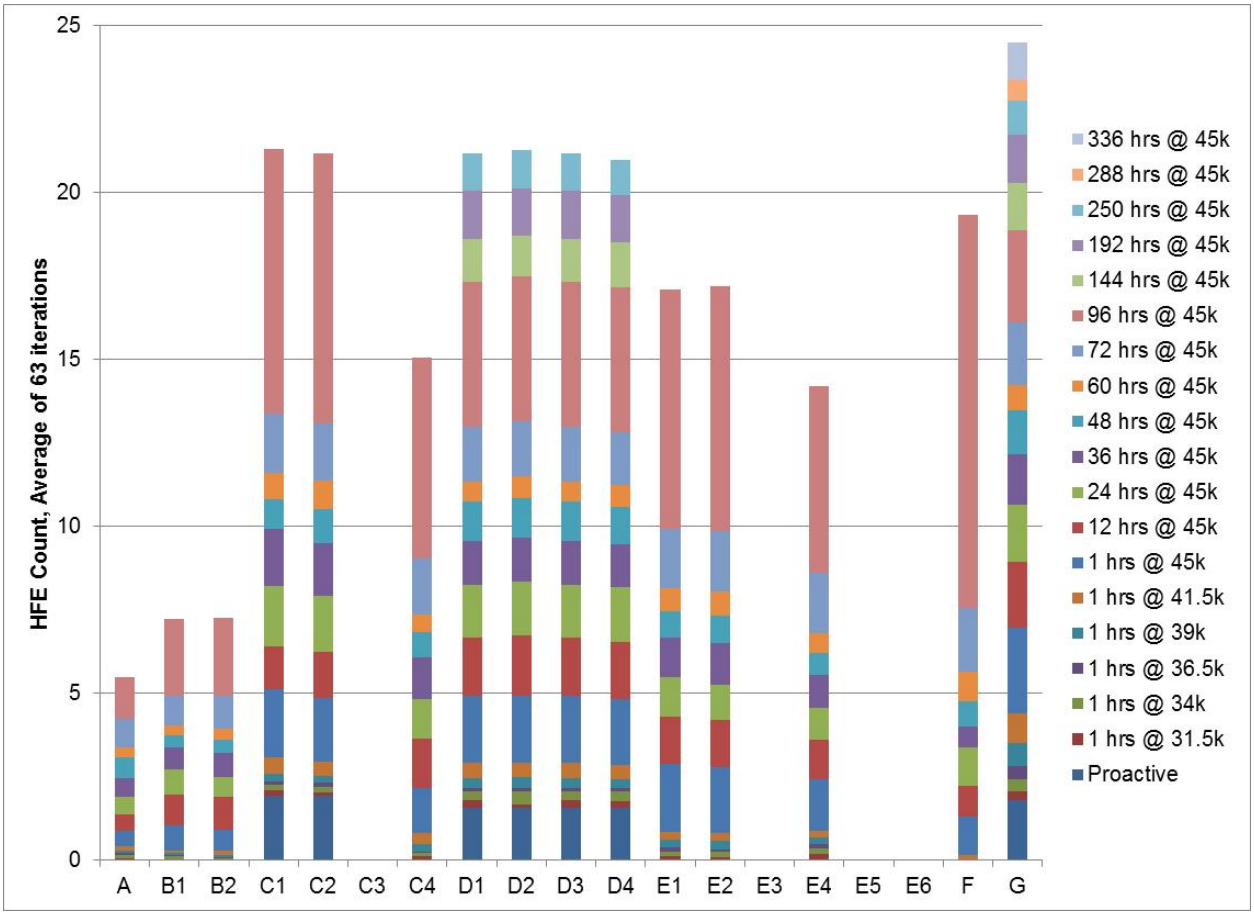

FIGURE J-8 Average Number of HFEs in the 20-Year LTEMP Period for LTEMP Long-Term Strategies

TABLE J-2 Recreation Response to Daily Maximum Flow

Flow (cfs)	Recreational Response
<3,000	Flows below 3,000 cfs are poor for boating and fishing.
3,000–8,000	Flows for fishing and boating get progressively better up to 8,000 cfs.
8,000–20,000	Flows are optimal for boating, fishing, and shoreline access.
20,000–31,500	Flows above 20,000 cfs get progressively worse for fishing and shoreline access.
>31,500	Flows above 31,500 cfs are poor for rafting, campable area, shoreline access, and fishing, and can adversely impact onshore recreational facilities.

the noted recreation responses, with higher values representing improved recreational experience. Daily FF values for discharges of 3,000 to 8,000 cfs and 20,000 to 31,500 cfs ranges were assigned values based on linear interpolation from 0 to 1 and 1 to 0, respectively. The daily FF is assigned as shown below, where the value in the right column within the brackets is assigned to FF if the equation in the left column is satisfied. Q_{max} refers to the daily maximum discharge released from the Glen Canyon Dam in cfs:

$$FF_{Daily} = \begin{Bmatrix} \text{if } Q_{max} \leq 3{,}000 \text{ cfs}; & 0 \\ \text{if } 3{,}000 < Q_{max} < 8{,}000\ cfs; & (Q_{max} \times 0.0002) - 0.60 \\ \text{if } 8{,}000 < Q_{max} < 20{,}000\ cfs & 1 \\ \text{if } 20{,}000 < Q_{max} < 31{,}500\ cfs; & 2.74 - (0.0000870 \times Q_{max}) \\ \text{if } Q_{max} \geq 31{,}500 \text{ cfs}; & 0 \end{Bmatrix}$$

An overall annual mean index value for the 20-year modeling period was computed for each alternative and used as the performance metric.

$$GCIM_{annual} = \{0.15\left(\frac{\sum_{winter} FF_{Daily}}{\sum Days_{winter}}\right) + 0.31\left(\frac{\sum_{spring/fall} FF_{Daily}}{\sum Days_{\frac{spring}{fall}}}\right) + 0.54\left(\frac{\sum_{\text{summer}} \text{FF}_{\text{daily}}}{\sum Days_{summer}}\right)\}$$

An overall annual mean index value for the 20-year modeling period was calculated as follows:

$$GCIM = Average\ (GCIM_{annual})_{2014-2033}$$

J.2.6.2 Glen Canyon Inundation Metric—Results

Results for the GCIM for LTEMP long-term strategies are shown in Figure J-9. Results are similar for all of the long-term strategies, except for Alternative F and, to a lesser extent, B2. Overall, index values are all high, above 0.9 for all but Alternative G, which has a mean value of about 0.85. Such high values indicate that discharge rates are in a range preferred for a variety of recreational activities most of the time under all alternatives and long-term strategies. The index value for Alternative F is reduced due to the large number of HFEs overall and to the high percentage of 96-hr HFEs, which together produce a relatively high number of days annually with flows above preferred levels. Similarly, high flows during hydropower improvement tests under B2 reduce its index value relative to B1 and most other long-term strategies. Other long-term strategies have values very close to that for Alternative A, with small deviations both higher and lower.

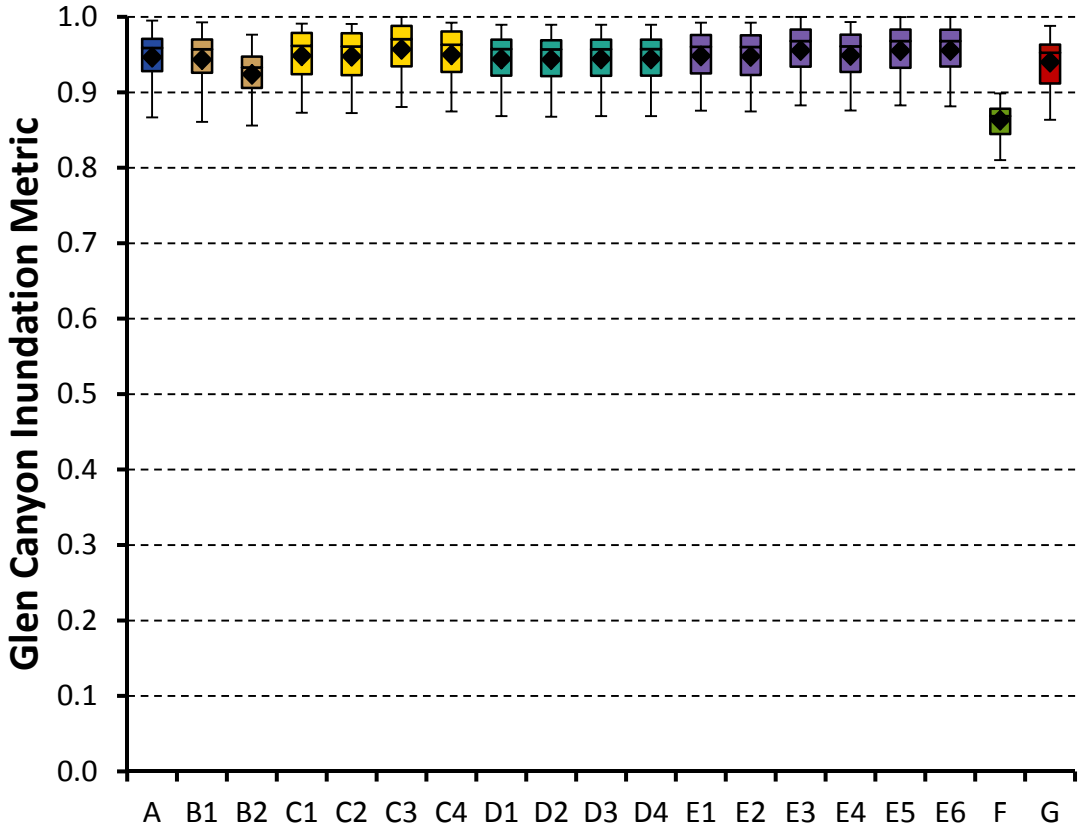

FIGURE J-9 Glen Canyon Inundation Metric for All LTEMP Long-Term Strategies (Increasing values indicate increasing frequency of flow levels preferred for recreation. Note that diamond = mean; horizontal line = median; lower extent of box = 25th percentile; upper extent of box = 75th percentile; lower whisker = minimum; upper whisker = maximum.)

J.3 LAKE POWELL AND LAKE MEAD DOCK ACCESS

Lower-than-normal lake levels have been occurring in Lake Powell upstream of the Glen Canyon Dam and in Lake Mead, which lies at the end of the 277-mi stretch of the Colorado River through GCNP. At Lake Powell, low lake elevation has rendered some boat launch sites inaccessible, and, in October 2005, NPS completed a General Management Plan (GMP) Amendment for Low Water Conditions and Finding of No Significant Impact (NPS 2005), which identified a strategy for low-water operations. This amendment ensured the maintenance of the boat launch sites at Lake Mead despite low water levels by either extending or relocating existing launch ramps and marinas so as to be functional down to an elevation of 1,050 feet above mean sea level (AMSL). Similarly, at Lake Powell, a connection channel called Castle Rock Cut, located directly across from Wahweap Bay from the Stateline launch ramp, became inaccessible at lake levels below an elevation of 3,580 ft AMSL in 2014 (Elleard 2014).

Modeled end-of-month lake elevations from 63 historical traces were compared against these two elevations (1,050 ft AMSL for Lake Mead and 3,580 ft AMSL for Lake Powell) to determine the percentage of time that lake levels would potentially fall below these critical levels. The percentage of traces where monthly lake elevation fell below critical elevation for any month within a season over the 20-year LTEMP period for Lake Powell is shown in Figure J-10 for the recreational summer seasons of May, June, July, and August and in Figure J-11 for the recreational fall and spring months of March, April, September, and October. Figures J-12 and J-13 show the analogous percentages for Lake Mead. Note that since these figures were generated by recasting past hydrology, they show the potential future variability and range of lake elevation conditions relative to the access reference elevations, but they do not predict conditions for any particular future year or year-to-year trends. Thus, the year dates on the *x* axis have meaning only in the sense that they show a hypothetical future 20-year period.

These graphs show that monthly lake elevations fall on or below critical elevations during spring and summer months for roughly 22% of historical trace simulations for Lake Powell and roughly 25% of historical trace simulations for Lake Mead for all alternatives and long-term strategies over the LTEMP period. Table J-3 shows the percentages for all alternatives. While rates of access issues are substantial, the difference among alternatives is small, indicating overall impacts at the launch sites of Lake Mead or the Castle Rock Cut connection channel in Lake Powell are driven mainly by hydrology. At Lake Powell, on average over all seasons, all alternatives have slight increases in access impacts relative to Alternative A. Conversely, at Lake Mead, all alternatives exhibit slight decreases in access issues compared to Alternative A. It is not clearly the case, but this behavior might be the result of Alternative A having the lowest number of HFEs of all alternatives. Large volumes of water taken from Lake Powell for an HFE might temporarily drop the lake level below the access threshold when the lake level is near the threshold, while similarly reducing the frequency of access issues at Lake Mead, which receives an input pulse from an HFE.

[a] Percentage difference from Alternative A in frequency of access issues; Alternative A has predicted access issues in 21.75% of future seasons for Lake Powell and 25.48% of future seasons for Lake Mead based on historical hydrology.

J.4 SUMMARY

Values for the means of the six metrics and frequency of Lake Powell and Lake Mead access issues discussed above are summarized in Table J-3. An index of 0 to 1 is used for CAI, NRI, FI, TORI, and GCIM, while GCRM is the estimated number of actual visitor trips lost due to HFEs. Access issues for Lake Powell and Lake Mead are the percent differences from Alternative A in the expected frequency of traces in which lake elevation falls below access thresholds in at least one month in either the spring–fall or summer seasons. The values shown in the table are mean values for 63 modeled hydrology–sediment conditions. Quartile values and minimum and maximum values for the six metrics can be seen in the respective box-and-whisker plots (Figures J-1 to J-9).

APPENDIX K:

HYDROPOWER SYSTEMS TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX K:

HYDROPOWER SYSTEMS TECHNICAL INFORMATION AND ANALYSIS

This appendix provides details on three analyses that are related to hydropower system electricity production, powerplant capacity, costs, and electricity service charge rates and that are conducted for the Glen Canyon Dam Long-Term Experiment and Management Plan (LTEMP) Environmental Impact Statement (EIS). The first analysis (presented in Section K.1) evaluated the impacts of changes in Glen Canyon Dam operations associated with LTEMP alternatives on the economic value of the powerplant's capacity and energy production. The impacts were measured in terms of changes in the value of regional power system capacity (the power system comprised of Western Area Power Administration's (WAPA's) long-term firm (LTF) customers) and overall system-level electricity production costs (the entire Western Interconnection). The second analysis (presented in Section K.2) studied how system resources and operations under LTEMP alternatives affect the wholesale electricity rates paid by LTF customers that receive federal preference power produced by Glen Canyon Dam. The third analysis (presented in Section K.3) studied the effects of alternatives on electricity rates paid by retail customers.

K.1 ECONOMIC VALUE OF GLEN CANYON DAM POWERPLANT CAPACITY AND ENERGY PRODUCTION

This first analysis studied the impacts of changes in Glen Canyon Dam Powerplant operations associated with LTEMP alternatives on the economic value of its capacity and energy production. Power system impacts are measured in terms of increases in capacity expansion expenditures and overall electricity production costs that would result from changing current Glen Canyon Dam operating criteria to different operating criteria as defined under LTEMP alternatives.

K.1.1 Power Systems Background

The Glen Canyon Dam Powerplant generates large amounts of energy that yield economic benefits to the grid. It also provides the grid with firm capacity that contributes to system reliability. Argonne National Laboratory (Argonne) staff conducted a power systems analysis of Glen Canyon Dam's economic benefits under each of the LTEMP alternatives. These alternative-specific operating criteria are summarized in Table 2-1 of the EIS.

The total water release volume from Lake Powell during each water year (WY) is nearly identical under all alternatives (see Section 4.2). However, at varying restriction levels, alternative criteria define the daily and hourly operational flexibility at Glen Canyon Dam, and affect Lake Powell reservoir elevations and monthly water release volumes. LTEMP alternatives also differ in their inclusion of various experimental releases such as high flow experiments (HFEs) and trout management flows (TMFs). The frequencies of these experimental releases differ among the alternatives.

Glen Canyon Dam energy production serves the electricity demands (loads) of a dynamic system that responds to its operations. Therefore, economic impacts of changes in Glen Canyon Dam operations are measured for the system as a whole. Some of the responses to changes in Glen Canyon Dam operating criteria, such as system unit dispatch adjustments, would occur very quickly. System dispatch refers to the amount of generation that each powerplant unit produces over time to match system loads plus system energy losses. In contrast, other system responses are much slower. For example, Glen Canyon Dam operating criteria affect its maximum output at times of peak load, and therefore system-wide capacity expansion pathways; that is, the timing and type of new units that will be built in the future. This methodology measures the spectrum of system economic impacts from hourly time intervals to multi-year processes.

The system modeled consists of 11 hydropower plants (including the Glen Canyon Dam Powerplant) marketed and scheduled by the Colorado River Storage Project (CRSP) Management Center of WAPA, the loads of all LTF power customers, and the resources owned and operated by the eight LTF power customers that have the largest allocations of capacity and energy (see Section K.1.3.2 for more detail). The combined loads and resources of these entities are referred to at the Salt Lake City Area Integrated Projects (SLCA/IP) market system.

The economic impacts of LTEMP alternatives on the value of electricity within the Western Interconnection were determined, but the financial impacts on individual grid participants were not. Impacts on individuals are analyzed in the rate payer and wholesale rate analyses presented in Section K.3. The economic analysis presented here focuses on the total differences in the economic value of SLCA/IP federal hydropower resource among alternatives benchmarked to existing operating criteria (Alternative A). This difference is referred to as the economic cost of an alternative and is quantified as the net present value (NPV) of the cost that would be accrued during the 20-year LTEMP period. System interactions within the broader Western Interconnection are also represented. It should be noted that this is an economic analysis that measures the net cost difference for the system as a whole, not a financial analysis of individual entities (e.g., a utility company) that operate within the system.

Operating criteria impact power economics because they affect the timing and routing of water releases through the dam. From a system dispatch perspective, power produced by Glen Canyon Dam yields the highest economic benefits when the limited amount of water released during a WY is routed through the powerplant's generating turbines to produce power during seasons of the year and times of the day when it displaces either energy generation or demand curtailment from expensive grid resources. For example, Glen Canyon Dam has a high economic value when the energy it produces either reduces or eliminates the operation of a generating unit with a high production cost. On the other hand, it has a much lower value when it displaces lower-cost power generation.

During most HFEs, water release rates from Glen Canyon Dam are greater than the maximum flow rate of the powerplant's turbines. Therefore, some water is released through the dam's hollow jet tubes, bypassing powerplant turbines. Non-power water releases such as these produce no electricity and therefore yield no energy value. Because water is limited, the bypass water reduces the overall economic value of power because this water could have otherwise been

stored in Lake Powell and released to produce energy at another time to displace the dispatch of more costly system resources.

Glen Canyon Dam capacity also has considerable value because the powerplant can generate energy during times of peak demand. Without the Glen Canyon Dam Powerplant, other resources would need to be constructed or acquired in order to ensure that load-serving utilities have adequate generating capabilities available to reliably meet system loads. Operating criteria that affect the Glen Canyon Dam Powerplant's firm capacity may impact WAPA's firm commitment levels to load-serving entities that purchase its capacity. In turn, contractual obligations affect the amount of capacity load-serving utilities can rely upon to meet system peak loads and will impact their long-term integrated resource plans, including the timing and amount of new power plant construction.

The methodology used for power systems analysis mimics decisions that could be made by system entities based on contractual and financial considerations that affect economic outcomes. For example, the borrowing rate for capital may impact both capacity expansion decisions and therefore economic outcomes. Economic costs include the following components: (1) energy production costs for the entire system and (2) capital investment plus fixed O&M costs for constructing and operating units built for system capacity expansion. Energy production costs are comprised of fuel expenditures, variable O&M costs, and unit startup expenses. All costs are estimated over the 20-year LTEMP period starting at the beginning of calendar year (CY) 2015 and extending through the end of CY 2034. To be consistent with the analyses performed for other resource areas, the start of the study period was adjusted to CY 2015. Please refer to Section K.1.9 for a description of how the adjustment was made. Emphasis is placed on accurately estimating the cost of an alternative compared to Alternative A in terms of both economic ranking and the relative magnitude of cost differences. Therefore, costs such as fixed O&M costs are not computed for existing units that remain unchanged across all alternatives.

K.1.2 Glen Canyon Dam, Reservoir, and Powerplant Background

Glen Canyon Dam is a U.S. federal resource that was built by the Bureau of Reclamation (Reclamation) between 1956 and 1964 as part of the CRSP that was authorized by the Colorado River Storage Project Act on April 11, 1956. The Act authorized the Secretary of the Interior to develop the water resources of the Upper Colorado River Basin by constructing, operating, and maintaining the CRSP and other participating reclamation projects. The dam is a 710-foot–high concrete arch structure with a crest length of 1,560 ft, containing 4,901,000 yd^3 of concrete. The thickness of the dam at the crest is 25 ft, and its maximum base thickness is 300 ft. The reservoir formed by the dam, Lake Powell, has a total water storage capacity of 27 million acre-feet (maf), with an active capacity of approximately 20.9 maf when full. Under normal water surface elevation levels, the reservoir has a length of 186 mi and a surface area of 161,390 ac. The dam controls a drainage basin approximately 108,355 mi^2 (Harpman and Rosekrans 1996).

Currently, there are eight generating units at Glen Canyon Powerplant with a total sustained operating capacity of approximately 1,320 megawatts (MW). The first two Glen Canyon units began generating power in September 1964, and the eighth and final unit came

online in February 1966, as recorded in Power Operations and Maintenance Form 59 (Form PO&M-59). When water is released from the reservoir through power plant turbines, the energy generated partially serves the electricity demands of the SLCA/IP wholesale customers.

Lake Powell was filled for the first time in 1980, when it reached a maximum reservoir water elevation of 3,700.6 ft. Displacing power generation and associated air emissions mainly from powerplants that burn fossil fuels such as coal, oil, and natural gas, the average annual gross electricity generation from the Glen Canyon Dam Powerplant between CY 1980 and 2013 was about 4,716.5 GWh. This statistic does not include generation production for years prior to 1980, because a portion of water inflows into Lake Powell were used to fill the reservoir prior to that time. From 1980 through 2013, annual generation has varied by more than a factor of 2.6. Generation was at a low of 3,299 GWh in CY 2005 and at a high of 8,703 GWh in CY 1984. The high level of annual generation variability of the Glen Canyon Dam Powerplant since 1980 is attributable to variations in Lake Powell inflow levels, which are strongly influenced by precipitation. Hydrologic variability and uncertainty reduce generation value. Therefore, other resources need to be made available to serve system loads and reliability requirements.

Operational limitations at Glen Canyon Dam were minimal from 1964 through May 1990. Minimum releases from Lake Powell were 1,000 cfs from Labor Day to Easter and 3,000 cfs during the rest of the year. These minimums are only a small fraction, approximately 3% to 9%, of the physical maximum turbine flow rate of 33,000 cfs at full reservoir. There were no institutional limitations on maximum flow rates, hourly ramping, or daily changes in flow. The relatively low minimum release rate requirement, combined with limits that were only constrained by the physical powerplant and dam characteristics, allowed for flexible operations that maximized the hydropower generation.

Legislation was introduced in Congress in 1990 addressing dam operations after the Glen Canyon Environmental Studies Program published its report in 1987 describing the impacts of dam operation on the national and recreational resources of the Grand Canyon. Reclamation began to restrict operations on June 1, 1990, when it conducted research discharges as part of the Glen Canyon Environmental Studies. Numerous test flows were conducted during a 14-month period that concluded at the end of July 1991. The purpose of these research releases was to collect and analyze data at different flow levels in order to investigate the effects of flow patterns on the riverine environment downstream of Glen Canyon Dam. Interim flow operating constraints were imposed at Glen Canyon Dam on August 1, 1991, and were in effect until February 1997, when the 1996 Glen Canyon Dam Environmental Impact Statement Record of Decision (ROD) was implemented.

The 1996 ROD requires releases from Lake Powell to be at least 8,000 cfs between the hours of 7:00 a.m. and 7:00 p.m., and 5,000 cfs or more during all other hours of the day. The maximum allowable release is limited to 25,000 cfs. In very high release months, the maximum limit can be exceeded, but the release rate must be constant during the entire month. The 1996 ROD operating criteria also limits release fluctuations during all rolling 24-hour periods. The fluctuation level permitted depends on the amount of water that will be released from Glen Canyon Dam during a month. The allowable daily fluctuation is 5,000 cfs/24 hr when the monthly scheduled water release is less than or equal to 600 kaf. Daily fluctuations are restricted

to 6,000 cfs/24 hr for those months in which the scheduled release is equal to or greater than 600 kaf but less than 800 kaf, and at 8,000 cfs/24 hr for months with releases equal to or greater than 800 kaf. Finally, the 1996 ROD operating criteria also limited the rate at which Lake Powell water release are allowed to ramp up and down. The maximum ramp rate is 4,000 cfs/hr when increasing, and 1,500 cfs/hr when decreasing. Operating criteria reduced the flexibility of operations, diminished dispatchers' ability to respond to market price signals, and decreased the economic power benefits of the Glen Canyon Dam. Between 1997 and 2005, this decrease in economic benefit was estimated to range from $38 million to $50 million per year (in 2009$) (Veselka et al. 2010). This range may not be indicative of future economic costs due to a number of factors including changes in power market structures and utility fuel prices. It should be noted that all of the LTEMP alternatives are significantly less flexible than actual operations prior to the 1991 interim operating criteria. Only Alternative B has slightly less operating restrictions than current operations.

The 1996 ROD operating criteria include "emergency exception criteria" that recognize the fact that the Glen Canyon Dam Powerplant is an important grid resource. When emergency exception criteria are invoked, normal operations are suspended until the emergency has ended or WAPA has been cleared of its North American Electric Reliability Corporation (NERC) emergency operation responsibilities. Emergency exception criteria allow Glen Canyon Dam to dispatch up to all of its available capacity at Glen Canyon Powerplant, depending on the severity of the system emergency, by rapidly increasing generation output in response to events such as insufficient system generating capacity, transmission system problems, and system restoration.

In addition, Glen Canyon Dam generators provide system regulation to WAPA as the operator of the Western Area Colorado Missouri (WACM) balancing authority (BA) area. The Glen Canyon Dam Powerplant responds to a regulation signal developed and electronically transmitted to the dam by WAPA for continuous response to power system load and frequency changes. WAPA is required to react to moment-by-moment changes in system frequency, time error, and tie-line loading within the WACM BA via powerplant automatic generation control (AGC) equipment at Glen Canyon Dam and some of the other SLCA/IP federal hydropower plants to adjust the power output of the generators to match variations in system load in accordance with prescribed NERC criteria. The degree to which WAPA responds to these system changes is computed by an area control error (ACE) equation.

The ACE signal that is sent to Glen Canyon Dam adds to or subtracts from the existing scheduled hourly generation set point. Therefore, at any instant in time, the powerplant is typically producing more or less power than the current hourly scheduled set point. Deviations from the set point typically fluctuate from negative to positive values many times during any hour. However, the resulting output from Glen Canyon generators on average approximates the hourly scheduled level. Because post-ROD operating criteria specify release restrictions in terms of hourly average levels, Glen Canyon Dam can provide regulation services while scheduling set point levels at minimum and maximum allowable flow limits. It can also ramp set points within up and down limitations (see http://www.wapa.gov/crsp/planprojectscrsp/gcopswhite.html).

The 1996 ROD operating criteria currently restrict Glen Canyon Dam operations in terms of both the operational range of water releases and the rate at which water releases are permitted to change over time. It also provides the operating criteria for Alternative A.

K.1.3 Power Systems Geographic Scope

The Glen Canyon Dam Powerplant is part of a large dynamic power grid that responds to its operations. It is also a component of WAPA's SLCA/IP, which is composed of 11 federal hydropower facilities marketed and scheduled by the CRSP Management Center. WAPA markets these facilities as a bundled resource. Therefore, power economic impact analyses are based on a systems approach that measures the collective responses of system components to changes in Glen Canyon Dam operating rules and experimental releases. The focus area is on SLCA/IP federal hydropower resources, and the utilities operated by WAPA's SLCA/IP LTF power customers. For the purpose of this appendix, this primary impact area is referred to as the SLCA/IP market system (or SLCA/IP system). However, as described in more detail below, the methodology also recognizes that this system does not operate in isolation. Instead, it interacts with the much larger Western Interconnection power grid.

The power systems method uses a three-tiered approach. All simulate the system on an hourly basis over the 20-year LTEMP period. The top tier models the loads and resources of the entire Western Interconnection to gain a broad perspective on the future development of the larger overall system (see Section K.1.3.1). Both Western Interconnection system capacity expansion and economic system dispatch are modeled.

The middle tier models SLCA/IP LTF customer utility loads and resources along with future Western Interconnection interactions via non-firm bilateral energy transaction. It also projects SLCA/IP market system future capacity additions, determines day-ahead unit commitments, and performs economic dispatch. It focuses on SLCA/IP customer resources at a higher level of fidelity than the Western Interconnection tier. The top and middle tiers both rely on projections found in the *Annual Energy Outlook* (EIA 2014) published by the U.S. Energy Information Administration (EIA). The *Annual Energy Outlook* uses an even broader perspective that incorporates overall U.S. and global macroeconomic drivers into the projection of U.S. energy futures.

The bottom tier focuses on SLCA/IP federal hydropower resources. It models the long-term management and routing of water resources within the Colorado River Basin. Future water management is compliant with all applicable laws and water rights. Given this projection of long-term water management, simulation of powerplant dispatch is performed based on market price drivers projected by the Western Interconnection tier and key physical and institutional constraints on reservoir operations and powerplant dispatch. Hourly dispatch is subject to numerous physical and institutional constraints, including those specified under an LTEMP alternative.

The top tier represents a large geographical area, but at a relatively low level of fidelity. Increasing attention to detail and accuracy is paid as the geographical coverage becomes more

focused. By using this approach, power systems comparative analyses are able to determine how changes in Glen Canyon Dam Powerplant operations affect its economic value. This top-down modeling approach is further described below. More details about the selection of the power system's geographical scope and detail are provided in Attachment K.1.

K.1.3.1 Top Tier: General Western Interconnection Perspective Modeling

North America is comprised of two major and three minor alternating-current power grids. The Western Interconnection is the major power grid that stretches from Western Canada south to Baja California in Mexico, and eastward from the Pacific Ocean to the Rockies and the Great Plains. All of the electric utilities in the Western Interconnection are electrically tied together during normal system conditions and operate at a synchronized frequency that averages 60 Hz. The Western Electricity Coordinating Council (WECC) region of NERC facilitates regional transmission expansion planning for the interconnection, and the Western Governors' Association acts as a state/provincial steering committee. These entities work collaboratively to develop long-term electricity supply futures, estimate transmission requirements, and prepare long-term interconnection-wide transmission plans (see http://energy.gov/oe/services/electricity-policy-coordination-and-implementation/transmission-planning/recovery-act-0). These plans are voluntarily created and serve to provide a high-level look at possible futures.

Argonne power system analysts modeled the long-term capacity expansion, unit commitments, and hourly unit dispatch of Western Interconnection resources using the AURORAxmp model (referred to as AURORA). The Western Interconnection topology and supporting model inputs were provided by EPIS, Inc., the AURORA model developers. A depiction of this topology is shown in Figure K.1-1. Each "bubble" in the diagram roughly represents groups of utilities, single BAs, or combinations of BAs. Bidirectional limits on the links that connect bubbles restrict network energy transfers. User-defined limits can vary hourly. The location of SLCA/IP federal hydropower resources in the AURORA Western Interconnection topology is indicated in the figure. The Glen Canyon Dam Powerplant is labeled "GC," and the Flaming Gorge and Fontenelle Powerplants are labeled "FG" and "FN," respectively. The location of powerplants in the Wayne D. Aspinall Cascade and all other SLCA/IP hydropower plants is labeled "Aspinall & Others."

The primary driver of many variables that define Western Interconnection future developments were based on projections published in EIA's 2014 *Annual Energy Outlook* (hereafter 2014 AEO; EIA 2014) for the reference scenario that was released in April 2014. Model results are consistent with state integrated resource plans (IRPs). A more detailed description of AURORA is provided in Section K.1.5.9.

In addition to estimating the capacity expansion pathways and system production costs, AURORA also projects future locational marginal prices (LMPs) throughout the Western Interconnection. The LMPs measure the incremental cost to serve an additional 1 MW of load at a specific point in the grid; that is, the cost to change the dispatch of system resources to serve a slightly higher load. This typically involves increasing the power generation at one of more units or reducing loads via a demand response management (DSM) agreement.

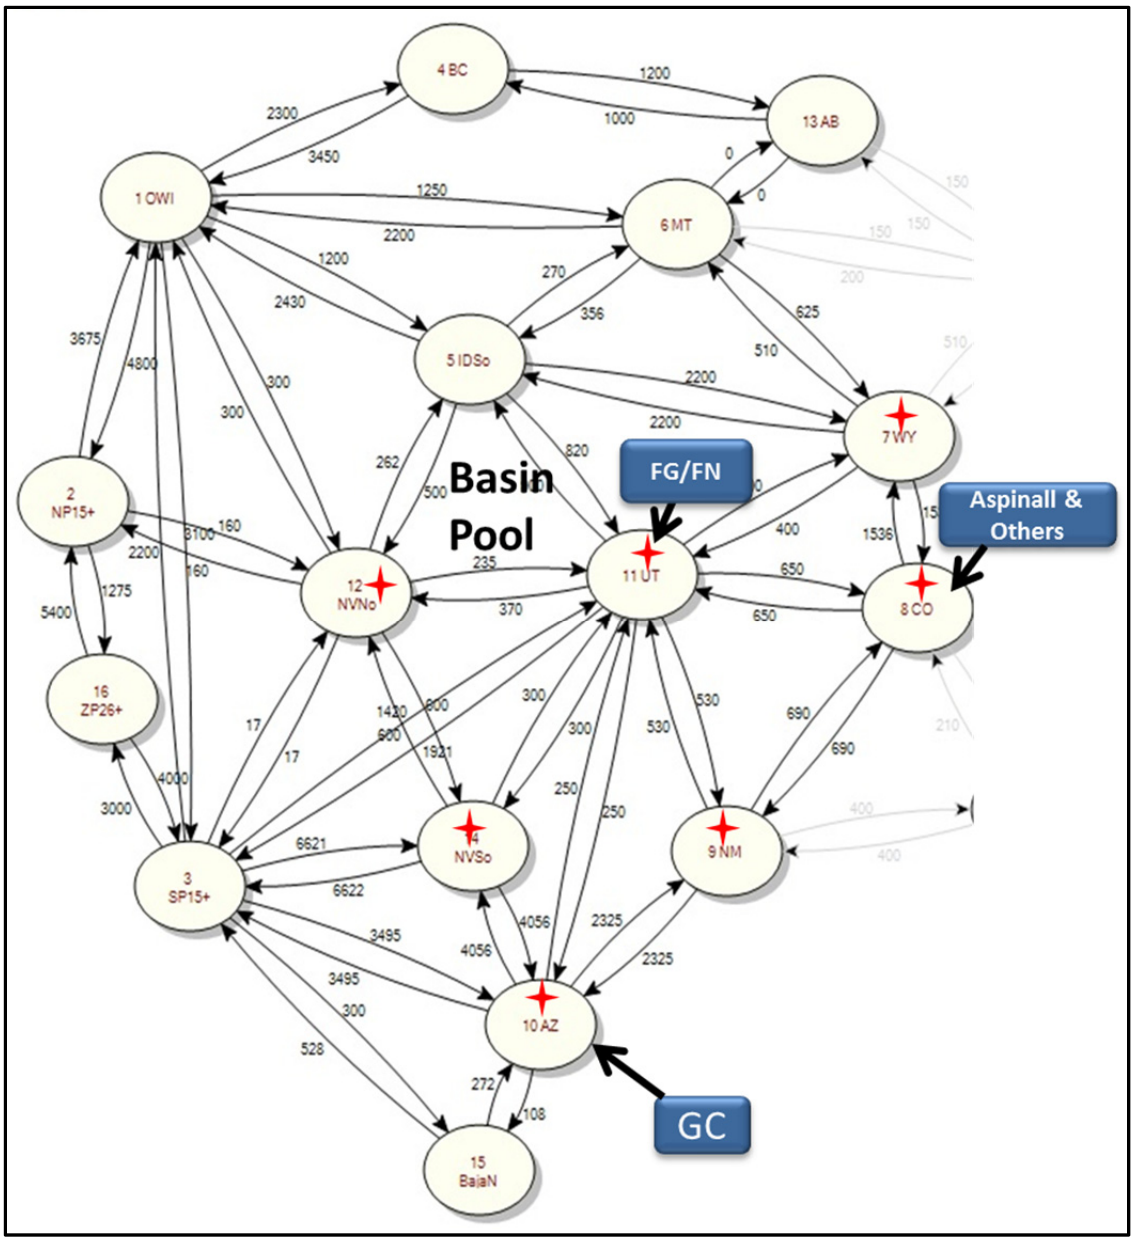

FIGURE K.1-1 Network Topology Used by the AURORA Western Interconnection Model

AURORA Western Interconnection projections of hourly LMPs at the Palo Verde marketing hub are used by the LTF customer and Western SLCA/IP federal resource tiers (i.e., middle and bottom tiers). This hub was selected as a representative point for LTEMP EIS modeling because prices at this location are often used by schedulers at the Western's Montrose Energy Management and Marketing Office (EMMO) as a benchmark for short-term bilateral transactions. Palo Verde hub prices have also been used extensively in the past for other economic and financial analyses of SLCA/IP hydropower resources (see http://www.usbr.gov/lc/region/programs/strategies/FEIS/AppO.pdf and http://www.usbr.gov/uc/envdocs/eis/

AspinallEIS/Vol2-Appdx-D.pdf). As discussed in Attachment K.1 (Geographic Scope of the Analysis), alternative operations at Glen Canyon Dam are expected to have a negligible impact on prices within the Western Interconnection and patterns outside of the SLCA/IP market system, and are therefore assumed to be static (i.e., given values) and identical under all alternatives.

LTEMP alternatives will have a relatively small impact on bilateral market interactions between the SLCA/IP market system and the rest of the Western Interconnection; that is, a maximum decrease of about 4.3% for power sales and decrease of 1.4% for power purchases. The use of LMPs to measure the economic impact of changes in Western Interconnection transactions yields a very good approximation because the LMP represents the system resource cost to serve the marginal load at a specific point. Therefore, a SLCA/IP market system sale to the Western Interconnection displaces higher cost generation in the interconnection. Likewise, a power purchase by the SLCA/IP market system displaces higher cost generation in the SLCA/IP system by increasing production in the interconnection at a cost that approximately equals the LMP at the Palo Verde hub minus transmission costs.

K.1.3.2 Middle Tier: LTF Customer Utility Systems

The primary focus of the power systems analysis is the SLCA/IP federal hydropower resources and the utilities operated by its LTF power customers. The SLCA/IP federal hydropower resources that the CRSP Management Office markets and the Montrose EMMO schedules are described in more detail in Section K.1.3.3. This section describes the approximately 138 customer entities that have SLCA/IP LTF contractual agreements with WAPA.

WAPA sells power to wholesale power customers on both a firm and non-firm basis, including cities and towns, rural electric cooperatives, public utility and irrigation districts, federal and state agencies, investor-owned utilities, power marketers, and American Indian Tribes (Tribes). In total, these entities provide retail electric service to millions of consumers in the Western Interconnection. However, others are end-use customers, including federal and state agencies, and irrigation districts that use power directly for their own purposes. Various laws, including the Reclamation Project Act of 1939 and the Federal Power Act, require WAPA to give preference to certain types of nonprofit organizations seeking to purchase federal power. Those entitled to preference status include cities and towns, state and federal agencies, irrigation districts, public utility districts, rural electric cooperatives, and Tribes (see https://www.wapa.gov/About/Pages/customers.aspx).

For economic analysis purposes, the system modeled in the middle tier includes LTF customers that are categorized as either large or small. Accounting for about 75% of WAPA's LTF energy and capacity sales, the eight largest customers, in terms of capacity and energy allocation, are Deseret Generation and Transmission Cooperative (Deseret), the Navajo Tribal Utility Authority (NTUA), Salt River Project (SRP), Utah Associated Municipal Power Systems (UAMPS), Utah Municipal Power Agency (UMPA), Platte River Power Authority (PRPA), Tri-State Generation and Transmission Association (Tri-State), and Colorado Springs Utilities

(CSU). Except for NTUA, all large LTF customers own and operate generating resources. About 130 remaining customers were aggregated for the analysis into two "small customer" entities accounting for the remaining 25% of LTF sales. Individually, each small customer receives less than 2.5% of WAPA's total SLCA/IP LTF capacity and energy sales. Lastly, WAPA has LTF contracts to serve project use loads such as pumping for irrigation. Serving these loads has the highest priority for delivery.

In CY 2013, the eight large SLCA/IP LTF power customers owned and contracted for the use of specific physical resources. Based on data contained in EIA Form-860 and information obtained from both IRPs and the EPIS AURORA database, the total firm capacity of these resources was approximately 12,670 MW. As discussed in more detail in Section K.1.7.5, firm capacity in this power systems study is based on the maximum output level that a resource is expected to reliably produce during the time of peak demand. For some generating units, the firm capacity is significantly different from the nameplate capacity.

As shown in Figure K.1-2, over 50% of this capacity is owned by SRP and another 19% is owned by Tri-State. The remaining six large customers account for the remainder. In addition to these supply resources and the aforementioned SLCA/IP LTF contracts, additional firm capacity for is secured through other federal power purchases from WAPA's Loveland Area Projects and the Desert Southwest Offices and through non-federal power contracts. In addition, DSM measures are credited as firm capacity resources. Based on data contained in Federal Energy Regulatory Commission (FERC) Form-714 and utility IRPs, these resources and non-firm energy transactions were used to serve combined service territory loads of almost 61 TWh in CY 2013.

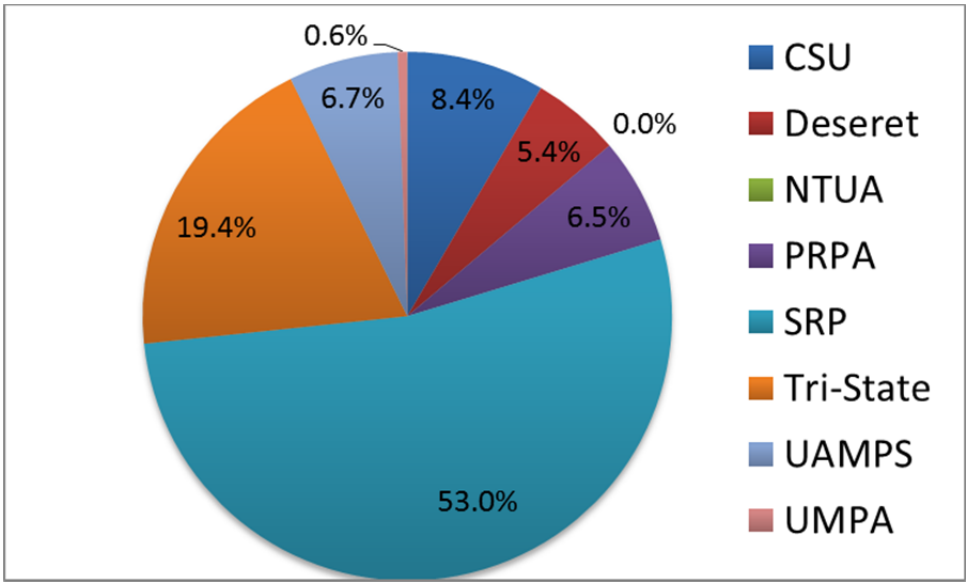

FIGURE K.1-2 Percentage of Total Generation Resources Owned by Individual Customers

Figure K.1-3 shows a simplified topology for the SLCA/IP market systems that was used by the AURORA model. It contains both large and small LTF customers. Where applicable, bubbles for large customers (shown as Pool A in Figure K.1-3) contain both loads and resources. Depending on the customer's location, loads and resources are designated as east or west regional entities. In the figure, small customer and project use bubbles only contain loads that have been aggregated by location. Energy flows among entities via system linkages. Some links have limitations and/or associated costs. More details about the SLCA/IP market system topology are described in Section K.1.6.

It should be noted that the Glen Canyon Dam Powerplant and all other federal hydropower plants are modeled as resources that are directly available to WAPA's customers. In reality, energy and capacity from these resources are sold by the CRSP Management Center to customers through LTF contracts. Argonne staff, in consultation with WAPA, Reclamation, and the NPS, decided not to include a representation of these contracts in the modeling process because the vast majority of the SLCA/IP federal resource is under contract to ultimately serve LTF customer loads and capacity needs. Financial complications associated with covering short-term and hourly long and short energy positions would have made the modeling process significantly more expensive and time consuming. It was also judged to have little impact on the assessment of the relative impacts of LTEMP alternatives. Given the time and budget

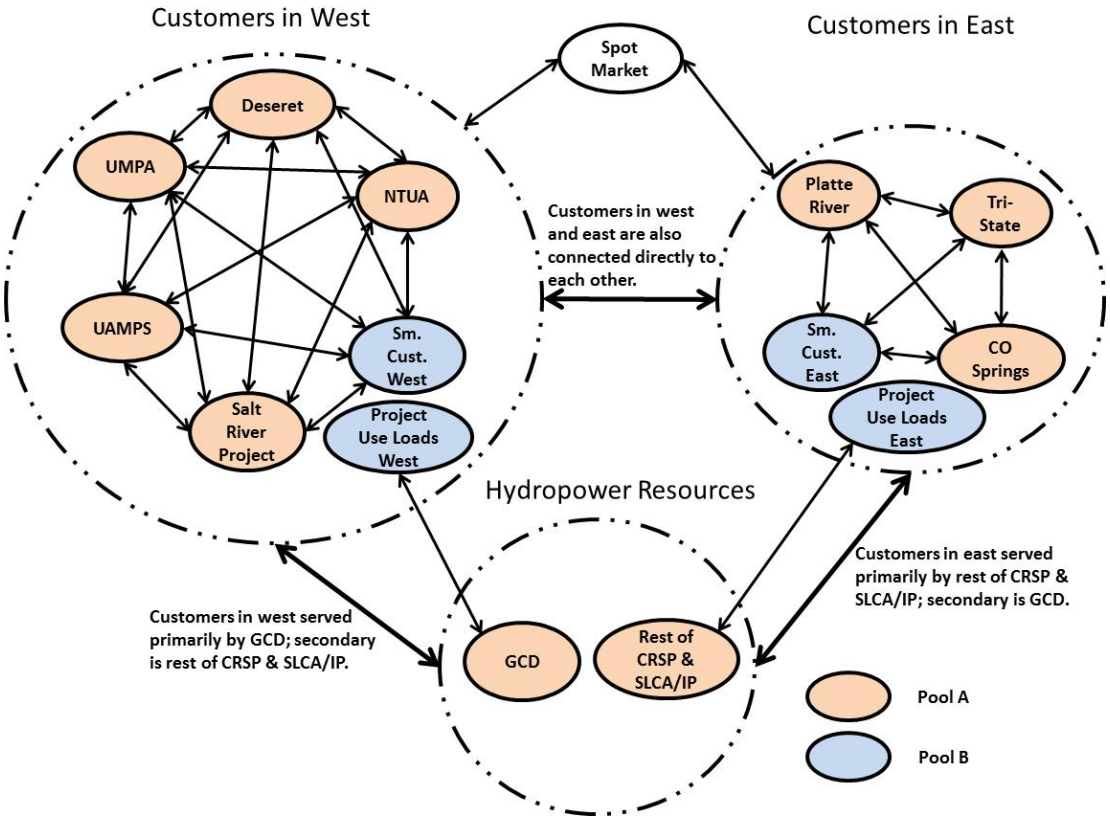

FIGURE K.1-3 Simplified Network Topology of the SLCA/IP Market System

constraints, it was decided that the more direct approach of modeling hydropower resources was sufficient.

Power systems modeling of the SLCA/IP market system assumes a very high level of cooperation and coordination among WAPA and its LTF power customers. Capacity expansion planning, unit commitment schedules, and least-cost hourly dispatch for the entire system were based on a "single operator/decision maker" model. This is a higher level of cooperation and coordination than what actually occurs. However, WAPA and its customers do cooperate on a number of different levels. For example, several large LTF customers jointly own capacity of some of the same facilities. They also buy and sell energy through long-term, day-ahead, and hour-ahead bilateral agreements using various market signals. The SLCA/IP market system topology also includes energy transfer costs that dampen power transfers relative to a "single-decision maker" model that does not incur these costs.

The AURORA topology of the SLCA/IP market system does not model physical transmission constraints. It does, however, limit flows on some links between bubbles. Energy flows on links connecting SLCA/IP federal hydropower resources to LTF customer loads are limited by contract rate of delivery (CROD) allocations (WAPA 2015). CROD is the firm capacity the CRSP Management Center agrees to have available for delivery. It may or may not be accompanied by energy supplied by WAPA (see https://www.wapa.gov/crsp/opsmaintcrsp/dictionary.htm#c). When not all of the CROD is being utilized for WAPA power deliveries, a customer can use the remainder to schedule the delivery of other energy transactions. In addition, 5% of the energy that flows on these links is lost between the point of injection and the delivery point. This represents EMMO current transmission losses for SLCA/IP federal hydropower deliveries. Under wet hydrological conditions in which SLCA/IP total federal hydropower generation exceeds the total CROD, the excess energy flows on links that represent shorter term WAPA energy transactions with its LTF customers.

Regardless of the amount of firm capacity that is available from SLCA/IP federal hydropower resources, WAPA's CROD is assumed to be identical under all alternatives. Currently, some customers voluntarily use the difference between the CROD and sustainable hydropower (SHP) on WAPA's transmission system for customer displacement power (CDP). The SHP is the minimum amount of power and energy the EMMO must deliver to its LTF customers regardless of SLCA/IP federal hydropower conditions. The CDP replacement option is specified under an amendment to the SLCA/IP firm electric service contract to accommodate replacement power decisions. Therefore, it is assumed that any loss in firm capacity under an alternative will free up transmission capacity for CDP transactions (Loftin et al. 1998).

Transfers of energy among LTF customers are virtually unconstrained, which may lead to an overestimation of the amount of energy transfers and underestimation of cost impacts among LTF customer utilities. However, there are significant on- and off-peak costs for energy flows on lines that connect customers to each other. These costs tend to dampen bulk power transactions among the bubbles. Information from WAPA regarding hourly transmission rates for five of WAPA's large customers and six other investor-owned utilities in the surrounding area (Wicks 2014) was used to set transfer costs on links between any two firm electric service customers to $6.5/MWh and $3.5/MWh for peak and off-peak, respectively.

Lastly, it is assumed that additional capacity built by customers as a result of any losses at Glen Canyon Dam will be located to help alleviate transmission congestion. Note that Glen Canyon Dam is remotely located from major load centers. This may also result in a somewhat lower energy loss on the transmission lines since more heavily loaded lines during peak hours have higher losses than during cooler off-peak periods. For example, replacement capacity for SRP would likely be built closer to the Phoenix load center than the Glen Canyon Dam. Because the LTEMP analysis was an economic analysis and not a financial one, it did not address the impacts of siting each potential replacement power plant. See the discussion in the section "Capacity Expansion Candidate Unit Characteristics" in Section K.1.6.3.

Assumptions and simplifications associated with the topology and representation of the SLCA/IP market system will affect modeling results. However, the intent of the power systems analysis is to perform a comparative economic study to identify the relative ranking and magnitude of alternative impacts using Alternative A as a benchmark. Because any inconsistencies in results will be present in the evaluation of all alternatives, the relative differences among alternatives are expected to be robust. Despite the simplifying assumptions and potential effects on modeling results, the AURORA dispatch model does provide reasonable results for LTEMP power systems analyses. As discussed in more detail in Section K.1.6.2, a 2013 benchmark analysis of utility-level generation by fuel type for the eight large customers modeled by AURORA were very similar to values reported by each utility in EIA Form-923. This result assured Argonne modelers that, from a production cost standpoint, the modeling approach and the results obtained were reasonable.

K.1.3.3 Bottom Tier: WAPA SLCA/IP Hydropower Resources

Of the three analysis tiers, the bottom tier is modeled at the finest level of granularity. It simulates the hourly operation of WAPA's 11 SLCA/IP powerplants that are marketed and scheduled by the CRSP Management Center. For this study, six of these facilities are classified as large plants. The largest is at Glen Canyon Dam. Its powerplant consists of eight generating units with a combined capacity of about 1,320 MW. As shown in Figure K.1-4, Glen Canyon Dam accounts for about 72% of WAPA's total SLCA/IP federal hydropower nameplate capacity. Other SLCA/IP federal hydropower plants in the system that are classified as large SLCA/IP federal hydropower facilities include powerplants contained in the CRSP and the Seedskadee Project. All large plants except Fontenelle are in the CRSP. The Blue Mesa Powerplant has two generators, the total capacity of which is 86.4 MW. Located 12 mi downstream from Blue Mesa on the Gunnison River, the Morrow Point Power Plant has two units with a combined capacity of 165 MW; another 6 mi farther downstream, the Crystal Powerplant has an installed capacity of approximately 32 MW from one unit. Blue Mesa, Morrow Point, and Crystal are part of the Wayne D. Aspinall Cascade (also referred to as the Aspinall Cascade). The Fontenelle Powerplant has a nameplate capacity of 10 MW and it is the only powerplant associated with the Seedskadee Project. Flaming Gorge Dam is located on the Green River downstream of Fontenelle Dam. The Flaming Gorge Powerplant has three generating units. Each unit has a nameplate capacity of 50.65 MW for a total of approximately 152 MW. However, because of turbine limitations, the operable capability of the powerplant is approximately 141 MW.

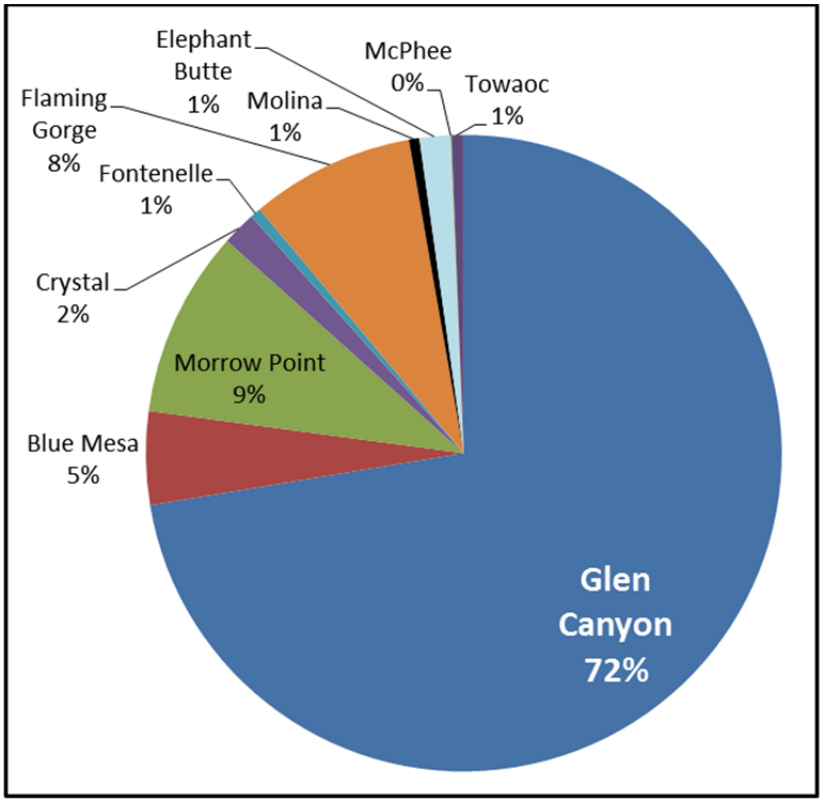

FIGURE K.1-4 Percentage of SLCA/IP Federal Hydropower Nameplate Capacity by Facility

The SLCA/IP hydropower facilities that are classified as small include the Upper and Lower Molina complex in the Collbran Project with a combined nameplate capacity of 13.5 MW, the Elephant Butte Powerplant in the Rio Grande Project with 28 MW, and in the Dolores Project, the McPhee and Towaoc Powerplants with total of 11.5 MW. Combined, these small facilities account for less than 3% of WAPA's SLCA/IP hydropower resources.

Modeled hourly energy production from federal hydropower resources are input into the SLCA/IP market system as a time series of power injections and from bubbles indicated in Figure K.1-3 as "Hydropower Resources." As discussed in more detail in Section K.1.5, both the middle and bottom tier models use a consistent set of LMP projected by the Western Interconnection model (top tier).

K.1.4 Overview of Power Systems Methods

The Argonne team of power system analysts and modelers developed a collection of tools that are linked together to evaluate the economic costs of LTEMP EIS alternatives. The processes by which these tools were used and information flows among them are summarized in this section. The next section describes each tool in more detail, and the ones that follow provide more information on model input data and applications.

Incorporating all aspects of the three tiers discussed earlier, Figure K.1-5 shows the modeling sequence and data flows for the power systems analysis. Using Western Interconnection topology depicted in Figure K.1-1, the AURORA model models the top tier. Palo Verde market hub LMPs produced for CY 2013 are calibrated to closely match observed levels. LMP calibration factors are discussed in more detail in Attachment K.2 and are applied to future years through the end of the study period.

The bottom tier, which represents WAPA's SLCA/IP federal hydropower plants, is modeled next. Due to the complexities of SLCA/IP hydropower operating criteria and mandates unrelated to power production, AURORA could not directly model either the firm capacity or the hourly operations of the larger and more complex SLCA/IP federal hydropower resources. Therefore, the Colorado River Simulation System (CRSS) model, the Sand Budget Model (SBM), a simplified version of the Generation and Transmission Maximization (referred to as GTMax-Lite) model, and spreadsheet tools were used to project powerplant-specific hourly production levels over the study period at a level of detail sufficient for estimating power economic impacts that would potentially occur from alternative Glen Canyon Dam operations.

The CRSS model developed by Reclamation models the future operations of water-related resources on the Colorado River. Power systems analysis utilized 21 CRSS projected monthly hydrological futures for large WAPA SLCA/IP federal hydropower plants including Glen Canyon Dam. Separate CRSS model runs are made for each alterative, resulting in unique projections of monthly reservoir elevation and water volume releases for Glen Canyon Dam. The monthly operations of all other SLCA/IP dams are unaffected by an alternative.

A simplified version of the Generation and Transmission Maximization model (called GTMax-Lite) developed by Argonne optimizes the economic value of hourly energy produced by both Glen Canyon Dam and all other large SLCA/IP federal hydropower facilities. The dispatch depends on unit availability as simulated by an outage model, LTEMP EIS operating criteria, SBM monthly water releases, and a time series of energy market prices.

For each alternative, the GTMax-Lite configuration that represents Glen Canyon Dam was run for all traces under two different conditions. The first condition assumes that no distinctive release events such as HFEs will occur in the future; that is, CRSS monthly results and Western Interconnection calibrated LMPs drive hourly SLCA/IP operations. No TMFs or HFE are conducted in this first set of model runs. Using these initial results from CRSS and GTMax-Lite, the Reclamation SBM schedules various HFEs that differ in terms of peak water release rate, duration, and timing. The SBM also reallocates CRSS monthly water release volumes among the months of a single WY in order to enable higher water releases during months with experiments. Due to the reallocation of monthly water releases and the scheduled TMFs and HFEs, the GTMax-Lite model that represents Glen Canyon Dam must be run a second time using the SBM results. It is this second GTMax-Lite run that is used for Glen Canyon Dam for all power systems economic analyses.

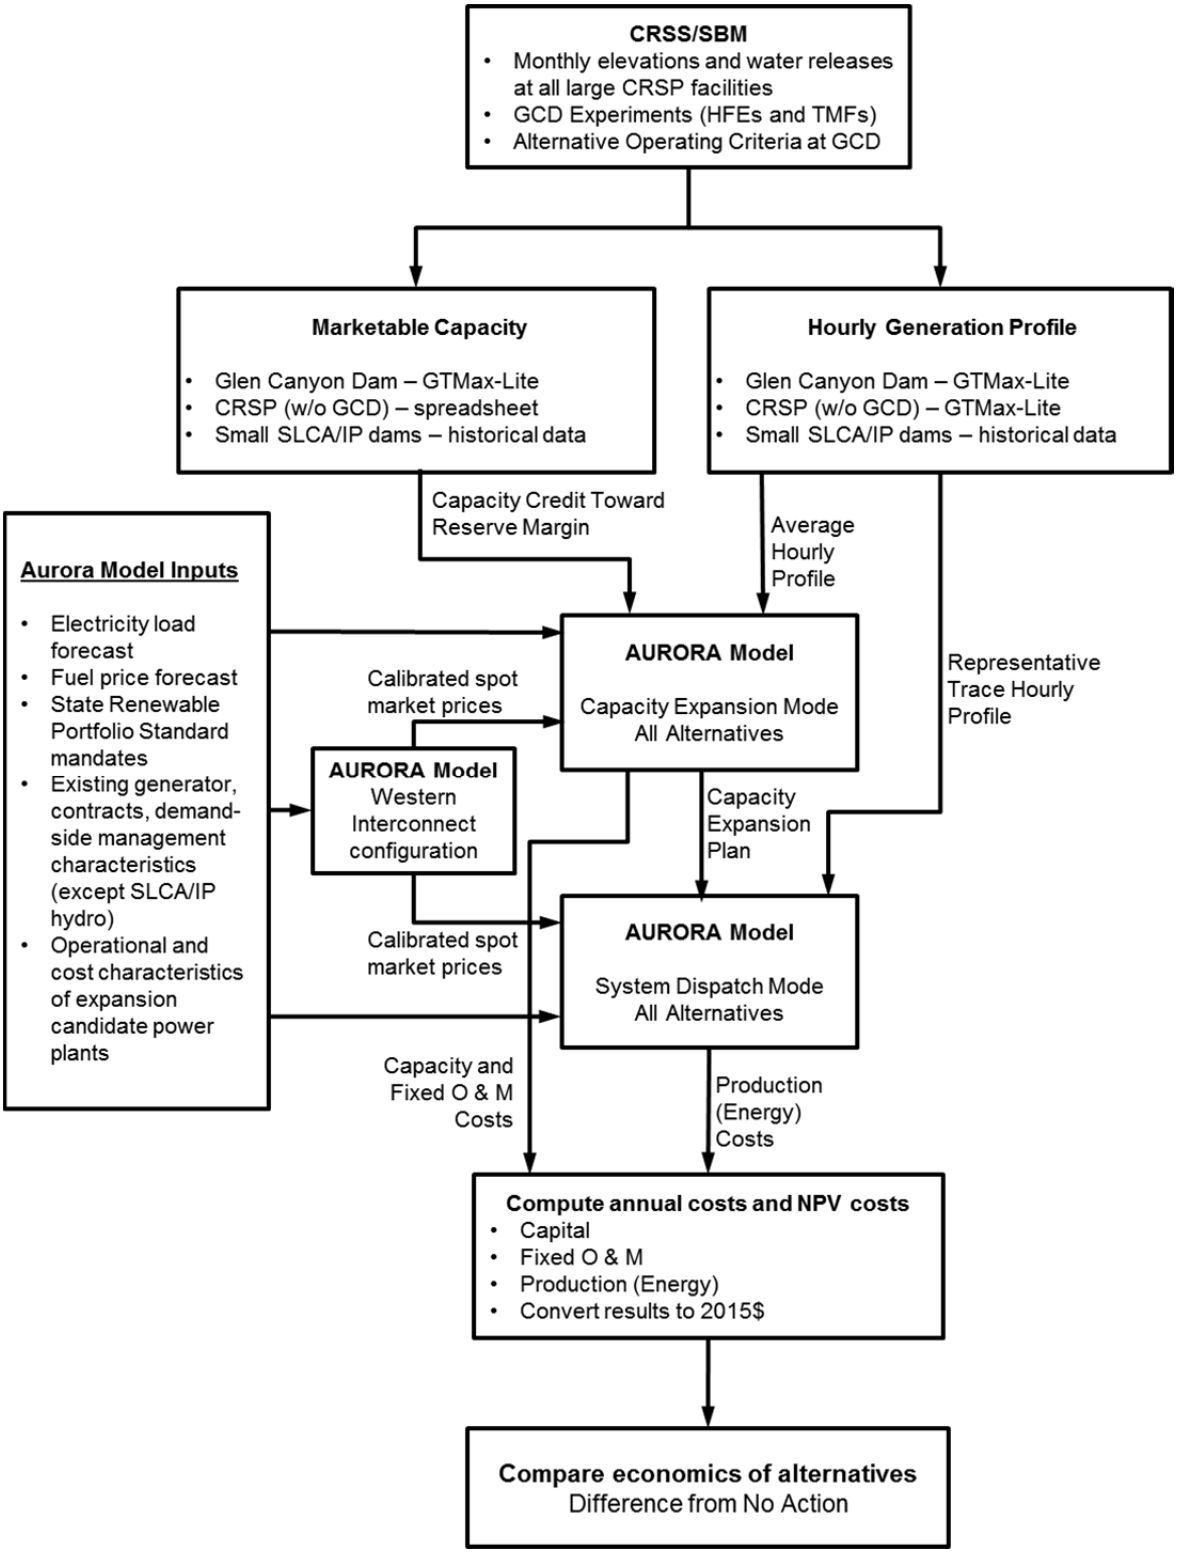

FIGURE K.1-5 Flow Diagram of the Power Systems Methodology Used in the LTEMP EIS

A second configuration of GTMax-Lite configuration simulates the operation of other large SLCA/IP powerplants. It also uses input data from the CRSS model and calibrated Western Interconnection LMPs. The Glen Canyon Dam LTEMP EIS alternative operating criteria and experimental releases conducted at Glen Canyon Dam do not impact the operations of these upstream resources; therefore, the SBM does not consider these resources in the determination of when HFE events will occur. GTMax-Lite optimization for these plants was performed for a condition that represents an average hydrological condition as projected by CRSS and for the CRSS projection, also known as a trace, which was judged by Argonne staff to be "representative" of the 21 projections. The selection of this representative trace is described in Attachment K.3.

The firm capacity of WAPA's SLCA/IP federal hydropower resources is computed by spreadsheet tools that estimate the maximum potential output of these resources during the time of peak system load. Depending on an alternative's operating criteria, the maximum output level at the Glen Canyon Dam Powerplant is suppressed. For example, flat flow alternatives are associated with relatively low firm capacity levels, while higher firm capacity levels are attained under less stringent operating criteria such as under Alternative B. As described in more detail in Sections K.1.5 and K.1.7, determination of Glen Canyon Dam Powerplant capacity is based on GTMax-Lite hourly results for all 21 projected futures. Other large SLCA/IP hydropower plant firm capacities are based on CRSS projected futures and power equations that estimate maximum output levels.

The middle tier is modeled by the SLCA/IP market system configuration of AURORA. This configuration contains all of the loads and resources that are in the utilities operated by SLCA/IP LTF wholesale customers and a point that represents a connection to the rest of the Western Interconnection. At this interconnection point, energy is bought and sold at the calibrated Palo Verde market hub price. Hour-by-hour energy injections into the system from WAPA's hydropower resources are prescribed as determined by GTMax-Lite.

For each alternative, AURORA was used for two major purposes: (1) to determine the cost of capacity expansion pathway over time during the study period for the SLCA/IP market system; and (2) to compute production costs associated with a least-cost unit commitment and system dispatch for a given expansion pathway and a single representative hydrology future or trace. Therefore, AURORA is run in two modes. The first, or "expansion," mode is used to determine the type of technologies that will be built in the SLCA/IP market system and the time when system capabilities will be expanded. It also considers scheduling the retirement of existing generating units. The second, or "dispatch," mode determines unit commitments and performs a system dispatch of a static set of both existing and new resources. This static resource set was determined by previous AURORA capacity expansion runs.

As shown in Figure K.1-5, calibrated market prices are used by both the capacity expansion and system dispatch modes for all alternatives. However, the AURORA capacity expansion model runs use the hourly energy production from WAPA's SLCA/IP hydropower resources, based on an average hydropower condition, while AURORA dispatch runs use generation level projected by the representative trace.

Results of the AURORA dispatch model consist of costs to produce the electrical energy to meet the system load demand. Production costs are the sum of powerplant fuel costs, variable O&M costs, unit startup costs, and the cost of power purchased from the spot market minus spot market sales revenues. Results from the AURORA expansion and dispatch models (namely capital, fixed O&M, and production or energy costs) were combined to determine the total annual costs for each alternative. The NPV stream of costs was also calculated to facilitate comparisons among alternatives. This single lump-sum value was based on a discount rate of 3.375%, a rate that is used by Reclamation for cost-benefit studies of projects. The use of this discount rate was in part based on information contained in Attachment K.4, which was provided by Reclamation staff. At the recommendation of WAPA staff, a second discount rate of 1.4% was used in a sensitivity study.

K.1.5 Description of Individual Power System Models

As described in the previous section, Argonne used several tools and models of varying levels of detail and complexity to estimate the economics of LTEMP EIS alternatives. Additional information on each of these tools and models, along with a description of other supporting algorithms, is provided below.

K.1.5.1 Colorado River Simulation System Model (Bottom Tier)

The CRSS model was developed by Reclamation to model future operations of water-related resources on the Colorado River, including both the upper and lower portions of the basin. The Glen Canyon Dam is the lowest reservoir in the upper basin. For the LTEMP EIS, CRSS projected 105 monthly hydrological futures over a 48-year time period from 2013 through 2060, inclusive. Each future or trace is based on a historical time series of hydrological conditions. Power system analyses utilize the first 21 years of CRSS projections of reservoir elevations and water release volumes for CRSP and the Seedskadee Project; that is, the set of large plants. Of the 105 traces projected by CRSS, a common set of 21 was used by all EIS research areas including power systems analyses.

For the initial structured decision-making exercises, all of the simulation cases included three separate options for sediment conditions (high, moderate, and low), effectively multiplying the number of simulations required by a factor of three. Once the detailed results were generated, the three sets of findings were assigned relative weightings in order to combine and condense the findings into weighted averages. For expediency in the power systems analysis, all of the simulation runs will be based on a single sediment option (the moderate case, also designated "s2" in previous treatments), which was weighted by 63.1% for combining the detailed results. This greatly reduces the number of cases to be examined, and based on previous findings it does not affect comparisons or conclusions regarding impacts of the alternatives.

Separate CRSS model runs are made for each alterative, resulting in a unique projection of monthly reservoir elevation and water volume releases for Glen Canyon Dam. However, monthly operations of all other SLCA/IP dams are identical under all alternatives. Therefore,

operations for all large SLCA/IP federal hydropower plant model runs of GTMax-Lite used CRSS results for Alternative A.

K.1.5.2 Representative Trace Tool (Bottom Tier)

The Representative Trace Tool contains supplemental software written by Argonne specifically for the LTEMP EIS. It assists in the selection of a single hydrological trace for the detailed hourly dispatch of WAPA's large SLCA/IP hydropower plants. The trace chosen best meets a set of criteria for being "representative." The representative trace must have annual variations in hydrological conditions at Glen Canyon Dam that are similar to the hydrological distribution of the entire population of the 21 common trace set for sediment condition 2. The mean Glen Canyon Dam annual water release of the representative trace must also be approximately equal to the mean of all 21 traces. For consistency, the selected trace is also applied to the other five large SLCA/IP federal hydropower plants.

K.1.5.3 Hydropower Outage Model (Bottom Tier)

The Hydropower Outage model and supporting spreadsheets are used to simulate unit outages at all six large SLCA/IP federal hydropower powerplants. This includes both scheduled outages and forced outages that are caused by random mechanical and electrical events. Designed and written by Argonne, a methodology was developed to incorporate the number, cause, and duration of forced outages that may potentially occur during the 20-year study period. The model uses a random number generator to simulate the timing and cause of forced outages using data contained in the NERC Generating Availability Data System (GADS). Several instances of the model were run. The time series of random outage selected for LTEMP analyzes was the one that closely matched GADS statistical averages. The outage methodology is discussed in more detail later in Section K.1.7.3 and in Attachment K.5. The same time sequence of representative outages was used under all alternatives.

Reclamation provided Argonne with maintenance schedules over the study period for large SLCA/IP facilities. The timing and length of outages at large SLCA/IP powerplants is in general the same under all EIS alternatives. However, during HFEs and TMFs, it was assumed that a scheduled maintenance outage would not be conducted.

K.1.5.4 Generation and Transmission Maximization-Lite (Bottom Tier)

GTMax-Lite is a simplified version of the full GTMax model. Both were developed by Argonne. GTMax-Lite has limited scope and data requirements compared to the full version of GTMax. The two versions of GTMax-Lite used for the LTEMP EIS represent only the physical characteristics of hydropower plants, downstream flow requirements, and both water release and reservoir operating criteria. The primary modeling objective of the lite version is to maximize the economic value of hydropower resources. This differs from the full GTMax model, in which the full model represents other factors such as customer power delivery requests sent to the EMMO,

short-term purchase and sale commitments, and non-economic EMMO dispatch goals and guidelines. Although full GTMax and GTMax-Lite differ, they share many of the same features and in general produce similar generation patterns and estimates of hydropower economic value.

The GTMax-Lite model configuration used for LTEMP power systems analyses optimizes the economic value of hourly energy produced at both Glen Canyon Dam and all other large SLCA/IP federal hydropower facilities. Operations depend on both unit availability as simulated by the outage model and a set of operating criteria. For the LTEMP EIS, two configurations of the model were constructed. One represents the operation of only Glen Canyon Dam, and the other optimizes the operation of the remaining large hydropower facilities.

GTMax-Lite was used because many thousands of weekly runs with hourly time steps need to be performed rapidly. It was customized to address a specific problem by tailoring the objective function, the input and output routines, and the model constraints to be consistent with LTEMP modeling needs; that is, it models federal hydropower resources without LTF contractual obligations. Multiple model runs and data handling are controlled by a Microsoft Excel® spreadsheet, and the objective function is optimized using the Lingo software, which simultaneously identifies the best pattern of hourly energy production over time that satisfies all operational constraints. The Lingo optimization software was developed by LINDO Systems and is widely used by educational institutions and large corporations.

Glen Canyon Dam Configuration

The Glen Canyon Dam GTMax-Lite model was run thousands of times in support of the structured decision analysis (SDA) process (Appendix C). This includes nearly 1,000 LTEMP scenario optimizations (combinations of 19 long-term strategies based on the 7 alternatives [see Section 4.1], 21 hydrology traces [based on 105 years of historical data], and three sediment traces [based on 50 years of historical data]) that optimize water releases (each run consisting of 180,000 hr of Glen Canyon Dam flows). The GTMax-Lite hourly water release results were used by analysts in each resource area, such as sediment, fish, recreation, and riparian vegetation. Analyses of power systems economics leverages the outputs produced by this process.

Initial SDA exercises used all of the simulation cases, including the three separate sediment input traces (high, moderate, and low input). The power systems simulation runs used a single sediment trace (the moderate case). This reduced the number of cases to be examined by two-thirds, and, based on previous findings, does not affect comparisons or conclusions regarding impacts of the alternatives.

GTMax-Lite simulated operations at Glen Canyon Dam were made for all 21 projected hydrological futures over the entire study period. As described below, all runs were performed twice. The Glen Canyon Dam configuration uses hourly AURORA calibrated prices projected by the Western Interconnection configuration to maximize the economic power value of operations during representative 1-week periods for each month during the study period. Hourly prices input into the model are average values based on weekday, Saturday, and Sunday/holiday Palo Verde hub LMP projections. Model results for hourly Glen Canyon Dam generation are greatly

influenced by the hourly LMP profile, a weekly water release requirement, Lake Powell Reservoir elevation, and LTEMP alternative operating criteria.

To achieve more accurate/realistic results, both GTMax-Lite configurations explicitly model scheduled and forced outages. Reclamation provided a maintenance schedule for all six CRSP facilities over the study period (Clayton 2013). A methodology was developed to incorporate the number, cause, and duration of forced outages that would be expected during the study period. Data on forced outages for hydroelectric turbines were obtained from GADS, which is a database of operating data on electric generating equipment maintained by the NERC. This information was input into an algorithm that produced a plausible series of random outages for units at the Glen Canyon Dam Powerplant. For large SLCA/IP federal hydropower facilities, based on the cause of forced outages and associated average down times using data contained in the NERC GADS for hydropower plants that had capacities greater than 30 MW.

Market prices input to LTEMP power system models represent the economic value of hydropower generation at hourly intervals. These prices directly influence the generation schedule produced by the models when optimizing SLCA/IP hydropower resources. To the extent possible, the GTMax-Lite model uses its limited-energy/water resource stored in a reservoir (i.e., Lake Powell at the Glen Canyon Dam) to first generate electricity during on-peak hours when it has the highest economic value. Any remaining energy is scheduled during lower-priced hours.

Model-generated operations comply with any operating constraints and downstream flow targets placed upon the hydropower system for environmental or institutional reasons. Operating constraints include limits on water release up- and down-ramp rates, limits on reservoir water release rate changes over a rolling 24-hour period, ancillary service requirements, and others.

Figure K.1-6 illustrates a typical Glen Canyon Dam GTMax-Lite result for a 24-hour period. The green bars represent hourly Glen Canyon Dam Powerplant production, the total of which is highly influenced by the mandated monthly water release volume. The light green line shows hourly market prices. In general, energy production is the highest when it has the most value. Note that the production levels are such that the total of hourly generation multiplied by the market price (i.e., energy production value) over the day is as large as possible. The production pattern adheres to all operating criteria such that the power output pattern complies with minimum and maximum flow rate constraints, ramp-rate limits, and daily change restrictions. Also note in this example that some of the constraints are binding. In this case, the minimum and maximum generations do not bind the solution; that is, generation levels do not operate at either of these levels. Generation pattern is bound or limited by daily change and both up and down hourly ramp rate constraints. However, when more water is released for power generation, the maximum limit becomes binding because peak generation levels are possible within the daily change constraint. On the other hand, when hydropower generation is low, the minimum constraint becomes binding. Therefore, hydropower conditions often dictate when a constraint is either binding or not binding.

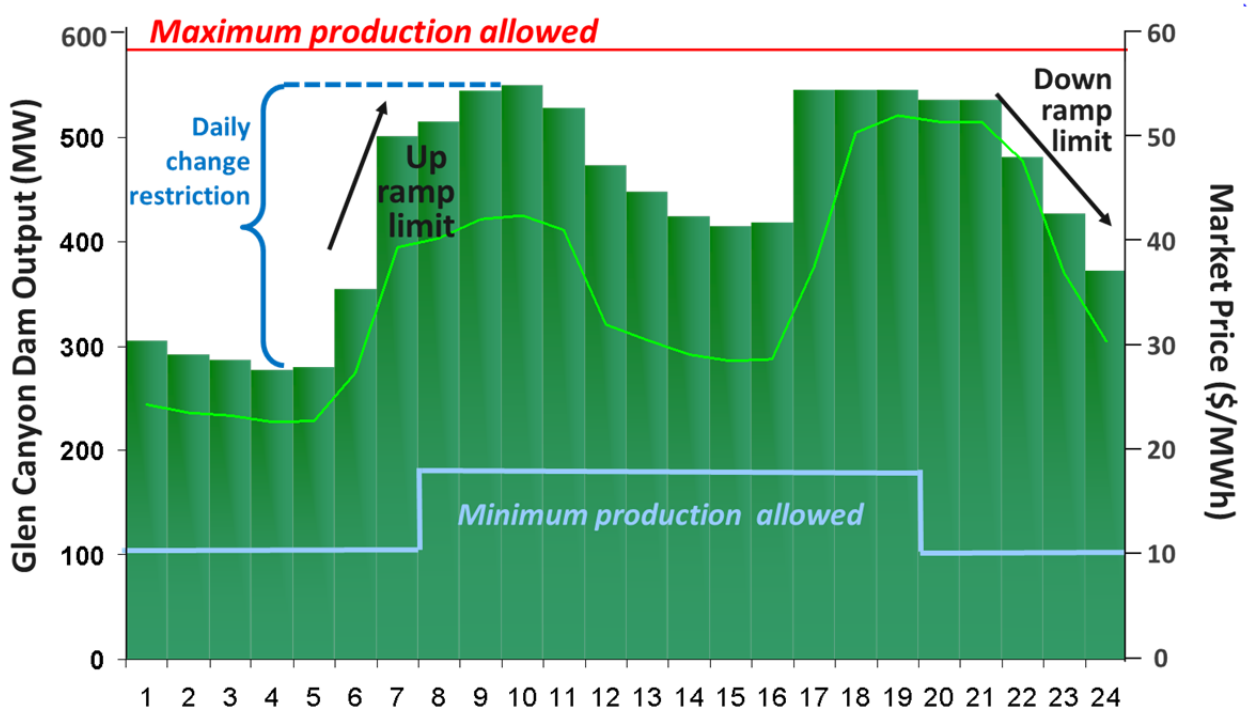

FIGURE K.1-6 Illustration of a Typical GTMax-Lite Result for a 24-Hour Period

More operational flexibility at Glen Canyon Dam always translates into higher or equal economic value. For example, if there was no daily change constraint, powerplant output in Figure K.1-6 would have been at the minimum during the nighttime, when prices are lower, and ramped up over a few more hours to reach the maximum output level when prices are the highest. A further relaxation of operating criteria by removing hourly ramping constraints, lowering the minimum, and increasing the maximum would have resulted in a higher concentration of Glen Canyon Dam generation in the hours with the highest demand. The daily maximum generation level would have also been higher. Therefore, limits not only constrain the economic value of energy, but also impact the maximum output that Glen Canyon Dam produces during system peak loads and therefore reduce its firm capacity.

The Glen Canyon Dam version of GTMax-Lite compresses the full 8760 hr per year into 12 "typical week" periods of 168 hr for each month. Outputs include hourly turbine and non-turbine water release and power generation schedules for a series of representative 1-week time periods (i.e., sequence of 168-hour time periods) that maximize the economic value of hydropower energy resources. The Glen Canyon Dam GTMax-Lite configuration utilizes a "wrap" technique that significantly reduces model end-effects associated with running typical weeks. The technique essentially connects the modeled beginning hours to those at the end of the optimized week. Because the model mathematically repeats the same weekly pattern infinitely, ending model solutions are positioned such that it is starting in a good position for operations during the following week.

Because the GTMax-Lite model only simulates operations for one representative week in each month, the results are repeated to reflect full months of hourly operations for each year of the study. This is accomplished by assigning the typical water and generation release pattern estimate by GTMax-Lite for specific day types to each day of the month. For example, the Sunday optimized pattern is assigned to all Sundays and holidays that occur in a month. It should also be noted that GTMax-Lite is provided with the number of day types that occur in each simulated month. Using this information, GTMax-Lite produces a weekly result such that the repeated daily results over a month release the exact amount of specified monthly water release.

The GTMax-Lite configuration that represents Glen Canyon Dam was run under two different of assumptions. The first assumes that no distinctive release events such as HFEs will occur in the future, in which case CRSS data are used to drive operations. This information was input into the SBM in order for the model to schedule HFEs and adjust CRSS monthly water release volumes and Glen Canyon Dam reservoir elevations. This intermediate solution was only used by the SBM.

For a second run of the Glen Canyon Dam GTMax-Lite model, it is assumed that HFEs will occur as scheduled by the SBM. The LTEMP EIS defines several different types of HFE, each with a unique specified hourly water release pattern. GTMax-Lite models operations when an HFE is *not* scheduled. A separate routine is used to compute Glen Canyon Dam Powerplant generation based on the prescribed HFE water release pattern. This pattern depends on the type of HFE that would be conducted. Under most HFEs, there are time periods when water release requirements exceed the combined maximum flow rate of Glen Canyon Dam Powerplant turbines. Therefore, the routine tracks both turbine water and non-turbine water releases. It also computes power production levels based on Lake Powell's water elevation. During days in a month in which an HFE is not scheduled, Glen Canyon Dam hourly generation simulated by GTMax-Lite accounts for the SBM monthly water release volume, the amount of water that was released during the HFE, and the number of normal operating days (i.e., day without the HFE) in the month.

Other Large Federal SLCA/IP Hydropower Resources Configuration

Because WAPA markets power from combined SLCA/IP facilities, of which Glen Canyon Dam is the single largest component, a second GTMax-Lite configuration was developed. It represents the remaining CRSP hydropower powerplants, including Blue Mesa, Morrow Point, Crystal, and Flaming Gorge, and the Fontenelle Powerplant of the Seedskadee Project. Although Fontenelle is not technically part of CRSP, it is included in this configuration because it is operated as a cascade with Flaming Gorge and the CRSS model projects both monthly reservoir elevations and releases for these facilities. This GTMax-Lite configuration and its key operating constraints, shown in Figure K.1-7 below, were developed specifically for the LTEMP EIS.

GTMax-Lite is a scaled-down version of the full GTMax model. Both represent all the physical CRSP and Seedskadee powerplants and downstream flows at gages in the Green River. However, the lite version omits the representation of SLCA/IP firm contracts. Instead, large

SLCA/IP hydropower plant operations are driven directly by electricity market price signals—not contracts. This streamlined process involves far fewer model operator steps and solves the problem considerably faster than the full GTMax model. The omission of SLCA/IP firm contractual loads has a very minor impact on the dispatch of the Glen Canyon Dam Powerplant because price patterns are highly correlated with loads, and operating constraints under all alternatives restrict the flexibility of Glen Canyon's response to hourly changes in prices and load patterns. Instead, operations follow a general on-peak and off-peak pattern that is restricted by the daily change criterion.

The GTMax-Lite configuration that represents these five large SLCA/IP powerplants was run once for an average hydrological condition to support AURORA capacity expansion model runs, and a second time using the representative trace to support SLCA/IP detailed system dispatch runs. It optimizes operations during all hours of the study period, based on input data from the CRSS model and AURORA Western Interconnection calibrated market prices for the Palo Verde market hub. LTEMP EIS alternative and experimental releases conducted at Glen Canyon Dam, such as HFEs and TMFs, do not affect the operations of these five upstream resources. Therefore, this configuration uses CRSS results for Alternative A. Therefore, the SBM did not adjust CRSS results.

As shown in Figure K.1-7, GTMax-Lite contains two water cascades. The first consists of the Fontenelle and Flaming Gorge Reservoirs and the second consists of the Aspinall Cascade, which includes the Blue Mesa, Morrow Point, and Crystal reservoirs. Operationally, reservoirs in

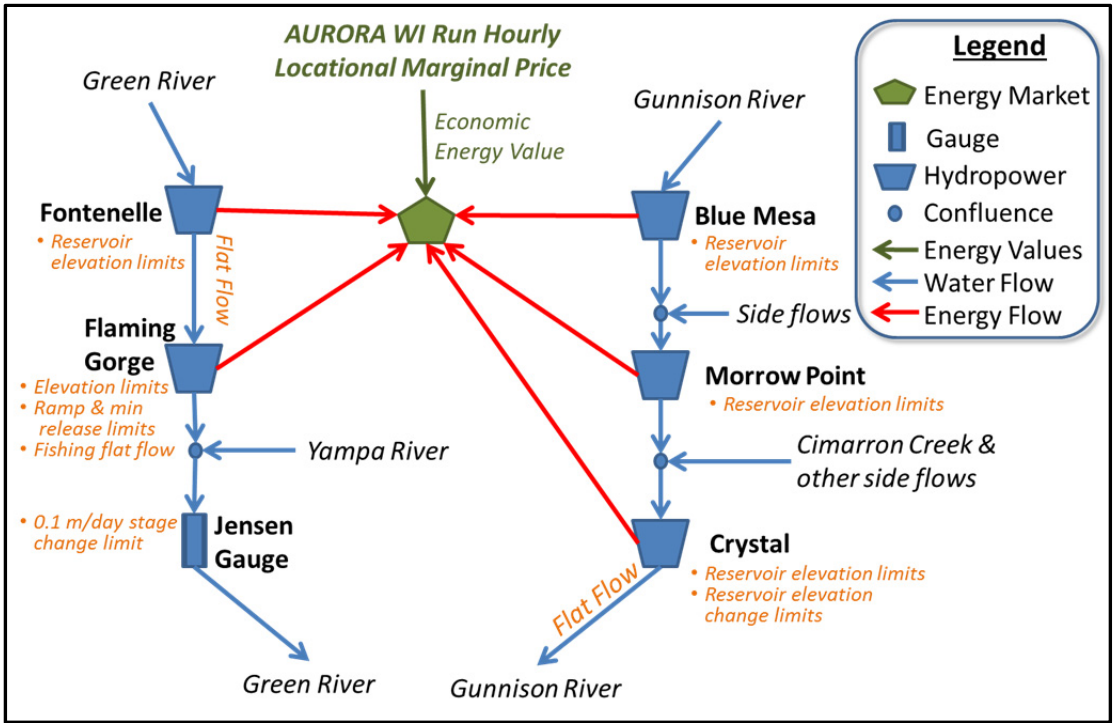

FIGURE K.1-7 GTMax-Lite Network Topology for the Large SLCA/IP Hydropower Resources Other Than Glen Canyon Dam

the first cascade are very loosely connected, but reservoirs in the Aspinall Cascade are very tightly coupled.

Monthly releases and reservoir elevations were obtained from CRSS model results for Alternative A. CRSS also provides information about water inflows into reservoirs, side flows that occur between connected reservoirs, and reservoir evaporation. Other inputs included operating constraints placed on the facilities, such as restrictions on water release ramp rates and flow requirements at the Jensen Gage downstream of Flaming Gorge. The objective function simultaneously maximizes the economic value of the hydropower resource at these five large facilities. The output is an hourly schedule of water releases and electric generation that maximizes the economic value of hydropower resources within the bounds of all operating constraints.

Operating constraints include maximum and minimum limits imposed on all reservoirs and a complex set of restrictions at the Crystal Reservoir that bound the rate of elevation changes over time. In order to ensure that water releases do not violate reservoir operating constraints, the GTMax-Lite model computes hourly water mass balances and reservoir elevations using reservoir elevation-volume functions. Water balancing equations account for water inflows, side flows, evaporation, upstream reservoir water releases, and all releases from the reservoir of interest.

Flows at the Jensen Gage are restricted to daily stage changes of 0.1 meters/day. Because gage flows are directly affected by upstream water releases from the Flaming Gorge Reservoir, GTMax-Lite models gage flows that comply with the daily gage constraint. To optimize Flaming Gorge operations, water travel time distribution (WTTD) functions are used to estimate the time it takes water to flow through Green River reaches, and the attenuation of releases as water travels downstream. For this study, two reaches are defined. The first is from the Flaming Gorge Dam to the confluence of the Green and Yampa Rivers and the second is from this confluence down to the gage. Although WTTD can vary by hydrological condition, for this study a typical WTTD function was derived from Streamflow Synthesis and Reservoir Regulation (SSARR) model outputs. SSARR was written by the Army Corps of Engineers. In general, it takes about 24 hr for the first fractional amount (less than 1%) of a Flaming Gorge release to reach the gage. Typically, all of the water passes the gage 48 hr after the release. Gage readings are computed using a function that relates the flow rate at the gage to the gage stage. Yampa River water flows into the Green River are based on historical monthly data. Based on historical records, for this study a monthly 50% flow exceedance was input into GTMax-Lite.

The temporal modeling methods used by GTMax-Lite for the five large hydropower plants differ from the Glen Canyon Dam configuration because it simulates operations for all hours during every study period day. It was structured and configured differently from Glen Canyon Dam GTMax-Lite because the operating constraints at powerplants and reservoirs in the Aspinall Cascade are fundamentally different from those at Glen Canyon Dam. The imposition of gage constraints at Jensen is also unique. The five-plant configuration of GTMax-Lite needs to be run far fewer times than the Glen Canyon Dam configuration, and therefore it is computationally efficient to model all days.

As shown in Figure K.1-8, time in the five large plant configuration of GTMax-Lite is separated into three periods that include history, primary optimization, and extension. The historical period is required because operations in the past affect future operation. These include operations in the Aspinall Cascade that constrain Crystal Reservoir elevation changes over 1-day and 3-day periods. In addition, operations at the Flaming Gorge Dam need to comply with gage flow constraints. Note that the water travel time from the Dam to the gage is about 2 days. For the first model run, actual historical operations are input into the model. However, for all subsequent optimizations, "history" is obtained from the previous model run. For this study, hourly results for the last 3 days of the primary optimization period are used.

To reduce model end effects and place operations at the end of the simulated period in a good position for the following days, a 1-week extension period is included in each model run. This differs from Glen Canyon Dam GTMax-Lite model runs that apply the previously described wrap technique to reduce model end effects. Results for the extension period are not used by AURORA or in any economic calculations. Instead, results for the extension period are erased and replaced with primary optimization period results from a subsequent model run.

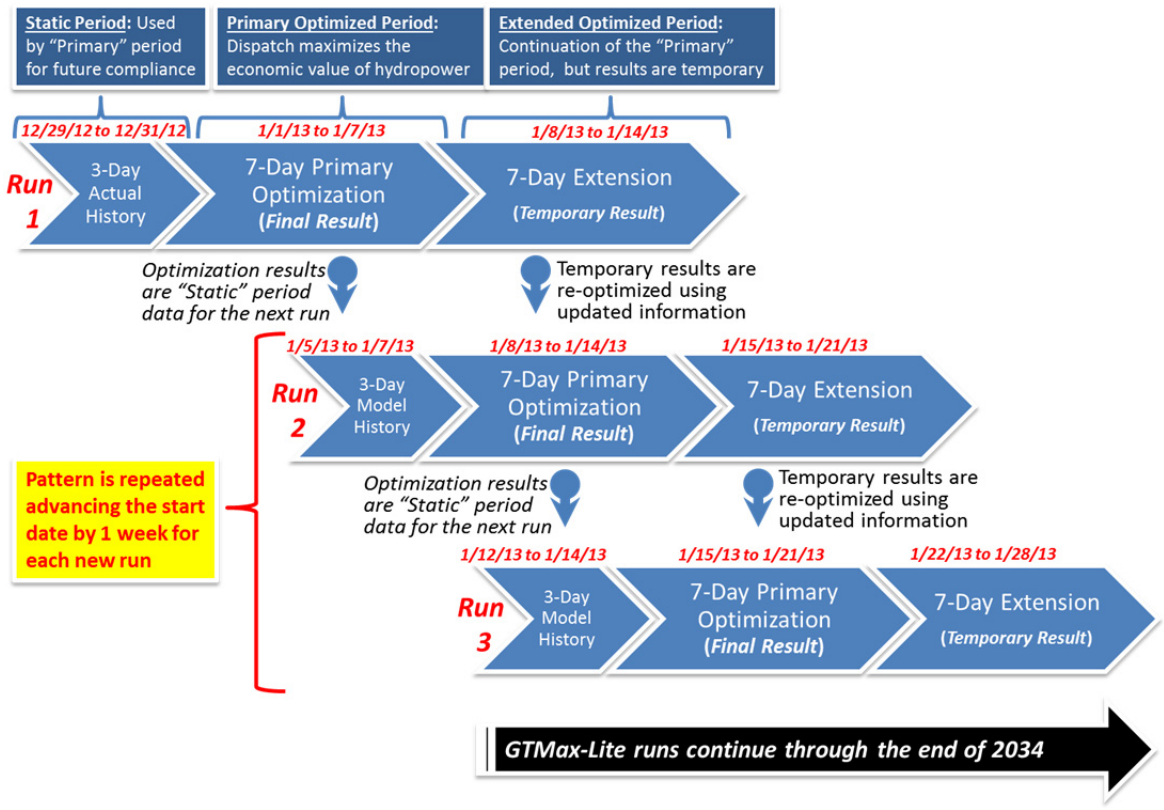

FIGURE K.1-8 Illustration of Temporal Modeling Method Used in the GTMax-Lite Five Large SLCA/IP Plant Configuration

K.1.5.5 Sand Budget Model (Bottom Tier)

The Reclamation SBM schedules various HFEs that differ in terms of peak water release rate, duration, and timing. It uses results from the CRSS model and the intermediate Glen Canyon Dam GTMax-Lite solution. The model is run for each alternative using alternative specific triggers to schedule future HFEs under all 21 hydrological futures and three sediment futures.

SBM maintains the annual WY release volumes specified by CRSS, but reallocates monthly volumes in order to enable higher water releases during months with experiments. Due to the reallocation of water releases, the Glen Canyon Dam GTMax-Lite model is run a second time using the SBM results. It is this second GTMax-Lite run that is used for all economic analyses.

K.1.5.6 Large SLCA/IP Powerplant Spreadsheets (Bridges Bottom and Middle Tiers)

Several spreadsheets were developed by Argonne and reviewed by WAPA for the LTEMP EIS power system analyses. These large SLCA/IP powerplant spreadsheets perform the following functions:

- Create alternative-specific hourly Glen Canyon Dam generation input data for the SLCA/IP market system configuration of AURORA. One set of generation data contains average hourly values computed from GTMax-Lite results for the 21 SBM traces. These values are used for SLCA/IP capacity expansion simulations. The second set of Glen Canyon Dam generation is based on GTMax-Lite results for the representative trace and used for AURORA dispatch model runs.

- Determine the amount of Glen Canyon Dam capacity that will be reserved and available for ancillary services for each day of the simulation period. If these services cannot be entirely fulfilled by the Glen Canyon Dam Powerplant, the amount that needs to be supplied by Aspinall powerplants is computed. Although monthly water release volumes as projected by CRSS are constant among alternatives, the hourly dispatch may be altered at WAPA's discretion during a few hours of the LTEMP period. Therefore computations for Glen Canyon Dam and Aspinall are performed for each alternative.

- Find and store the maximum daily generation level contained in Glen Canyon Dam GTMax-Lite outputs for all alternatives and traces. These data are used by the Firm Capacity Spreadsheet that computes aggregate firm capacity level for SLCA/IP federal hydropower resources.

- Create alternative-specific hourly generation input data for AURORA that represents the five large SLCA/IP powerplants. One set of generation data is

based on GTMax-Lite that models these five large plants based on average monthly releases and reservoir information that is derived from CRSS trace results. These values are used for SLCA/IP capacity expansion simulations. The second set of large SLCA/IP hydropower generation values is based on GTMax-Lite results for the representative trace and used for AURORA dispatch model runs.

- Determine the maximum potential output level from the five large SLCA/IP powerplants. Maximum output levels are computed for all combinations of unit outages at each powerplant based on operating criteria, turbine capacities, forebay elevation, tailwater elevation calculations, and water-to-power conversion factors as a function of head. Except for minor adjustments that account for Aspinall spinning reserve and regulation service duties, maximum output levels are identical across all alternatives. Based on user-defined risk level, spreadsheet results are also used by the Firm Capacity Spreadsheet to set the aggregate firm capacity level for WAPA's SLCA/IP federal hydropower resources.

K.1.5.7 Small SLCA/IP Powerplant Spreadsheet (Bridges Bottom and Middle Tiers)

The capacity and dispatch of relatively small SLCA/IP federal hydropower resources including Deer Creek, Elephant Butte, Towaoc, McPhee, and Molina are estimated using the Small SLCA/IP Powerplant spreadsheet. Estimates of future hourly plant-level generation are on based on historical Form PO&M-59 data and powerplant duty cycle (i.e., baseload or peaking). This spreadsheet is also used to estimate maximum output levels for use in computations of WAPA's SLCA/IP hydropower firm capacity. The same hourly generation and maximum output values are used for all alternatives for both AURORA capacity expansion and dispatch model runs.

K.1.5.8 Loads Shaping Algorithm (Middle Tier)

In order to project hourly customer loads for LTF large and small customers, Argonne analyzed several years of historical load data for the eight large customers that was contained in the FERC Form-714. Normalized loads for CY 2006 were selected to serve as a representative profile and used as the basis for projecting future chronological hourly loads for all LTF customers. The basis for selecting this year is described in more detail in Section K.1.6.3. Normalized profiles cannot simply be multiplied by a constant value (e.g., monthly peak load) to scale loads for a future year, because load factors are projected to change over time as reflected in utility IRPs. The Loads Shaping Algorithm is used to compute hourly scaling factors that, when applied to the normalized profile, produce a time series of chronological hourly loads that simultaneously match both a projected monthly peak load and monthly total load.

The Loads Shaping Algorithm uses a quadratic programming technique that minimizes differences between a normalized load duration curve (LDC) constructed from historical data and a reshaped LDC generated by the model. Figure K.1-9 shows the original LDC, constructed from historical loads for one of the large customers and the reshaped LDC. The reshaped curve is consistent with a projected monthly load factor. Upper and lower load constraints may be specified by the user to bind the model's solution. For each point in the LDC, a scaling factor, shown on the secondary y-axis, is then computed as the ratio of the reshaped load to the original load. Finally, the algorithm constructs a scaled chronological hourly profile based on the load scaling factors and an associated original hourly load. The end product, as shown in Figure K.1-10, is a chronological load time series that exactly matches the monthly projected peak and total load.

K.1.5.9 AURORA (Top and Middle Tiers)

The AURORA model is at the core of the methodology used to identify SLCA/IP federal hydropower interactions with the power grid. It was developed by EPIS, Inc., and it is used by utilities throughout the United States to model capacity expansion pathways, simulate unit commitments, and perform hourly unit dispatch. Based on information contained in the EPIS,

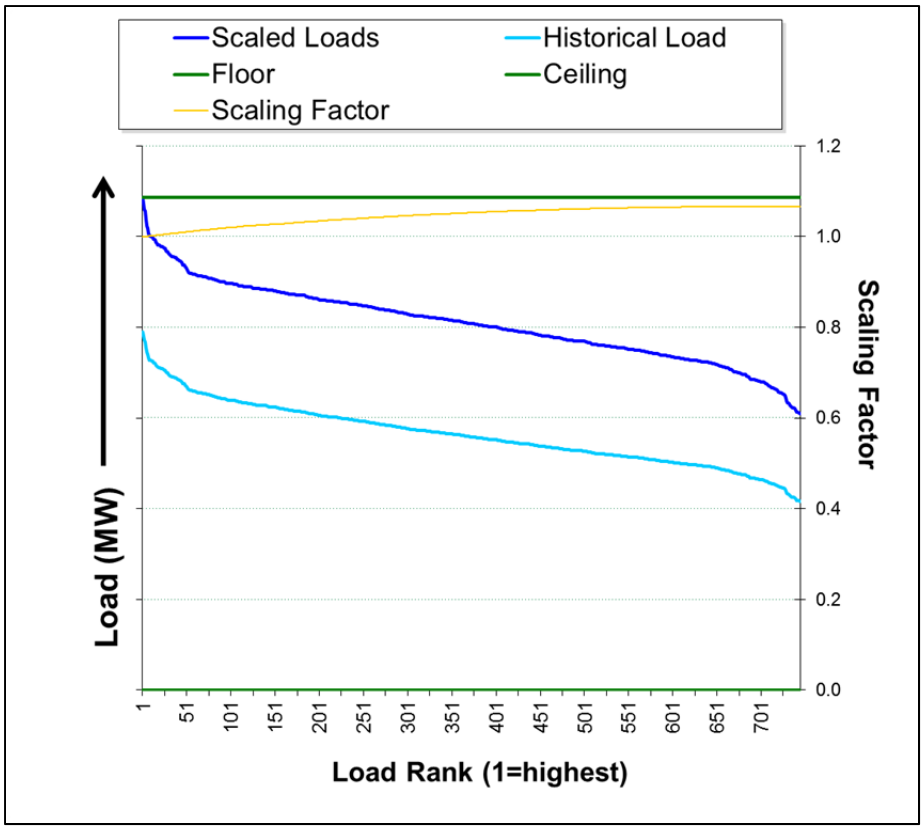

FIGURE K.1-9 Example of the Load Scaling Algorithm LDC

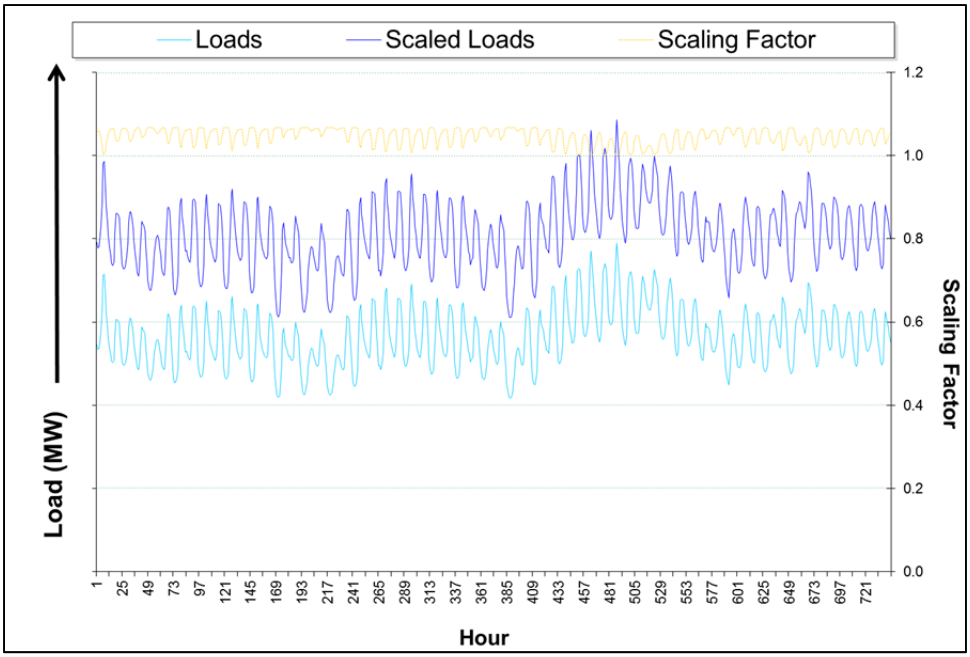

FIGURE K.1-10 Example of the Load Scaling Algorithm Chronological Hourly Loads

Inc., Web page (http://epis.com/AURORA_xmp/long_term_expansion.php), one of the primary uses of AURORA is for lifecycle analysis and resource capacity expansion optimization studies.

AURORA uses hourly demands and individual resource-operating characteristics in a transmission-constrained, chronological dispatch algorithm. This algorithm also models the deployment of curtailments at market price trigger points. LMPs projections are made in user-defined market bubbles over long-term planning horizons. For the LTEMP EIS, it computes LMPS at each of the bubble shown in Figure K.1-1.

A recursive modeling process identifies the set of resources among existing and potential future resources with the highest and lowest market values to produce economically consistent capacity expansion and retirement schedules. Based on the NPV of hourly market prices, it chooses to build one or more technologies contained in a user-defined list of new resource candidates. AURORA compares those values to existing resources in an iterative process to create a capacity expansion path of new units over time. The end result is a coordinated forecast of capacity expansion schedules for multiple market areas that meet planning reserve margin targets. Information from both state renewable portfolio standards (RPSs) and utility-specific IRPs regarding renewable resource development goals were input into the AURORA model to estimate the future expansion of wind and solar resources in the system.

Capital investment decisions made in AURORA use levelized capital investment costs that spread the cost of building a new unit into payments that are made at set time intervals (i.e., weekly, monthly, annually) over the book life of the project, similar to home mortgage payments. In this study, these payments are made and accounted for from the time a new unit

comes online through the end of the LTEMP study period. This reduces modeling end-effects because new units contained in the AURORA expansion path will operate long beyond the end of the LTEMP period. For example, if a new unit is brought online during the last year in the study, only 1 year of capital payments are included in the economic cost calculations, not the entire cost of the project. This reduces issues associated with evaluating technologies that have disparate capital costs and operational characteristics on timelines that do not cover the entire life of the candidate resources.

This levelized cost methodology is equivalent to incurring all capital cost expenditures when the unit comes online and later receiving a salvage value payment at the end of the study period. The salvage value represents the economic value of the resource at the end the study. This approach is used in the Wien Automatic System Planning (WASP) Package. Developed in 1972 by the Tennessee Valley Authority and the Oak Ridge National Laboratory, it has long been in continuous use by many utilities around the world for power generation expansion planning. When using the WASP sinking fund depreciation accounting method, WASP mathematics are equivalent to NPV results used by Argonne in this study (IAEA 1980).

For the LTEMP EIS, AURORA is used in the order listed below for the following purposes:

1. Project Palo Verde market hub prices/LMPs (top tier),

2. Determine construction schedules for new units in the SLCA/IP market system (middle tier), and

3. Simulate unit commitments and perform SLCA/IP market system dispatch (middle tier).

Modeling for the top tier is performed once—the results are used across all LTEMP EIS alternatives. The middle tier of AURORA is run for each alternative.

AURORA is first used to project future hourly energy market prices throughout the Western Interconnection during the study period; that is, for top tier modeling. Without alteration, it uses a Western Interconnection topology and dataset that were provided by EPIS. It should be noted that EPIS derived model input data for load growth, utility fuel price projections, and the cost and performance for new candidate units for system capacity expansion based primarily on information contained in EIA's 2014 AEO (EIA 2014).

For the LTEMP EIS, LMPs at the Palo Verde marketing hub were selected as a representative hourly time series. These market prices are the primary economic driver that shape SLCA/IP hydropower operations in both versions of the GTMax-Lite model and the Small SLCA/IP Power Plant Spreadsheet. The same price set was used for all alternatives. As discussed in Attachment K.1, Argonne assumes that alternative operations at Glen Canyon Dam will have an effect of less than a few cents/kWh on Western Interconnection LMPs outside of the SLCA/IP market system.

The second purpose of the AURORA model was to project system capacity expansion paths and unit retirement schedules for utilities in the SLCA/IP market system based on the assumption that customers will engage in cooperative agreements that are mutually beneficial; that is, middle tier modeling. It uses detailed unit-level information about existing powerplant units owned and operated by WAPA and its LTF customers. The model also includes information about candidate units that could be built in the future. Projected power demands consist of WAPA project use loads (which are described later) and loads for SLCA/IP LTF customers as described above. Capacity is constructed such that the reserve margin of the aggregate eight large customers never drops below 15%.

The firm capacity credit assigned to SLCA/IP federal hydropower resources in AURORA is estimated by the WAPA Firm Capacity Spreadsheet. The firm capacity logic used in this tool is in part based on a risk level consistent with a dry (i.e., low) hydropower condition such that the CRSP Management Center and the EMMO will be able to meet its LTF contractual capacity obligations with SLCA/IP federal hydropower resources 90% of the time. This is consistent with the level of risk to which WAPA has been exposed in the past.

SLCA/IP utility system energy transactions with the rest of the Western Interconnection are assumed to be priced at levels projected by the AURORA Western Interconnection model run. For the purpose of determining capacity expansion paths, it was assumed that the SLCA/IP market system would only make power purchases. This assumption was made to ensure that the SLCA/IP market system would not construct capacity on a speculative basis for the purpose of selling energy to the Western Interconnection; that is, it constructs capacity primarily for internal purposes. Because the Western Interconnection prices tend to be more expensive than production costs in the SLCA/IP market system, purchases from the Western Interconnection tend to be small. However, the Western Interconnection energy was made available for purchase in situations where internal SLCA/IP production costs became expensive. In addition, reserve margin requirements were configured to exclude WAPA LTF purchases because Western's contracts are considered extremely reliable (i.e., non-contingent) from the buyer's perspective.

The third purpose of the AURORA model was to perform a detailed dispatch analysis of the SLCA/IP market system which consists of the SLCA/IP hydropower facilities and WAPA's SLCA/IP LTF customers. Resources available for hourly dispatch are based on a previous capacity expansion run made by AURORA.

K.1.5.10 LMP Calibration Spreadsheet (Top Tier)

Spot market prices were modeled for CY 2013 through CY 2033 by the Western Interconnection AURORA model. Prices from the first year of this run, 2013, were compared against actual day-ahead market (DAM) prices published by the Intercontinental Exchange (ICE) and the California Independent System Operator to determine model accuracy. The Palo Verde market hub was chosen for the LTEMP analysis to represent prices for the spot market in the AURORA network topology because it is a major hub relatively close to Glen Canyon Dam and is often used as the benchmark price for WAPA energy transactions.

In general, AURORA prices differed significantly from both ICE and California independent system operator day-ahead market (CAISO DAM) historical prices for 2013. Therefore, the LMP Calibration Spreadsheet was written to scale AURORA hourly LMPs to more closely match actual nominal values in terms of 2013 dollars. The ICE publishes day-ahead weighted average peak, off-peak, and Sunday off-peak electricity prices for each day. Sunday off-peak hours are the 16 daytime hours that have the highest loads; they correspond to the 16 hr classified as peak in the other 6 days of the week. Hourly prices generated by the AURORA model were subdivided into seven categories: holiday, Sunday daytime, Sunday nighttime, Saturday peak, Saturday off-peak, weekday peak, and weekday off-peak. AURORA 2013 monthly averages were computed for each category and compared against the monthly average ICE prices in these categories.

A scalar (ratio of the ICE to AURORA prices) was generated for each month and each category. Prices generated by the AURORA model were generally lower than the ICE prices. Prices in off-peak hours were lower by about 5 to 15%, and prices in peak hours were lower by as much as 20 to 50%. To adjust prices, both AURORA 2013 and projected LMPs for Palo Verde were multiplied by the aforementioned scalar.

LMPs at the Palo Verde hub were projected by applying AURORA model price growth rates to the calibrated 2013 price (Figure K.1-11). Future spot market prices are difficult to accurately forecast because they are dependent on many factors, each of which cannot be projected with certainty. Therefore, many future scenarios are possible. For the power systems analysis, the 2014 AEO (EIA 2014) reference case was used to supply AURORA with variable inputs that drive future prices. One of the most important of these is natural gas prices. Figure K.1-12 shows a very strong correlation between historical on and off-peak prices at the Palo Verde hub and natural gas prices. This correlation is due the fact that the resources that are on the margin (i.e., last ones dispatch and determine the LMP) frequently burn natural gas. This strong correlation is expected to continue in the future. AURORA model results support this expectation. Figure K.1-13 shows that the 2014 AEO (EIA 2014) forecasted annual average delivered natural gas price to increase in the future. By 2033, natural gas prices are expected to be about 83% more expensive than prices in 2013. Calibrated LMPs follow this same basic trend. By 2033, Palo Verde price projections, which are based on the aforementioned methodology, are expected to increase by 78%. Factors that lead to a slightly slower growth in LMPs include the emergence of more-efficient gas-fired electricity generating technologies that burn less fuel per MWh of fuel consumed and a projected increase in the penetration of variable energy resources (VERs).

K.1.5.11 Firm Capacity Spreadsheet (Bridges Bottom and Middle Tiers)

The Firm Capacity Spreadsheet uses maximum daily output levels from the Large and Small SLCA/IP Powerplant spreadsheets and an assumed risk preference to estimate the amount of firm capacity that is available to the SLCA/IP market system for credit toward the system reserve margin. It also applies outage results produced by the Hydropower Outage model the five large SLCA/IP federal hydropower plants. GTMax-Lite runs of Glen Canyon Dam incorporate outages into estimated daily peak powerplant operations under all 21 hydrological traces.

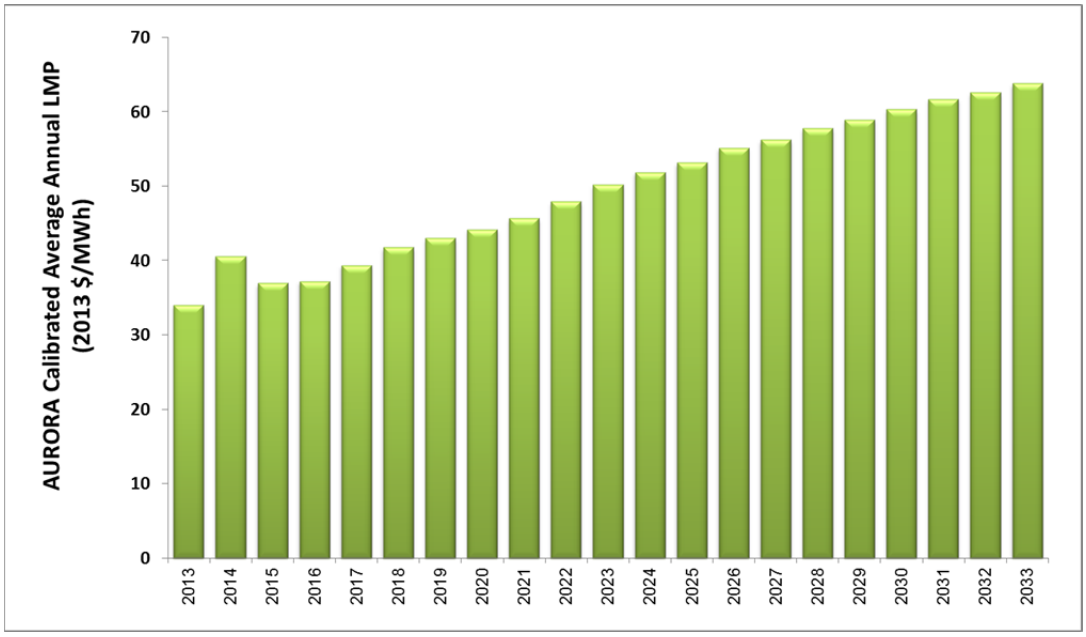

FIGURE K.1-11 Projected Annual Average Calibrated AURORA LMPs at the Palo Verde Market Hub

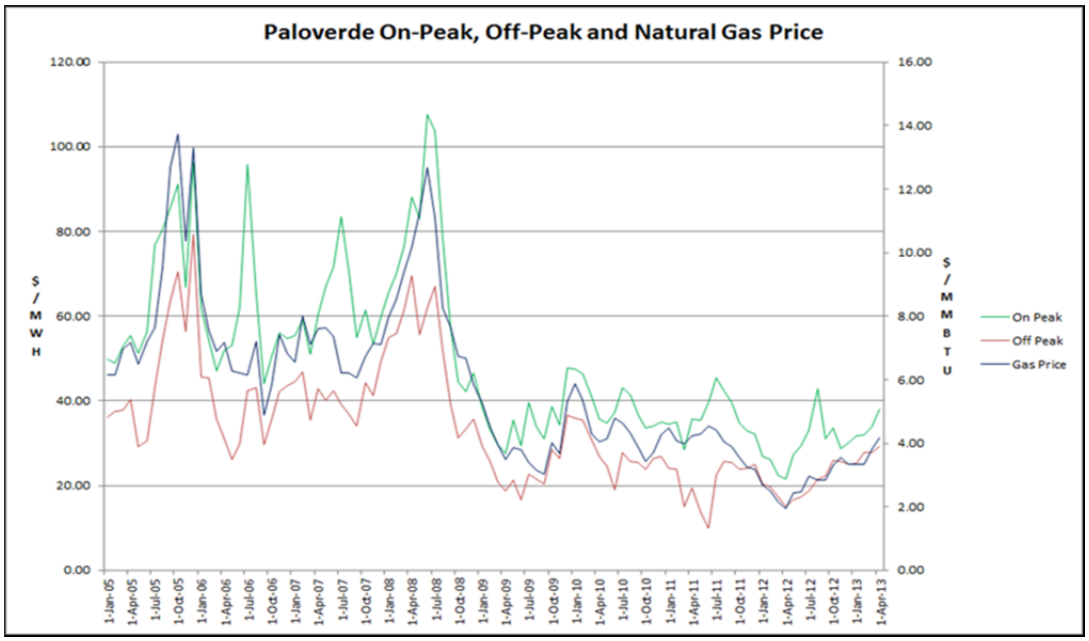

FIGURE K.1-12 Historical Palo Verde On- and Off-Peak Electricity Prices Compared to Natural Gas Prices

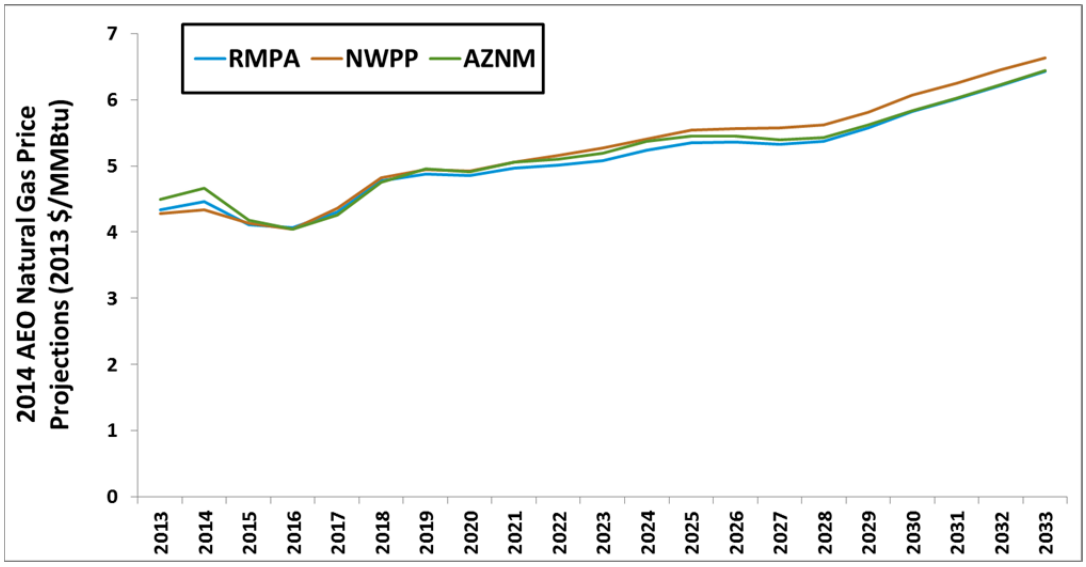

FIGURE K.1-13 2014 AEO (EIA 2014) Projected Delivered Utility Natural Gas Prices

In addition to outages, the spreadsheet incorporates a large number of factors in the determination of firm capacity. As explained in more detail in Section K.1.7, these factors include the following:

- The time of the year the system peak load is projected to occur;
- The probability distribution of the coincidental hydropower peak output potential from SLCA/IP hydropower facilities that consist of all SLCA/IP large and small federal hydropower plants as computed by Glen Canyon Dam GTMax-Lite and the Large SLCA/IP Powerplant Spreadsheet tools;
- Projected ancillary service obligations;
- Projected capacity levels that will be reserved to for project use obligations;
- Expected future system transmission losses; and
- The risk tolerance level associated with SLCA/IP federal hydropower having a lower production capability than the declared firm capacity level during the time of the system peak load.

Firm capacity results vary significantly by alternative and are sensitive to both assumptions regarding the selected risk tolerance level and the month in which the peak load is projected to occur in the future. For the LTEMP EIS, the capacity that is available to the SLCA/IP market system is a fixed amount over the entire study period. Spreadsheet firm

capacity results are input into the AURORA SLCA/IP market system runs that simulate capacity expansion.

K.1.6 SLCA/IP Market System, Data Sources, and Model

The power systems methodology assesses the economic impacts of changes in Glen Canyon Dam Powerplant operations at the systems level using the three-tiered approach briefly described in the Power Systems Geographic Scope section. The middle tier represents SLCA/IP federal hydropower resources marketed and scheduled the CRSP Management Center and all of the utility systems that receive LTF SLCA/IP energy and capacity.

Previous sections described federal hydropower resources and hourly prescribed energy injections into the SLCA/IP market system based on GTMax-Lite model results. This section provides additional information about modeling the loads and resources of CRSP Management Center LTF power customers. There are approximately 129 LTF SLCA/IP wholesale customer entities that are categorized as either large or small. Accounting for about 75% of WAPA's LTF energy and capacity sales, the eight largest customers are Deseret, NTUA, SRP, UAMPS, UMPA, PRPA, Tri-State, and CSU. Except for NTUA, all large LTF customers own and operate generating resources. There are about 130 remaining customers, which are aggregated into east and west "small customer" entities, accounting for the remaining 25% LTF sales. Energy received by a few customers under WAPA LTF contracts are used to serve project use loads such as pumping for irrigation. Figure K.1-3 shows a simplified topology for the SLCA/IP systems that was used by the AURORA model to simulate the capacity expansion pathways and dispatch under each alternative. The following sections describe key model input and modeling assumptions for the SLCA/IP system.

The AURORA model is used to simulate unit commitment scheduling, for resources dispatch, and for capacity expansion in the SLCA/IP market system. Details on model inputs for initial historical conditions and for simulating future operations are provided below.

K.1.6.1 Historical Data Sources

The first year simulated by AURORA is CY 2013. It set initial model conditions based on historical information and serves as a starting point for modeling the future. A considerable amount of data is needed for AURORA to model SLCA/IP market system operations including hourly load data, characteristics of existing powerplants, and firm hydropower contracts that WAPA's customers have with offices other than the CRSP Management Center. Primary data sources for this information include the following:

- EPIS—AURORA database containing general/default power systems data;
- EIA—existing powerplant ownership, capacity, technology type, primary mover, historical delivered fuel prices, plant fuel consumption, historical annual generation;

- ICE and CAISO Web sites—sources of historical day-ahead peak and off-peak electricity prices;

- NERC—power plant maintenance and forced outage characteristics from GADS;

- FERC—historical hourly load data for utilities and BAs;

- Large customer IRPs—a report filed by each of WAPA's customers and contains characteristics of existing power plants, utility system loads, and DSM programs; and

- WAPA—data and information on LTF contracts from the CRSP Management Center and other regional offices from which WAPA customers receive federal hydropower and detailed information on federal hydropower plant and WACM BA operations, including factors related to ancillary services and the transmission system.

The AURORA model uses a database constructed by EPIS that contains Western Interconnection-wide powerplant characteristics, fuel price projections, and hourly load profiles. These data were compared to the aforementioned data sources to verify their accuracy and consistency. Because the methodology calls for WAPA's eight large customers to be modeled in detail, Argonne staff constructed hourly load profiles for SLCA/IP system entities and carefully examined power plant characteristics data contained in the AURORA inventory and benchmark them against data on powerplant characteristics compiled by EIA.

Historical 2013 Loads

SLCA/IP market system loads were generated for three types of LTF customers: large, small, and project use. Project use loads are based on information provided by CRSP Management Center staff. These loads are aggregated into east and west groups and are assumed to be constant over each month. Project use loads are projected to increase over the study period, but are relatively small, ranging from a total project use monthly peak load of 4.15 to 51.42 MW. Project use loads are higher in the summer and lower in the winter.

The power systems modeling effort began at a time when historical FERC Form-714 load data for CY 2013 were not yet available. Argonne staff therefore constructed a time series of CY 2013 hourly loads for each of the eight large customers and for each of the two small customers groups classified as east and west.

Loads for 2013 were constructed by the Loads Shaping Algorithm. For the eight large customers, the algorithm scaled representative nominal hourly shapes to CY 2013 levels such that hourly loads were consistent with projected monthly peak and total load targets. As described previously, CY 2006 hourly load profiles were used as the basis for constructing these

nominalized shapes. CY 2013 load targets were based primarily on information contained in large customer IRPs.

Aggregate small customer loads in the west were based on the UAMPS load profile that was scaled to match 2013 small customer energy data used for retail rate analyses. UAMPS projected growth rates were also applied to the west small customer group. An identical method was used for the small customer group in the east, except in this case load profiles and growth rates for CSU were scaled to match small customer energy targets.

Although Western almost exclusively sells LTF capacity and energy to utilities in its service territory, special arrangements were made to enable Tribal entities to receive SLCA/IP federal hydropower capacity and energy. For 48 Tribes that do not operate their own electric utilities, WAPA made an administrative change to allow them to directly receive an allocation of power through a benefit crediting arrangement. In this benefit crediting arrangement, WAPA delivers the Tribe's allocation to its electric service supplier. Because the SLCA/IP rate is lower than the supplier's production cost, the supplier provides the Tribe with a payment that is equal to the Tribe's electric allocation from WAPA multiplied by the difference in rates. The payment received by the Tribe is the financial equivalent of a direct delivery of electricity. Through this arrangement, Tribes ultimately receive the same services, pay the same rates for both capacity and energy, and abide by the same terms as all other customers. For power systems economic modeling, these financial transactions are not explicitly simulated because the effects on overall system-level economics did not appreciably differ among alternatives.

2013 Powerplant Characteristics and Fuel Prices

Recent data (from 2012 and 2013) on thermal power plant characteristics were obtained from EIA Form-860. This information was coupled with monthly cost and quality fuel deliveries from EIA Form-923 to estimate delivered 2013 fuel prices for each of the thermal powerplants in the unit inventory of WAPA's large customers. Fuel prices for 2013 are typically used. However, when this information is not available, 2012 prices are used as a surrogate. AURORA model generating unit capacity levels vary by month, with generally higher capacities in the winter than in summer months.

In AURORA, delivered fuel prices are not directly assigned to each powerplant in its database. Instead, AURORA applies unit-specific fuel price multipliers to a common price. Henry Hub is used as a price reference point for natural gas, and state-level coal prices are used as coal reference points. The EPIS-supplied representation of the Western Interconnection uses actual and projected monthly natural gas prices at Henry Hub for the year 2010 in terms of nominal 2010 dollars. For power systems analysis, AURORA unit-level delivered natural gas prices are converted to 2013 dollars. Prices at points of delivery are typically higher than the Henry Hub price. Therefore, prices are adjusted to account for delivery costs by applying unit-specific price multipliers in the model. Natural gas prices for 2013 are based on plant delivery costs reported in FERC Form-923. Similarly, 2013 coal prices in 2013 nominal dollars are computed in AURORA by applying unit-level multipliers to state-level prices.

Natural gas prices in AURORA differ by month; generally, prices are higher in the winter as compared to the spring and autumn. These same seasonal trends were used for the LTEMP power systems study. No seasonal changes in coal or distillate fuel prices were assumed; that is, coal and distillate fuel prices are constant throughout 2013.

Only one small oil-fired unit is owned by WAPA's large customers. It is rarely dispatched. No adjustments were made to the EPIS default nuclear fuel price. Only one nuclear plant is partially owned by SRP. It is dispatched as a base load unit, and production levels do not vary significantly among alternatives. Therefore, production cost differences for this plant do not have a significant bearing on economic cost differences among alternatives.

O&M Costs for Existing and Committed Units

Real variable O&M costs for existing units and ones that are committed to be constructed are held static at 2013 levels throughout the study period. Note that real costs exclude inflation; therefore it is assumed that the economic cost of O&M for power production in the future will change at the same rate as inflation. Also, federal Principles and Guidelines (P&Gs) for economic and environmental evaluation of water-related resources precludes the use of speculative projections concerning capital and O&M cost.

Fixed O&M costs only factor into LTEMP EIS economic calculations for capacity expansion units because the retirement schedule of existing units and online dates for committed units do not change among alternatives; therefore the economic difference of these "fixed" costs between Alternative A, which serves as a reference point, and other alternatives is equal to zero. However O&M costs for newly constructed powerplants in the future differ by alternative and are therefore tracked and accounted for in the power systems analysis.

2013 Unit-Level Heat Rates

Documentation in the AURORA model acknowledges shortcomings in the default heat rate data in the EPIS-provided database. It recommends that EIA sources of historical generation data, like Form-923, be consulted to confirm plant-specific heat rates. This information was coupled with monthly powerplant generation and the cost and quality fuel deliveries from EIA Form-923 to generate heat rates and delivered fuel prices for each of the thermal powerplants in the unit inventory of WAPA's large customers. AURORA default heat rates differed by as much as 60% from levels calculated from current EIA data. Therefore, in this analysis heat rates calculated from EIA data replaced AURORA default values. However, EIA data was not reported for some thermal powerplants; in those cases, default AURORA values or surrogate values based on similar type plants were used. Some differences were also found when comparing AURORA default delivered fuel prices with those calculated from recent EIA data. When discrepancies were found, calculated fuel prices were used in this analysis. However, AURORA defaults were used for plants that either had no EIA data or where fuel prices were outside of a reasonable range.

2013 Firm Power Contracts

As described previously, contracts between the CRSP Management Center and its LTF customers are not directly modeled. Instead, power systems economic analyses assume that federal SLCA/IP hydropower plants are supply resources for meeting SLCA/IP system (i.e., large and small customer utility) loads. In addition to SLCA/IP capacity and energy, some customers also receive federal hydropower from other regional offices within the WAPA organization. Information on these non-SLCA/IP contracts was supplied by WAPA. These contracts are modeled in AURORA as virtual hydropower plants, the operation of which is constrained by contract monthly minimum and maximum hourly contract limits and total monthly energy bounds.

In addition to federal contracts, customers have contracts with entities that are either within the modeled SLCA/IP system and/or other Western Interconnection entities that are outside of the SLCA/IP market system. Information on these contracts was ascertained from customer IRPs. Details on these other contracts were typically not available. Therefore, Argonne power system modelers created simple representations of these contracts in AURORA using the information that was available in the IRPs. Contracts are modeled in AURORA as virtual thermal power plants with operating limits.

2013 Renewable Energy Resources (Water, Wind, and Solar)

The AURORA model also includes a representation of existing renewable energy resources. These resources include SLCA/IP system non-federal hydropower and wind and solar Variable Energy Resources (VERs) that produce power and serve system loads. Non-federal hydropower plant resources were modeled as AURORA hydropower plants based on the operating characteristics of the resource (i.e., run-of-river or peaking). For 2013 operations, monthly generation levels were benchmarked to actual levels recorded in EIA Form-923. Power production from VERS is represented as a fixed time series of hourly power injections into the grid using locational profiles provided by EPIS in the AURORA Western Interconnection database.

K.1.6.2 AURORA Model Dispatch Results for 2013

Initial model AURORA model runs of CY 2013 produced results that significantly differed from historical monthly generation levels. Model runs were mainly driven by EPIS input data that was supplied with the model. However, after system representation and input data refinements were made, the model results more closely mimicked historical production patterns. Figure K.1-14 shows that the 2013 AURORA generation profile by fuel type for WAPA's eight large LTF customers is similar to actual 2013 levels as found in EIA Form-923. Generation for hydropower plants by LTF customer utilities exactly match prescribed historical levels.

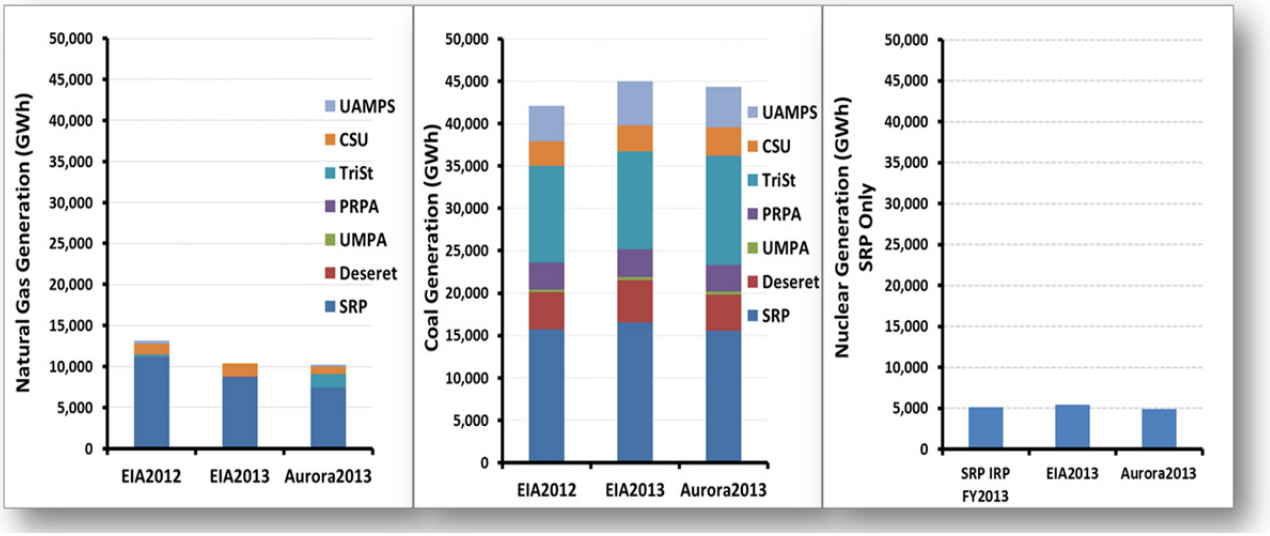

FIGURE K.1-14 Comparison of Modeled and Actual Annual Aggregated Generation Levels (from the EIA) for Natural Gas, Coal, and Nuclear Powerplants under the No Action Alternative

K.1.6.3 SLCA/IP Market System Projections

SLCA/IP market system supply and demand attributes, time value of money assumptions, and projections driving variables such as load growth, delivered utility fuel prices, and new unit technology characteristics play a major role in the development of the system and LTEMP EIS power system results. Projected future developments in the SLCA/IP market system rely on several information sources that include the following:

- Large customer IRPs—future fossil-fuel powerplant additions, VER powerplant planned additions and future expansion goals, and DSM initiatives;

- EIA announced (or committed) new unit additions, 2014 AEO (EIA 2014) candidate technology characteristics, utility fuel price, and load projections as driven by broader forces such as overall U.S. and global macroeconomic developments; and

- WAPA—changes in project use loads and outlooks for future ancillary service requirements.

WAPA LTF customers are required to submit IRPs in order to receive federal hydropower capacity and energy. Information contained in these IRPs was used as a principal source of model inputs for future developments in terms of load growth and resource capacity expansion. However, not all IRPs cover the entire timeframe of the LTEMP EIS study period. Therefore, projections found in the 2014 AEO (EIA 2014) were used to supplement LTF customer IRPs and provide projections that were based on a common and consistent basis.

Load Growth Projections

This section will describe in detail how the hourly loads for the eight large customers and the two groups of aggregate small customers were developed for the years in the LTEMP study period. As noted earlier, small customers were aggregated into an east group or bubble and a west group or bubble.

Developing hourly loads was a three-step process. First, historical hourly load data was gathered for each utility to be modeled. Second, a historical year was selected that best represented the load profiles of all years for which data was collected. The year selected had the best matches to both the average weekly load factor and the average annual load factor across all years. Third, the Hourly Load Forecast Algorithm was used to generate hourly load profiles for all future years for each utility. The model scaled hourly loads so they followed the profile of the representative year and at the same time also match forecasted monthly peak and total monthly energy for each utility modeled.

To find the representative historical year, hourly loads were collected from each large customer for the years 2006 to 2009. The data were compiled by FERC in Form-714 and are publicly available via software downloaded from the FERC Web site (available at http://www.ferc.gov/docs-filing/forms/form-714/view-soft.asp). These years were chosen because they were the only recent set of years for which complete annual datasets were available for all eight customers. For more details on load data collection, see Attachment K.7.

Small Customer Loads. As noted earlier, small customers were aggregated into an east bubble and a west bubble. Staff from WAPA assisted Argonne in classifying whether small customers should be placed into the east or west bubble. In general, small customers in Colorado, New Mexico, and Wyoming were put into the east bubble, while small customers in Arizona, Nevada, and Utah were put into the west bubble. Small customer load shapes were based on the representative year from one of the eight large customers. For small customers in the east bubble, the profile from CSU was used; for small customers in the west bubble, UAMPS was used. UAMPS is in the western part of the CRSP Management Center customer territory and is comprised of many cooperating small customers. Therefore, it was judged that UAMPS load shape was representative of small customers in the west bubble. CSU is a municipal utility in the eastern part of WAPA's service territory; therefore, its load shape was used to represent small customers in the east bubble. These load shapes were scaled to match their estimated historical total load based on information that was collected for the retail rate payer analysis described in Section K.3.

Representative Load Shape. After collecting the historical data, total hourly coincidental loads were computed for the eight large utilities for the 2006 through 2009 time period. A weekly load factor (WLF) was calculated for each week in each year for which FERC Form-714 data were available. An average weekly load factor (AWLF) across all years was also calculated. Then the sum of the squared differences (SSD) between the WLF and the AWLF was calculated using the equation SSD (WLF) = $\sum$ (WLF-AWLF).^{2} A similar calculation was

performed to find the SSD between the annual load factor (ALF) for each year and average annual load factor (AALF) across all years or SSD (ALF) = $\sum$ (ALF-AALF)^2. The sum of the squared differences (squared errors) for both the WLF and ALF were then summed. CY 2006 had the smallest errors and therefore was selected as the representative year for all customer loads because it had the smallest sum, which indicated that, among all years, its relative shape was the closest to the average. Using a common year for all utilities correctly captures load diversity among the utilities, including those resulting from large-scale weather patterns.

After selecting the representative year, the Hourly Load Forecast Algorithm was used to generate hourly load profiles for future years for each of the eight large LTF utilities and for each small customer bubble. Inputs into the algorithm were the utility's hourly load profile for the representative year and the forecasted monthly peak load and energy for each future year. Based on the data that were available, a load forecast was generated using a customized method for each utility. The following describes the method used to generate each load forecast.

Salt River Project

1. Historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. Total annual energy for 2012 was specified in the 2013 IRP (SRP et al. 2012). From 2013 to 2033, the annual energy was assumed to grow at the same annual rate as the total electricity sales forecast for the Southwest region of the Western Electricity Coordinating Council in the 2014 AEO (namely, Table 91 in EIA 2014)).

3. Annual peak loads for 2012 to 2016 were specified in the 2013 IRP (SRP et al. 2012). From 2017 to 2033, the peak load was assumed to grow at the same annual rate as used for the total annual energy shown above (namely, the data from Table 91 of the early release of EIA 2014).

Navajo Tribal Utility Authority

1. The historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. Annual peak loads and energy for 2012 to 2030 were obtained from the October 2012 IRP (NTUA 2012).

3. Annual peak loads and energy for 2031 to 2033 were calculated using the same growth rate as 2030.

UMPA

1. The historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. Annual peak loads and energy for 2012 to 2033 were obtained from the IRP 5-year plan (UMPA 2013).

UAMPS

1. The historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. UAMPS staff provided historical monthly energy and peak demand data for 2011 to 2013 (Anderson 2014).

3. There were no growth forecasts in the UAMPS IRP (UAMPS 2013), so the same growth rates were assumed for annual peak and energy as those provided in the UMPA IRP for 2014 to 2033. Members of UAMPS were assumed to have similar energy demand profiles as members of UMPA.

Deseret

1. The historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. Annual peak loads and energy for 2012 to 2018 were obtained from the IRP update (Deseret 2012).

3. From 2019 to 2033, the annual peak load and energy were assumed to grow at the same rate as the total electricity sales forecast for the Rocky Mountain region of the Western Electricity Coordinating Council in the 2014 AEO (namely, Table 94, in EIA 2014).

Tri-State Generation and Transmission Association

1. The historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. Annual peak loads and energy for 2012 to 2029 were obtained from the IRP (Tri-State 2010).

3. Annual peak loads and energy for 2030 to 2033 were assumed to grow at the same rate as 2029.

Colorado Springs Utility

1. The historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. Annual peak loads and energy for 2012 to 2031 were obtained from the IRP (CSU 2012).

3. Annual peak loads and energy for 2032 to 2033 were assumed to grow at the same rate as 2031.

Platte River Power Authority

1. The historical hourly load profile for 2006 was used. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from 2006.

2. Annual peak loads and energy for 2012 to 2020 were obtained from the IRP (PRPA undated).

3. Annual peak loads and energy for 2021 to 2033 were assumed to grow at the 5-year average growth rate from 2016 to 2020.

Small Customer—West

1. The historical 2006 hourly load profile for UAMPS selected as representing small customers in this bubble.

2. Data was collected for 2012 on retail energy sales from EIA Form-861 and summed for all small customers in this bubble.

3. The annual load factor for UAMPS was assumed to be representative of this small customer group. The annual peak load for 2012 was computed from the retail energy sales in 2012 and the UAMPS load factor.

4. Annual peak loads and energy for 2013 to 2033 were assumed to grow at the same rate as for UAMPS.

5. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from the 2006 UAMPS load profile.

Small Customer—East

1. The historical 2006 hourly load profile for CSU selected as representing small customers in this bubble.

2. Data for 2012 was collected on retail energy sales from EIA Form-861 and summed for all small customers in this bubble.

3. The annual load factor for CSU was assumed to be representative of this small customer group. The annual peak load for 2012 was computed from the retail energy sales in 2012 and the CSU load factor.

4. Annual peak loads and energy for 2013 to 2033 were assumed to grow at the same rate as for CSU.

5. The monthly peak loads and energy were based on the ratios of monthly peak to annual peak and monthly energy to total annual energy from the 2006 CSU load profile.

Peak and total load growth rates may be different, resulting in future load profiles that are either more or less "peaky" in the future relative to historical levels. Also, both peak and total load growth rates differ among individual large utilities and for small customer aggregates. Using this method allows the model to grow loads and transform load shapes uniquely for each profile as reflected in IRPs' long-term trends.

Figures K.1-15 and K.1-16 show stacked bar charts of customer non-coincidental monthly peak load and total monthly load projections, respectively. As described in sections that follow, projections of the eight large customer system summer peak load is particularly significant. Any reduction in Glen Canyon Dam Powerplant capacity as a result of more stringent operating criteria does not incur an economic cost until all of the excess capacity in the system is fully depleted. The year in which this occurs is heavily dependent on large customer utility system load growth. Attachment K.6 contains more detailed results for individual large customers and for the two aggregate small customer bubbles.

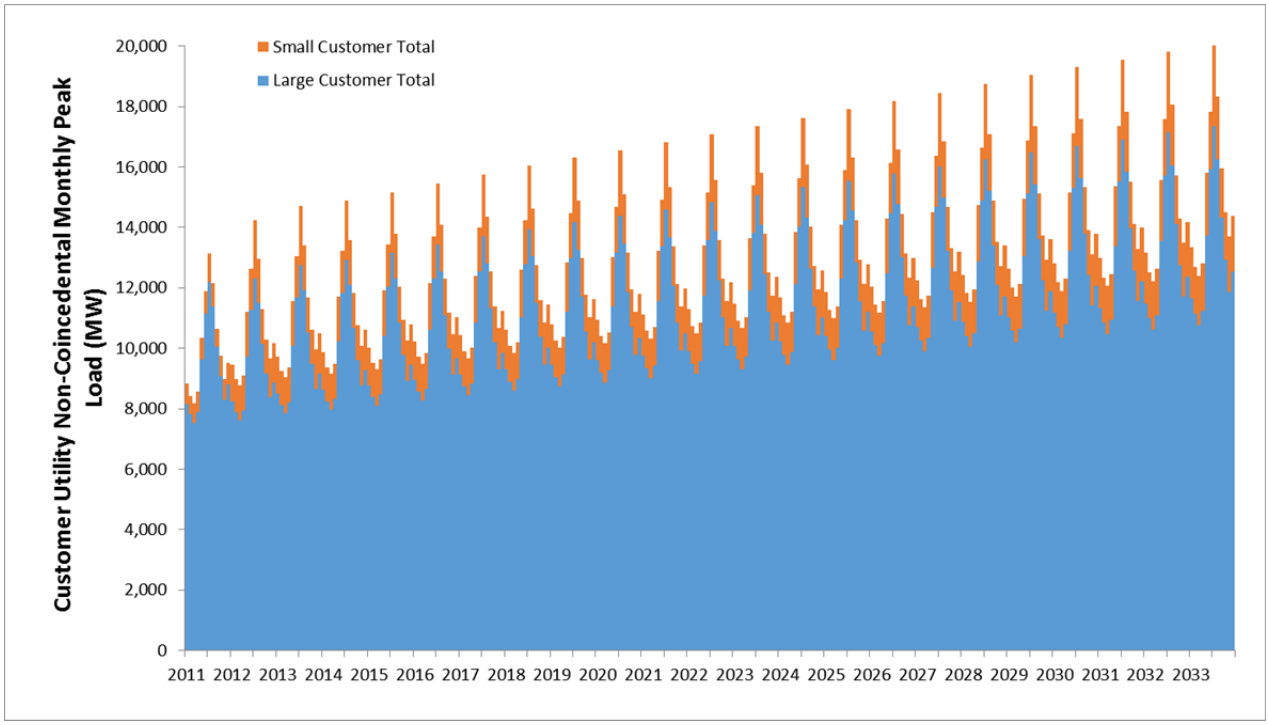

FIGURE K.1-15 Total Non-coincidental Peak Loads for the SLCA/IP Market System

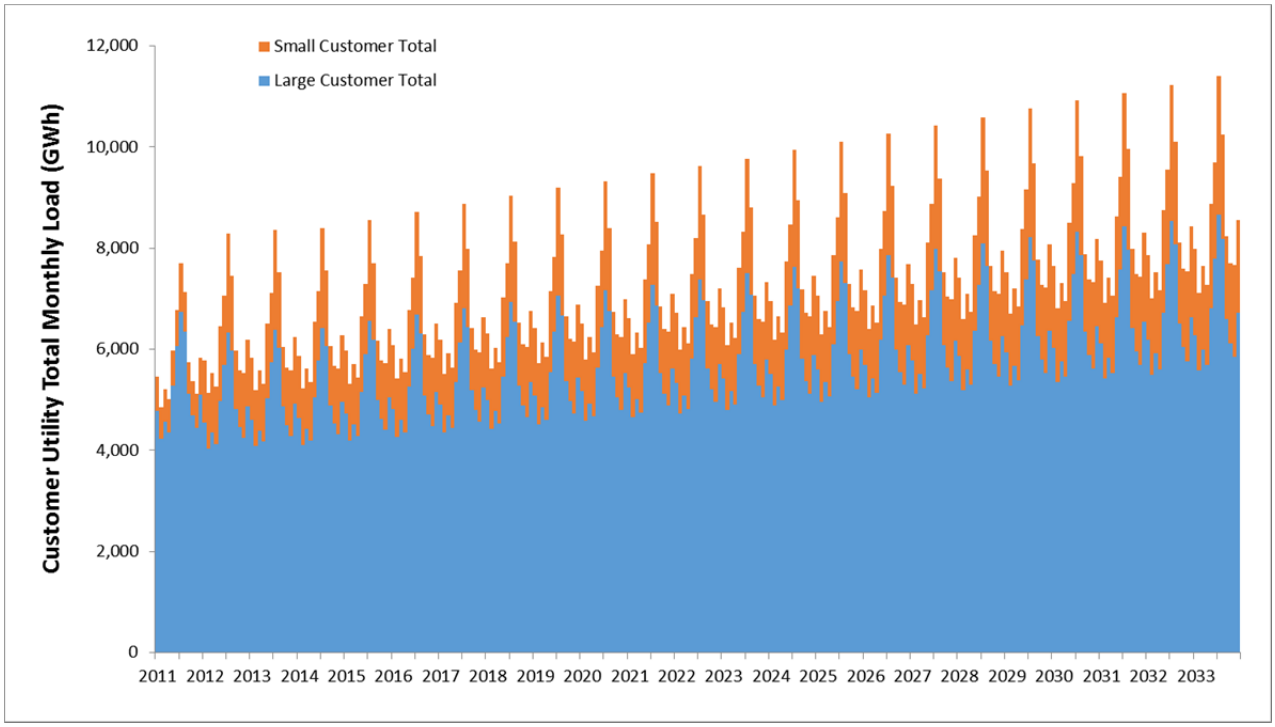

FIGURE K.1-16 Total Monthly Loads for the SLCA/IP Market System

Capacity Expansion Candidate Unit Characteristics

To reliably meet the forecasted increases in electricity demand and to replace powerplants that will be retired during the study period, new powerplants will be constructed in the SLCA/IP market system.

Argonne staff used the AURORA model to create system capacity expansion paths and unit retirement schedules for utilities in the SLCA/IP system for each of the EIS alternatives. As described previously, AURORA uses detailed unit-level information about existing and committed generating units owned and operated by WAPA's LTF customers. The model also includes information about candidate units that could be built in the future. The type and number of new technologies added over time was determined by Argonne staff by tunneling AURORA model capacity expansion runs. In this context, "tunneling" refers to restricting the number of possible model solutions to a smaller set of capacity expansion possibilities (e.g., restricting the number of possible new gas-turbines built in a specific year and location [i.e., bubble], to one to three units instead of the model default of zero to unlimited new units). This technique is often used in capacity expansion planning when the number of combination of expansion technologies is otherwise enormous. It often requires multiple iterative model runs as the user explores different tunnel boundaries such that the solution is not bounded by the user-defined limits. Capacity is constructed such that the capacity reserve margin of the aggregate eight large customers never drops below 15%. Table K.1-1 shows the cost, in terms of 2013 dollars, and performance characteristics of a suite of candidate plants from which the AURORA model could choose to expand capacity of the power system.

Note that the list of candidate technologies input into the AURORA model includes a range of types and sizes. The model "builds" units taking into account load growth, costs, and technology attributes, including the size of each candidate. AURORA makes a trade-off between building large units with economies of scale (lower $/MW cost for large units) that often leads to excess capacity that may persist for a few years, versus building several small ones that better follow capacity needs (smaller excesses) but are more expensive to build in terms of $/MW.

Expanding capacity for the aggregate customer group leads to a lower cost as opposed to building capacity for each individual utility. By doing so, customers take advantage of economies of scale and lower amounts of new capacity. The sharing of new capacity can be accomplished via joint unit ownerships and long-term firm capacity agreements among customer utilities.

Expansion candidates were selected from the suite of new central station electricity generating technologies in the 2014 AEO (EIA 2014). The suite includes conventional and advanced thermal units and renewables. Performance characteristics in the table include unit capacity, heat rate, and fuel type, and cost characteristics include capital costs, fixed and variable O&M costs, book life of the unit, and number of years it takes to construct. Costs are shown as a range because WAPA's customers are located in three different geographic regions identified by the EIA 2014 AEO (EIA 2014) electricity market module; each has powerplant-specific labor multipliers. Different labor multipliers were factored into the powerplant costs from EIA depending upon where the plant would be located. Labor costs vary by region where the plant is

TABLE K.1-1 Cost and Performance Characteristics of Capacity Expansion Candidates

Expansion Candidate Technology	Capacity (MW)	Heat Rate (Btu/kWh)	Fuel Type	Unit Book Life (yr)	Construction Lead Time (yr)	AFUDC (% of overnight cost)	Levelized Capital Cost (2013$/MW/yr)		Fixed O&M Cost (2013$/MW/yr)		Variable O&M Cost (2013$/MWh)	
							Min	Max	Min	Max	Min	Max
Scrubbed Pulverized Coal	600	8,800	Coal	30	4	9.83	194,080	197,146	31,491	31,982	4.51	4.59
Integrated Gasification Combined Cycle	550	8,700	Coal	30	4	9.83	250,755	253,980	52,015	52,684	7.31	7.40
Conventional Combined Cycle	300	7,050	Natural Gas	30	3	7.26	59,953	60,429	13,456	13,563	3.68	3.71
Advanced Combined Cycle	400	6,430	Natural Gas	30	3	7.26	66,931	67,407	15,708	15,825	3.34	3.37

Source: EIA (2014).

constructed; a regional multipliers table is located on the EIA Website (http://www.eia.gov/forecasts/capitalcost).

Overnight capital expenses and fixed O&M costs are based on 2014 AEO (EIA 2014) data and expressed in 2012 dollars. AEO documentation indicates that these costs are applicable to new units built in 2014 and later. It is assumed that these costs will not change in real terms; therefore, capital costs for a specific technology in real terms do not change as a function of online date. The AEO costs do not include expenses paid by plant owners that are plant specific and can vary significantly between two virtually identical plants in the same geographic region. Therefore, financing-related costs are excluded from AEO capital costs, and items like insurance, property taxes, asset management fees, and energy marketing fees are excluded from AEO fixed O&M costs (EIA 2013). The AEO cost values were converted to 2013 dollars using the "Powerplants" index contained in the "Bureau of Reclamation Construction Cost Trends" table (Reclamation undated). The values for January were used because it was assumed that new plants came online at the beginning of the year. Fixed O&M costs were converted to 2013 nominal dollars using this same table, except in this case the "Powerplant Accessory elect. & misc. equip" index was used. Variable O&M costs for new construction are converted to 2013 nominal dollars based on the producer price index (PPI) for "Electric power transmission, control, and distribution energy production" (series ID code pcu22112-22112-) (BLS undated).

In the AEO, capital costs are shown as an "overnight" cost, which is an estimate of the cost at which a powerplant could be constructed assuming that the entire process from planning through completion could be accomplished in a single day. However, in reality a plant takes several years to construct. Money borrowed or committed to a project during its construction must be repaid with interest. The term for this expenditure is allowance for funds during construction (AFUDC). Because capital costs from the 2014 AEO (EIA 2014) for expansion candidates were overnight costs, they did not include AFUDC. Therefore, these additional expenditures were added to the overnight capital cost before the capital costs are levelized. Calculation of AFUDC assumes that a certain percent of the total overnight cost is borrowed at regular intervals during construction. The time series of expenditures is often referred to as an "S curve" of capital spending. The time series of expenditures from the S curve coupled with the interest rate of the borrowed money and the time period over which it is borrowed yields the amount of interest paid per dollar or as the amount of AFUDC as a percent of the overnight cost.

AFUDC is estimated for each technology using a spreadsheet model. For this study, a Weibull distribution was used to represent the S curve of capital spending and the interest rate assumed was 4.28%. Table K.1-1 shows the amount of AFUDC as a percent of the overnight cost. It estimates interest payments monthly using a blended average of long-term taxable and municipal bond rates, which are estimated using information from several sources including the following:

1. WM Financial Strategies (undated)

2. Bloomberg Business (undated)

3. BondsOnline (undated)

Assumed construction times used for the study period were also obtained from the 2014 AEO (EIA 2014). The average projected bond rate in real terms (i.e., actual quoted levels less projected inflation) is expected to vary slightly over time. As a simplification, an annual average bond rate of 4.28% was used regardless of when construction begins. This is the average rate over the 2017 through 2033 time period. It should be noted that during this time period the weighted average annual bond rate fluctuates between 4.16% in 2033 and 4.39% in 2019; that is, a range of only 0.23%.

It should be noted that in order for the power systems analysis to be consistent with other LTEMP resource study areas, the analysis period and assumed implementation date of all alternatives is assumed to occur retroactively. Therefore, in order to best capture the economic impacts of an alternative, capacity replacement for lost Glen Canyon Dam Powerplant capacity may be brought online in the model sooner than what may be physically possible.

Capital costs used for this analysis are similar to those recommended by Energy and Environmental Economics, Inc. (E3), for WECC 10- and 20-year planning studies (E3 2014). Similar to this study, E3 used AEO new powerplant construction cost information as the basis for its recommendations to WECC. However, E3 used data from the 2013 AEO, while this analysis used more recent data contained in the 2014 AEO (EIA 2014). The costs between the two sources were slightly different. Overnight capital costs for the two key technologies selected by AURORA for SLCA/IP market system expansion are somewhat lower in the 2014 AEO (EIA 2014) compared to the 2013 AEO; costs are 5.2% less for advanced combustion turbines and 7.6% less for advanced natural gas combined cycle plants.

E3 also used a method similar to that used in this study by adjusting overnight capital costs to account for additional expenditures like AFUDC. The AFUDC multipliers applied by Argonne are slightly greater than those used by E3. For example, Argonne used an IDC multiplier of 1.0476 for advanced combustion turbines, while E3 used a multiplier of 1.035. For advanced natural gas combined cycle technologies, Argonne used a multiplier of 1.0983 while E3 used a multiplier of 1.068.

Finally, the levelized cost of capital plus fixed O&M cost used in Reclamation's (2007a) *Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead* (Interim Guidelines EIS) is consistent with levels used in this study. For a natural gas combined cycle plant, the total cost presented in that EIS was $75,800/MW-yr (in 2007$; i.e., approximately $83,400/MW-yr in 2013$). In comparison, this study uses a levelized capital cost of capital plus fixed O&M that, depending on location, ranges between $82,639/MW-yr and $83,232/MW-yr. No other technologies were considered in the Interim Guidelines EIS; therefore, a comparison cannot be made for the combustion turbine technology.

In an email response (James 2014) sent to LTEMP co-lead agencies following the March/April 2014 Stakeholder Workshop, the Colorado River Energy Distributors Association (CREDA) suggested using capital cost data from a document published by the Electric Power Research Institute (EPRI 2013). In this document, the overnight capital cost of a natural gas–fired combined cycle plant was shown to have a range of 900 to 1,150 $/kW (in 2011$); the lower cost unit used wet cooling and the higher cost dry cooling. The wet cooling value was

similar to the value from the 2014 AEO (EIA 2014), which also assumed wet cooling. When AFUDC was added, the cost range became 1,025 to 1,325 $/kW, which equates to an AFUDC multiplier of about 15% above the overnight cost. This multiplier is substantially more than AFUDC multipliers used by either Argonne or the E3 report. The EPRI report did not provide a rationale for using such a high multiplier. The discount rate assumed by the EPRI study was also greater than the one used by Argonne (i.e., 5% vs. 4.28%, respectively).

CREDA supplied its own capital cost estimate for a natural gas–fired combined cycle plant because it believed that the EPRI data did not fully account for higher elevations and harsher ambient conditions that exist in CREDA member service regions. The capital cost given by CREDA ranged from 1,130 to 1,426 $/kW. It was assumed that AFUDC was included in these capital costs, but assumptions about calculating the AFUDC were not given. Therefore, we were unable to compare Argonne's and E3's assumptions to CREDA's.

CREDA also supplied an estimate of levelized cost for the natural gas–fired combined cycle plant; the cost range was 108,000 to 132,000 $/MW-yr. This cost was based on actual Southwest utility experience. Although CREDA did not state the exact discount rate used to determine the levelized cost, it did acknowledge it was greater than 5%. However, based on the capital cost range in units of $/kW that CREDA supplied, its discount rate would be approximately 6.25%, which is substantially higher than the discount rate used by Argonne.

The economic cost to build a new generating unit and the financial outlays that a utility incurs to build a new generating unit are fundamentally different. For example, utility outlays for taxes and insurance are excluded from an economic analysis because these are transfer payments that are not part of the cost of construction. These costs, however, are important for a utility and therefore are key financial elements in utilities' cost calculation. Also, the EIA costs used in this study are typical values that are adjusted for broad regional construction costs such as material and labor. These data are not utility- or site-specific, which would take into account other factors such as the availability of cooling water. Although these considerations are important for a specific site, more generic/typical values are applied for this analysis. For example, it is assumed that a natural gas combined-cycle (NGCC) unit would be constructed at a site where there is sufficient cooling water to operate the facility, thereby eliminating the need to build expensive dry cooling technologies.

Generating Unit Operating Cost and Fuel Price Projections

This section will describe how fixed O&M costs of expansion candidates generating plants were projected into the future and will also describe how fuel prices for both existing and new generating plants were projected.

Variable O&M Costs for Existing and Committed Units. The AURORA model default database currently contains unit-level estimates of variable O&M costs for the year 2010 in terms of nominal 2010 dollars. These costs are converted to 2013 nominal dollars based on the PPI for "Electric power transmission, control, and distribution energy production" (series ID code pcu22112-22112-) (BLS undated). This equates to an increase in nominal cost of approximately 6.9%, which is reflected in AURORA inputs, thereby affecting unit-level total power production cost.

Future Natural Gas Prices for Existing Units. Unit delivery multipliers are adjusted for future time periods to be consistent with anticipated real price projection changes forecasted regionally by the 2014 AEO (EIA 2014). The cumulative percent increase in natural gas prices are provided in Table K.1-2. Note that all multipliers in the table are relative to the 2013 price.

TABLE K.1-2 Cumulative Annual Percentage Increase in Natural Gas Prices at the Henry Hub[a]

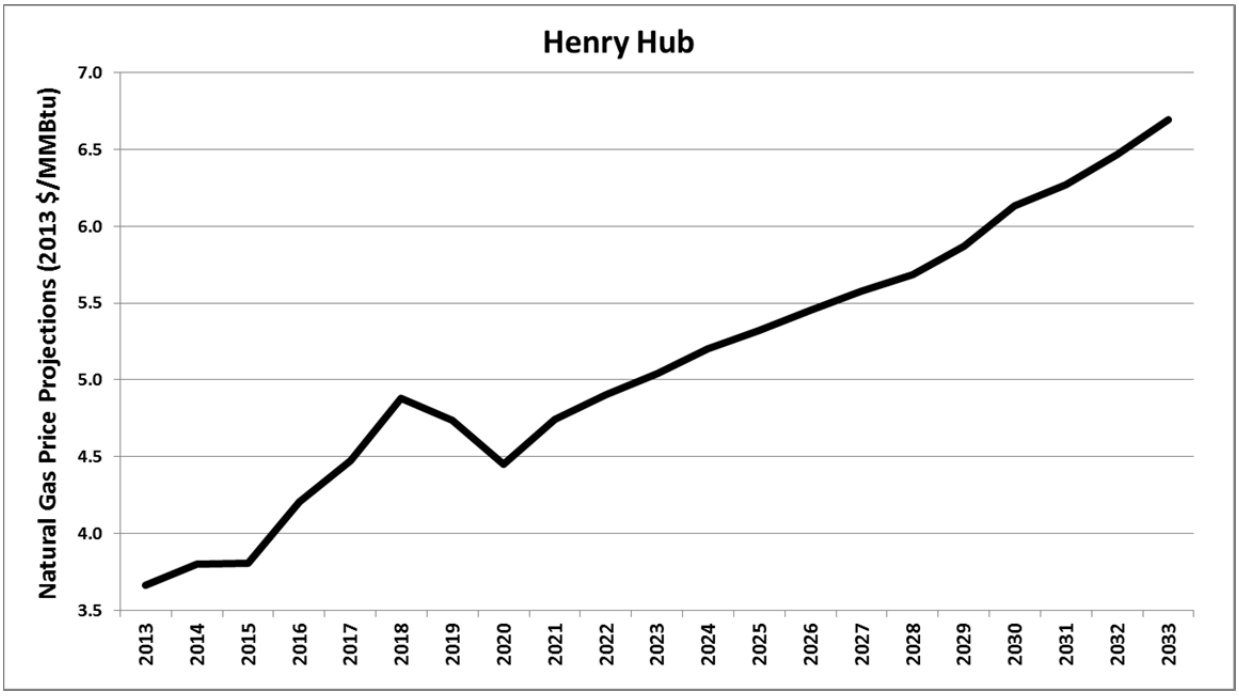
Year	Percentage Increase
2014	3.7
2015	3.9
2016	14.9
2017	22.2
2018	33.2
2019	29.3
2020	21.5
2021	29.5
2022	33.9
2023	37.6
2024	42.1
2025	45.3
2026	48.8
2027	52.3
2028	55.3
2029	60.4
2030	67.5
2031	71.3
2032	76.5
2033	82.8

[a] Natural gas prices are highly volatile, and prices may have changed by the time the EIS was published.

Future Natural Gas Prices for New Expansion Units. Future natural gas prices for new units constructed by AURORA model expansion plans are specified by bubble and duty cycle. These prices are linked to the absolute real 2013 price levels and price changes over time that are consistent with the 2014 AEO (EIA 2014) prices shown in Figure K.1-17. Prices can also vary by technology type. The 2014 AEO (EIA 2014) price projections are specified in terms of 2012 dollars. These were converted to 2013 dollars using the GNP IPD based on the GNP IPD for January 2013 relative to January 2012 GNP IPD (see http://research.stlouisfed.org/fred2/data/GDPDEF.txt).

Natural gas prices in AURORA differ by month; generally, prices are higher in the winter as compared to the summer. In the AURORA EPIS default database, this monthly price pattern is most distinct (i.e., relatively large price range during the year) in early forecast years and gradually diminishes over time. These same seasonal trends were used for the LTEMP power systems study.

Future Coal Prices for Existing Units. AURORA base coal prices are entered at the state level and change annually. Unit delivery coal price multipliers are adjusted for future time



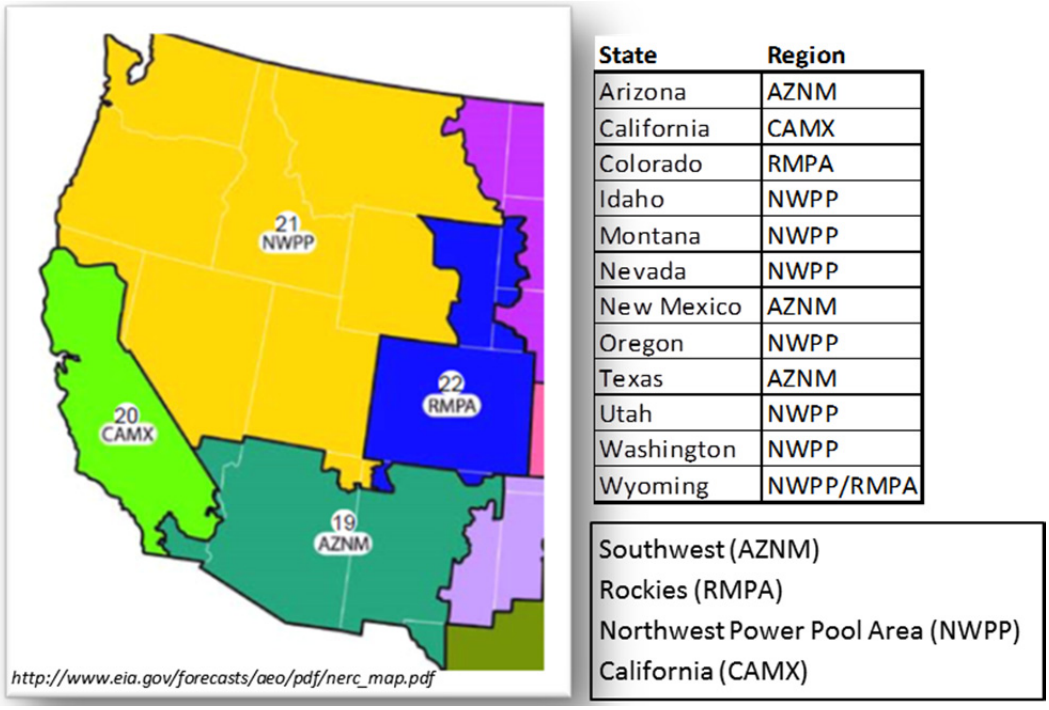


FIGURE K.1-17 Projected 2014 AEO (EIA 2014) Natural Gas Prices at the Henry Hub (Note that natural gas prices are highly volatile, and prices may have changed by the time the EIS was published)

periods to be consistent with anticipated real price projection changes forecasted regionally by the 2014 AEO (EIA 2014) electricity market module shown in Figure K.1-18. Regional multipliers are shown in Table K.1-3.

Multipliers are applied at the unit level, depending on the state in which it resides. Therefore, as shown in Figure K.1-18, states were paired with the AEO regions. Because Wyoming is split between two regions, an average of the two was used.

Future Coal Prices for New Expansion Units. Future coal prices for new units constructed by the AURORA model expansion plan are specified by bubble (i.e., large customer) and duty cycle. These are consistent with absolute real-price levels and changes over time projected by 2014 AEO (EIA 2014), as shown in Figure K.1-19. The 2014 AEO (EIA 2014) price projections are specified in terms of 2012 dollars which are converted to 2013 dollars using the GNP IPD.

Future Distillate Fuel Oil for Existing Units. Future delivered price multipliers are adjusted for future time periods to be consistent with anticipated real price projection changes forecasted regionally by the 2014 AEO (EIA 2014). Regional multipliers are shown in Table K.1-4.

State	Region
Arizona	AZNM
California	CAMX
Colorado	RMPA
Idaho	NWPP
Montana	NWPP
Nevada	NWPP
New Mexico	AZNM
Oregon	NWPP
Texas	AZNM
Utah	NWPP
Washington	NWPP
Wyoming	NWPP/RMPA

FIGURE K.1-18 2014 AEO (EIA 2014) Electricity Market Module Regions and the Mapping of States to Regions

Future Nuclear Fuel Price for Existing Units. EPIS-supplied nuclear fuel prices and projections were used for power systems modeling. As previously noted, there is only one nuclear plant in the SLCA/IP market system whose production levels do not vary significantly among alternatives.

Renewable Resource Projections

Future renewable resource additions are built by the model such that each utility complies with information included in its IRP. One simplification is that a utility employs a single type of renewable generation to serve future load in each state (namely, solar for Arizona and New Mexico and wind for Utah and Colorado).

K.1.7 Glen Canyon Dam Powerplant Capacity Cost and Benefit Methodology

The difference between the firm capacity level of Alternative A and the firm capacity level under a specific alternative is the amount of additional capacity that will eventually need to be built. It is referred to as lost Glen Canyon Dam capacity and will be replaced at some point in the future by one or more entities in the SLCA/IP market system, which consists of WAPA and its LTF customers. The economic costs of this lost firm capacity is based on the capital and fixed O&M costs that would be expended to construct and operate new units that replace it. The amount of replacement capacity that would need to be built is dependent on several factors, including the level of current and committed system resources, future annual system peak loads, and system reliability criteria. Economic impacts are measured for the system as a whole, where system-wide capacity expansion pathways are simulated and associated costs are computed for each alternative. A time series of costs differences relative to Alternative A is then computed and expressed as a single NPV for each alternative. Capacity replacement costs include capital investment for new capacity plus fixed O&M costs for operating the newly constructed units.

K.1.7.1 Treatment of Glen Canyon Dam Capital and Fixed O&M Costs

The Glen Canyon Dam and Powerplant were constructed between June 1960 and September 1966. Preceding the construction of the dam, diversion tunnels were dug and a coffer dam was built upstream to divert water from the main dam construction site (see http://www.usbr.gov/uc/rm/crsp/gc/history.html). All of the capital costs to build the dam and powerplant were incurred in past. Therefore, the economic costs of these past expenditures are treated as sunk investments under all alternatives; that is, economic costs for building the dam and powerplant are set equal to zero because past expenditures cannot be altered. Furthermore, it is assumed that any additional capital investment in the dam and powerplant that will be incurred in the future is unaffected by an alternative. It therefore follows that capital investment differences among alternatives is also zero. Similarly, Glen Canyon Dam fixed O&M costs are assumed to be unaffected by all of the alternatives. It is also assumed that the total physical 1,320 MW of nameplate capacity at Glen Canyon Dam is identical under all LTEMP EIS alternatives and that the capacity of all powerplant units will not change over the study period.

Past Glen Canyon Dam construction costs and interest expenses are paid by WAPA SLCA/IP LTF customers through WAPA's firm energy and capacity rates. Revenues from the sale of CRSP power are deposited in the U.S. Treasury. These power revenues also pay for irrigation assistance, O&M costs, salinity control, and environmental programs. CRSP power revenues have funded more than $287 million of costs associated with environmental programs in the Grand Canyon. Of this amount, Glen Canyon Dam environmental experiments recommended through the Glen Canyon Dam Adaptive Management Program have cost $63.3 million since 1992.

K.1.7.2 WAPA's SLCA/IP LTF Obligations and Glen Canyon Dam Replacement Capacity

Currently, Glen Canyon Dam capacity primarily benefits SLCA/IP LTF customers. Through its marketing program, WAPA currently sells customers bundled SLCA/IP federal hydopower resources, not individual plants. For power systems analysis, firm capacity is therefore determined for the entire system, based on the coincidental sum of maximum daily energy outputs from all SLCA/IP federal hydropower facilities and other factors such as those described in the Firm Capacity Spreadsheet section (Section K.1.5.11). For the LTEMP EIS, Argonne conducted a study of WAPA's SHP commitment levels over the last 10 years; the study is described later in this appendix, in the Firm Capacity Risk Level section. The study found that capacity has historically been marketed such that 90% of the time WAPA's 11 SLCA/IP federal hydropower plants had sufficient maximum operating capabilities to meet customers' total peak requests for energy within the bounds specified by SLCA/IP LTF contracts. This same 90% level is used to determine the firm capacity under all of the alternatives. However, in the future WAPA may choose to market capacity at either a higher or a lower risk level.

Operating criteria differ by alternative in terms of the distribution of monthly water release volumes during a WY and the level of operating flexibility that is allowed at Glen Canyon Dam. Both affect the maximum output level that the Glen Canyon Dam Powerplant is

allowed to deliver during times of SLCA/IP market system peak load. The difference between the Alternative A capacity and the capacity under another specific alternative is the amount of additional capacity that will eventually need to be built above the Alternative A capacity expansion plan. This lost capacity will be replaced at some point in the future by one or more large SLCA/IP LTF customer utilities. For the purposes of economic impacts, it is assumed that the identification of the entities that replaces this lost capacity is inconsequential. As stated previously, this is an economic analysis that measures the net cost difference for the system as a whole, not a financial analysis of individual entities (e.g., a utility company) that operate within the system.

The wholesale rate and retail rate studies that are presented in Sections K.2 and K.3, respectively, discuss potential impacts on individual entities within the SLCA/IP market system. The wholesale rate study also discusses rates under a scenario in which WAPA replaces lost capacity, as well as another scenario in which WAPA makes capacity and energy obligations based on the chronological capabilities of SLCA/IP federal hydropower resources. The latter scenario requires that SLCA/IP LTF customers replace the lost capacity.

K.1.7.3 WAPA SLCA/IP Firm Hydropower Capacity

Argonne used several tools and models of varying levels of detail and complexity to estimate SLCA/IP federal hydropower plant firm capacity levels; that is, the maximum power output that system operators can usually, but not always, rely upon to meet peak loads. Argonne also developed capacity expansion paths for each alternative and associated costs for the SLCA/IP market system. An expansion path describes the timing and type of new units that will be built in the future. It is based on a host of factors such as SLCA/IP firm capacity, the system capacity reserve margin goal, projected fuel prices, the characteristics of existing powerplants, and peak load growth.

Firm capacity is based on the coincidental sum of maximum daily energy outputs for all SLCA/IP federal hydropower facilities. The method used varies by powerplant size and operating criteria. Figure K.1-20 lists SLCA/IP federal hydropower facilities grouped by size. The figure also provides information on the models, parameters, and data used for estimating firm capacity.

The entire physical capacity of SLCA/IP federal hydropower resources is not available to meet LTF customer loads. Instead capacity is reserved for other purposes. As shown in Figure K.1-21, some of these purposes include capacity set aside to serve project use loads such as pumping for irrigation, replacing transmission losses, providing spinning reserves, and performing regulation services. A more detailed description of these components is provided next.

From an operational standpoint, the capacity that is reserved for these purposes is known with a relatively high degree of certainity. However, at any single point in the future, the impacts of unit outages, reservoir elevation, and enviromental operating critera on hydropower resource capacity are highly variable and cannot be predicted without forecast error. Therefore, SLCA/IP

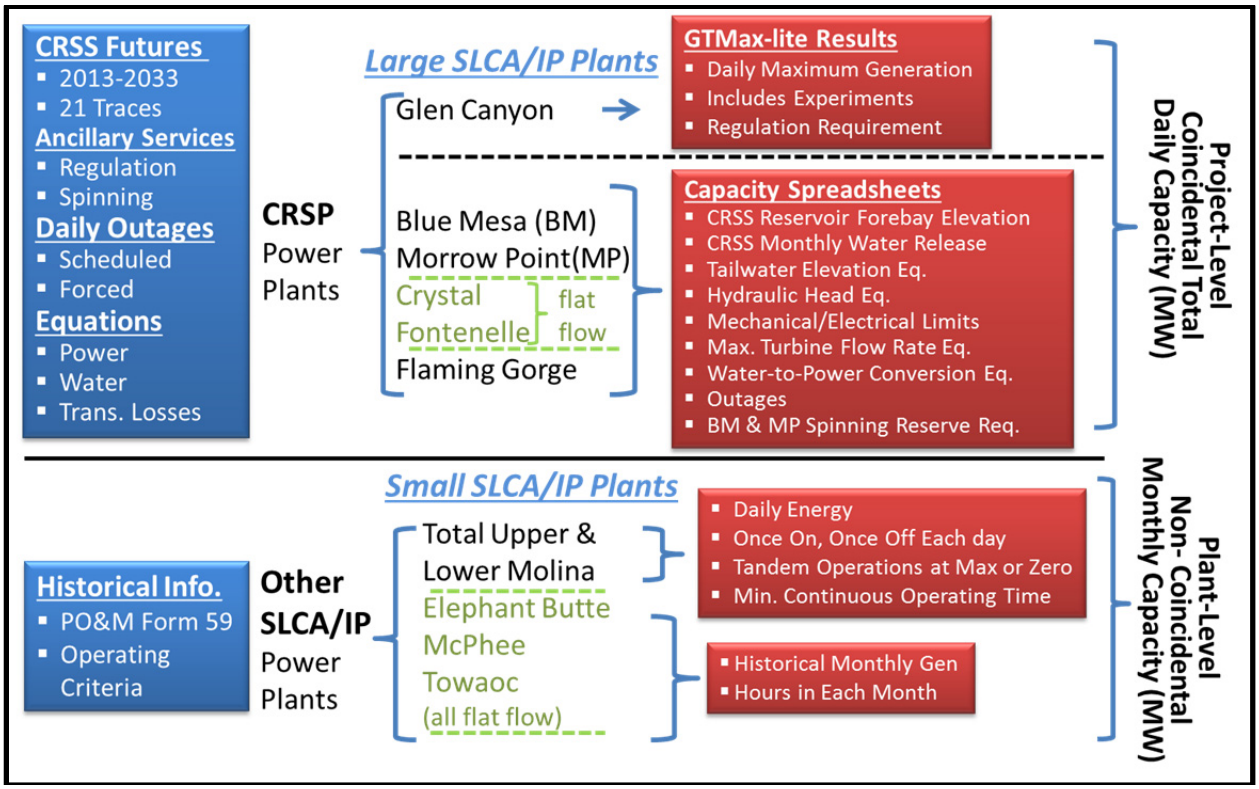

FIGURE K.1-20 WAPA SLCA/IP Hydropower Powerplants

federal hydropower resources are exposed to risks because the future of both reservoir conditions and the operating state of generating units are not known with certainty. This risk level is directly related the amount of firm capacity that is assumed (that is, the lower the amount of firm capacity, the lower the risk). The power systems methodology uses a probabilistic approach to quantify this risk.

Project Use Loads

WAPA has an obligation to serve project use loads such as pumping for irrigation. These loads are also given a high priority in LTEMP power system models; that is, these loads must be satisfied before other SLCA/IP market system loads are served. Summary data that describes project use obligations was obtained from the CRSP Management Center. These obligations were transformed into hourly "flat" load vectors. During the study period, one new project use load will come online: the Navajo-Gallup Water Supply Project. From discussions with CRSP Management Center staff, it was determined that there would be additional project use loads from this project of 5 MW load in 2018, 2023, 2024, and 2029, for a total increase of 20 MW. Loads are assumed to be identical for both capacity and energy economic analyses. In addition, these loads are assumed to be unaffected by alternative.

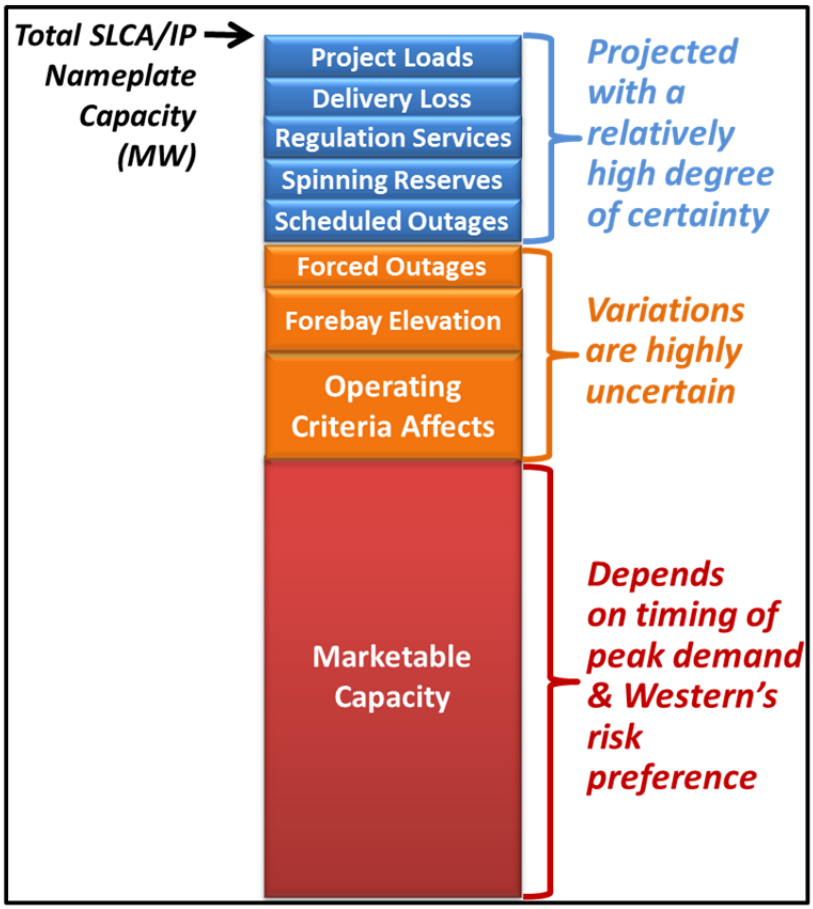

FIGURE K.1-21 SLCA/IP Federal Hydropower Capacity Uses and Variability Factors

Delivery Losses

Energy is lost in the process of transporting energy from SLCA/IP federal hydropower generation points to points of energy delivery. Under current accounting practices, which were established after system consolidation measures were implemented, transmission system losses are set to 5% (Scheid 2015). Therefore, it is assumed that marketable capacity that is delivered to customers is reduced by this same percentage. For example, when the Fontenelle Powerplant produces its maximum output of 10 MW, it is assumed that only 9.5 MW is delivered to demand points; that is, for accounting purposes, 0.5 MW is lost during the transmission process. As described in section K.1.3.2, 5% losses for SLCA/IP energy deliveries are also accounted for in AURORA model capacity expansion and dispatch simulations.

Ancillary Services

As part of its power pool agreements, WAPA has an obligation to provide ancillary services. SLCA/IP resources provide regulation reserves and fast spinning reserves. As shown in

Table K.1-5, both of these ancillary services are projected to increase by up to 80 MW. The maximum requirement is reached in 2025 for regulation reserves and in 2030 for fast spinning reserves. A total of 160 MW of ancillary will then be maintained from 2030 into the foreseeable future. Estimates of future ancillary service levels were provided by Reclamation based on a discussion with WAPA staff in May 2013.

TABLE K.1-5 Assumed Ancillary Services Provided by SLCA/IP Hydropower Facilities from 2013 to 2030

	Ancillary Services (MW)		
Year	Fast Spinning Reserves	Regulation Reserves	Total
2013	43	60	103
2014	45	62	107
2015	47	63	111
2016	50	65	115
2017	52	67	118
2018	54	68	122
2019	56	70	126
2020	58	72	130
2021	60	73	134
2022	63	75	138
2023	65	77	141
2024	67	78	145
2025	69	80	149
2026	71	80	151
2027	73	80	153
2028	76	80	156
2029	78	80	158
2030+	80	80	160

Figure K.1-22 shows how the methodology used for this study explicitly reduces the operating range of plants that provide one or more ancillary services. A plant's hourly maximum output is reduced by the level of regulation service and spinning reserve provided. In addition, when providing regulation services, the minimum generation level is also increased by the level of regulation service provided. Note that under current power pooling agreements, a powerplant simultaneously provides identical levels of up and down regulation. Based on discussions with power system operators, the priority for ancillary services provided by SLCA/IP federal hydropower resources is as follows. The first priority is to serve both regulation services and spinning reserves at Glen Canyon Dam. However, if the Glen Canyon Dam Powerplant has insufficient capacity to serve both or doing so would increase Glen Canyon Dam non-power water releases, spinning reserves will be off-loaded to powerplants located in the Aspinall Cascade and, if absolutely necessary, followed by regulation services.

When Glen Canyon Dam serves regulation services, it instantaneously fluctuates above and below a fixed generation set point. For example, when the hourly set point is 500 MW and regulation services is 60 MW, generation will go to a minimum of 440 MW when regulating down and go up to a maximum of 560 MW when regulating up. Based on conversations with EMMO staff, the net energy generated to provide regulation over a 1-hour time period is very close to zero; that is, instantaneous fluctuations in generation above and below the generation set point sum to zero. In the example above, 500 MWh of generation would be generated during the hour.

Because water release restrictions at Glen Canyon Dam are specified in terms of average hourly flow rates, and not instantaneous limits, regulation services can continue to be provided when releases are at an environmental flow rate limit. For example, a powerplant's generation can be set for an hour to a level that exactly releases the minimum water flow rate requirement. When providing regulation services during this hour, instantaneous flow rate will sometimes be lower than the environmental "hourly rate" minimum (regulating down), but these low flows will be offset by instances when it is higher than the minimum flow (regulating up).

Regulation services will affect the operating range at Glen Canyon Dam. The sum of the regulation service plus the operational set point cannot exceed the physical maximum MW output of the *entire* powerplant. The maximum physical output of the plant is dependent on the number of units that are operational and Lake Powell's water elevation. At the other extreme, the set point operation minus regulation service cannot be less the minimum operating limit of a *single* Glen Canyon Dam unit.

Spinning reserves only affect the maximum set point at Glen Canyon Dam. Under normal operating conditions, this spare or reserved capacity is not utilized. However, events such as a unit forced outage or downed power lines may result in a sudden grid energy imbalance; that is, there is not enough energy production to serve load. To overcome this deficiency, spinning reserves are deployed and one or more powerplants increase output to return the system to a balanced state as quickly as possible.

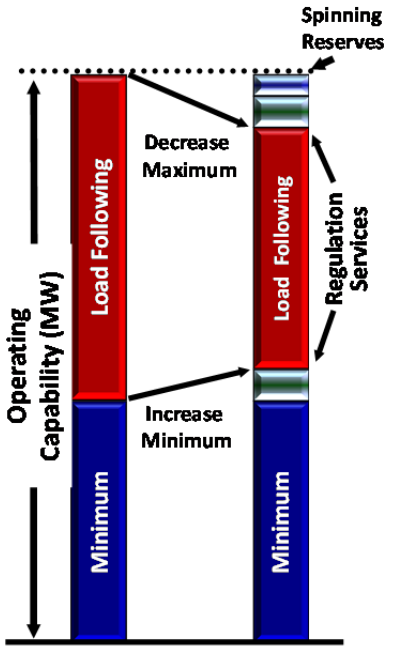

FIGURE K.1-22 Reductions in Operating Range when Providing Ancillary Services

When spinning reserves are deployed at Glen Canyon Dam, the powerplant very quickly ramps up production by a maximum of 60 MW. Under these conditions, the water release up-ramp is allowed to exceed environmental operating limits. Glen Canyon Dam "emergency exception criteria," which are stipulated under all alternatives, allows Glen Canyon Dam to operate outside of minimum and maximum flow limits, daily changes constraints, and both maximum hourly up- and down-ramp rates in the event of a power system emergency (e.g., grid energy imbalance events). However, similar to regulation services, the set point generation level plus the spinning reserve service cannot exceed the physical maximum MW output of the *entire* plant. As shown in Figure K.1-22, when both ancillary services are being served, the sum of set point, regulation, and spinning reserves cannot exceed then maximum output capability of the plant.

The economic cost of providing ancillary services at Glen Canyon Dam varies by alternative, such that the greater the operational flexibility is, the higher the cost of serving regulation and spinning reserves will be. Under flat flow alternatives, ancillary services do not typically affect the operating range because there is no flexibility in the system. On the other hand, ancillary services at times bind (i.e., lower) the maximum output level at Glen Canyon Dam. These binding events occur when the monthly water release volume allows for a relatively large daily operating range and a higher base flow. Glen Canyon Dam unit outages and lower reservoir elevations exacerbate the economic impacts of this constraint by essentially lowering the maximum physical output of the plant.

The time series of ancillary service projections shown in Table K.1-5 was used in GTMax-Lite model runs that determine differences in capacity and energy value among LTEMP EIS alternatives. Glen Canyon Dam currently supplies a total of 67 MW of ancillary services,

and this is not expected to increase during the LTEMP study period. Therefore, a sensitivity study was performed to determine how firm capacity levels will change if a different ancillary services schedule is used. The sensitivity study and results are reported in Section K.1.10.8.

Outage

All of the SLCA/IP hydropower resources undergo both scheduled and forced unit outages, during which times a unit either produces no output or produces at a level that is lower than its full capability; that is, the capacity is temporarily de-rated. Maintenance is normally performed during a scheduled outage, while forced outages typically occur at random, and are precipitated by the failure of one or more unit/plant components.

For the LTEMP study, the Reclamation provided Argonne with unit-level maintenance schedules for the six largest SLCA/IP facilities over the study period. When a unit is taken out of service for maintenance, the maximum output of that unit is set to zero in all pertinent modeling processes, including both versions of GTMax-Lite and spreadsheet tools that estimate maximum physical output levels at large SLCA/IP hydropower resources other than Glen Canyon Dam.

To represent unit forced outages at large SLCA/IP powerplants, a methodology was developed to incorporate the number, cause, and duration of forced outages that may potentially occur during the study period. Data on forced outages for hydroelectric turbines were obtained from the GADS. This database is maintained by NERC and contains operating information on electric generating equipment. GADS data were input into an algorithm that produces a plausible series of random outages for units at the Glen Canyon Dam Powerplant. Using a different set of random draws for each run, the forced outage model performed numerous simulations. The run that produced the most representative time series of outages in terms of matching overall GADS statistical averages was selected. It should be noted that the forced outage model only represents full unit outages. It therefore does not directly represent partial outages. However, the model uses equivalent outage statistics that implicitly account for these types of outages. For example, if a unit is de-rated by 25% over a 6-month time period, the equivalent outage rate would be 12.5%. Details of the forced outage algorithm and methodology are described in Attachment K.5.

Scheduled and forced outages are not explicitly modeled for small SLCA/IP federal hydropower resources. However, outages are reflected in the model to the extent that unit down time is reflected in Form PO&M-59 data, which is ultimately used to model small federal hydropower facilities. For example, if the McPhee unit was down for an entire month, a zero generation level would be reported by Form PO&M-59 for that month, which would affect the results produced by the Small SLCA/IP Powerplant Spreadsheet model. Although this methodology is not the most accurate modeling approach, it should be noted that the total small facilities capacity is less than 3% of the entire SLCA/IP federal hydropower capacity. Therefore, modeling errors were judged by Argonne staff to be negligible.

Maximum Power Plant Output, Forebay Elevations, and Monthly Releases

The surface water elevation in a reservoir affects both hydropower maximum possible output level and the amount of water that needs to be released through a turbine to produce a unit (MWh) of energy. For the large SLCA/IP hydropower resources, end of the month reservoir elevations, also referred to as forebay elevations, were projected using Reclamation's CRSS and the SBM models.

Because EIS alternative operating criteria affect monthly Glen Canyon Dam water releases, and therefore Lake Powell water elevations, CRSS and SBM make separate projections for each alternative. Future hydrology conditions are not known with certainty; therefore, the CRSS model projected 105 possible outcomes at the end of each month throughout a 2013 through 2060 time period, inclusive. Although 48 years of monthly outcomes were projected, only the first 21 calendar years (20 water years) were used for analysis in the EIS. Each outcome, also known as a "trace," is based on a unique historical series of hydrological conditions. Therefore, hydrological conditions are deterministic and it is extremely unlikely that any one trace will ever be repeated. Of these 105 traces, a common set of 21 was used by all EIS research areas.

Using this information, the GTMax-Lite model is used to optimize the hourly operations of the Glen Canyon Dam such that is maximizes the economic value of energy. As described previously, GDC GTMax-Lite runs were performed twice. The first provides input to the SBM and the second run accommodates experimental releases using altered SBM monthly water release volumes and reservoir elevations. Hourly operations are projected over the entire time period for all 21 traces for each alternative. Daily maximum daily generation levels from Glen Canyon Dam GTMax-Lite output for all alternatives and traces are stored for use by the Firm Capacity Spreadsheet.

The maximum monthly physical output levels for the other five large SLCA/IP hydropower resources were computed over the entire study period for all 21 CRSS traces. Each powerplant's maximum possible output level is based on the following set of conditions, limits, and equations;

1. Mechanical/electrical turbine capacity limit;

2. Unit operating status (either operating or out of service);

3. Reservoir elevation as a function of water storage;

4. Maximum turbine water release as a function of head (forebay minus tailwater elevations);

5. Tail-water elevation as a function of maximum flow rate; and

6. The water-to-power conversion factor that is a function of reservoir forebay elevation.

In order to solve for the above set of relationships, an iterative process is used to converge all interdependent relationships to a consistent set of values. Interdependencies occur because the tailwater elevation is a function of the turbine flow and the turbine flow is a function of the system head, which is the difference between the tailwater and reservoir forebay elevations. In addition, the total turbine flow rate, and therefore tailwater and head, depend on the number of units that are operating. End-of-month reservoir forebay elevation levels that are used in the dispatch process for the other five large SLCA/IP hydropower plants are obtained from the CRSS model.

The physical maximum output level for the small SLCA/IP federal hydropower plants was set to the nameplate capacity. However, for small run-of-river hydropower plants, historical maximum output levels are based on the MWh of energy that a plant produced during a month divided by the number of hours that occurred during the month. The maximum output is typically achieved only at the Molina units.

Operating Criteria Effects on the Maximum Output Level

In addition to physical limitations, operations at all SLCA/IP hydropower plants are required to remain within a set of institutional and environmental limitations. For power systems analysis, SLCA/IP modeled operations are restricted by three types of limitations. These include (1) reservoir operating restrictions, (2) reservoir water release constraints, and (3) downstream gage stage and water flow limitations. Each of these affects the maximum daily output level. Depending on the situation, operating criteria do not allow a powerplant to reach its maximum physical output potential.

Glen Canyon Dam. The impact of operating criteria on Glen Canyon Dam maximum output levels is both complex and situational, involving not only the criteria, but also other factors such as the ancillary service requirements, monthly water release volumes, Lake Powell Reservoir elevation, and the number of operational units. End-of-month Lake Powell Reservoirs were obtained from the SBM.

To provide accurate estimates of the operating criteria on Glen Canyon Dam maximum output levels, Argonne optimized its hourly dispatch using a configuration of the GTMax-Lite model that only models Glen Canyon Dam. The GTMax-Lite model incorporates all environmental constraints imposed on Glen Canyon Dam from the current operating regime, such as restrictions on reservoir water release up/down ramp rates, minimum and maximum hourly release rates, and flow rate changes over a rolling 24-hour period. It also includes a projected maintenance schedule provided by Reclamation and a set of random unit forced outages. When physically possible and economically advantageous, the Glen Canyon Dam Powerplant also has ancillary service requirements, which, as discussed above, can impact Glen Canyon Dam's operational range.

For Glen Canyon Dam, the daily capacity level is set to the maximum output level that was modeled each day by GTMax-Lite. Although all operating criteria at Glen Canyon Dam

potentially affect the maximum output potential, the daily change constraints in combination with water availability typically are the most binding. In addition to the aforementioned operating criteria, HFEs also affect capacity.

Aspinall Cascade: Blue Mesa, Morrow Point, and Crystal Dams. The Aspinall Cascade is operated as a tightly coupled, multipurpose system with a total nameplate capacity of approximately 283.4 MW. Plants in the cascade include Blue Mesa, Morrow Point, and Crystal. At the top of the cascade (i.e., highest elevation), the Blue Mesa Powerplant operates in a peaking mode. Located 12 mi downstream from Blue Mesa, the Morrow Point Power Dam is in the middle of the cascade. When tour boats operate in the Morrow Point Reservoir, there is a minimum reservoir elevation requirement of 7,151 ft. In addition, the Morrow Point Reservoir cannot be drawn down by more than 3 ft per rolling 24-hour period if the surface elevation is below an elevation of 7,144 ft. When tour boats are not operating, the minimum reservoir elevation is 7,125 ft.

The Crystal Powerplant is at the bottom of the cascade. In addition to functioning as a power generation unit, its operations stabilize the flow of water through Gunnison National Park. The flat flow requirement precludes it from rapidly changing its power output from one hour to the next. Operating criteria for the Crystal Reservoir are season specific. During the wet season (March 1 to June 30), the operating criteria limit reservoir drawdown to no more than 4 ft in a 24-hour rolling period, 5 ft over a 48-hour rolling period, or 6 ft over a 72-hour rolling period, and so on. In addition, once an elevation of 6,748 ft is reached, the reservoir level may not drop by more than 0.5 ft per 24-hour rolling period. During the remainder of the year, there is a 10-ft-per-24-hr-period fluctuation limit, with a maximum 3-day drawdown of 15 ft. If the reservoir elevation is below 6,733 ft, there is a 5-ft-per-24-hr-period drawdown limit, with a maximum drawdown of 20 ft per 7-day period.

Cascade reservoir restrictions can at times affect the hourly dispatch of powerplant units. However, for the LTEMP EIS, it is assumed that these operating criteria do not affect the maximum output level that can be achieved at the Blue Mesa and Morrow Point. Generation at both of these powerplants can be ramped up or down from a zero output level to maximum capability in a matter of minutes without adverse effects on the power equipment. In addition, the plants are scheduled in advance, so reservoirs can usually accommodate water releases associated peak powerplant output levels without violating reservoir operating criteria. Therefore, it is assumed that Blue Mesa and Morrow Point maximum output levels are limited only by the reservoir level and the number of units that are in service as described in the Forebay Elevation section above.

The Crystal Dam however has a flat flow requirement that precludes it from rapidly changing its power output from one hour to the next. Therefore, the maximum output level from this plant is assumed to equal the monthly generation at the plant divided by the number of hours in the month.

Green River: Fontenelle Dam and Flaming Gorge Dam. The Fontenelle Powerplant also releases water at a constant rate (or flat flow), and output levels are nearly constant during daily operations. Therefore, maximum output level from this plant is assumed to equal the monthly generation at the plant divided by the number of hours in the month.

Operations at Flaming Gorge Dam are subject to set of complex limitations that affect maximum daily capacities. These include a minimum flow rate of 800 cfs, a maximum up-ramp rate of 800 cfs/hr, and a down-ramp rate limit of 1,000 cfs/hr. Water releases are further constrained to a constant rate (i.e., flat flow) in the summertime during the hours of the day when people are likely to be fishing below the dam. In keeping with current practices, the computation of Flaming Gorge capacity assumes the following:

1. The daily water release volume is the same for all days of a month;

2. The hourly water release pattern is identical each day of the week;

3. There is a one-hump release pattern during the summer; and

4. There is flat flow in summer between the hours of 6:00 AM and 7:00 PM (i.e., a duration of 13 hr every day).

The trapezoidal methodology utilized in the Large Plant Capacity Spreadsheet is illustrated in Figure K.1-23. It applies simple geometric equations to estimate Flaming Gorge base and peaking capacities using daily water release volumes and reservoir elevations derived from CRSS model results. The base capacity is computed by multiplying the 800 cfs minimum flow requirement by a water-to-power conversion factor that is a function of hydraulic head. It requires a significant volume of base load water to be released each day (i.e., constant 800 cfs release over a 24-hour period).

The water volume that remains after sustaining the daily base release is used to estimate peaking capacity as the height of a trapezoid. The length of the top of the trapezoid is 13 hr (i.e., fishing duration) and length of its bottom/base is equal to 13 hr plus the up and down ramping times. As shown in Figure K.1-24, these ramping times increase as a function of peaking water volume and subjected to a total time limit of 11 hr (i.e., 24 hr less the 13 hr flat flow period).

Furthermore, the sum of the base load and peaking capacities cannot exceed the total physical turbine flow limit multiplied by the water-to-power conversion factor, as described in more detail in the Forebay Elevation section; both the maximum turbine flow limit and the power conversion factor are a function of the hydraulic head. The total turbine water release, and therefore the maximum output level, is reduced when turbines are taken offline due to a scheduled or forced unit outage at Flaming Gorge. The results of performing trapezoidal computations over a large range of daily water volumes are shown in Figure K.1-25. This relationship between daily water volume and maximum turbine flow rate is fairly accurately described by a sixth order polynomial. Multiplying the maximum flow rate by the water to power conversion factor yields a capacity estimate.

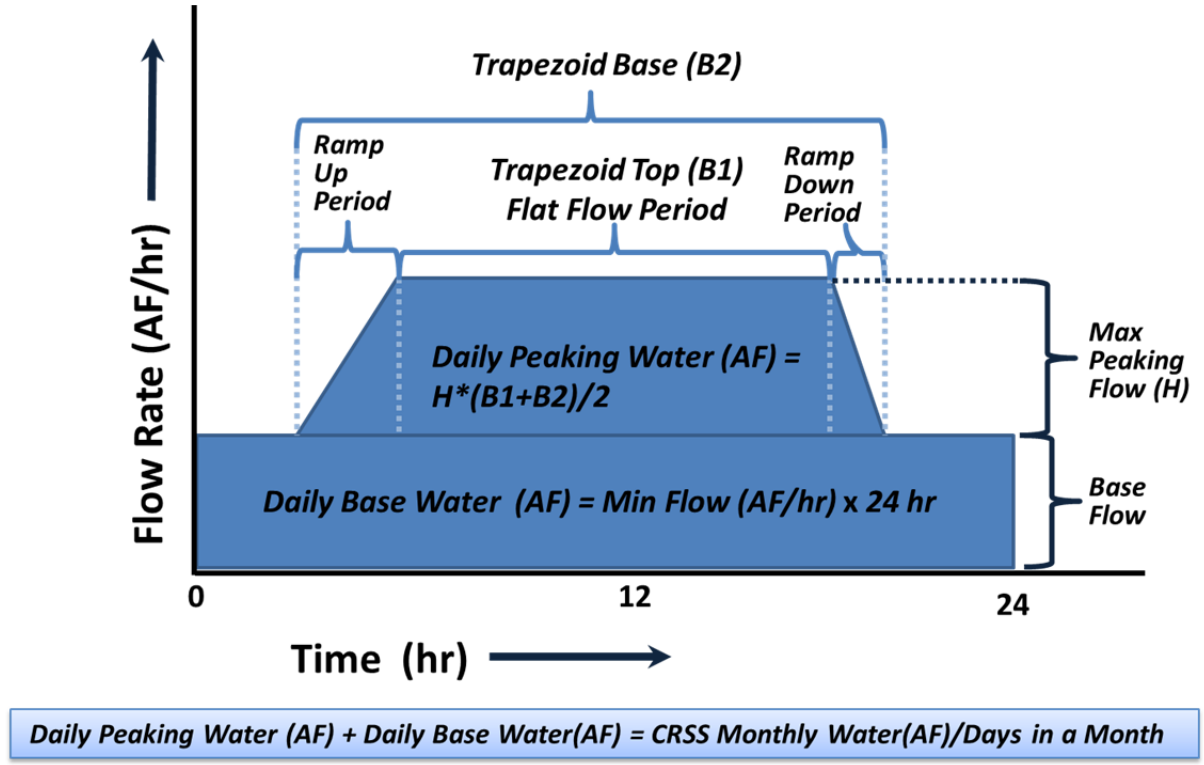

FIGURE K.1-23 Illustration of the Trapezoidal Method Used to Compute Capacity at Flaming Gorge Dam

To protect endangered native fish in the Green River basin, the U.S. Fish and Wildlife Service released a biological opinion (FWS 1992) designed to protect the Colorado Squawfish and Razorback Sucker. The overall intent of the opinion was to structure releases from the Flaming Gorge reservoir so that they resemble natural hydrograph and water temperature conditions. A final set of restrictions was implemented in WY 2006 following completion of a final EIS on the operation of Flaming Gorge Dam (Reclamation 2005) and issuance of its ROD (Reclamation 2006) in February 2006.

High spring release volumes are being structured to enhance river flows during spring spawning periods. Flow volumes include full powerplant output (approximately 4,500 cfs or 141 MW) to full plant output plus bypass tubes and spillways combined. The high release period could be held for as long as 4 weeks. The actual volume and duration of release from Flaming Gorge is determined by the river volume desired on the Green River below the Jensen measurement gage at Jensen (or Jensen Gage) and inflow support from the Yampa River. The high spring release is patterned around the peak runoff period, which varies each year based on weather conditions and endangered fish spawning activities. High peak spring releases transfer water that historically was released during summer and winter peak months to spring months. This shifting of water among months of the year is factored into CRSS model runs that provide input data into the Large Plant Capacity Spreadsheet.

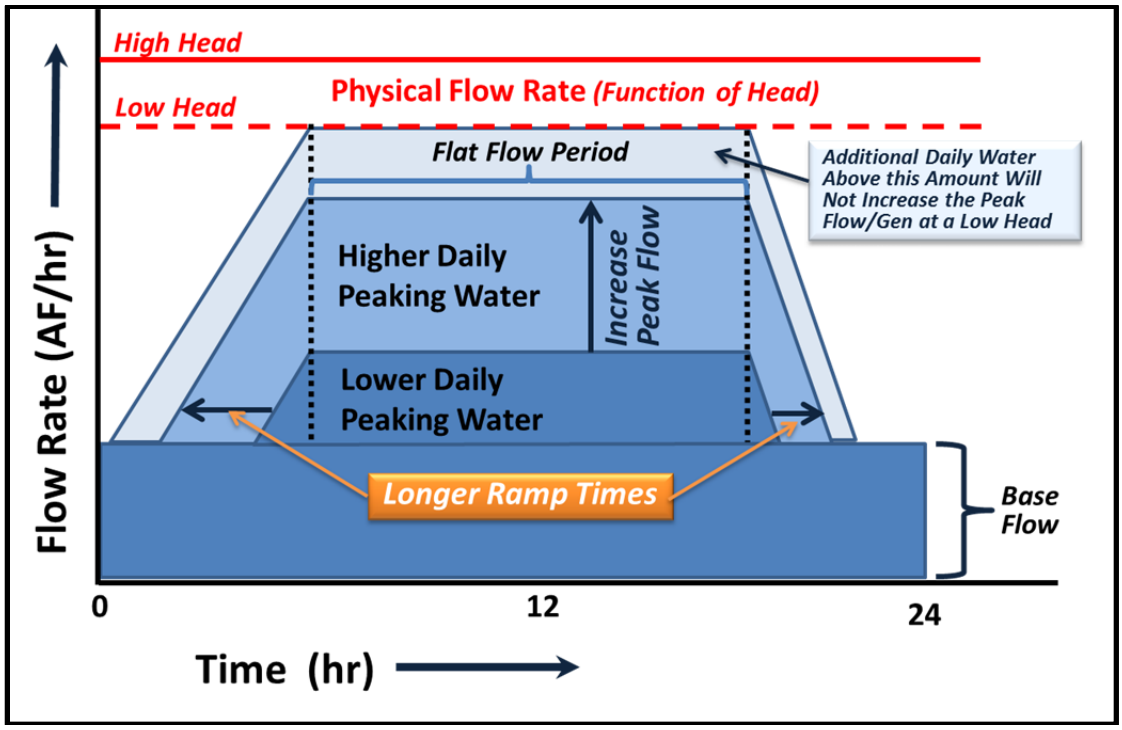

FIGURE K.1-24 Illustration of Ramping Time Increase as a Function of Increasing Water Volumes at Flaming Gorge Dam

After the high spring release is completed, flows on the Green River below the Jensen Gage are held to an average of 1,600 cfs, if possible. The gage is about 94 mi downstream of the reservoir, receiving water not only from Flaming Gorge but also from the uncontrolled Yampa River, which joins the Green River approximately 65 mi downstream of the dam. This means that releases from the Flaming Gorge power plant are held to a minimum of 800 cfs (25 MW) until a time when the combined average flows on the Green and Yampa rivers below Jensen fall below the desired level of 1,600 cfs average. This powerplant restriction can last from 3 to 8 weeks, depending on snowpack conditions.

Flaming Gorge operations must also be patterned such that daily stage readings at the Jensen Gage do not fluctuate by more than 0.1 m. These stage readings are a function of hourly water releases from Flaming Gorge, inflows into the Green River from the Yampa River (105 km [65 mi] downstream of the dam), downstream flow rate attenuations, and water travel times. Although the influence of Jensen Gage constraints are not factored into the capacity estimate, at low daily water release volumes the daily range of Jensen Gage flow rates are also low.

Small SLCA/IP Resources. Relatively small SLCA/IP hydropower plants including Towaoc, McPhee, Elephant Butte, Upper Molina, and Lower Molina power plants. In total, these facilities contribute a relatively small amount of capacity and all but the Molina power plants are flat flow facilities. Powerplant capacities for small powerplants are computed in a spreadsheet based on historical monthly generation data as archived in Form PO&M-59. For the small

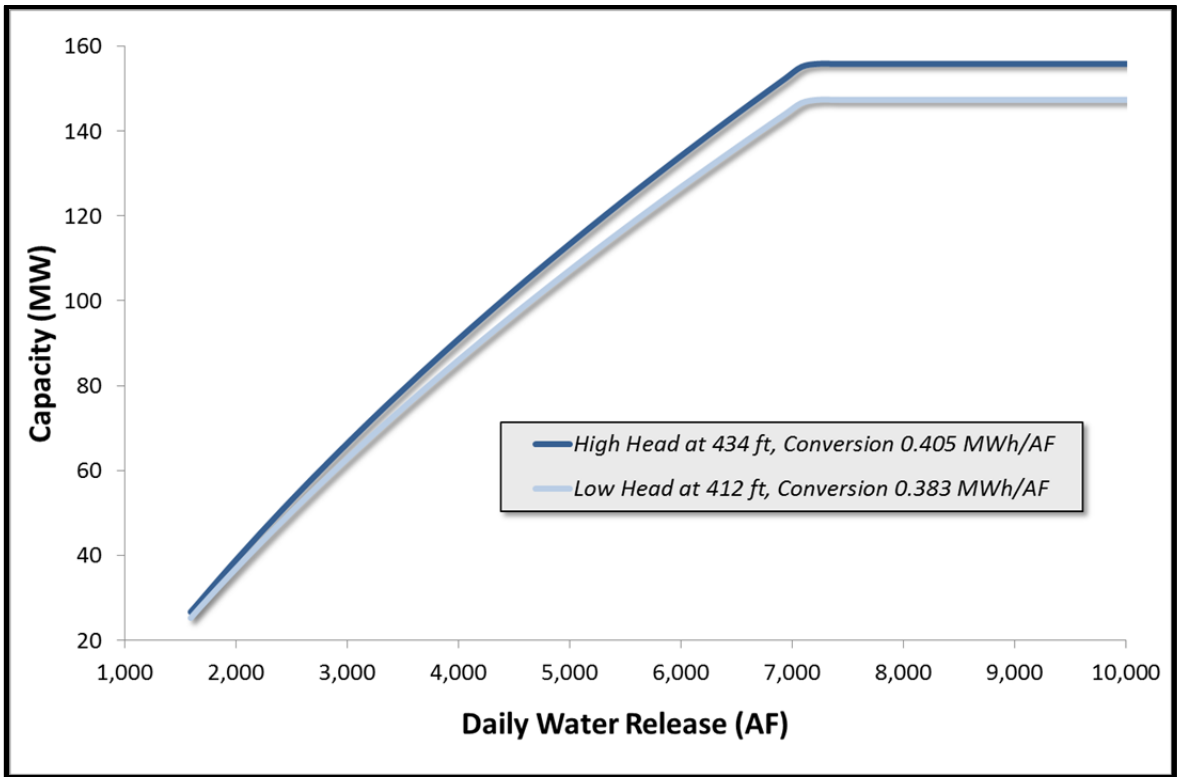

FIGURE K.1-25 Capacity Values at Flaming Gorge Dam Calculated over a Wide Range of Daily Water Releases Using the Trapezoidal Method

powerplants that are run at flat flow, the firm capacity credit is primarily a function of monthly estimates of total energy production divided by the number of hours in a month.

However, Molina powerplants are dispatchable and operated in unison. The spreadsheet algorithm evenly divides Form PO&M-59 monthly generation among all days in the month. The spreadsheet then operates Molina at maximum output continuously until the entire daily generation is exhausted; that is, the units start and stops once per day and no power is produced in any other hours. The block of operating hours is based on market prices such that the economic value of Molina resources is maximized.

Risk-Based Firm Capacity Operating Criteria

As discussed previously, numerous factors influence the amount of firm capacity that is credited toward reserve margin computations for SLCA/IP system. Two of these factors are discussed in this section. These include (1) the month when system peak load occurs and (2) the percentage of time that the entire firm capacity or more will be available to meet the system peak load.

System Peak Load Month. The month in which the system peak load occurs and upon which firm capacity calculations would be based was debated and ultimately jointly decided upon by staff from Reclamation, WAPA, National Park Service (NPS), and Argonne. August was chosen as the month when the system peak load occurs. This decision was made after examining historical FERC Form-714 data for CY 2006 through CY 2012, inclusive. Hourly load data were available for all eight large customer utilities. However, NTUA and Deseret data was only available for the first 4 of the 7 years. No hourly load data were available for any of the small LTF customers.

An examination of large LTF customer historical peak loads over this time period showed that individual customer peaks almost always occurred during the summer. A few exceptions occurred. CSU experienced one annual peak load in April 2006 and another peak in December 2009. In addition, NTUA, which has the lowest peak load of the eight large customers, experiences its peak load in either December or January. Figure K.1-26 shows that the NTUA peak load is about 1% of the non-coincidental sum of the eight large customer average annual historical peak loads. The sum of these annual non-coincidental peaks changed very little during the 2006 to 2012 time period, and averaged approximately 11,800 to 11,900 MW.

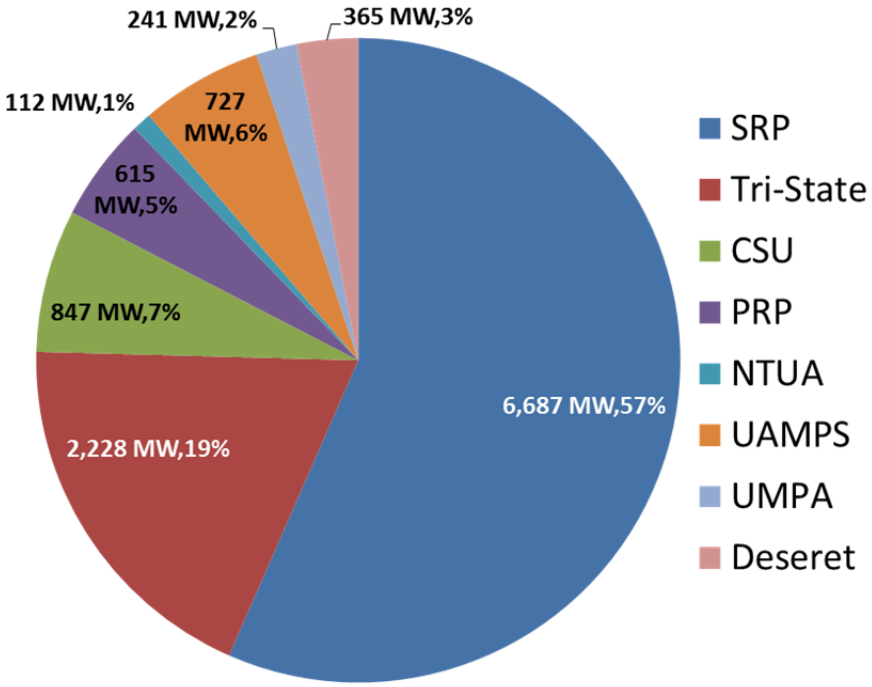

FIGURE K.1-26 Average Historical Non-coincidental Annual Peak Loads (in MW) for the Eight Large Customers and Percentages Relative to the Total

When the peak occurs in the summertime, it almost always occurs in either July or August. Only CSU experienced a different summer peak; it occurred in June of 2012 and was 2 MW greater than the highest load in July. A close examination of when the peak occurred also revealed that, for several utilities, there was no clear pattern of which month the peak occurs in. For example, SRP, which accounts for a majority of the non-coincidental total, experienced 3 years during which the annual peak occurred in July and 3 years during which the peak occurred in August. In 2007, the maximum load in July equaled the maximum in August. In addition, July and August maximum loads tend to be very similar across all systems.

Coincidental annual peak loads were also examined. The coincidental peak was determined by first summing up the available loads for the eight large customers on an hourly basis and then identifying the month in which the maximum total hourly load occurred. Results of this exercise also showed that, historically, July and August both had very similar maximum loads. Figure K.1-27 shows annual coincidental monthly maximum loads for 4 years (CY 2006 through CY 2009), based on data for all eight large SLCA/IP customers. In chronological order, the bars show annual peaks and the line shows the average. Figure K.1-28 shows the same information, except it is for an additional 3 years (CY 2010 through CY 2012) and is based on only six utilities. Information is presented in two separate figures because all load data were not available for all 7 years. As mentioned previously, FERC hourly data were not available for NTUA and Deseret during this time period. It should be noted that, for CY 2011 and CY 2012, the August peaks were markedly higher than those in July. The representative lead profile for the large customers has a coincidental peak load of about 12,370 MW.

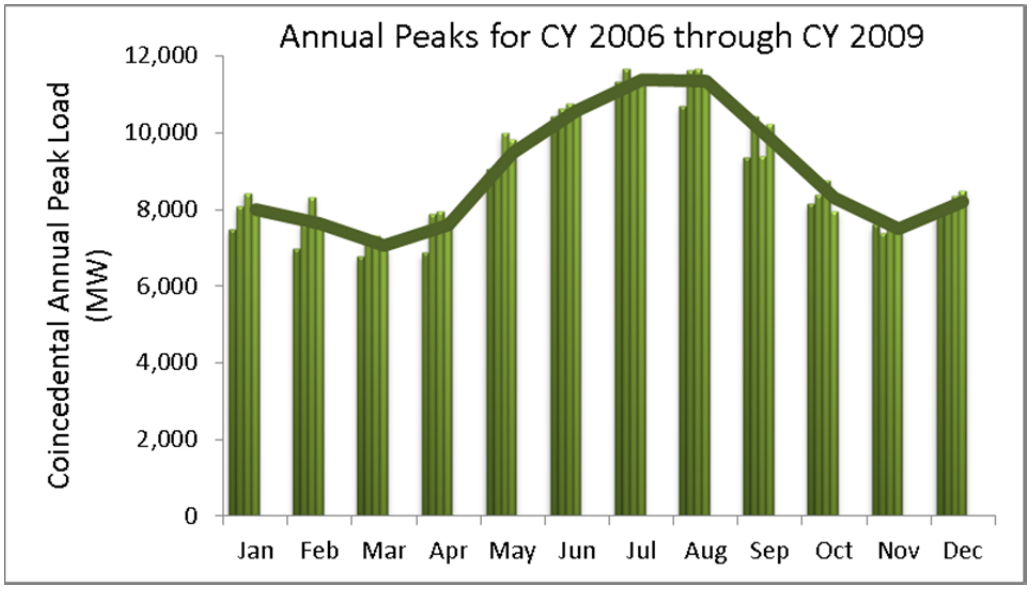

FIGURE K.1-27 Historical Coincidental Annual and Average Peak Loads for the Eight Large Customers during the CY 2006 through CY 2009 Time Period

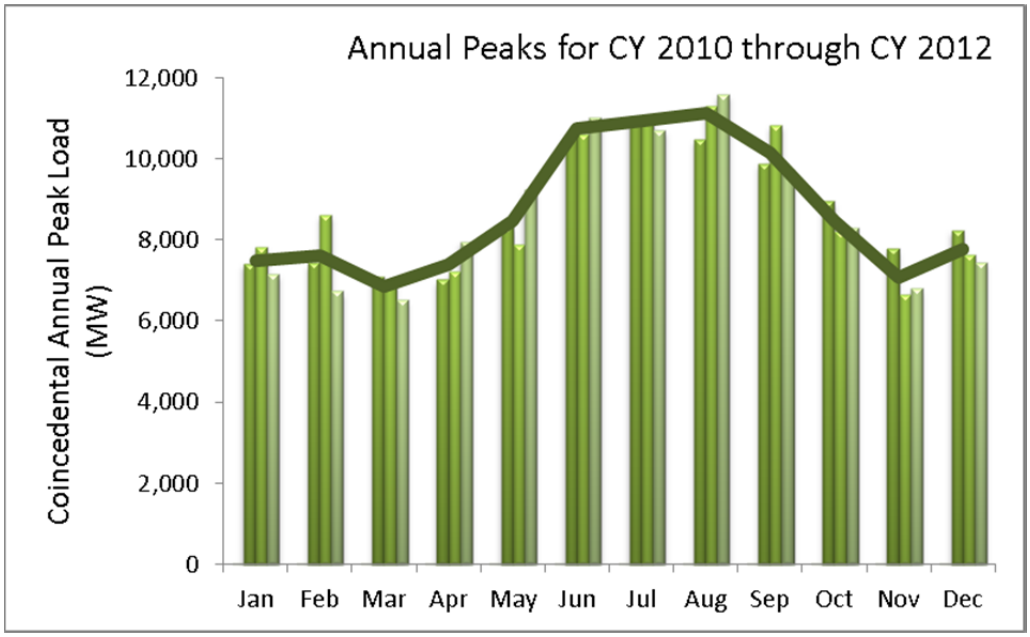

FIGURE K.1-28 Historical Coincidental Annual and Average Peak Loads for Six Large Customers during the CY 2010 through CY 2012 Time Period

Firm Capacity Risk Level. Assumptions regarding the level of risk that would be used in the LTEMP power systems analyses to determine firm capacity levels under each alternative were debated and jointly decided upon by staff from Reclamation, WAPA, NPS, and Argonne. Again, historical information was used to help in the decision-making process. However, unlike the process that was used to determine the timing of the peak load, which primarily relied on historical data, these methods also required the use of modeling tools—most of which were previously described in the Modeling Tools section.

Under terms of the SLCA/IP 2004 LTF contracts, WAPA's CRSP Management Center Office is obligated to provide its LTF customers with a minimum capacity level (SHP). The SHP level must be supplied regardless of the state or condition of SLCA/IP hydropower resources. These LTF contracts became effective on October 1, 2004, and will continue until September 30, 2024. When SLCA/IP resources are incapable of fulfilling WAPA's entire obligation, WAPA must make power purchases to cover any shortfalls. Therefore, WAPA and its LTF customers are exposed to market risks because the future of both reservoir conditions and the operating state of generating units are not known with certainty. Argonne conducted an analysis to roughly approximate risk levels to which WAPA is exposed under its current SHP obligation. For this analysis, risk exposure is measured as the probability that WAPA will not be able to meet its daily SHP obligations during peak summer load months. Argonne staff estimate this probability by computing daily SLCA/IP hydropower powerplant capacity under many possible hydrological futures while accounting for the impacts of unit-level outages and environmental operating limits. This analysis is merely a retrospective study of WAPA's SHP level using current hydrological data. The methodology used in this analysis was not necessarily used by WAPA to determine its current SHP obligations.

SLCA/IP hydropower facilities span a large range of powerplant sizes and operational flexibility. For this analysis, WAPA's SLCA/IP hydropower resources are divided by size as shown in Figure K.1-20.

The capacity from the WAPA SLCA/IP system is estimated using the models and method shown in Figure K.1-29, which leverages LTEMP tools and methods. A brief overview of capacity computations is as follows:

1. Glen Canyon Dam Powerplant resource capacity under many plausible futures is based on Reclamation's CRSS and SBM models, along with maximum daily production levels projected by the Argonne GTMax-Lite model;

2. Other CRSP and Fontenelle daily capacities under many plausible futures are estimated by the Large Powerplant spreadsheets that compute unit-level maximum output based on CRSS model results and unit-level outages;

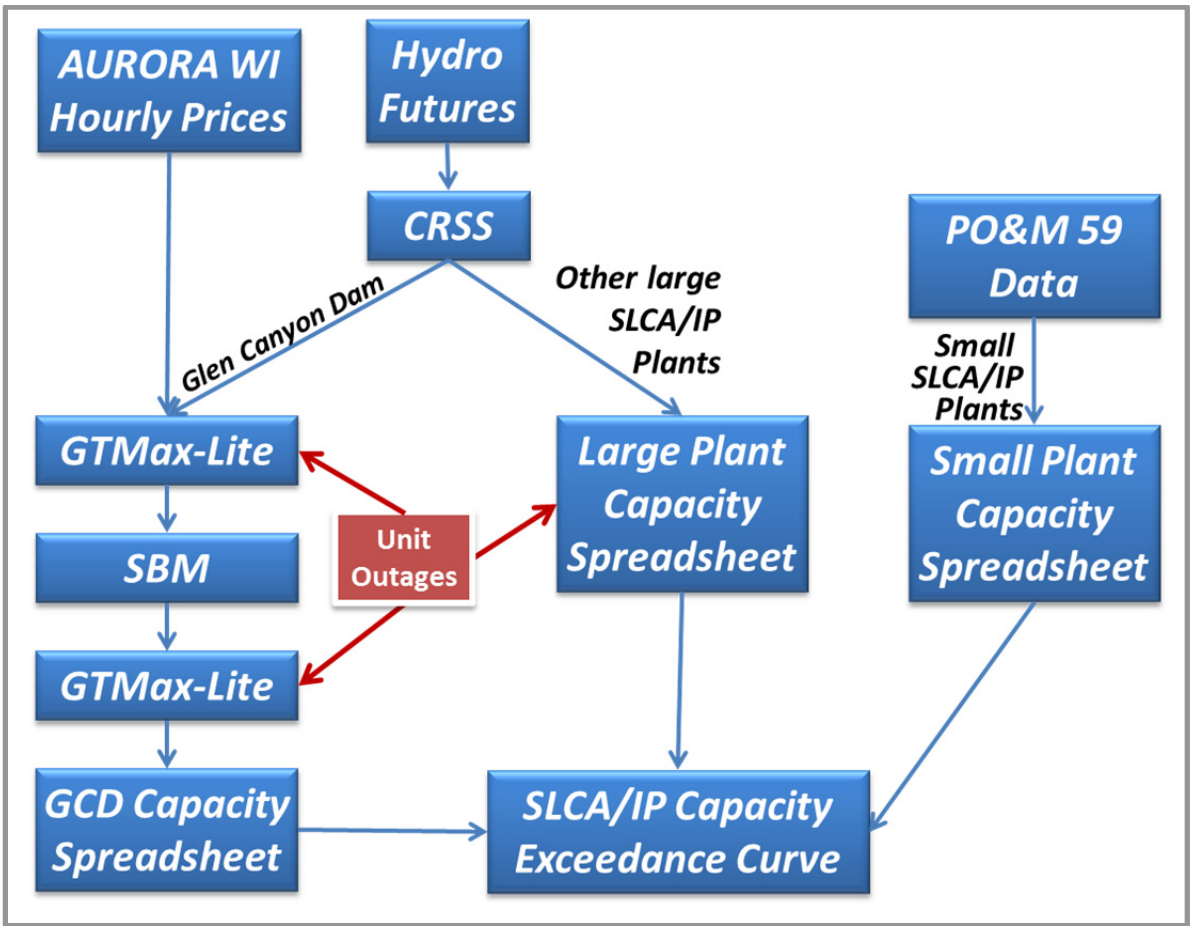

FIGURE K.1-29 SLCA/IP Models Used for Estimating SHP Capacity

3. Flaming Gorge capacity is further reduced under most hydrological conditions because operating criteria and other agreements further constrain its maximum daily output; and

4. For the remaining SLCA/IP resources (i.e., Towaoc, McPhee, Elephant Butte, Upper Molina, and Lower Molina), monthly capacity computations are based on historical monthly operating information contained in Form PO&M-59.

After trace-specific time series of plant-level capacities are computed, the Firm Capacity Spreadsheet creates SLCA/IP hydropower capacity exceedance curves. For each day in a month, the routine totals the daily coincidental peak capacities of all large powerplants. To this sum the routine adds monthly capacities for all small powerplants and subtracts capacity that is reserved for other purposes as described in previous sections.

After a time series of plant-level capacities was computed for all facilities and all traces over the 20-year study period, the data were processed further in a separate routine to determine exceedance levels for the peak loads months of July and August. For each day in a month, the routine totals the daily coincidental peak capacities for both Glen Canyon Dam and the other large SLCA/IP federal facilities for 21 hydrology traces over the 20-year study period. The resulting values are used to create SLCA/IP hydropower marketable capacity exceedance curves.

WAPA's current sustainable hydropower (SHP) commitment level was located on these exceedance curves to determine how much of the time SLCA/IP resources would be able to meet all of WAPA's current contractual and operating obligations. SHP is the minimum aggregate level of LTF capacity and energy that will be provided by WAPA to all SLCA/IP customers through the contract period, regardless of the hydropower condition. The location of the WAPA's SHP commitment on the exceedance curve will determine the level of capacity risk to which WAPA is currently exposed.

From WAPA's data over at least the last 10 years, its SHP commitment for July has been about 750 MW. As shown on the SLCA/IP capacity exceedance curve in Figure K.1-30, this level is exceeded about 89.5% of the time; in other words, there is a 10.5% probability that WAPA will need to make purchases to fulfill its entire SHP. In August the risk is somewhat lower. Figure K.1-31 shows that WAPA has enough SLCA/IP hydropower capacity to meet its SHP capacity obligation of 721.4 MW about 91% of the time. Therefore, WAPA's current capacity risk is at about the 90% exceedance level.

K.1.7.4 Firm Capacity Curves for LTEMP Power Systems Analyses for the Peak Month of August

Similar to the above assessment of risk for the CRSP Management Center, exceedance curves were constructed to analyze risk levels associated with firm capacity used for SLCA/IP system reserve margin calculations. The left panel of Figure K.1-32 shows the marketable capacity for the seven primary alternatives at exceedance levels ranging from 10% to 99% for

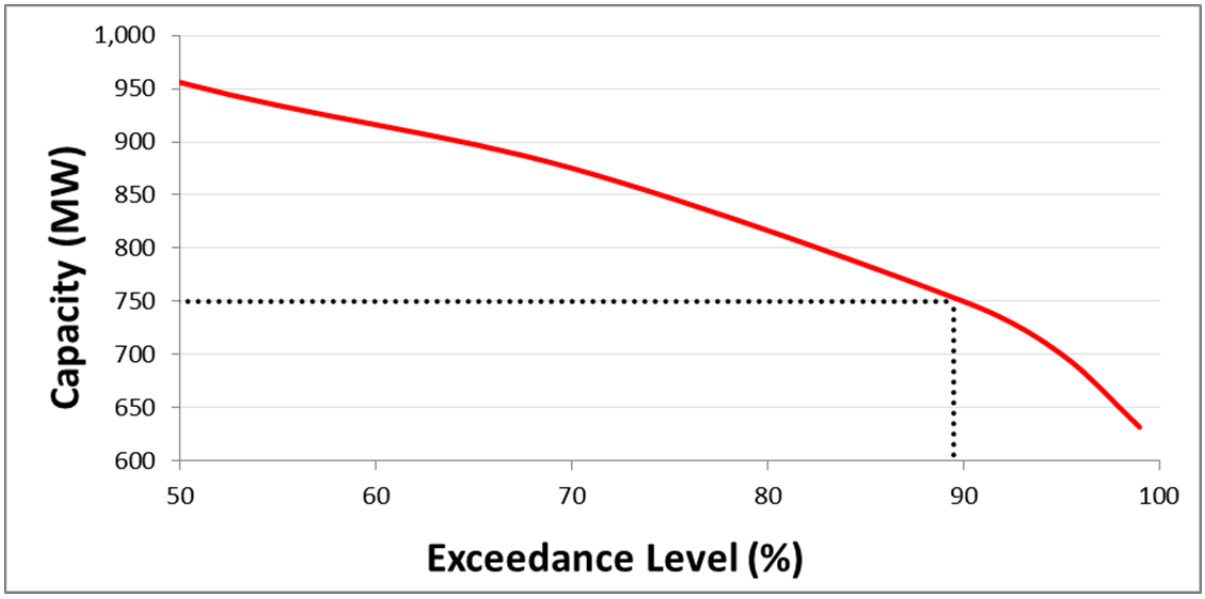

FIGURE K.1-30 Historical SHP Capacity Obligation and WAPA Estimated Risk Level in July

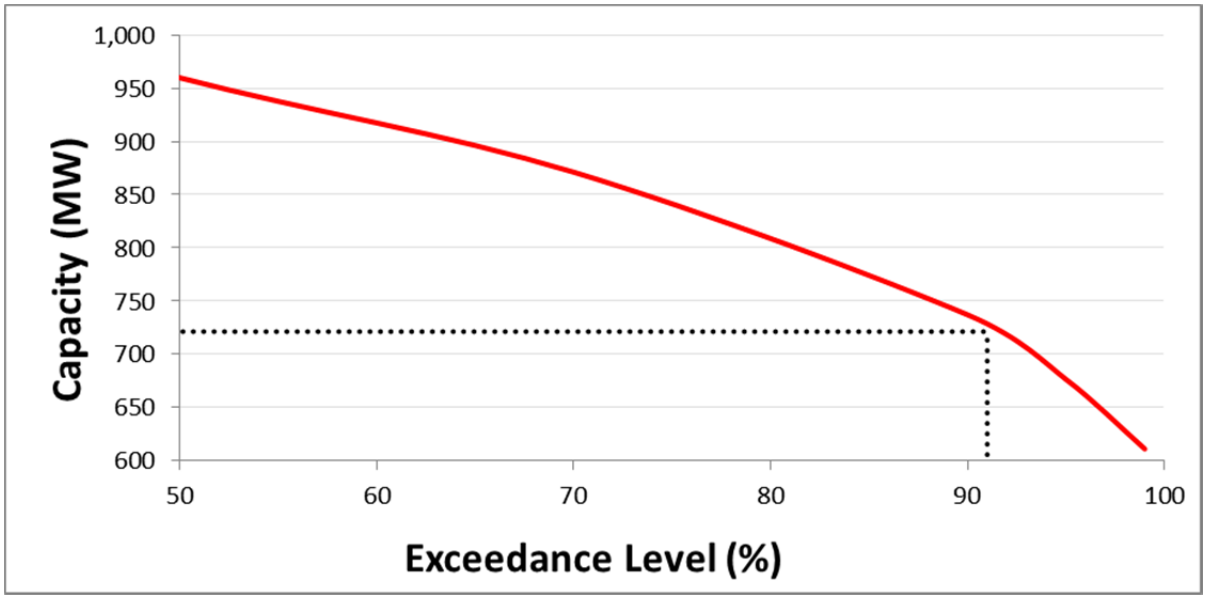

FIGURE K.1-31 Historical SHP Capacity Obligation and WAPA Estimated Risk Level in August

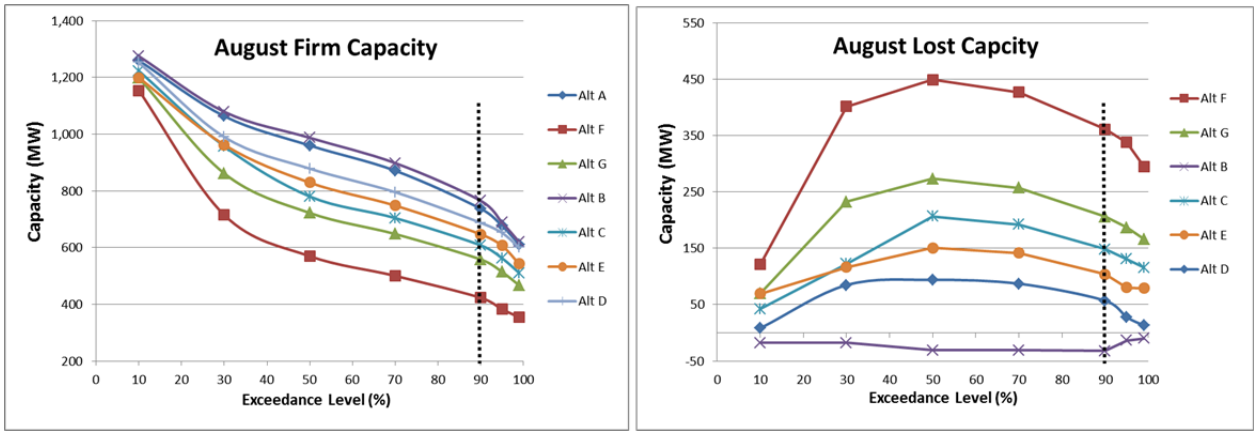

FIGURE K.1-32 Comparison of Firm Marketable Capacity Determinations across Alternatives, Exceedance Levels, and Summer Peak Months

combined SLCA/IP federal hydropower resources. These results assume that the peak system load will occur in August. All alternatives except for Alternative B have less firm capacity at all exceedance levels than Alternative A; this is expected, however, because Alternative B has the least restrictive operating restrictions of any alternative.

Under the assumption that the peak load occurs in August, the right panel of Figure K.1-32 shows the difference in firm capacity compared to Alternative A. The graphs show that the greatest difference in capacity occurs at the 50% exceedance level and the smallest at the 99% exceedance level. Based on the current CRSP Management Center risk exposure of 10%, the determination of firm capacity for all LTEMP alternatives will also be based on this risk level. Note that the results reported in Chapter 4 of the main document also assume a 10% risk level (90% exceedance level) for a peak load that is anticipated to occur in August. However, WAPA has no obligation to use this exceedance level when setting future LTF capacity offers to its preference customers; therefore a sensitivity analysis that uses a range of exceedance levels was conducted. The results of the analysis are presented in Section K.1.10.4.

The power systems methodology assumes that lost Glen Canyon Dam Powerplant capacity replacement costs due to more stringent operating criteria under an alternative will be assessed at the systems level.

The costs of past expenditures to build a powerplant, including the Glen Canyon Powerplant, cannot be altered. Therefore, capital investment differences among alternatives for these facilities are zero. Similarly, fixed O&M costs are assumed to be unaffected by any of the alternatives because retirement schedules and powerplant improvements are assumed to be static. It is also assumed that the total physical 1,320 MW of nameplate capacity at Glen Canyon Dam is identical under all LTEMP EIS alternatives, and that the capacity of all powerplant units will not change over the study period. Therefore, the only differences in the economic cost of capital and fixed O&M costs among alternatives is due to changes in capacity expansion pathways. The sections below describe the method that is used to determine these pathways.

Capital costs only factor into LTEMP EIS economic calculations for capacity expansion units because the retirement schedule of existing units and the online date of committed units does not change among alternatives; therefore, the economic cost difference between Alternative A and other alternatives is equal to zero. Fixed O&M costs only factor into LTEMP EIS economic calculations for capacity expansion units because the retirement schedule of existing units and online dates for committed units do not change among alternatives; therefore, the economic difference of these "fixed" costs between Alternative A, which serves as a reference point, and other alternatives is equal to zero.

K.1.7.5 AURORA Capacity Expansion Reserve Margin Targets and Capacity Additions

The AURORA model was used as a tool to aid power system modelers and analysts at Argonne in finding reasonable capacity expansion plans for each LTEMP alternative using the topology previously shown in Figure K.1-3 and described in Section K.1.5.9. This section provides more details on how it was used for capacity expansion. The network topology shown in Figure K.1-3 consists of two power pools. Pool A is made up of all SLCA/IP hydropower resources and WAPA's eight large customers. Pool B consists of the aggregate of WAPA's small customers and all project use loads.

The network was modeled as two power pools for the purpose of calculating a system reserve margin. WAPA's eight large customers and hydropower resources were put into Pool A because these customers (except for NTUA) satisfy their loads from a combination of their own generation, generation owned jointly with another large customer(s), WAPA firm hydropower allocations, bilateral contracts, and market purchases. Customers in Pool B have no generation and serve loads only through WAPA firm hydropower allocations, bilateral contracts, and market purchases. It is assumed that customers in Pool A would satisfy their combined reserve margin by constructing new generation. Customers in Pool B would satisfy their reserve margin by making individual purchases from large Pool A customers and from the Western Interconnection market transactions.

The model builds new units when the capacity reserve margin of the aggregate SLCA/IP system, which includes WAPA and all of its LTF customers, would otherwise drop below 15%. Based on a review of utility IRPs in the Western Interconnection, it was found that a 15% reserve margin is a typical capacity expansion goal. This value was therefore used as a reserve margin goal for the LTEMP power systems analysis.

Capacity that is credited toward the reserve margin frequently differs from the rated nameplate capacity, because the maximum output from the powerplant may differ from the rated level. For example, a high atmospheric temperature typically reduced the maximum output from gas-turbine technologies. Therefore, the firm capacity that is used in the reserve margin calculation is less than the nameplate capacity if the system peak load is expected to occur during a hot summer afternoon. The firm capacity that is given to VERs can be very complicated. It is often based on system-level reliability calculations that determine an equivalent "100% reliable" capacity that yields the same loss-of-load probability as the VER.

The power system analysis uses an estimate of firm capacity for all existing and new units instead of the nameplate capacity. In some cases, this requires that sometimes the nameplate capacity is significantly derated. For example, it is assumed that the firm capacity credit of new solar and wind farms is only 10% of the nameplate capacity. This is the default used by AURORA. The firm capacity of WAPA's SLCA/IP hydropower resources that is credited toward this system reserve margin was described in Section K.1.7.4. In addition, as noted previously, only the daily capacity of Glen Canyon Dam differs among alternatives.

Figure K.1-33 provides a simplified illustration of the impact of the firm capacity credit at Glen Canyon Dam on the timing of new construction to meet future loads and the reserve margin target. Two cases are shown in this example for illustrative purposes only. Under Case 1, Glen Canyon Dam has a larger firm capacity and Case 2 has a smaller credit. The orange line shows the annual coincidental peak load for the system. Because WAPA's firm allocation is non-contingent, that capacity amount can be subtracted from the system peak load before calculating the reserve margin. The reserve margin is then applied to that resulting curve to obtain a revised load curve that includes the required reserve margin. This curve is then compared with the capacity in Pool A to determine where they intersect. The year in which they intersect is when

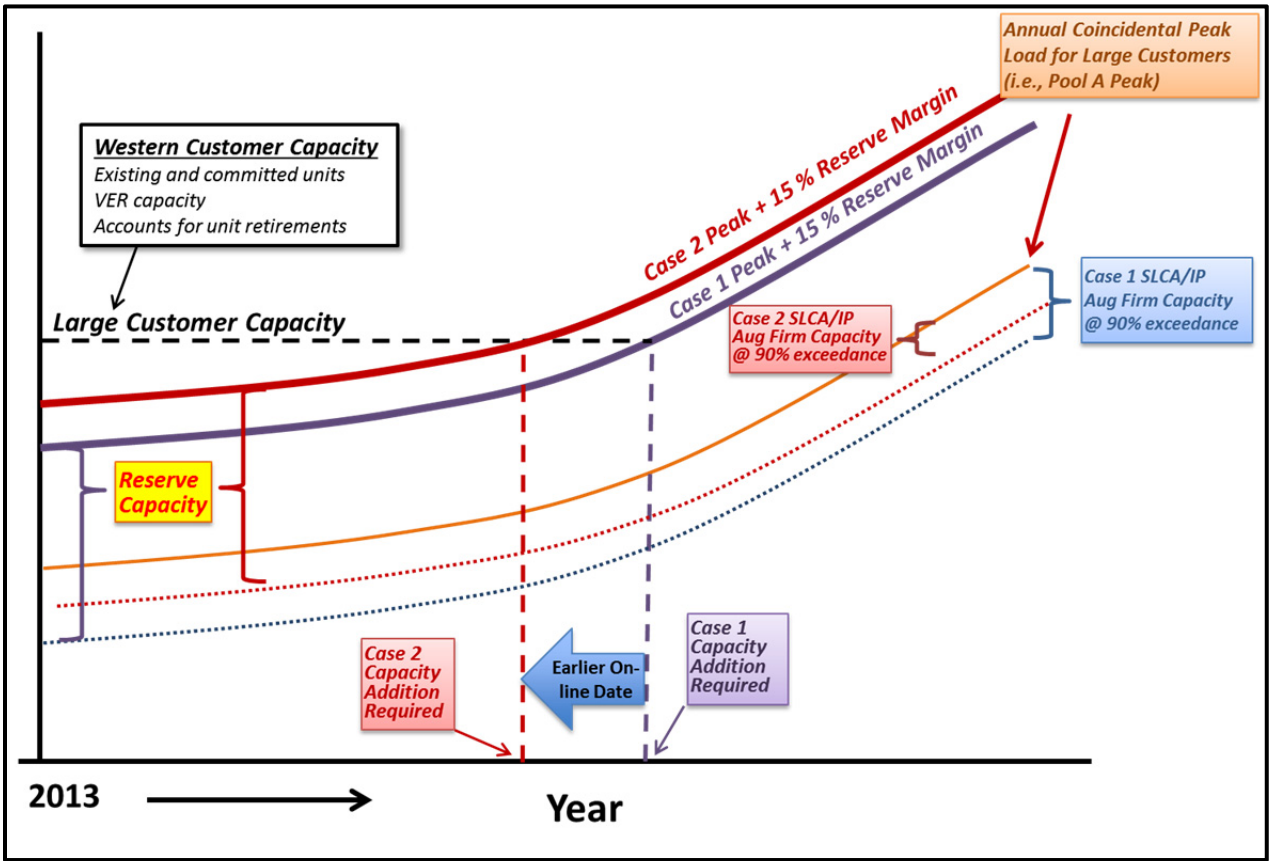

FIGURE K.1-33 Timing of Capacity Additions in AURORA

new capacity is needed to meet the reserve margin. The graph shows that Case 2 needs new capacity before Case 1 because WAPA's firm capacity credit under Case A is smaller.

To reliably serve projected load growth, fossil and non-fossil generation units are constructed by AURORA. AURORA also sheds load at specified market price trigger points.

Capacity shortfalls that remain after complying with renewable resource expansion goals specified in each utility's IRP are resolved by building new electric generating units from a list of candidates. The cost and characteristics of candidate technologies for future capacity expansion that were used for power systems analysis were provided in Table K.1-1. These technologies and associated attributes and costs were based for data found in EIA's 2014 AEO (EIA 2014).

The AURORA capacity expansion feature was used to guide the selection of a plausible capacity expansion plan for the SLCA/IP system. The methodology utilized models the expansion path for an aggregate eight large customer pool labeled "Pool A" in Figure K.1-3. The expansion plan determined under each alternative meets a 15% target reserve margin for pool A (large customers and SLCA/IP federal hydropower resources), plus additional capacity to replace lost Glen Canyon capacity that is allocated to small customers. Under an alternative, large customers therefore replace the entire lost capacity even though only a portion (i.e., about 75% under current SLCA/IP LTF capacity allocations) of this lost capacity would contractually affect these larger utilities. Small customers pay for this capacity by purchasing it from the large customers via LTF contracts.

Because the AURORA model builds capacity for the "joint system," it implicitly assumes that a capacity shortfall in one customer utility system could be temporarily fulfilled by another utility that has excess. Conceptually, this could be achieved via a short-term firm bilateral capacity contract between the two systems, thereby delaying a physical capacity addition by the utility that is "short" capacity. For example, because small customers would most likely not build capacity in the future, it was assumed the lost capacity allocated to these small utilities (i.e., about 25%) would be replaced via the capacity expansion pathways of the aggregate eight large systems (Pool A).

The modeling approach used simplifies reality because currently, there is no centralized energy or capacity market in the region of the Western Interconnection where SLCA/IP federal hydropower resources and WAPA's LTF customers are located. Capacity expansion decisions and energy transactions in this area are done autonomously to meet the objectives of each independent utility. In addition, each utility has limited information about the entire grid and the independent actions/decisions made by other entities in the system. In contrast, the AURORA mode assumes "perfect" information about the entire system to optimize a system-wide objective and builds new powerplants to meet the pool-level reserve margins, not to serve the objectives of each independent utility.

The "joint system" capacity expansion model therefore assumes a level of cooperation and coordination that currently exceeds current-day practices. However, it would be unrealistic for each individual utility to build capacity independently. Only a few customers own capacity;

most rely solely on purchasing capacity and energy resources from other utilities to serve all of its load requirements. Also, it is not uncommon for utilities in the region to cooperate. For example, some of the large customer utilities that own capacity have jointly built generating resources. For example, Salt River Project, Platte River Power Authority, and Tri-State G&T all have joint ownerships in both Units 1 and 2 at the Craig plant. The Salt River Project partly owns Unit 2 at the Hayden Plant. Also, Desert and UAMPS have ownership shares in Hunter Unit 2, and Desert and UMAP have joint ownerships in both Units 1 and 2 of the Bonanza power plant.[1] These cooperative ventures have benefited all parties involved, because a large plants is less expensive to build on a $/MW basis than several smaller ones.

Another modeling simplification is that transmission capacity limits were not considered in the AURORA model topology. It was assumed that capacity replacement would be built by customers at locations such that power injections did not create additional transmission congestion. It should also be noted that Glen Canyon Dam output under all alternatives except Alternative B tend to be lower during critical times of daily peak load, thus freeing some transmission line capacity that could potentially be used to transfer power among customers. Under most alternatives, generation at Glen Canyon tends to be higher during off-peak hours, but transmission congestion is normally minimal during these times. In addition, WAPA customers can also take advantage of customer displacement power (CDP) that allows customer utilities to use WAPA's transmission lines up to CROD levels when lines are not congested. Lastly, EIS power transfers among customers account for transmission costs that tend to dampen energy transactions among utilities. These costs are included in both AURORA capacity expansion and dispatch model runs.

The two modeling simplifications discussed above regarding utility cooperation and transmission may potentially underestimate capacity expansion costs. For example, a customer utility may decide to add capacity instead of making a short-term firm capacity purchase and/or reject CDP for long-term planning purposes based on reliability considerations. Underestimates, however, would occur under all alternatives, including Alternative A. Therefore, these errors tend to either cancel out or be significantly reduced because the power systems analysis uses a comparative analysis that focuses on the difference between Alternative A and another alternative, not the absolute value of each alternative independently. Also, the methodology is based on the economics of the entire system. Financial transactions among individual utilities, such as short-term firm capacity purchases and sales, are considered.

As discussed previously, new units are constructed when the capacity reserve margin of the aggregate system would otherwise drop below 15%. Additions are made in unit capacity increments resulting in a plan that has a "lumpy" reserve margin time series. The reserve margin requirement (i.e., modeled as a "hard" constraint) also produces a solution that almost always exceeds the 15% target. These relatively small excess capacities that fluctuate over time are beneficial to the system dispatch and production-cost economics. Although most analyses would assume that this excess capacity has no value, it could potentially be sold to a neighboring utility outside the SLCA/IP marketing area, thereby reducing expansion costs. A simple post-model

[1] It should be noted that there are several other joint ownerships in addition to those described in this paragraph.

sensitivity study was performed that assumed this capacity could be sold. The results of the study are reported later in this appendix.

Depending on AURORA model parameters and run settings, the expansion plans suggested by AURORA can be considerably different for Alternative A, and, in many instances, add significantly more generating units than the number required to maintain a 15% reserve margin. This in part stems from the fact that the optimization problem AURORA attempts to solve is extremely difficult to find. After discussion with EPIS staff and examinations of expansion results, Argonne concluded that new capacity addition decisions made by the model are based on financial objects rather than a single global economic objective. AURORA builds a new unit if it is financially attractive. The end result is a realistic expansion path. However, solutions that focus on local unit additions that are financially viable based on the NPV of costs and revenues over the study period result in expansion pathways that often differ from the one that costs the least over the entire multi-utility system.

Given the size of the modeled SLCA/IP area, the focus/capabilities of AURORA, and Argonne staff skill level in the use of the model, finding the global least-cost economic solution for Alternative A is intractable; that is, Argonne could not mathematically prove that any one of the many solutions produced by AURORA was the global least-cost solution. It was also judged that the mathematical optimum path would most likely not be found within a reasonable amount of time and effort (i.e., several weeks or months). Given this modeling limitation, however, the technologies selected by AURORA consistently indicated that combustion turbines (CTs) and natural gas-fired combined cycle units will be constructed in the future. This solution is consistent with available IRPs that Argonne reviewed for SLCA/IP large customers and several large systems (typically investor-owned utilities) that neighbor the SLCA/IP marketing area. A summary of these IRPs is shown in Table K.1-6 (see Table 2 of Attachment K.9 for additional information). More detailed information about these IRPs is provided in Attachment K.9.

It should be noted that the methodology only represents SLCA/IP physical assets and production levels. It does not reflect changes in SLCA/IP contract that may be implemented in October 1, 2024, or financial implications as they affect WAPA and individual customers. This topic will be discussed in the Wholesale Rate Analysis section.

K.1.7.6 Dispatch Performed by AURORA Model Capacity Expansion Runs

The methodology used represents all of SLCA/IP hydropower energy assets in the AURORA model to measure the economics of changes in Glen Canyon Dam operating criteria. GTMax-Lite and customized small SLCA/IP resource spreadsheet results provide AURORA with alternative-specific SLCA/IP dispatch and an hourly schedule of energy injections into the power grid. By doing so, AURORA recognizes the basic role of hydropower resources as they affect the dispatch of the SLCA/IP system and energy transactions with the Western Interconnection.

Due to the complexities of SLCA/IP hydropower operating criteria and non-power considerations, AURORA could not model the dispatch of these resources at the level of detail

TABLE K.1-6 Summary of Utility IRPs for Four Large SLCA/IP Customers and Other Large Utilities in Areas Neighboring the SLCA/IP System

Utility	Utility Type	Type of Generation Added	When Added	Capacity Added (MW)
Public Service of CO	Investor	Gas Turbines	2018 to 2022	1,211
	Owned	Combined Cycle	2023 to 2032	1,929
Public Service of NM	Investor	Gas Turbines	2016 to 2033	736
	Owned	Solar PV	2015 to 2022	283
Rocky Mountain Power	Investor	Combined Cycle	2014, 2024	645, 423
	Owned	Wind	2024	432
Arizona Public Service	Investor	Natural Gas (unspecified)	2019 to 2029	4,200
	Owned	Renewable (unspecified)	2019 to 2029	425
Tucson Elect. Power	Investor	Natural Gas (unspecified)	2015 to 2028	1,214
	Owned	Renewable (unspecified)	2014 to 2028	529
Nevada Power Company	Investor	Combined Cycle	2018 to 2024	3,813
	Owned	Gas Turbines	2023 to 2032	2,043
		Solar PV	2016 to 2021	50
Sierra Pacific Power	Investor	Gas Turbines	2023 to 2029	1,975
	Owned	Combined Cycle	2025	571
Platte River Power	WAPA Customer	Gas Turbines	2021	Unspecified
Colorado Springs Utilities	WAPA	Gas Turbines	2029 to 2031	39
	Customer	Renewable (unspecified)	2018 to 2029	20
Tri-State G & T Assn.	WAPA	Combined Cycle	2019 to 2026	1,176
	Customer	Renewable (unspecified)	2016 to 2027	350
Salt River Project	WAPA Customer	Natural Gas (unspecified)	FY2018+	Projected 581-MW gap in 2017

required for this study. Instead, powerplant-specific hourly production levels were projected over the study period using the previously discussed two GTMax-Lite model configurations and the Small SLCA/IP Powerplants Spreadsheet. Energy injections into the system from Glen Canyon Dam are based on average hourly GTMax-Lite results over all 21 hydrology traces from the SBM. Hourly energy injections from all other large SLCA/IP resources are based on GTMax-Lite results, which use average monthly hydrological conditions over the 21 hydrology traces produced by CRSS. Last, energy injections from small SLCA/IP hydropower plants are based on average historical conditions reported in Form PO&M-59.

Annual CY energy generation for Glen Canyon Dam and all other SLCA/IP hydropower resources combined are shown in Figure K.1-34 under Alternative A. Annual generation from the Glen Canyon Dam Powerplant averages about 4,114 GWh, and ranges from about 3,665 GWh to 4,338.2 GWh. The lowest generation value occurs in 2013 due to low initial reservoir elevations that were observed at the end of CY 2012. That is, because the simulation starts out at a point in time when the Glen Canyon Dam reservoir is low, water releases tend to be less since more water is retained in the reservoir in an attempt to increase the water storage level. On average, Glen Canyon Dam is expected to account for about 72% of the total annual SLCA/IP hydropower generation. Because annual WY releases are nearly the same under all

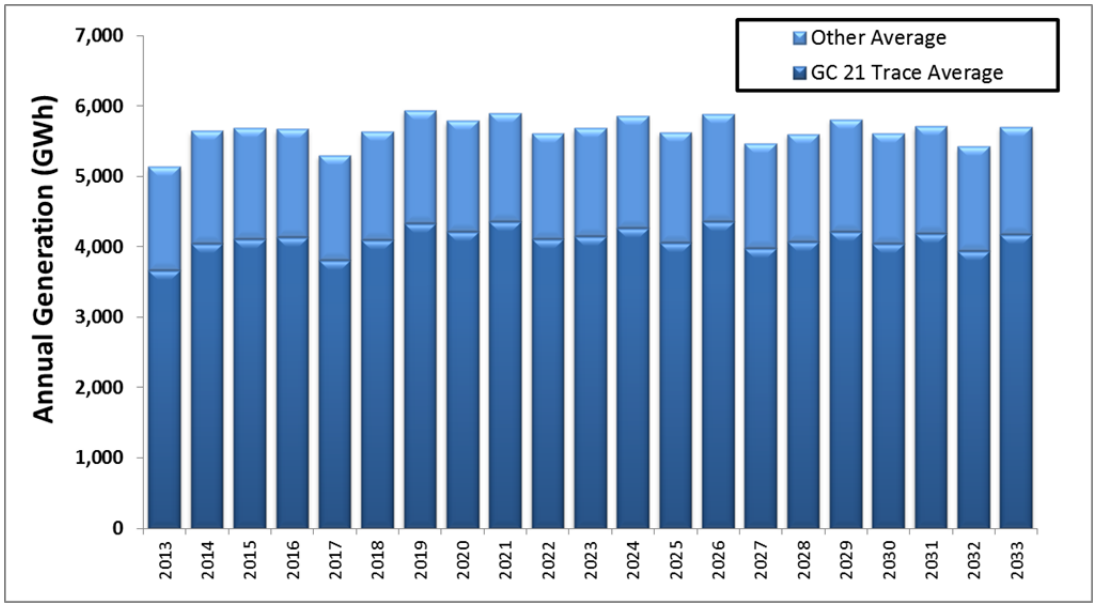

FIGURE K.1-34 Annual Average Hydropower Generation for the Glen Canyon Dam Powerplant and the Aggregate Generation for All Other SLCA/IP Resources

alternatives, total CY annual generation levels for all alternatives are within about 1.7% of Alternative A. Those alternatives that have more HFEs tend to have lower annual average generation levels. This topic will be discussed in more detail in Section K.1.10.

Although annual Glen Canyon Dam generation levels are similar among alternatives, the monthly distribution of generation within a year is substantially different among alternatives. Projected monthly generation produced by other SLCA/IP hydropower resources is essentially identical under all alternatives. Figure K.1-35 shows that alternatives such as Alternatives A and B have high Glen Canyon Dam average daily generation levels during the peak summer months when marginal energy production costs are relatively expensive. These energy levels produce higher economic values than those with lower summertime generation levels, such as Alternative F.

Interactions between all entities in the SLCA/IP marketing area and the rest of the Western Interconnection are represented by a single point where non-firm hourly energy transactions occur. This point, labeled "Spot Market" in Figure K.1-3, contains an inelastic time vector of market prices for system energy purchase and sales.

Power transfers between utilities and the Western Interconnection node incur a charge that varies by on-peak and off-peak periods. All purchases and sales that a customer makes incur an additional transfer cost that also varies by on-peak and off-peak periods. The eight large customer utilities and small customers only purchase energy from the spot market node; spot sales are not possible. This assumption was made to ensure that the SLCA/IP system would not construct capacity on a speculative basis for the purpose of selling energy to the Western Interconnection; that is, it constructs capacity primarily for internal purposes. Because the

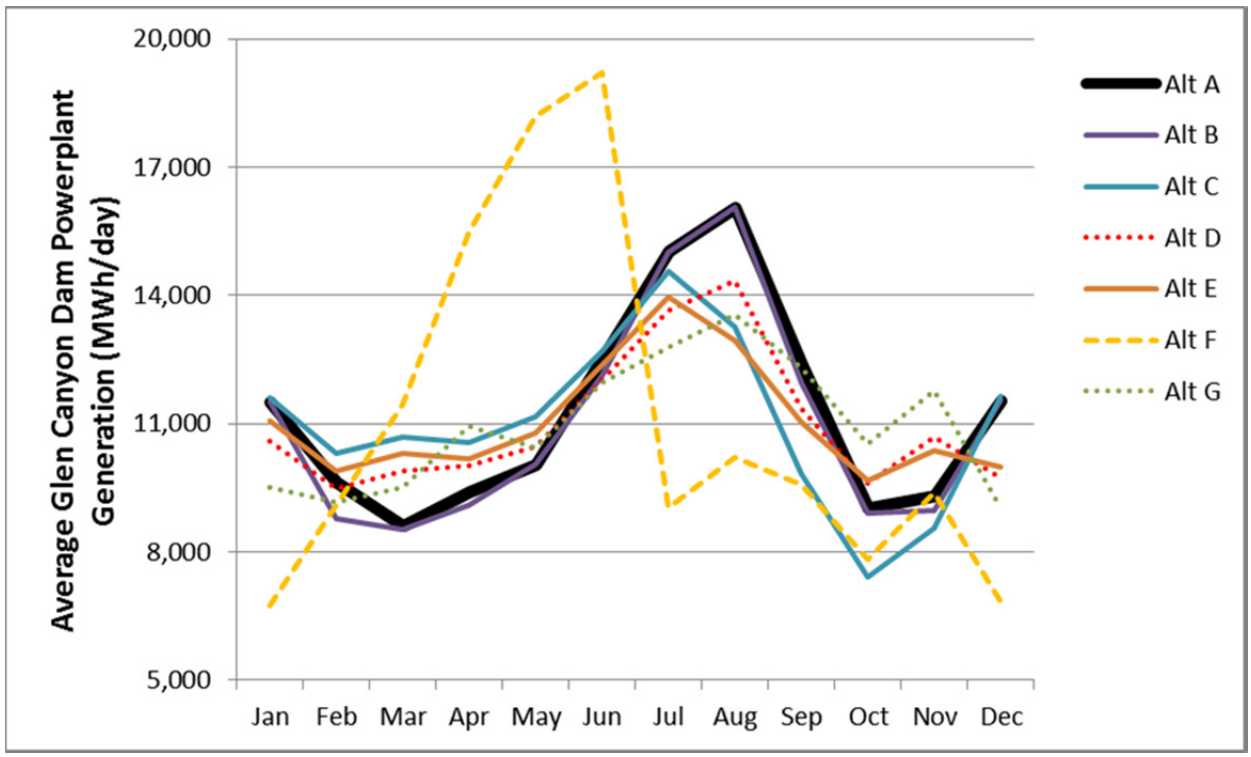

FIGURE K.1-35 Average Daily Glen Canyon Dam Powerplant Hydropower Generations by Month Based on the Average of All 21 CRSS/SBM Hydrology Traces

Western Interconnection prices tend to be more expensive than production costs in the SLCA/IP system, purchases from the Western Interconnection tend to be small. However, the Western Interconnection energy was made available for purchase by the SLCA/IP systems in situations where internal production costs became expensive. In addition, reserve margin requirements were configured to exclude Western Interconnection purchases as a source of firm capacity. Therefore, the SLCA/IP system is prevented from leaning on the Western Interconnection for capacity during times of peak load.

Depending on the customer's location, loads and resources are designated as east or west regional entities. Energy flows among entities via system linkages. Some links have limitations and/or associated costs. Energy flows on links connecting SLCA/IP resources to WAPA's customer loads. Limits on energy transfers on those links represent customer CROD allocations. Under hydrological conditions in which SLCA/IP total generation exceeds the total CROD, the excess energy flows on links that represent WAPA's shorter-term energy transactions with its LTF customers.

Very small cost premiums are placed on some connections to represent WAPA's service priorities and to roughly approximate energy flows. Energy generated by Glen Canyon Dam is transmitted to loads in the following priority order: (1) project use in the west region, (2) project use in the east region, (3) LTF customers in the west region, and (4) LTF customers in the east region. The higher the priority, the lower the power delivery cost; that is, the lower the assigned

link cost. Energy flow priorities for other SLCA/IP resources mirror the Glen Canyon Dam pattern. The priority order for SLCA/IP resources other than Glen Canyon Dam is (1) project use in the east region, (2) project use in the west region, (3) LTF customers in the east region, and (4) LTF customers in the west region.

Figure K.1-3 also shows that an LTF customer has direct connections to all other LTF customers in the region where the customer resides. These connections are used for energy transactions but are subject to transmission costs of $3.5/MWh during off-peak hours and $6.5/MWh during on-peak hours based on historical information provided by WAPA. This topology/configuration assumes a higher level of cooperation and coordination among WAPA and its customers than what actually occurs. However, WAPA and its customers do buy and sell energy via both day-ahead and hour-ahead bilateral agreements using market signals, insights, and data such as that provided by ICE as a guide. Also, energy transfer costs among LTF customers dampen power transfer levels relative to a centralized market arrangement, such as a regional transmission operator (RTO) market, which does not incur these transmission costs in the system dispatch. The resulting system dispatch for large customers is consistent with historical operations as shown in see Figure K.1-14).

K.1.7.7 Rationale for the Selection of Hydrology Conditions Used for Capacity Expansion Runs

The low hydropower condition of 90% exceedance used to select SLCA/IP hydropower capacity credits is fairly conservative because the system is slow to respond to capacity shortfalls. New units take a relatively long time (years) to plan/engineer, permit, construct, test, and eventually bring online. Therefore, if insufficient capacity is built, the system may experience years of unacceptably high reliability risks when hydrology/hydropower capacity is low.

On the other hand, average energy conditions are used for power injections into the grid for capacity expansion modeling because the system quickly adapts to various hydrological situations through system dispatch and short-term energy transactions (e.g., purchases when hydropower energy production is below normal). Although it does not provide an exact estimate of energy economics, given all of the other uncertainties involved with long-term projections, an average hydrological condition provides a good approximation of the *relative* economics among the enormous number of capacity expansion pathways that are theoretically possible for the SLCA/IP study area.

K.1.8 Glen Canyon Dam Energy Economic Benefits Methodology

The Glen Canyon Dam Powerplant generates large amount of energy that yields significant economic benefits to the grid. It serves SLCA/IP market system demands and this system responds/reacts to its powerplant operations. Therefore, the economic impacts of changes in Glen Canyon Dam operations are measured for the system as a whole by computing SLCA/IP market system operating costs. On the production side, costs include energy production costs that

are comprised of fuel expenditures, variable O&M costs, and unit startup expenses. Costs are also incurred to deploy price-sensitive loads. The AURORA model run in dispatch mode was used to estimate production levels and associated costs for each generating unit and DSM program in the SLCA/IP market system during the study period.

AURORA dispatch mode computations are based on a given set of resources, as previously determined by AURORA runs that were made in capacity expansion mode. Hourly SLCA/IP federal hydropower production input into AURORA is based on GTMax-Lite runs for Glen Canyon Dam and the other five large hydropower plants. These runs adhere to all physical and institutional operating criteria, including those needed to supply project use loads and fulfil ancillary service requirements. Energy costs for each LTEMP alternative are computed as the difference between the AURORA dispatch results for Alternative A and another alternative.

The LTEMP EIS affects the system-level operating costs and therefore energy economics because operating criteria bind the timing and routing of water releases through Glen Canyon Dam. From a system dispatch perspective, power produced by the Glen Canyon Dam Powerplant yields the highest economic benefits when the limited amount of water it releases during a WY is routed through the powerplant's generating turbines to produce power that either displaces energy generation or demands curtailment from expensive grid resources. For example, Glen Canyon Dam has a high economic value when the energy it produces reduces or eliminates the operation of an old, inefficient gas turbine with high production costs. On the other hand, it has a much lower value when it displaces low-cost power generation. As discussed earlier, LMPs that are specified at the Western Interconnection spot market node interface represents Western Interconnection marginal cost production savings when it purchases power from the SLCA/IP market system. On the other hand, when the SLCA/IP market system buys from the Western Interconnection, operating costs of the system are reduced, but it pays for the purchase at the LMP price. For the LTEMP EIS, these prices were determined by the Western Interconnection model run and a scaling algorithm applied to the Palo Verde market hub. Purchases are only made when the LMP is less expensive than the incremental cost of both power production and DSM deployment.

The average annual energy produced by the Glen Canyon Dam Powerplant varies by less than 2% among alternatives. However, at varying levels of stringency, alternative criteria bind the daily and hourly operational flexibility at Glen Canyon Dam and affect both Lake Powell monthly reservoir elevations and Glen Canyon Dam monthly water release volumes. One of the primary differences between the AURORA dispatch in capacity expansion mode and when AURORA is run in dispatch mode is the hydrological information used for SLCA/IP federal hydropower conditions. When run in dispatch mode, the AURORA model uses GTMax-Lite results for Glen Canyon Dam and the other five large SLCA/IP federal hydropower plants, based on hydrological information for the representative trace. As shown in Figure K.1-36, average annual SLCA/IP federal hydropower plant generation for the representative hydrology trace (i.e., Trace 14) used for economic dispatch runs is significantly different from that used for AURORA capacity expansion runs, shown in Figure K.1-33. It should be noted that there is significantly more generation volatility in Glen Canyon Dam Powerplant energy production used for economic dispatch runs. The lowest annual Glen Canyon Dam generation level using Trace 14 is 2,781 GWh, which occurs in CY 2015. Generation under that same trace is

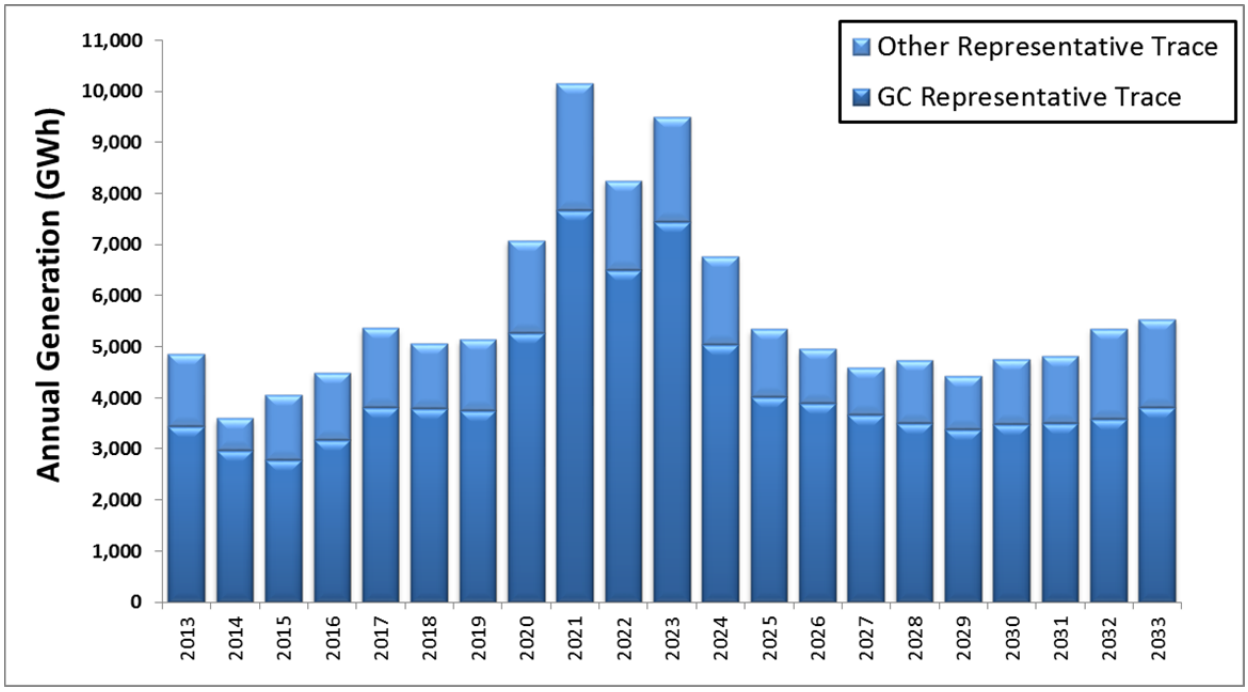

FIGURE K.1-36 Average Annual Glen Canyon Dam Powerplant Generation for the Representative CRSS/SBM Hydrology Trace

7,677 GWh in CY 2021; therefore, those years differ by a factor of about 2.7. This is consistent with historical volatility levels. As described in Section K.1.2, Glen Canyon Dam Powerplant annual generation varied by a factor of 2.6 between CY 1980 and CY 2013.

Trace 14 average daily generation over the LTEMP period produced by the Glen Canyon Dam Powerplant by month is shown in Figure K.1-37. These values are similar to the ones used for the AURORA capacity expansion runs shown in Figure K.1-34. It is one of the attributes of Trace 14 that make it "representative."

As described in more detail in Section K.1.10, the combination of LTEMP operating criteria, Glen Canyon Dam monthly water releases volumes, SLCA/IP market system loads, and spot market LMPs drive EIS differences in economic dispatch cost among alternatives. The system-level dispatch methodology for computing energy economic costs captures the following key aspects of EIS alternative operating criteria:

- Marginal dispatch costs at a location to serve loads increase as the system load-level increases. Resources with low costs are dispatched first. As the load increases, more expensive resources are dispatched to balance the supply and demand.

- The Glen Canyon Dam energy value is based on SLCA/IP market system cost reduction as a consequence of powerplant energy injections into the grid.

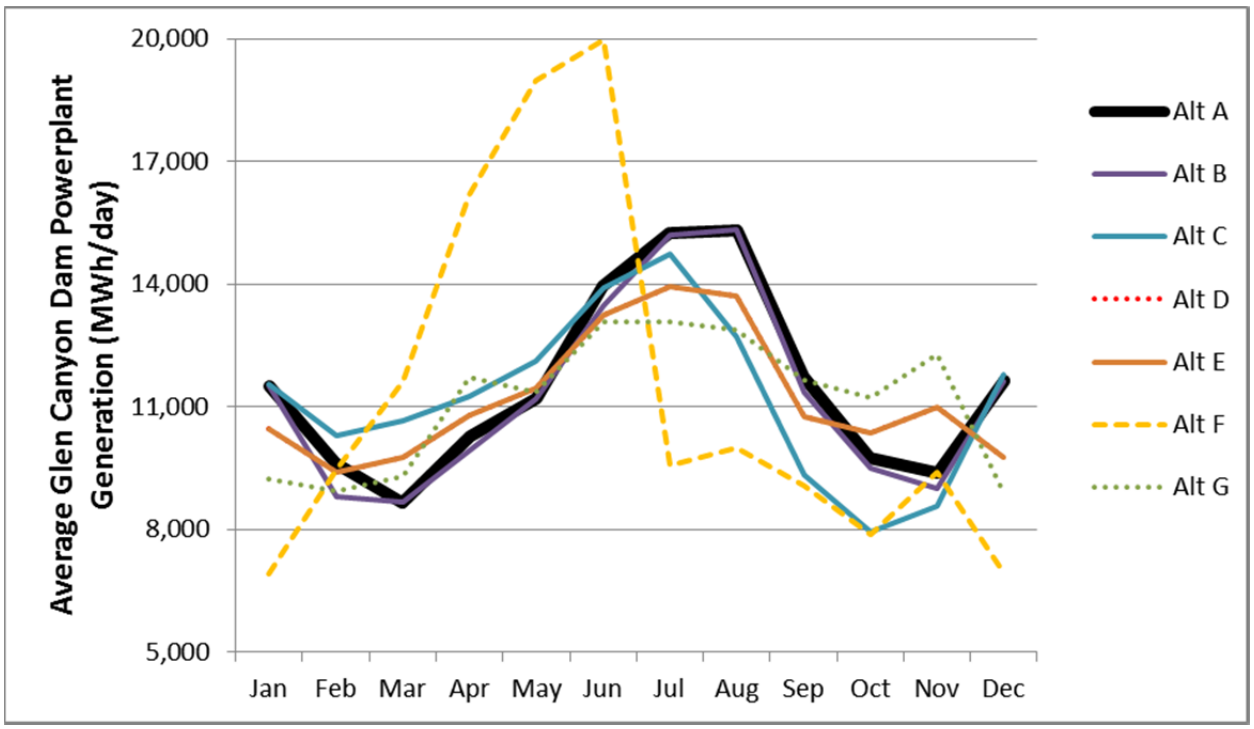

FIGURE K.1-37 Representative Trace Average Daily Glen Canyon Dam Powerplant Generations by Month

- Over short-term operations such as daily and weekly dispatch, energy economic differences among alternatives are highly dependent on operational flexibility allowed under the alternative and the marginal production cost and LMP spread between off- and on-peak periods. If costs and prices are always the same, operational criteria would have minimal impacts.

- On an annual timeframe, energy economic differences among alternatives are dependent on the correlation of monthly water release volumes to monthly marginal production costs and LMP. Alternatives with a positive correlation have a much higher energy economic value than those with a negative correlation. The larger the monthly price and cost spreads, the greater the economic cost of the alternative. If costs and prices are always the same, monthly water release volumes would have minimal impacts.

- Unlike daily, weekly, and monthly economic differences that are a function of price/cost spreads, economic differences from HFEs are a function of absolute energy price/cost levels. Some water bypasses the turbines because the required HFE flow rate can exceed the turbines' maximum flow capability. Water that bypasses the turbines does not generate electricity for sale to customers and therefore has zero power value.

K.1.9 Net Present Value Calculations and Study Period Adjustments

As described in previous sections, all costs input into GTMax-Lite and AURORA are expressed in 2013 dollars. For many of these inputs, this required that input values reported in the literature be converted to 2013 dollars. For example, the cost of candidate technologies for new construction was expressed in terms of 2012 dollars. The index used for dollar conversion is application specific. Attachment K.10 provides more information on the dollar year conversion process.

By expressing all present and future cost inputs in terms of real dollars, the effects of inflation are removed from all AURORA model calculations. Therefore, for each year all costs projected by the model are measured on a common and consistent basis. However, LTEMP EIS alternatives incur different levels of cost at different times over the study period. Therefore, to account for the time value of money in which the present worth of money is typically, but not necessarily, higher today than the same amount of money in the future, the NPV of all costs are calculated to facilitate a common point in time for cost comparisons among alternatives. The process of discounting is used to make costs that occur at different points in time commensurate with each other.

The NPV computation takes a chronological stream of values over time and discounts each one to a specified point in time based on a defined discount rate. These values are then summed. Although the mechanics of the discounting process are very straightforward, the magnitude of the discount rate greatly influences the degree to which future costs and benefits "count" in the decision. As a result, the choice of discount rate is the subject of much debate. For the LTEMP EIS, NPV calculations are based on a discount rate of 3.375%. The use of this discount rate was in part based on information contained in Attachment K.4, which was provided by Reclamation staff. At the recommendation of WAPA staff, a second discount rate of 1.4% was used in a sensitivity study.

Because of discounting, the NPV calculation places more importance on near-term economic costs as compared to those that occur in the more distant future. For example, a dollar cost incurred during the first year of the study period has a $1 NPV impact. However, at a 3.375% discount rate, the same dollar impact in the 20th year of the analysis has only a $0.5322 impact (i.e., slightly more than half) on the NPV. The selection of the representative trace does not consider the discount effect on NPV outcomes. It may be important, however, because the energy costs of an alternative are sensitive to hydrological conditions. The selected representative hydrology trace starts out dry, becomes very wet in the middle of the period, and by the last few years it returns to a dry condition. All other factors constant, the NPV calculation would yield a different value if the sequence of dry, average, and wet hydrological conditions differed from Trace 14. A sensitivity analysis of the impacts of the sequence of hydrological conditions on EIS energy NPVs would help quantify the range of possible outcomes.

All detailed model calculations were made and expressed in 2013 dollars. This was in part due to CRSS and SBM, which used the beginning of CY 2013 as a starting point. Cost was computed over the 20-year length of the long-term experiment: a period that begins at the start of CY 2013 and ends at midnight on the last day of CY 2032. However, to be consistent with other

EIS disciplines, the power system analysis period was directed by project co-leads to cover CY 2015 through CY 2034 and express all costs in terms of 2015 dollars. The request was made at a point in the modeling process when all model runs, computations, and most aspects of the analysis had been completed. It was therefore necessary to make adjustments to the CY 2013 to CY 2032 results. The power systems team and co-leads agreed that the following adjustments were reasonable given time and budget constraints.

1. All energy costs were shifted by 2 years. That is, CY 2013 energy costs were assumed to take place in CY 2015 using Trace 14 hydrology for CY 2013, energy costs in CY 2014 were assume to occur in CY 2016, and so on.

2. The energy costs were then adjusted to account for real changes in energy prices over time. This was accomplished in a two-step process. First, an energy price index benchmarked to 2013 dollars was computed. The index is based on the yearly average energy cost to serve load from the AURORA SLCA/IP market systems model. This index was then applied to the shifted energy costs from step 1 for all years. For example, because energy prices in real 2013 dollars decreased during CY 2013 to CY 2015 timeframe (according to AURORA and in actuality), the costs are adjusted downward using the AURORA-generated energy price index. The end result is chronological annual costs from CY 2015 through CY 2034 in beginning year 2013 dollars.

3. The energy cost time series is then converted to 2015 dollars using a general price index. For this analysis, the seasonally adjusted GNP IPD was applied to the 2013 dollars (see Table 1 in Attachment K.10).

4. The capital cost dollar for new unit construction from the EIA's 2014 AEO (EIA 2014) expressed in nominal 2012 was adjusted to beginning year 2015 dollars using the "Powerplants" index contained in Reclamation (undated). Fixed O&M costs were converted to 2015 dollars used the same table, except that the "Powerplant Accessory elect. & misc. equip" index was used.

5. No adjustments were made to the online dates of new units constructed to the study period, because the capacity reserve margin was greater than 15% in 2015 under all alternatives. However, because the analysis period is shifted, there were no AURORA capital or fixed O&M cost computations for the last 2 years. Therefore, average cost values over the last 5 years of the AURORA model run were assumed for CY 2033 and CY 2044.

6. The stream of all future costs are discounted to beginning year 2015 at an annual discount rate (i.e., 3.375%) specified by the Reclamation for cost-benefit studies of projects.

A final EIS and ROD will not be completed until after WY 2015. The reader should recognize that the economic analysis for electrical power systems is sensitive to the years that are modeled. Currently, the region affected by a change in the operation of Glen Canyon Dam is in

"capacity surplus." This means that generating capacity in the affected region currently exceeds peak electrical demand more than is necessary to achieve an acceptable level of reliability. However, a growing regional economy and population will soon cause electrical demand to catch up to supply. Depending on the actual ROD implementation date, the SLCA/IP market system and the Western Interconnection may need to build additional capacity above committed levels before completion of the ROD.

K.1.10 Power Systems Results

This section details the results of the power systems analysis, focusing primarily on total SLCA/IP market system costs under each alternative relative to Alternative A. It also describes the sensitivity studies that were performed to test the robustness of model results and analysis conclusions. One set of sensitivity studies was on the risk preference or exceedance level that is used to determine SLCA/IP federal hydropower firm capacity. The results in the main EIS were based on a 90% exceedance level. This section presents power system results for exceedance levels of 50% and 99% to reflect the possibility of WAPA considering different risk levels in future marketing efforts.

Another sensitivity study was performed on discount rate. The discount rate used in the main EIS was 3.375% because the Bureau of Reclamation is required to employ an administratively determined discount rate known as the federal plan formulation and evaluation rate, when undertaking economic analyses of water resource and related matters pursuant to 42 U.S.C. 1962d–17. The plan formulation and evaluation rate for fiscal year (FY) 2015 is 3.375% (Reclamation 2014a,b). This section will show how power system results will change if a lower discount rate, namely, 1.4%, is used. This value was used to explore a "real" interest rate based on treasury notes and bonds, as determined by the Office of Management and Budget in Circular A-94 Appendix C.

Two other sensitivity studies were also performed. One studied the sensitivity of the baseline capacity expansion pathway used in Alternative A to different assumptions about the candidate plants that would be constructed. AURORA invariably chose a combination of advanced combustion turbines and advanced combined cycle plants as the preferred expansion path. However, to test the sensitivity of the results to different expansion pathways, we ran the AURORA model for two extreme expansion pathways for Alternative A: one allowed construction of only advance combustion turbines, and the other only natural gas combined cycle plants.

The next study determined the sensitivity of the AURORA results to the choice of hydrological conditions. The results of another hydrological condition were compared against the results of the representative trace (i.e., Trace 14).

Finally, as described in Section K.1.7.3, ancillary services are no longer expected to increase as much and as rapidly as assumed in GTMax-Lite model runs. Therefore, a sensitivity study was performed to determine whether and by how much power system results would change if current ancillary service projection had been used. The results of the sensitivity study showed

that ancillary services assumptions under a range of plausible futures have little to no effect on firm capacity and energy value for the LTEMP alternatives (see Section K.1.10.8 for further detail).

K.1.10.1 Main Drivers of Differences among Alternatives

Among all alternatives, annual water release volumes differ by less than 1% and the total volume of water released from Glen Canyon Dam over the 20-year LTEMP period is nearly identical. Therefore, the economic cost of an LTEMP alternative is not caused by changes in long-term water release volumes, but rather from altering the routing and timing of water releases during monthly, daily, and hourly timeframes within a year.

Figure K.1-38 shows monthly average daily generation produced by water releases that are routed through the powerplant's turbines. Each alternative has a unique monthly water release pattern. For example, as compared to Alternative A, Alternative F turbine releases are much higher during March, April, May, and June and much lower during July and August. When water/generation is shifted from a month that has higher system production costs to a month with lower costs, the economic value of power produced by the Glen Canyon Dam Powerplant is reduced. Ultimately, this generation shift increases costs to the SLCA/IP market system, and therefore the cost of the alternative, because more expensive generation serves system electricity demand. Figure K.1-39 shows the average daily minimum, maximum, average, and range of electricity market prices by month forecasted for the Palo Verde market hub during the 20-year LTEMP period. In general, the more generation is produced in months with high electricity prices, the lower the alternative's cost will be relative to Alternative A. This allocation of limited water resources allows Glen Canyon Dam to serve system loads when the power it generates has the highest value.

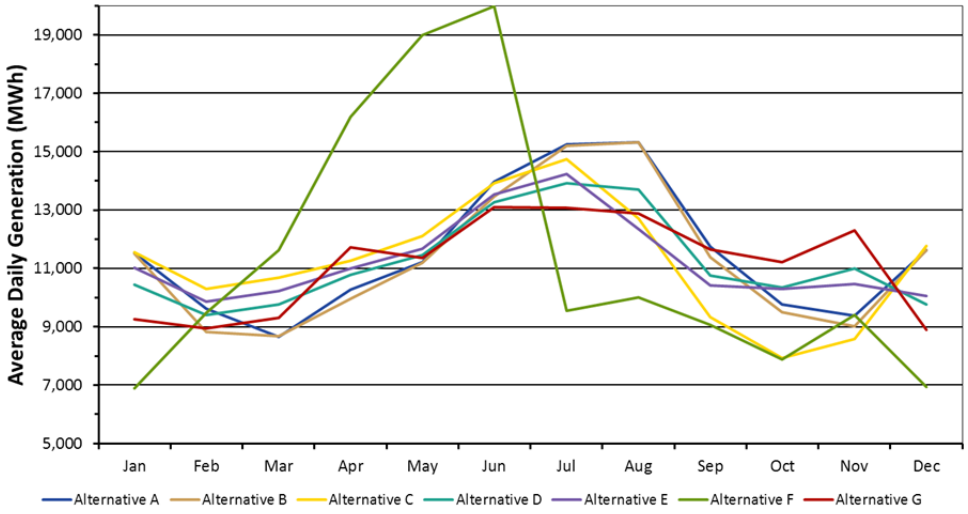

FIGURE K.1-38 Average Daily Generation by Month for Each Alternative

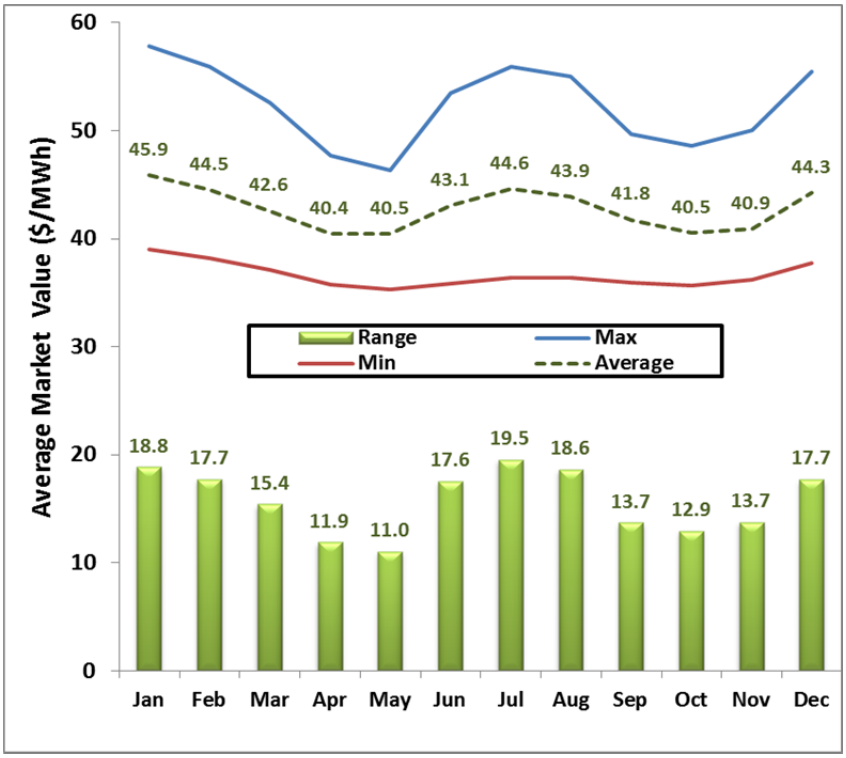

FIGURE K.1-39 Palo Verde Average Daily Electricity Market Price Statistics by Month during the 20-Year LTEMP Period

Alternatives also impact the daily profile of water releases. Changes in operating criteria, such as maximum and minimum release restrictions and mandates that limit water release changes over time, result in very different release patterns during most days. For example, except when transitioning between months or when HFEs are being conducted, Alternatives F and G require water releases from Glen Canyon Dam to be at a constant rate during each month. In contrast, other alternatives allow powerplant operators to change water release levels during a day in response to market price signals and system marginal production cost patterns. Alternatives that allow for only a small range between maximum and minimum releases and permit only minimal changes in water releases over time decrease the value of Glen Canyon Dam power production by shifting water releases from high price peak hours to low price off-peak hours. Figure K.1-40 shows typical Western Interconnection hourly electricity price patterns for winter and summer and the price spread between peak and off-peak hours.

Finally, alternatives affect the routing of water releases from the dam. Water is typically released through one or more of Glen Canyon Dam's eight turbines to produce electricity. However, depending on the pressure exerted by the water elevation in Lake Powell, only a limited amount of water can flow through turbines during an hour. In addition, the generating capacity of a unit indirectly limits the flow of water through it. Therefore, whenever a water release is required to exceed the combined flow capabilities of the generating units that are in operation, some of the water is released through hollow jet tubes (bypass) and spillways. These non-power releases produce no energy. Each alternative has a unique set of HFE specifications

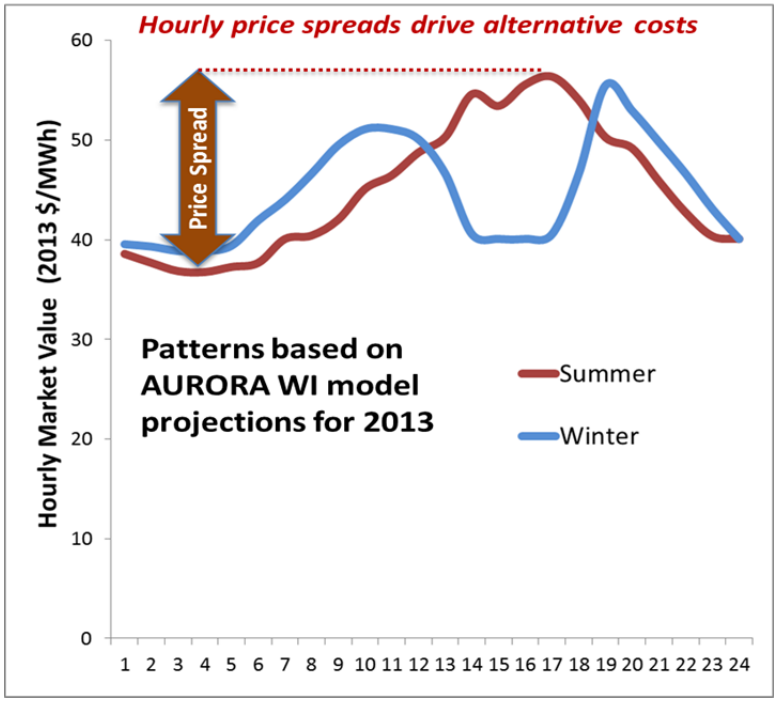

FIGURE K.1-40 Typical Hourly Winter/Summer Price Patterns in the Western United States

that affect the frequency and duration of Glen Canyon Dam non-power releases. Water is only released over the spillway (referred to as spilled water or spills) under emergency conditions associated with dam safety. Figures K.1-41 and K.1-42 show the average number of HFEs and the average amount of water spilled by alternative over the LTEMP period, respectively. Averages shown are based on all 21 hydrology traces of sediment Trace 2 and disaggregated by type of HFE. Alternative G has the highest number of HFEs; Alternatives C, D, E, and F have fewer HFEs; and Alternatives A and B have the fewest HFEs. Similarly, the greatest average volume of non-power releases occurs under Alternatives D and G; a lower volume of non-power releases occurs under Alternatives C, E, and F; and the lowest volume of non-power releases occurs under Alternatives A and B.

Water is also bypassed during very low (i.e., dry) hydropower conditions when the water elevation in Lake Powell is below the minimum turbine water intake level. During those times, it is assumed that all of the water released from Glen Canyon Dam produces no electricity until the water level rises to the minimum intake level. Figure K.1-43 shows the average annual number of hours, by alternative, the Lake Powell elevation is below the minimum penstock intake over the 20-year study period for all 21 traces of sediment Trace 2. Alternative G averages the greatest number of hours when the elevation is too low, resulting in an average of 8.5 hr over the 8,760-hr year, or 0.1% of the time; Alternatives A, B, C, D and E have somewhat fewer hours; and Alternative F has no hours when the elevation is too low to produce electricity.

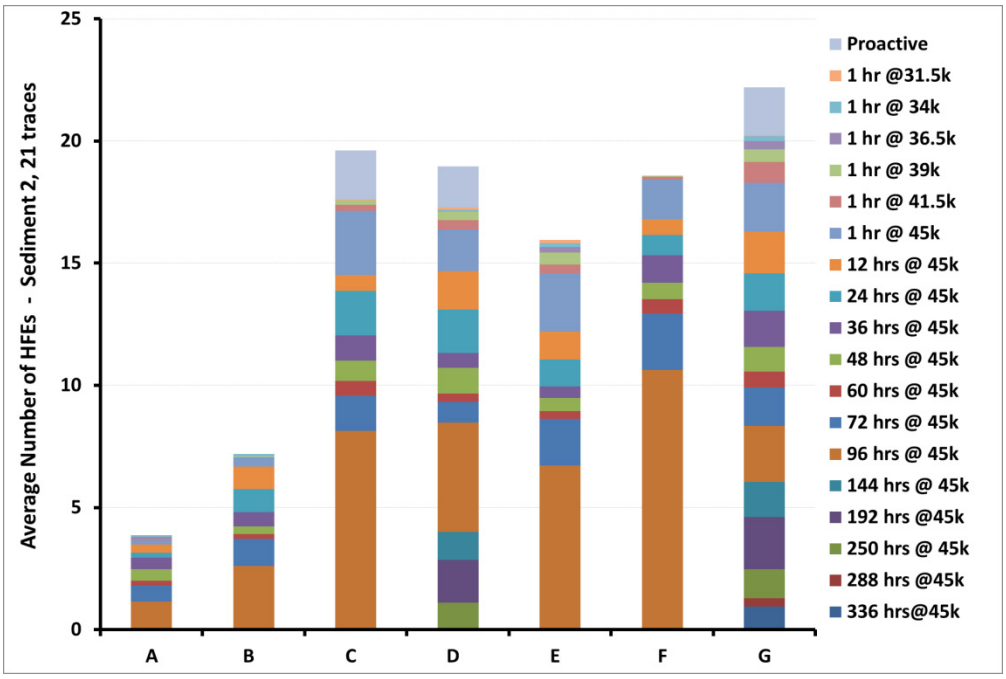

FIGURE K.1-41 Average Number of HFEs by Alternative for All 21 Hydrology Traces of Sediment Trace 2

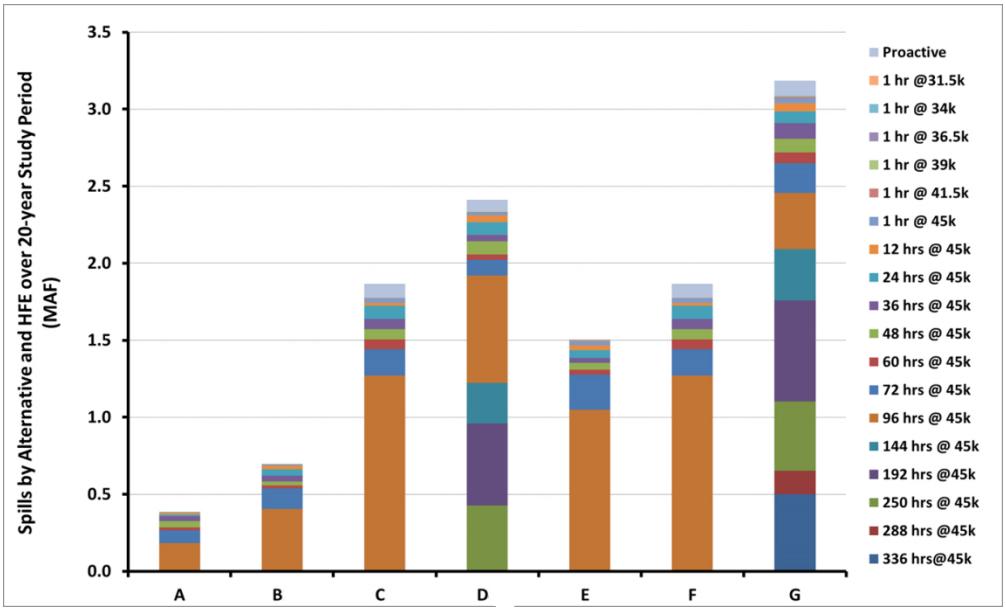

FIGURE K.1-42 Average Amount of Non-Power Water Releases by Alternative for All 21 Hydrology Traces of Sediment Trace 2

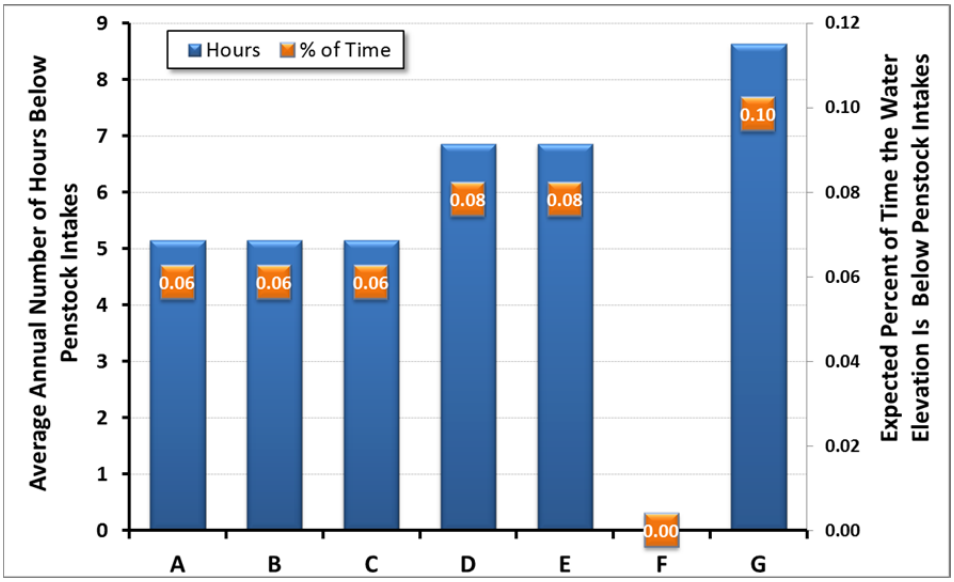

FIGURE K.1-43 Average Annual Number of Hours the Lake Powell Elevation Is below the Penstock Intake by Alternative for All 21 Hydrology Traces of Sediment Trace 2

Figure K.1-43 also shows that the percentage of time the reservoir at Glen Canyon Dam is expected to be below the penstock is very small (i.e., at most about one hourly occurrence out of every 1,000 hr). However, most of these occurrences are concentrated in fairly long, continuous periods of time. For example, under Alternative G, all hours with elevations below the penstocks occur during a continuous 3-month period starting in January 2018, under hydrology Trace 19, and during the entire month of April 2024, under hydrology Trace 8. Therefore, the risk of encountering zero generation periods is small, but when it does occur, the economic implications are very costly.

Finally, non-power water releases can also occur as a result of inflow forecast error. High reservoir conditions in combination with unanticipated large water inflow volumes into Lake Powell will result in bypassed or spilled water if there is inadequate spare reservoir capacity to accommodate all of the water inflows minus maximum turbine flow rates.

K.1.10.2 Capacity Expansion Modeling

Capacity expansion plans for each alternative during the study period are determined by running the AURORA model in capacity expansion mode. The plans specify the type of technology built, unit capacity, and the year a new unit begins operation. The model also computed the annual capacity investment and O&M costs for all new units built over the study period except those previously committed and contained in the unit inventory. As noted in section K.1.6.3, the AURORA model was given a wide selection of technologies from which to choose for future capacity additions, including conventional and advanced natural gas combustion turbines, conventional and advanced gas/oil combined cycle units, scrubbed and

pulverized coal units, integrated gasification combined cycle units, nuclear units, wind farms, and solar thermal and photovoltaic projects.

The firm SLCA/IP federal hydropower capacity input to the AURORA expansion model is credited toward meeting the system reserve margin. The quantity input depends on the combined operating capabilities of these resources at the time of the system peak demand, and on a defined exceedance level. Table K.1-7 shows marketable capacity by alternative at the 90% exceedance level (i.e., a 10% risk of having a lower peak operating capability than the specified firm level at the time of system peak load). The table also shows the difference in firm capacity compared to Alternative A (referred to as lost capacity). Except for Alternative B, which has 28.1 MW more firm capacity than Alternative A, all other alternatives have approximately 50 MW to 314 MW less firm capacity at the 90% exceedance level. This indicates that the need for additional generating capacity to replace capacity losses at Glen Canyon would range from 6.7 to 42.6% relative to Alternative A.

A retrospective study performed by Argonne on marketable capacity offered by CRSP Management Center over the last 10 years shows that it markets capacity at a 90% exceedance level. That is, WAPA has enough SLCA/IP federal hydropower resource capacity to meet its obligation 90% of the time. Therefore, the baseline LTEMP analysis used the same exceedance level to determine SLCA/IP federal hydropower firm capacity. However, in the future WAPA may choose another exceedance level to determine marketable capacity. Results are presented later in Section K.1.10.4 for exceedance levels of 50% and 99%; this range will bracket the risk preference level that the CRSP Management Center will likely, but not necessarily, choose to use when determining future LTF capacity commitment levels.

TABLE K.1-7 SLCA/IP Marketable Capacity at the 90% Exceedance Level

Capacity Type	Alternative A (No Action)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
SLCA/IP Firm Capacity (MW)[a]	737.2 (no change from current condition)	765.3 (3.8% increase)	608.1 (17.5% decrease)	687.6 (6.7% decrease)	647.0 (12.2% decrease)	423.1 (42.6% decrease)	558.2 (24.2% decrease)
SLCA/IP Lost Capacity (MW)[b]	Not applicable	–28.1	129.1	49.6	90.2	314.1	179.0

[a] Marketable capacity is calculated based on all 21 hydrology traces with median sediment input (sediment Trace 2), which has the highest likelihood of occurrence. It is calculated at the 90% exceedance level, using August as the peak load month. That is, combined SLCA/IP federal hydropower resources are able to attain peak output at the firm capacity level or higher 90% of the time during the August peak load.

[b] Lost capacity is the difference between the marketable capacity in Alternative A and the marketable capacity of another alternative; it represents the capacity that would need to be replaced somewhere in the power system if that alternative was implemented.

The AURORA expansion model only selected natural gas–fired technologies in its SLCA/IP market system plan to meet future demand; no other thermal or renewable technologies were chosen. Wind and solar plants were added in the expansion pathway, but only to meet the expansion goals specified in the utility IRPs as described in Section K.1.6.3. The natural gas–fired technologies chosen by AURORA were the 400-MW advanced combined cycle unit and 230-MW advanced combustion turbine.

The expansion pathway chosen by AURORA was consistent with projections made in the 2014 AEO (EIA 2014), and with expansion plans reported in IRPs developed by utilities in the region. Figure K.1-44 shows the 2014 AEO projects of cumulative capacity additions for the three geographic regions in the Western Interconnection for the next 20 years. In the future, the AEO projects only renewable generation; natural gas combined cycle plants and combustion turbines; and distributed peaking generation, which is most often fueled by natural gas.

As noted in Section K.1.6.3, Argonne conducted a survey of the current IRPs available on the websites (which typically had publication dates of either 2013 or 2014) of WAPA's customers and investor-owned utilities in the geographic and "electrical" area of WAPA's customers to determine the timing and type of resources these utilities were planning to meet future electric demand. The results of that survey were shown in Table K.1-6. As in the 2014 AEO (EIA 2014), utilities are forecasting that future capacity additions to their systems will consist of renewables (mainly wind and solar) and natural gas–fired combined-cycle plants and combustion turbines. A conclusion that can be drawn from Table K.1-6 is that because new generators are forecasted to come online in the very near term (the next 2 to 3 years) there will be little or no excess capacity in the region that would be available to replace capacity lost at Glen Canyon Dam at the time when the ROD is issued.

Figure K.1-45 shows the cumulative capacity additions selected by the AURORA expansion model for Alternative A (combustion turbines are labeled CT and natural gas combined-cycle units are labeled NGCC). Table K.1-8 shows the difference from Alternative A in cumulative capacity additions for each alternative. Because units are built in large increments, capacity expansion is often said to be "lumpy." The green line in the figure shows the amount of capacity in excess of the 15% reserve margin. Due to the lumpy expansion path, some years significantly exceed the 15% reserve margin target, while others have just enough to satisfy the reserve margin. However, the capacity above the reserve margin could be sold to utilities that are short of capacity at the market price, thereby reducing the total net cost to the SLCA/IP market system. Sales of excess capacity will be explored and quantified in the analysis of alternatives.

It should be noted that the first capacity addition under Alternative A comes online in 2018 under the current joint system analysis. Therefore, there will be very little or no excess capacity when operational changes at Glen Canyon Dam could possibly be implemented. Furthermore, lost capacity would need to be replaced soon after the ROD.

Although CRSP Management Center LTF customers typically engage in economical firm capacity and energy transactions, the joint planning approach assumes a higher level of coordination and cooperation among LTF customers than may currently exist. Results shown in Figure K.1-45 are based on a methodology that projects the expansion plan for the combined

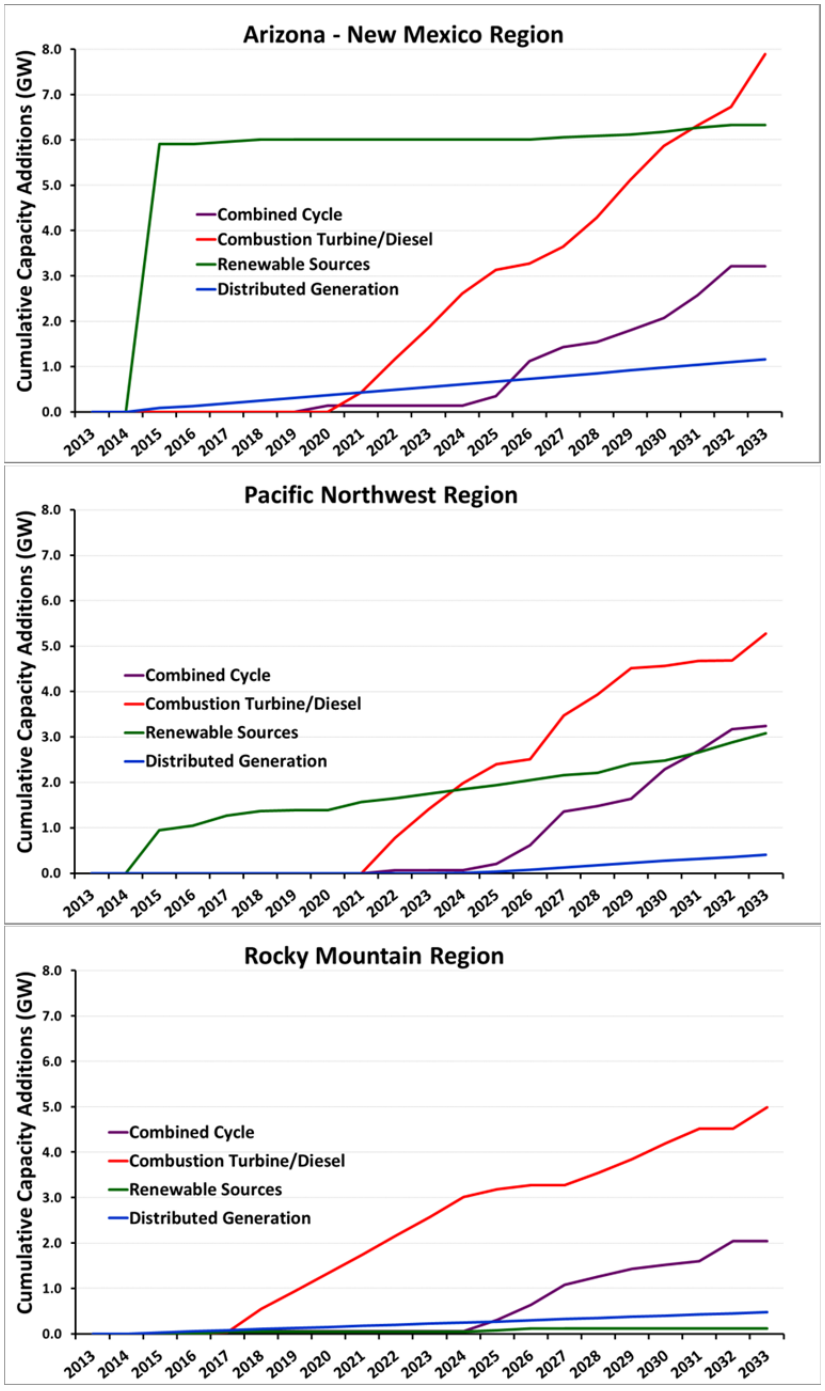

FIGURE K.1-44 2014 Annual Energy Outlook Projections of Capacity Additions in the Western Interconnection over the LTEMP Period

system in which the costs and benefits of new generating resources would be shared among both large and small customers. This approach has a number of advantages related to modeling efficiency while representing the general system response to changes in Glen Canyon Dam firm capacity, but understates the cost impacts. This joint planning approach indicates that numerous units would be constructed by the system. For example, by 2034, 14 new advanced combustion turbines and four advanced combined cycle units would be constructed under Alternative A (see Table K.1-9). Each unit could be operated by an individual utility or as a joint dispatch, whatever arrangement is more advantageous. If technical or institutional barriers did not allow joint unit dispatch, a new unit could be built by a single owner/operator. Furthermore, if the new unit created excess capacity in the owner's utility, it may be able sell capacity from other system resources that are more conducive to joint dispatch. Alternatively, the capacity-long system could sell the excess without specifying the individual supply resource.

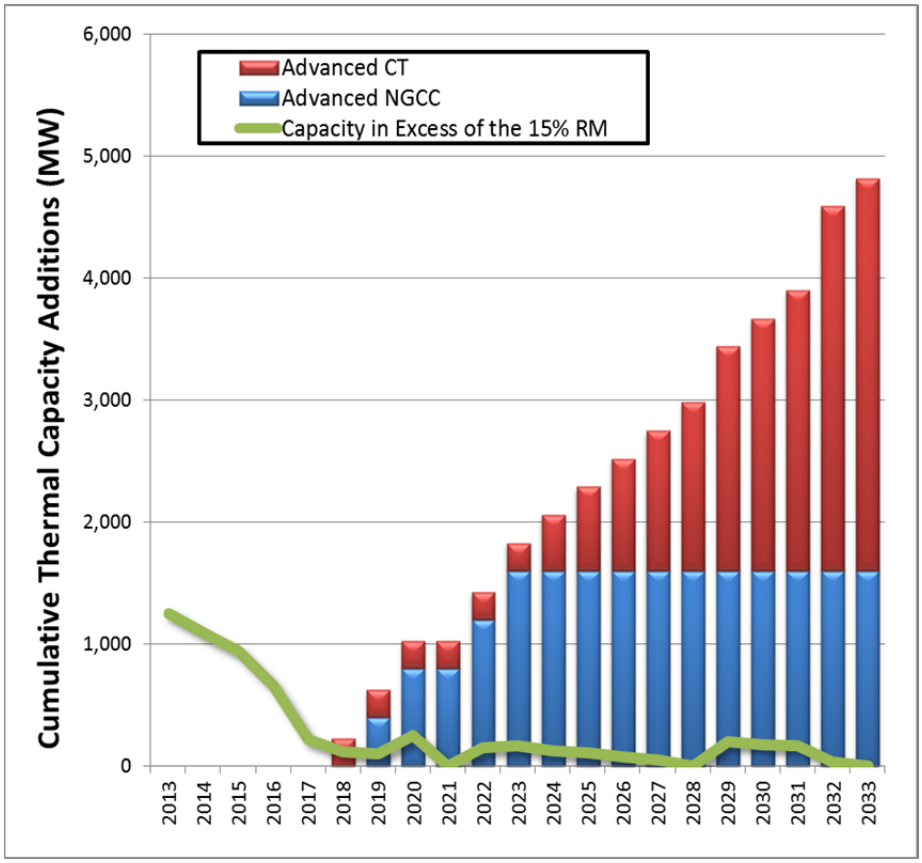

FIGURE K.1-45 Cumulative Capacity Additions for Alternative A (90% Exceedance Level)

The cost of capacity replacement in general would be higher if each individual utility were modeled as isolated entities (i.e., without mutually beneficial arrangements), which is how new units would actually be constructed. This model solution would, in many respects, be uneconomical and unrealistic because each utility that is capacity short would need to either (1) build a relatively large efficient unit to replace its allocation of the lost capacity, which in most cases is very small, or (2) build a very small unit that is typically less efficient and, because of economies of scale, is more costly per kilowatt of installed capacity to construct. Utilities that are capacity long may not need to construct any replacement capacity. The capacity expansion plan would also be very lumpy.

The capacity expansion pathway for Alternative A will replace existing powerplant capacity that will retire in the future and meet forecasted increases in electricity demand in the SLCA/IP market system. The expansion pathways for all other alternatives are a modification of this pathway. Differences in firm capacity among alternatives were evaluated in terms of the amount and timing of new generating units constructed in the future. All alternatives except Alternative B have a decrease in firm capacity compared to Alternative A. Alternatives that have less firm capacity would be expected to install capacity earlier and/or install more capacity than Alternative A. Conversely, Alternative B would be expected to have a delay in capacity additions

compared to Alternative A. Table K.1-9 compares the capacity expansion pathways for Alternatives A and F. Alternative F has the most lost capacity of all alternatives.

TABLE K.1-9 Comparison of the Amount and Timing of New Capacity Additions for Alternatives A and F (90% Exceedance Level)

On-Line Date	New Additions

2033	CT14	CT16

Table K.1-9 shows that Alternative F installs combustion turbines (labeled CT1, CT2, etc.) 1 to 7 years earlier than Alternative A. By the end of the LTEMP period Alternative F also installs more capacity, two more combustion turbines. Because the number and timing of natural gas combined cycle units (labeled NGCC1, NGCC2, etc.) is identical under both alternatives, lost Glen Canyon Dam capacity is replaced exclusively by advanced combustion turbines. This accelerated capacity addition schedule occurs because Alternative F has 314 MW less SLCA/IP federal hydropower firm capacity than Alternative A.

Table K.1-8 shows a comparison of capacity additions for all alternatives. This table lists the cumulative additional capacity for Alternative A and then shows the difference in cumulative capacity between it and the other alternatives. The difference represents the capacity that is constructed to replace lost Glen Canyon Dam capacity. Note that the replacement capacity in the table are –230 MW, 230 MW, or 460 MW; capacity changes occur in increments of an advanced combustion turbine unit. At the bottom of the table are values showing the average annual amount of replacement capacity, the lost firm capacity, and the difference between those two values. As expected, for each alternative, the amount of lost capacity and average annual capacity replacement amount ranges from −4 MW to 28 MW.

Under Alternative A, an estimated 4,820 MW of new capacity is built in the SLCA/IP market system. Capacity additions are phased in over time, such that a minimum 15% capacity reserve margin is attained in each year of the 20-year LTEMP period. Under all alternatives except Alternative B, more new generating capacity must be built and the capacity must also be built sooner. Like Alternative A, Alternative B adds 4,820 MW of new capacity by CY 2034; however, because Alternative B has slightly more firm capacity, one new generating unit would be constructed a year later than under Alternative A. All other alternatives have less firm capacity than Alternative A. Under Alternatives C, D, E, and G, 5,050 MW of new capacity additions would be required by CY 2034; this amounts to one more combustion turbine than Alternative A, which is an increase in capacity of 4.8%. Under Alternative F, 5,280 MW of new capacity is built by CY 2034, which is two more combustion turbines than Alternative A. This amounts to an increase in capacity of 9.5%.

In addition, it is noteworthy that because capacity is built in discrete sizes/increments that do not match the amount of lost capacity, system expansion differences among the alternatives do not typically match the amount of lost capacity. In some years, the replacement capacity is larger than the lost capacity, while in other years it is smaller. Again, this result shows the "lumpiness" of capacity expansion, which allows for possible sale of capacity above the 15% reserve margin to be sold at market price to reduce the total cost of an alternative.

K.1.10.3 Economic Impacts

When the capacity expansion pathways were determined for each alternative, the AURORA model was run in dispatch mode to simulate the operation of the system for every hour in the entire study period for hydrological Trace 14, which is the representative trace. Selection of the representative trace was discussed in Section K.1.5.2, and Attachment K.3 of this appendix describes in detail how that trace was chosen.

The AURORA dispatch model computes all SLCA/IP market system costs associated with the production of electrical energy to meet the system load and to generate additional energy for power sales to the spot market. Production costs are the sum of powerplant fuel costs, variable O&M costs, and cost of power purchased from the spot market. Revenues from the power sales to the spot market are subtracted from these costs to compute the net economic cost. This technique was used to compute the production costs of serving only SLCA/IP market load. Results from the AURORA expansion and dispatch models (i.e., capital, fixed O&M, and production or energy costs) are combined to determine the total annual costs for each alternative. The net present value stream of costs is also calculated to facilitate comparison of each alternative to Alternative A. This single lump-sum value is based on a discount rate of 3.375%, a rate used by Reclamation for cost-benefit studies of projects pursuant to U.S.C. 1962d-17.

The total economic impacts at the 90% exceedance level by alternative are summarized in Table K.1-10. Costs are disaggregated by system-wide net production cost, which was obtained from AURORA dispatch model simulations, and by capital costs and fixed O&M costs, which were both obtained from AURORA expansion model simulations. This table also includes calculating a benefit from the sale of excess capacity above that required to satisfy the reserve margin. This benefit would reduce the total cost of each alternative.

All alternatives except for Alternative B have less firm SLCA/IP federal hydropower capacity than Alternative A. Therefore, the NPV of capital and fixed O&M costs are higher than under Alternative A. Alternative B had the same total amount of new capacity at the end of the LTEMP study period as Alternative A, but the construction of one combustion turbine was delayed by a year due to its slightly higher firm SLCA/IP federal hydropower capacity, which resulted in slightly lower capital and fixed O&M costs. Although Alternatives C, D, E, and G have the same amount of new capacity at the end of the LTEMP study period, they have different NPVs for capacity and fixed O&M because of the difference in the timing of the installation of the new capacity. The differences in timing are found in Table K.1-8.

TABLE K.1-10 Total Economic Impacts by Alternative at the 90% Exceedance Level

Economic Impact Measure	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
System-level generating capacity additions (MW)[a]	4,820 (no change from current condition)	4,820 (no change from current condition)	5,050 (4.8% increase)	5,050 (4.8% increase)	5,050 (4.8% increase)	5,280 (9.5% increase)	5,050 (4.8% increase)

Difference in Adjusted Total Costs ($million) Relative to No Action	Not applicable	–29	135	84	95	405	265
Adjusted Rank (lowest to highest total cost)	2	1	5	3	4	7	6

[a] Additional generation capacity required under the LTEMP alternatives for WAPA's customers over the 20-year LTEMP period to not only meet future load demand and replace unit retirements, but also account for loss/gain in capacity at Glen Canyon Dam due to the alternative operating constraints.

[b] Net present value ($million 2015) of costs to meet total system electric demand over the 20-year study period for all SLCA/IP customers under representative trace. Discount rate is 3.375%. The excess capacity may have some economic value; however, that value would depend on the timing and details of the replacement, and thus results are presented both with and without this potential excess.

Table K.1-10 also shows the amount of potential sale of excess capacity of generating units constructed by WAPA's customers above that mandated by the reserve margin. As a result of the lumpy nature of capacity additions, there are short periods of time (i.e., typically less than 2 years) in which slightly more system capacity is built than is needed to meet the reserve margin target. It is assumed this small amount of capacity (i.e., less than the size of one generating unit) may have some value and could be sold to entities outside of the SLCA/IP system. Sales of this excess capacity lower the total cost of all alternatives, but do not substantially affect their relative ranking from lowest to highest cost alternative. If alternatives are ranked based on the difference in adjusted total cost, the order of alternatives from lowest to highest cost is as follows: Alternative B, Alternative A, Alternative D, Alternative E, Alternative C, Alternative G, and Alternative F. If the potential for sale of excess capacity is not factored into the total alternative cost, then the ranking of alternatives changes only slightly; Alternatives E and D change places in the ranking. All other alternatives remain in the same order.

Cost of Experimental Releases

LTEMP alternatives and associated long-term strategies are composed of operating criteria and several experimental elements, as shown in Table 4.1-1. Economic evaluations presented for the Structured Decision Analysis (SDA) (Appendix C) and detailed power systems analysis (Section 4.13 and Section K.1) bundle all of the costs associated with an alternative

(including operational changes and experiments) into a single value (NPV). This section provides estimates of the "unbundled" economic cost of several types of experiments.

These estimates are computed by comparing the estimated effects of long-term strategies of alternatives that differ only in inclusion of a particular experiment.[2] The one element that differs between the two alternatives is the element for which the economic impacts are measured. For example, to measure the economic cost of low summer flows, two long-term strategies for Alternative D are compared (D1 and D4). Both have identical operating criteria and the same experimental elements except that under long-term strategy D1 low summer flows are included in the second 10 years of the LTEMP period, while under long-term strategy D4 low summer flows would not be conducted. Subtracting NPV results for D4 from D1 yields the NPV cost of conducting the experiments over the 20-year LTEMP period. Using this methodology, the approximate cost of conducting different types of experimental elements can be "unbundled" from the total aggregate costs previously reported.

Although the SDA modeling results do not include all possible combinations of operating criteria and experiments, a general estimate of the relative costs of each type of experiment can be gained by comparing selected pairs of SDA NPV model results as described in the example above. Using information provided in Table 4.1-1, the following pairs of alternatives were selected to approximate costs associated with individual experimental elements:

1. Low summer flows

    a. Long-term strategies D4 (without low summer flows) and D1 (with low summer flows)
    b. Long-term strategies E3 (without low summer flows) and E5 (with low summer flows)

2. TMFs

    a. Long-term strategies D3 (without TMFs) and D1 (with TMFs)
    b. Long-term strategies E3 (without TMFs) and E6 (with TMFs)

3. Steady weekend flows for macroinvertebrate production

    a. Long-term strategies D1 (without steady weekend flows) and D2 (with steady weekend flows)

4. Fall HFE

    a. Long-term strategies C3 (without HFEs) and C4 (with HFEs)
    b. Long-term strategies E3 (without HFEs) and E4 (with HFEs)

[2] Mechanical trout removal is not included in the comparison of elements because it not a factor in estimates of either SDA or power systems costs.

Consistent with both the SDA and detailed power system results, costs for each experiment are computed for both Glen Canyon Dam Powerplant energy production and replacement capacity. These estimates are based on 21 hydrology traces over the 20-year LTEMP study period. Note that the cost of a single element type differs by alternative pairing. For example, the average NPV energy costs difference between long-term strategies E3 and E5 is bigger than the difference between long-term strategies D4 and D1. In this case, the difference is due to several factors including interactions among the experimental element that is being measured (i.e., low summer flows), and both the operating criteria and other experiments. Note that both E3 and E5 do not include other experiments while both long-term strategies D4 and D1 include TMFs and HFEs. It is therefore apparent that operating criteria and other experiments have an impact on the incremental cost of conducting a specific experiment.

As discussed in more detail below, the cost of conducting an experiment is dependent not only on the water release specifications of the experiment but also the frequency of the experiments and the length of time that it takes to conduct an individual experiment. For example, the energy cost to conduct each benthic invertebrate steady weekend flow experiment is relatively low, while it is much more costly to conduct an individual low summer flow. However, as shown in the following discussion, steady weekend flows are much more costly than low summer flows because of the high frequency of steady weekend flows throughout the 20-year LTEMP period. Approximately seventeen 2-day steady flows would take place every year under the former scenario while on average over all 21 traces less than one low summer flow 92-day experiment is expected over the entire 20-year LTEMP period under the latter scenario.

Capital costs for experimental elements display a pattern that is distinctly different from energy costs. For example, among the experimental elements, fall HFEs are one of the more expensive, while replacement capital costs are zero. Because these HFEs are conducted exclusively during the month of November, there are small impacts on Glen Canyon Dam Powerplant maximum output levels in August when firm capacity is measured. This is especially the case under dry hydrological conditions (e.g., 90% exceedance) under Alternative C and Alternative E operating criteria. There are also no firm capacity cost impacts associated with TMFs because these are conducted in May, June, and July and require no water reallocation among months of the year.

The following sections discuss in more detail each experimental element in terms of the cost to conduct an individual experiment, the frequency of experiments, and duration of each experiment.

Cost of Low Summer Flows. The average per trace difference in the NPV of energy costs over 20 years is $1.97 million between long-term strategies D1 and D4 and $3.36 million between long-term strategies E3 and E5. These costs are lower than both macroinvertebrate production flows and HFEs. This outcome is due to the timing and infrequent occurrence of low summer flow experiments. Among all 21 hydrology traces over the 20-year LTEMP period (i.e., 20 × 21 = 420 outcomes), only 15 low summer flow experiments were triggered

(an average of 0.714 experiments per trace). On an annual basis, the chance that a low summer flow will be conducted is only 3.6% (15/420 × 100). Furthermore, all low summer flows occur during the last 10 years of the LTEMP period. Because the NPV calculation uses an annual discount rate, a low summer flow experiment in a later year has a lower weight in the NPV calculation compared to the same experiment conducted in an earlier year. Based on the total energy cost of conducting low summer flow experiments over the 20-year LTEMP period and their frequency of occurrence, the average NPV energy cost of a single low summer flow experiment is about $2.76 million ($1.97 million/0.714) for Alternative D and about $2.21 million ($3.36 million/1.523, the average number of experiments for strategy E5) for Alternative E. Because a low summer flow experiment takes place during the entire months of June, July, and August (92 days), the average daily NPV cost to conduct a low summer flow experiment is about $30,000 for Alternative D and about $24,000 for Alternative E.

The annual levelized capacity replacement costs for low summer flows are approximately $0.91 million based on a comparison between long-term strategy D1 and long-term strategy D4 (or a per trace NPV cost of $13.03 million over 20 years), and about $1.24 million based on a comparison between long-term strategy E3 and long-term strategy E5 (or a per trace NPV cost of $17.86 million over 20 years). Because low summer flow experiments directly impact operations in the critical peak load month of August by reducing both monthly water release volumes and operational flexibility, there is an impact on firm capacity estimates and therefore the cost of lost capacity at the Glen Canyon Dam Powerplant. Based on the total NPV of the capacity replacement cost of the low summer flow experiments and their frequency of occurrence in the 20-year LTEMP period, the average NPV capital cost of a single experiment is about $18.25 million ($13.03 million/0.714) for Alternative D, and about $11.72 million ($17.86 million/1.523) for Alternative E; that is, an average daily NPV cost of about $198,000 for Alternative D and about $127,000 for Alternative E. Adding the low summer flow costs for energy and capacity yields a per experiment cost of $21.01 million and $13.93 million for Alternatives D and E, respectively.

In WY 2000, a low summer steady flow experiment was conducted and the financial energy cost of this experiment was estimated to be about $25 million in nominal dollars (Veselka et al. 2011). Because the low summer steady flow was a one-time experiment, it was assumed that there were no firm capacity impacts. The WY 2000 low summer steady flow experiment was several times more expensive than the projected energy costs of the low summer flow experiments considered for the LTEMP period, for which costs were estimated to be $2.76 million and $4.70 million for Alternatives D and E, respectively. Although both have similar-sounding names and are conducted in the summertime, there are several factors that make the historical low summer steady flow distinctly different from low summer flows under LTEMP. These include but are not limited to following:

1. The WY 2000 low summer steady flow lasted 6 months (Veselka et al. 2011). In contrast, LTEMP low summer flow experiments are 3 months long.

2. The WY 2000 low summer steady flow had zero operational flexibility, whereby water and therefore power plant output was almost always constant.

There is comparatively more operating flexibility allowed under the LTEMP low summer flow.

3. During WY 2000, energy prices were driven by the California market, which at that time experienced extraordinary price spikes due to the market design structure in place at that time (e.g., the average on-peak price in August was approximately $114.29/MWh) and daily price spreads between on- and off-peak periods were up to $90/MWh.

4. The WY 2000 low summer steady flow required two "spike flows" (the predecessor of HFEs) in the spring and fall.

Cost of Trout Management Flows. For TMFs,[3] the average per trace difference in the NPV of energy costs over 20 years is $3.49 million between long-term strategies D1 and D3 and $0.98 million between long-term strategies E3 and E6. Like low summer flows, these costs are relatively low compared to both the low steady weekend flow and the HFE experiments. The average number of TMFs conducted in a 20-year trace for Alternatives D and E is 7.76 and 2.38, respectively. Based on the total energy cost of conducting TMFs over the 20-year LTEMP period and their frequency of occurrence, the average NPV energy cost of a single TMF is about $450,000 ($3.49 million/7.76 TMFs over 20 years) for Alternative D and about $410,000 ($0.98 million/2.38 TMFs over 20 years) for Alternative E. Because a TMF takes place for a period of 5 days in May, June, and July, or a total of 15 days, the average daily NPV cost to conduct a TMF is about $30,000 for Alternative D and about $27,400 for Alternative E.

There is no capacity replacement cost for TMFs because these experiments only occur in the months of May, June, and July, and water is only reallocated within the same month to conduct the experiments; there is no water reallocation among other months of the year. Therefore, there is no capacity impact in the month of August when firm capacity is measured.

Cost of Macroinvertebrate Production Flows.[4] The average per trace difference in the NPV of energy costs over 20 years is $10.66 million between long-term strategies D2 and D1. Under this experiment, low steady weekend flows would be conducted each weekend in the months of May through August when implemented. The average number of macroinvertebrate production flow experiments conducted per trace under Alternative D was 12.24 over 20 years. Based on the total energy cost of conducting macroinvertebrate production flows and their frequency of occurrence, the average NPV energy cost of this experiment is about $871,000

---

3 Trout management flows consist of repeated cycles of high and low flows over a season (see Section 2.2.3.2 for a description of TMFs). The modeling conducted for the LTEMP considered three cycles—one each in May, June, and July. In the cost of experiment analysis, a TMF experiment is assumed to be a single three-cycle implementation.

4 Under this experiment, weekend days from May through August would be held steady at the minimum flow for each month to support increased production of aquatic macroinvertebrates.

($10.66 million/12.24 experiments over 20 years). Since there are 34 weekend days from May through August, the average daily NPV cost is about $25,600 ($871,000/34 days).

Macroinvertebrate production flows would have a capacity benefit of 42.3 MW. This benefit occurs because in the months of May through August, weekend flows are limited to the minimum flow for that month. Since there is no change in monthly releases for this experiment, lower weekend water releases result in larger water releases, more electric generation, and higher capacity on weekdays. Because capacity exceedance values are based on the peak month of August, an alternative with this experiment has more capacity available during weekdays, when peak loads occur, than an alternative that does not have this experiment.

The annual levelized capacity benefit for this experiment is about $2.12 million (i.e., $30.5 million over 20 years). Based on the total NPV benefit and the number of flows that can occur over 20 years, the cost per experiment is $2.49 million ($30.5 million/12.24 flows over 20 years). The average daily benefit would be about $73,200 ($2.49 million/34 days per year). Adding the cost of energy and the capacity benefit yields a per-experiment benefit of about $1.62 million. The average daily NPV benefit is about $47,600.

Cost of Fall High Flow Experiments. The average per trace difference in the NPV of energy costs over 20 years is $24.98 million between long-term strategies C3 and C4 and $24.54 million between long-term strategies E3 and E4. These costs are relatively high compared to the energy cost for other experiments. This outcome is due to the frequent occurrences of fall HFEs and the high energy cost associated with conducting each individual fall HFE. On average, 15.4 HFEs per hydrology trace would be conducted under long-term strategy C4, and 16 HFEs would be conducted under long-term strategy E4. Based on the total energy cost of conducting fall HFEs over the 20-year LTEMP period and their frequency of occurrence, the average NPV energy cost of a single fall HFE is about $1.62 million ($24.98 million/15.4 HFEs per 20-year trace) for Alternative C and about $1.65 million ($24.54 million/14.9 HFEs per 20-year trace) for Alternative E.

The number of days it takes to conduct a fall HFE experiment varies based on the type of HFE. An HFE can last from 2 to 16 days, including the up and down ramping periods. On average, a fall HFE lasts about 4.7 days under long-term strategy C4 and 4.6 days under long-term strategy E4. Therefore, the average daily NPV costs to conduct a fall HFE experiment in November is about $345,000 for Alternative C and about $358,000 for Alternative E. As discussed previously, there is no lost capacity cost associated with a fall HFE because November HFEs have little to no impact on maximum output levels at the Glen Canyon Dam Powerplant in August (i.e., the month with the highest peak load).

The cost for an individual HFE computed in this analysis is somewhat lower than the estimated cost of the fall HFE conducted in WY 2014, which ranged from $2.44 million to $2.59 million (Graziano et al. 2015). Several factors contributed to the higher historical costs and include (1) WY 2014 HFE was a longer 6-day event; (2) costs were not discounted; and (3) the WY 2014 HFE study was a financial analysis.

Experimental Element Summary. Table K.1-11 summarizes the results of the pairwise comparison of alternatives to determine the costs of individual experiments.

K.1.10.4 Sensitivity of Results to Exceedance Level

One sensitivity study investigated the effect of exceedance level on results. The previous section discussed results at the 90% exceedance level. This section will show results at the 50% and 99% exceedance levels and discuss how they compare to each other and to results at the 90% exceedance level. Table K.1-12 shows at each exceedance level and alternative the firm capacity, the capacity replacement requirement, and the system-level capacity additions at the end of the LTEMP study period.

Table K.1-12 shows that, compared to the 90% exceedance level, the 99% exceedance level results in a lower firm capacity and the 50% exceedance level results in a higher firm

TABLE K.1-11 Estimated Cost of LTEMP Experiments

Experimental Element and Pair	Average NPV Cost Difference over 20 Years ($ million)			Average NPV Cost Per Experiment ($ million)			Average Daily NPV Cost ($ million)

[a] Additional generation capacity required under the LTEMP alternatives for WAPA's customers over the 20-year LTEMP period to not only meet future load demand and replace unit retirements, but also to account for loss/gain in capacity at Glen Canyon Dam due to the alternative operating constraints.

[b] Lost capacity is the difference between the marketable capacity in Alternative A and the marketable capacity of another alternative; it represents the capacity that would need to be replaced somewhere in the power system if that alternative was implemented.

[c] Additional generation capacity required under the LTEMP alternatives for WAPA's customers over the 20-year LTEMP period to not only meet future load demand but also account for loss/gain in capacity at Glen Canyon Dam due to the alternative operating constraints

capacity. A higher exceedance level means SLCA/IP federal hydropower resources will be able to supply the system with all of the computed firm capacity more often than when a lower exceedance level is used. In addition, in the 50 to 99% exceedance range, the higher the exceedance level, the lower the firm capacity difference among alternatives. Therefore, the higher the exceedance level, the smaller the difference in in capital and fixed O&M costs among alternatives.

The AURORA model was run both in capacity expansion and dispatch mode to determine the NPV costs of the new expansion pathways and the production costs for the 50% and 99% exceedance levels for the representative trace. Figures K.1-46, K.1-47, and K.1-48 show results for the 50%, 90%, and 99% exceedance levels, respectively. These figures also show the difference in cost between various alternatives and Alternative A for each of the three components that compose the total cost of the alternative: capital, fixed O&M, and production or energy. The black bar for each alternative shows the total cost of the alternative if excess capacity above the amount required to satisfy the reserve margin is sold to the market. This sale of excess capacity could either raise or lower the total alternative cost compared to Alternative A. Results shown in all three figures are based on a 3.375% discount rate. The relative ranking of alternatives for these two sensitivity analyses are similar to the 90% exceedance level (that is, in order from highest to lowest, Alternatives B, A, D, E, C, G, and F). In addition, this ranking is identical whether excess firm capacity is either sold or not sold.

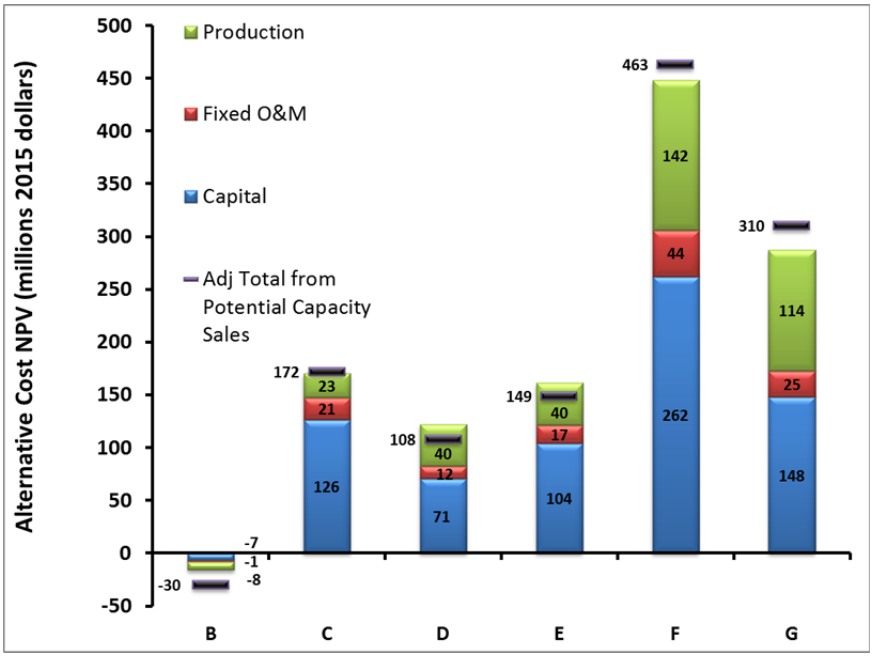

FIGURE K.1-46 Cost Difference of Alternatives Compared to Alternative A at 50% Exceedance Level and 3.375% Discount Rate

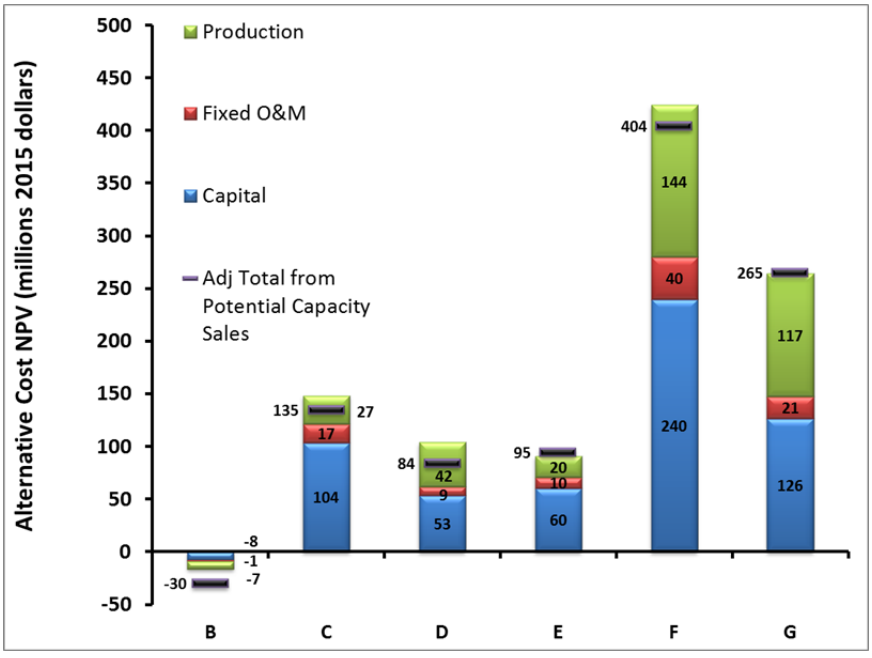

FIGURE K.1-47 Cost Difference of Alternatives Compared to Alternative A at 90% Exceedance Level and 3.375% Discount Rate

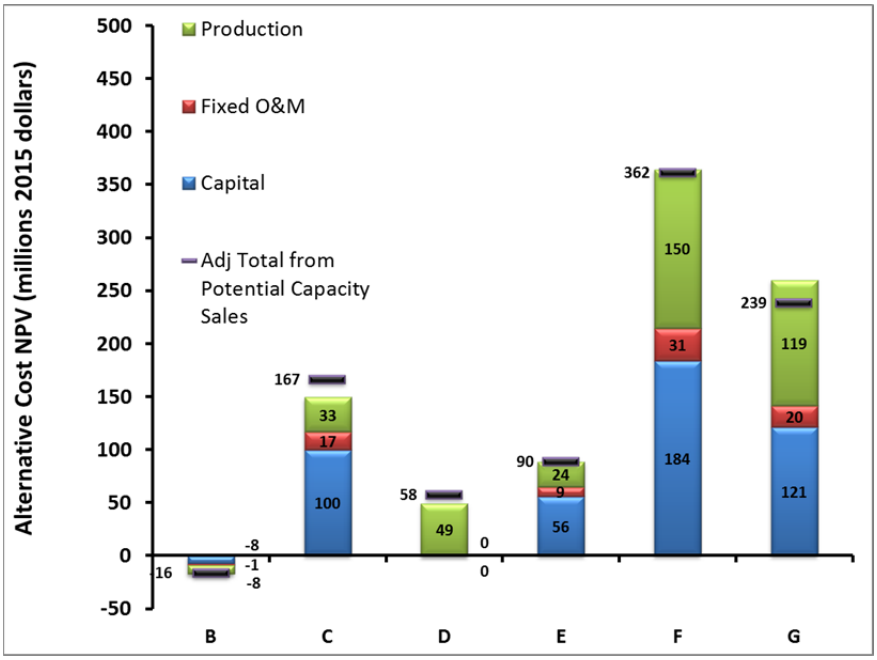

FIGURE K.1-48 Cost Difference of Alternatives Compared to Alternative A at 99% Exceedance Level and 3.375% Discount Rate

The figures show that as the exceedance level increases, the difference in the cost of each component and the total cost compared to Alternative A decreases. The alternative cost differences are smaller because the difference in firm SLCA/IP federal hydropower capacity between the various alternatives and Alternative A is lower as the exceedance level increases. Because a smaller amount of new capacity is needed to replace capacity lost at Glen Canyon Dam compared to Alternative A, each cost component and the total cost of the alternative is reduced.

At all exceedance levels, the cost of Alternatives F and G, which both have steady flow operating requirements, have the highest costs of all alternatives because they have the lowest firm capacity and no operational flexibility. Therefore, both require the largest amount of new capacity additions to replace lost Glen Canyon Dam capacity. Alternative F is the highest cost because, unlike Alternative G, it has very high monthly water releases at a time of the year (i.e., spring) with relatively low marginal production costs, and low releases during the high-production-cost summer months of July and August. In contrast, Alternative B is always the lowest cost alternative because it has a higher firm capacity than Alternative A and slightly more operational flexibility. The other three alternatives also have approximately the same ranking across all three exceedance levels.

Note that in Figure K.1-48 (the 99% exceedance level), the capital and fixed O&M cost differences between Alternatives A and D are zero. This occurs because the capacity expansion schedule is identical in both alternatives; that is, the amount and type of capacity is brought online at exactly the same time. Table K.1-12 has examples of other alternatives that have the same amount of capacity additions at the end of the LTEMP period as Alternative A, but still

have a difference in the capital and fixed O&M costs compared to Alternative A. This occurs because of the difference in timing of capacity additions. This result again illustrates the lumpy nature of capacity expansion due to the fact that plants used for capacity expansion have a discrete size; thus, adding one or a combination of several may exceed the capacity needed to just fulfill the reserve margin requirement.

Finally, the cost differences between an alternative and Alternative A are a very small percent of the total cost of the alternative across this wide range of exceedance levels. For example, Alternative F is the highest cost alternative at all three exceedance levels. At the 50% exceedance level, Alternative F costs more about $448 million more than Alternative A. However, this difference is only about 1.2% of the total cost of Alternative A, which is about $36.2 billion.

K.1.10.5 Sensitivity of Results to Discount Rate

Up to this point NPVs have been calculated using an annual discount rate of 3.375%, which is a rate used by Reclamation for project cost-benefit studies. The LTEMP hydropower subject matter expert team that helped guide this power systems study expressed concern that the 3.375% rate appears to be too high under current economic conditions. Therefore, a real annual discount rate of 1.4% was used for the sensitivity study. That value was obtained from the Office of Management and Budget Circular A-94, Appendix C (available at https://www.whitehouse.gov/omb/circulars_a094/a94_appx-c). That rate is the real interest rate on treasury notes and bonds with a maturity of 30 years.

Figure K.1-49 shows the 20-year NPV cost differences between each alternative and Alternative A for the representative trace at the 90% exceedance level using the 1.4% real discount rate. This figure should be compared to Figure K.1-47, which is the same exceedance level but for the baseline discount rate. When using a lower discount rate, the NPV costs of alternatives relative to Alternative A are larger because costs at the end of the study period have a larger contribution to the NPV. Note that the NPV cost difference between Alternatives F and A is approximately a half billion dollars ($508 million, if adjustment for potential excess capacity sales is not included). However, the relative ranking of alternatives from lowest to highest cost, and relative percent difference from Alternative A do not change for these two discount rates. Alternative B is the lowest cost alternative, followed by Alternatives A, E, D, C, G, and F. If it is assumed that excess capacity will be sold to an entity outside of the SLCA/IP market system, then Alternatives D and E change places in the alternative ranking.

K.1.10.6 Sensitivity of Results to the Base Capacity Expansion Path

The new generating unit additions projected by the AURORA capacity expansion model run for Alternative A represents a reasonable and plausible outlook that is consistent with utility IRPs in the region and the 2014 AEO (EIA 2014) projections. However, as stated earlier, the AURORA model bases capacity expansion decisions more on local financial objectives than on economic ones. Argonne power systems analysts also discovered that small changes in some

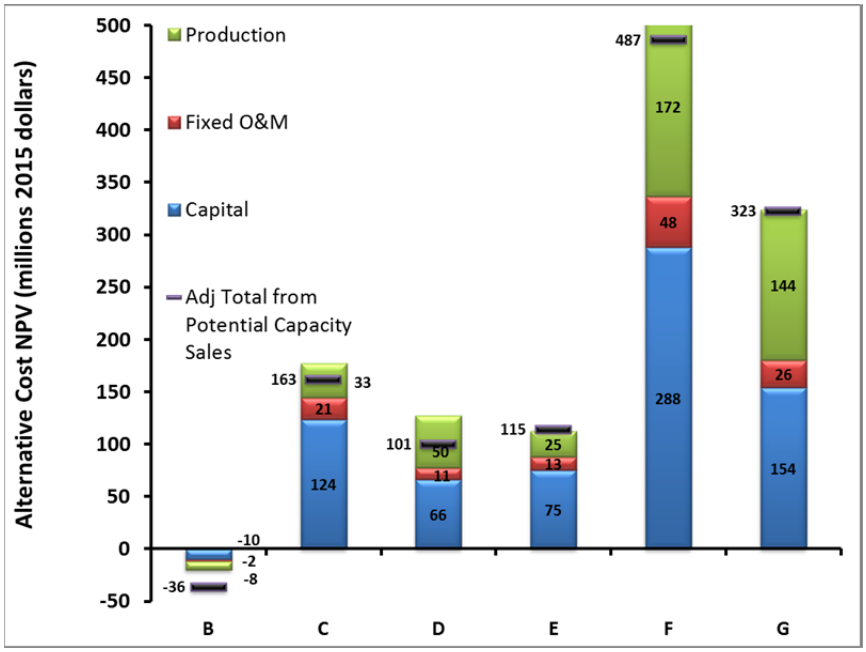

FIGURE K.1-49 Cost Difference of Alternatives Compared to Alternative A at 90% Exceedance Level and 1.4% Discount Rate

AURORA inputs would lead to substantial changes in capacity expansion pathways. This model behavior leads to uncertainty about the impact of Alternative A's expansion pathway on the final results and about the conclusions that could ultimately be made about power systems economic impacts.

Although pathways were different, it became apparent that the advanced combustion turbines and advanced combined cycle units were the two expansion candidates used almost exclusively by AURORA for new future additions. Therefore, additional model runs were made to measure the sensitivity of the base capacity expansion pathway on economic outcomes. Two extreme Alternative A pathways were tested. Both were based on a 90% exceedance level and a 3.375% discount rate. One pathway built exclusively advanced combustion turbines and the second pathway build only the advanced combined cycle plants. The base construction pathway (i.e., the type and timing of additions) for Alternative A was used as the starting point for each of the other alternatives. Advanced combustion turbines were added to (or in the case of Alternative B, subtracted from) a base expansion pathway to accommodate capacity changes at Glen Canyon Dam. Results for these two extreme pathways are shown in Figures K.1-50 and K.1-51.

For both pathways, the comparative results show the same basic pattern as all of the previously discussed results. Alternative ranking is basically the same. However, under the advanced combined cycle base expansion pathway, costs (stacked bars) are noticeably higher for Alternatives D and E as compared to the primary assumption set reported in Chapter 4 (i.e., mixed technology expansion, 90% exceedance, and a 3.375% discount rate shown in Figure K.1-47). Also under the advanced combustion turbine base expansion pathway, costs for

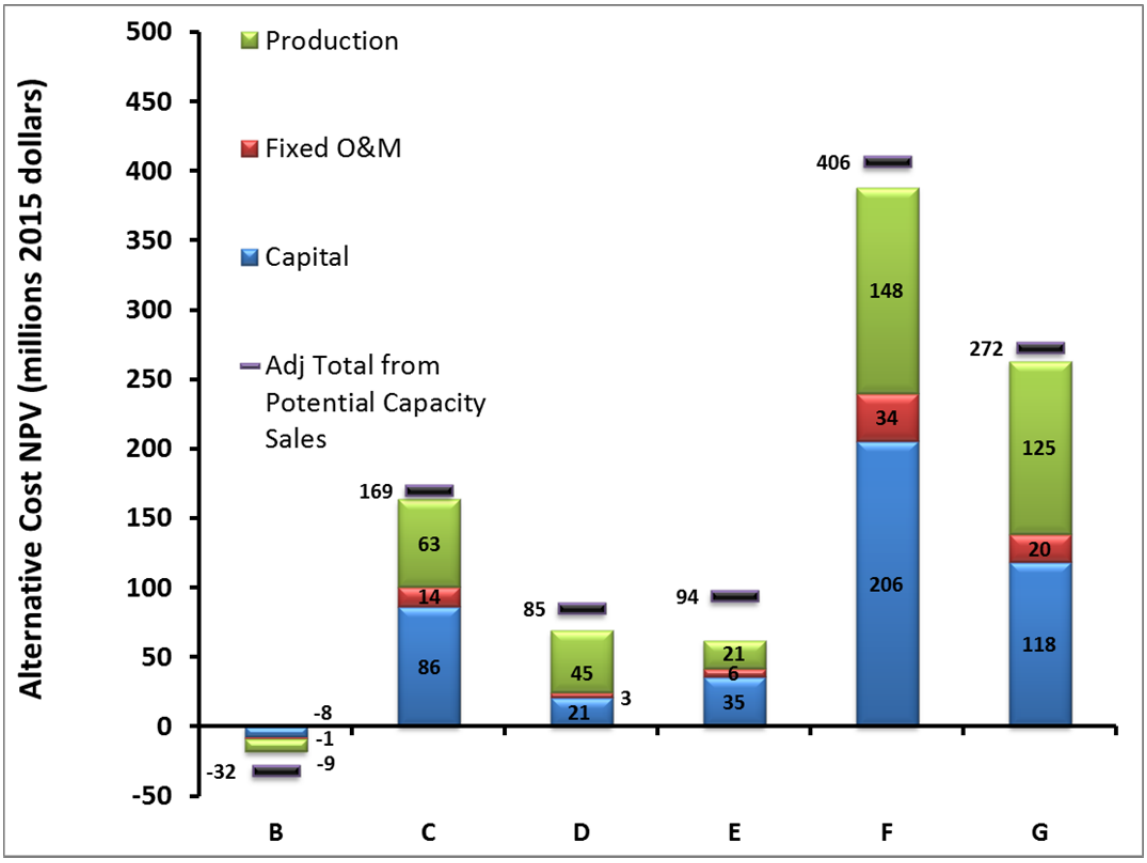

FIGURE K.1-50 Cost Difference of Alternatives Compared to Alternative A at 90% Exceedance Level and 3.375% Discount Rate, Assuming All Alternative A New Capacity Additions Are Advanced Combustion Turbines

Alternatives D, E, F, and G are lower. This is due primarily to the lumpy nature of capacity additions. If excess capacity can be sold, the effects of this lumpy behavior are significantly reduced. Note that for each alternative the black bars for the three base expansion pathways are very similar.

K.1.10.7 Sensitivity of Results to the Assumed Future Hydrological Conditions

Hydrology Trace 14 in combination with sediment Trace 2, which was the most probably sediment condition, was used as the representative trace. However, as noted earlier, the impacts of an alternative are dependent on the hydrological conditions. Therefore, the timing of dry, average, and wet hydrological condition is important because discounting in the NPV computation gives a higher weight to near-term costs as compared to costs that are incurred in the more distant future.

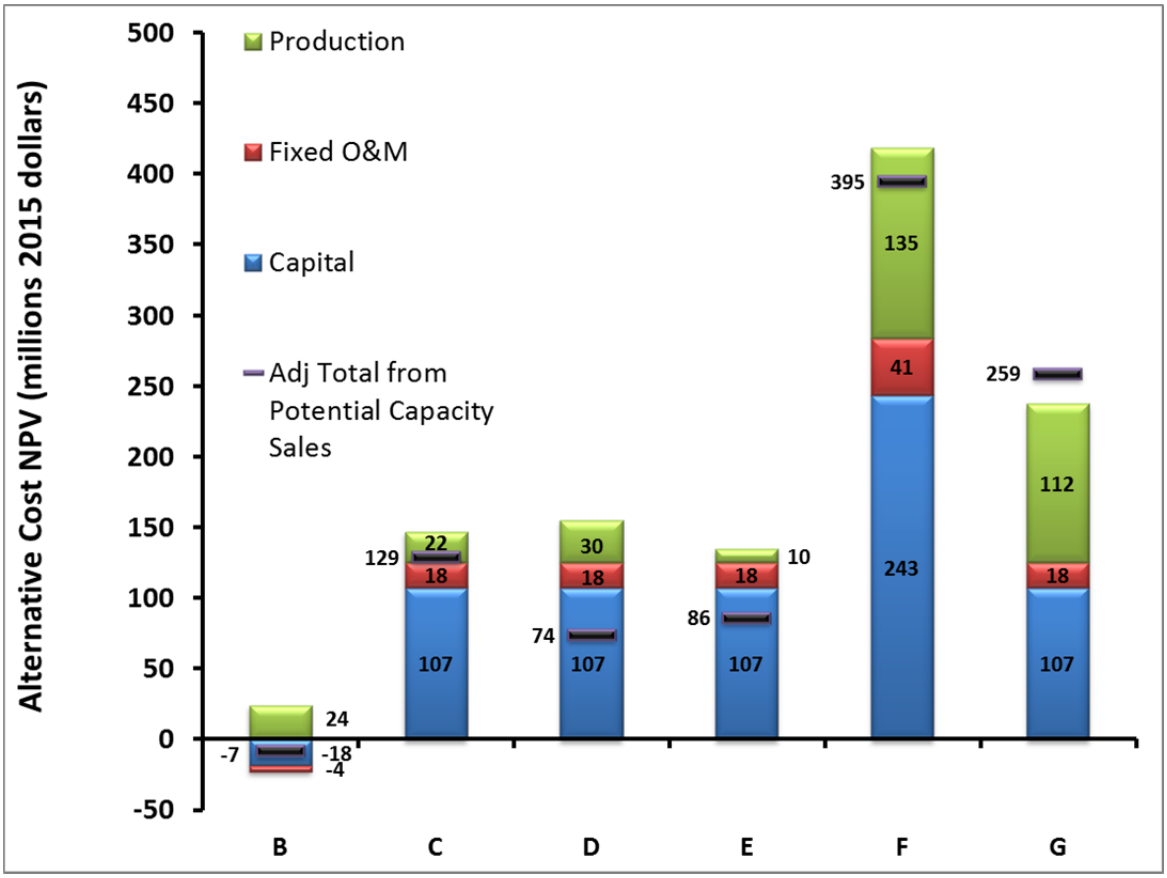

FIGURE K.1-51 Cost Difference of Alternatives Compared to Alternative A at 90% Exceedance Level and 3.375% Discount Rate, Assuming All Alternative A New Capacity Additions Are Advanced Combined Cycle

This section is intended to provide insights into the economic results' sensitivity to the selected hydrological condition. Ideally, all possible combinations of the 21 hydrology traces and three sediment traces would be simulated with the AURORA model in dispatch mode over the 20-year study period. However, such an effort would be very time consuming. As a simplification, only one other hydrological condition was run. For each hour of the LTEMP study period, this condition uses the average hourly generation from all 21 traces under sediment Trace 2 as projected by GTMax-Lite runs of Glen Canyon Dam. Results for this average hydropower condition are shown in Figure K.1-52.

Note that all capital and fixed O&M costs in Figure K.1-52, as shown by the blue and red bars, respectively, are identical to those shown in Figure K.1-47 for the primary assumption set. This occurs because capacity expansion decisions are made under uncertainty. For this power systems study, the expansion pathway for each alternative is based on a set of 21 plausible future hydrological conditions. It is also assumed that once the firm capacity level is determined and input into the AURORA model to determine an alternative-specific expansion path, the firm capacity level does not change regardless of the sequence of actual hydrological conditions that occur in the future. Therefore, the representative trace and the average trace use identical

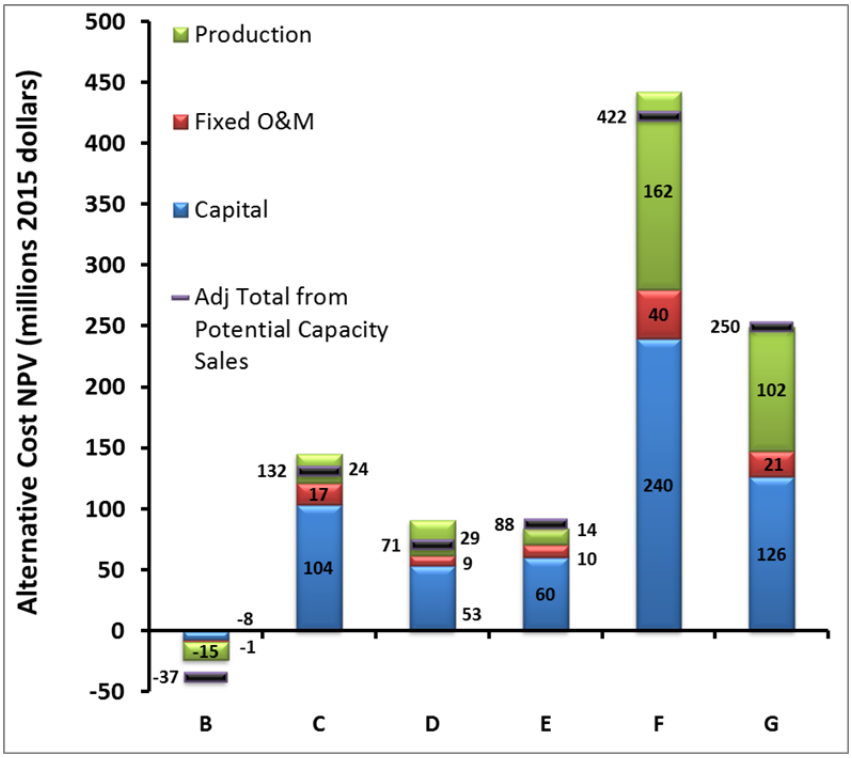

FIGURE K.1-52 Cost Difference of Alternatives Compared to Alternative A at 90% Exceedance Level and 3.375% Discount Rate Assuming Average Hydropower Conditions

capacity expansion pathways. If other hydropower conditions were run, each one would use this fixed expansion path.

Although capital and fixed O&M costs are identical, production costs (green bars) are slightly different. This does not provide definitive proof that the selected trace does not have a substantial impact on economic outcomes, but it does show that the representative trace—which has a sequence of dry, average, wet, average, and dry conditions over the study period—produces a result that is very similar to a sequence of average hydropower conditions.

K.1.10.8 Sensitivity of Results to Changes in Ancillary Services

A sensitivity study was performed on the effect changes in ancillary services (AS), which is the sum of regulation and fast spinning reserves, would have on the value of energy and firm capacity from Glen Canyon Dam. It was performed because assumptions about ancillary service requirements changed from when the GTMax-Lite model was run for the swing-weighting exercise in March 2014 (swing-weighting described in Appendix C). For this modeling, ancillary service requirements at Glen Canyon Dam were projected to be 103 MW in 2013 and then to increase to 160 MW by 2030. This case was called the high AS scenario. However, subsequent to this modeling, a second scenario was determined by WAPA to be more likely (i.e., ancillary

service requirements would remain at the same levels that exist today). Glen Canyon Dam currently supplies 67 MW of ancillary services and WAPA currently expects this not to increase during the LTEMP study period. This case was called the current AS scenario. This section reports the results of the study.

Using a lower ancillary service requirement will affect Glen Canyon Dam dispatch, firm capacity levels, and economic evaluations. In addition, alternatives that allow higher operational flexibility may be affected more than ones with very stringent limitations. Therefore, a sensitivity analysis was conducted to evaluate the magnitude of change that would occur in model results if the current AS scenario had been used.

Because it would have been costly to redo the entire analysis using current ancillary service requirements, a sensitivity analysis was performed that used a simpler methodology to gage differences in firm capacity and energy economics among Alternatives A, D, and F under two disparate ancillary service market assumptions. Prior to conducting the sensitivity analysis, it was determined that, if differences in the marketable capacity and energy for these three alternatives were dissimilar (e.g., more than 5% different) under the two AS cases, a second phase analysis would be performed. Since the results showed very little difference between the ancillary services scenarios, the more detailed second phase analysis was deemed unnecessary.

Alternatives A, D, and F were chosen because they span a wide range of firm capacities that the LTEMP alternatives exhibit. Alternative A is the current operating regime and has the second highest firm capacity; Alternative F is a steady flow alternative and has the lowest marketable capacity; and Alternative D represents a mid-range firm capacity level. To expedite the analysis, end-of-month elevations and monthly release values from the CRSS model for just Trace 14 (i.e., the representative hydrology trace) was analyzed. Monthly releases input to the Glen Canyon Dam GTMax-Lite model were not adjusted for experiments (either HFEs or TMFs) because CRSS results did not account for them. Experiments are only added by the SBM and are assumed to have relatively small impacts on firm capacity at exceedance levels over 50%.

The GTMax-Lite model was run and results were stored for hourly generation over the entire study period. Firm capacity for several exceedance levels above 50% under the three alternatives were then estimated for both sets of ancillary service values. The value of generation was determined by multiplying hourly generation levels by corresponding hourly Palo Verde LMPs. Hourly values were then summed to determine the total economic energy value. Next, differences in firm capacity and energy value among the three alternatives were computed and results from the ancillary services cases were compared.

Ancillary services sensitivity analysis results are shown in Tables K.1-13 through K.1-15 below. Table K.1-13 shows the capacity at exceedance levels ranging from 0 to 100% for the three alternatives and the two ancillary service scenarios. At capacity exceedance levels of interest for the LTEMP analysis (namely, 50% to 99%), the capacity differs by less than 5% between the two ancillary services scenarios.

TABLE K.1-13 Firm SLCA/IP Federal Hydropower Capacity (MW) at Various Exceedance Levels at Glen Canyon Dam by Alternative and Ancillary Service Scenarios

	Alternative A (No Action Alternative)		Alternative D (Preferred Alternative)		Alternative F	
Exceedance	Current AS	High AS	Current AS	High AS	Current AS	High AS
100	519	495	458	458	191	191
99	519	495	458	458	191	191
90	550	549	484	481	212	212
80	575	575	525	511	232	232
70	630	623	546	544	241	241
60	647	647	564	564	251	251
50	673	673	591	584	259	259
40	694	694	595	595	267	267
30	716	716	620	607	276	276
20	890	830	887	827	692	692
10	975	967	987	967	985	985
1	1097	1097	1097	1097	1097	1097
0	1097	1097	1097	1097	1097	1097

Table K.1-14 shows capacity (MW), energy (GWh), energy lost in non-power releases (bypasses and spills) (GWh), and the NPV of all cost components for the 3 alternatives. The capacity shown in Tables K.1-14 and K.1-15 is at the 90% exceedance level; it shows that there is a very small difference (less than 0.8%) in the capacity and energy, in terms of MW and GWh, respectively, between the high AS and current AS scenarios for Alternatives A and D. There is no difference between the ancillary service scenarios for Alternative F. The difference in total NPV between the two scenarios for Alternatives A and D is $2.86 million (0.08%) for Alternative A and $4.71 million (0.14%) for D. There is no difference between the ancillary services scenarios for Alternative F.

Table K.1-15 compares the differences in firm capacity and energy in Alternatives D and F relative to Alternative A for both ancillary services scenarios. Again, the ancillary services scenario has only a very minor effect on the relative difference between each alternative and Alternative A.

These results show very little difference among ancillary services scenarios. The primary reason for this is that under all three alternatives operating criteria do not allow the Glen Canyon Dam Powerplant to utilize a significant amount of its capacity under most hydropower conditions; that is, the criteria almost always restrict the maximum Glen Canyon Dam output to a level that is significantly below the physical maximum capacity. This gap between maximum output and physical capacity can be used for ancillary services because all alternatives allow exception criteria and restrict hourly average flow rates, but not instantaneous rates. For example, under Alternatives A and D, daily change specifications typically limit maximum output levels far (more than 160 MW) below the maximum physical output of the plant. Therefore, ancillary services requirements do not usually bind operations. Note that the power

TABLE K.1-14 Comparison of Capacity and Energy Values at Glen Canyon Dam by Alternative and Ancillary Services Scenarios at the 90% Exceedance Level

Ancillary Service Scenario and Alternative	Capacity (MW)	Energy (GWh)	Energy Lost in Non-Power Releases (GWh)	NPV ($millions)			Increase in Value Compared to Current AS
				Capacity	Energy	Total	
High AS Scenario							
Alternative A	548.9	88,754	1,824	422.77	3,054.06	3,476.82	Not Applicable
Alternative D	480.7	88,794	1,552	370.29	3,043.68	3,413.97	Not Applicable
Alternative F	212.3	88,081	1,918	163.53	2,916.39	3,079.92	Not Applicable
Current AS Scenario							
Alternative A	550.3	88,757	1,821	423.87	3,055.81	3,479.68	2.86
Alternative D	484.2	88,798	1,548	372.95	3,045.73	3,418.68	4.71
Alternative F	212.3	88,081	1,918	163.53	2,916.39	3,079.92	0.00

TABLE K.1-15 Difference Relative to Alternative A (value of Alternative A minus value of alternative)

Strategy	Capacity (MW)	Energy (GWh)	Non-Power Releases (GWh)	NPV ($millions)		
				Capacity	Energy	Total
High AS Scenario						
Alternative D	68.13	-40.77	272.04	52.48	10.38	62.85
Alternative F	336.55	672.59	-93.50	259.23	137.67	396.90
Current AS Scenario						
Alternative D	66.10	-41.04	272.31	50.92	10.09	61.00
Alternative F	337.98	676.04	-96.95	260.33	139.42	399.76
Difference (Current−High)						
Alternative D	-2.02	-0.27	0.27	-1.56	-0.22	-1.78
Alternative F	1.43	3.45	-3.45	1.10	1.76	2.86

systems analysis did not evaluate the value of any unused capacity (i.e., the differences between the physical powerplant capacity minus the sum of generation plus ancillary services).

Based on insights gained from this study, it was concluded that ancillary services assumptions under a range of plausible futures have little to no effect on firm capacity and energy value for the LTEMP alternatives. Therefore, it was not necessary to conduct more detailed analyses on ancillary services.

K.1.10.9 Sensitivity of Results to Customer Capacity Expansion Assumptions

There are uncertainties regarding the actual capacity replacement that may come to fruition. For example, utilities usually consider other factors beyond costs when determining new thermal power plant additions. Also capacity expansion models such as AURORA make many simplifying assumptions regarding plant siting, system unit commitments, and power plant operations in order to make the expansion problem it solves tractable. Models are therefore only an approximation of reality and decision makers typically factor modeling limitations into the capacity expansion planning process.

Because of modeling limitations and the complexity of determining optimal build schedules, a sensitivity analysis was performed. The sensitivity analysis considered a separate case in which capacity expansion changes relative to Alternative A would be made using a mix of 60% NGCC and 40% CT in terms of MW of capacity. This mix is approximately equal to the current average thermal capacity expansion mix contained in the IRPs in the joint system and utilities in surrounding area. It was derived from a review of IRPs that were available online in May 2016. Attachment K.11 provides a summary of capacity additions through the end of CY2034.

The capacity expansion analysis performed with the AURORA model and described in Section K.1.10.2 shows that in the future, the joint system would build a combination of advanced CT and NGCC units along with renewable technologies under all alternatives. However, as shown in Table K.1-8, only the timing and number of CT unit additions differ among alternatives; that is, the NGCC build schedule remained static. Therefore, the lost capacity at Glen Canyon Dam due to more restrictive operating criteria under Alternatives C, D, E, F, and G would be exclusively replaced by CT capacity additions. Alternative B shows a delay in the construction of one CT unit.

In terms of $/MW, both capital and fixed O&M costs are higher for the advanced NGCC technology as compared to the advanced CT technology (see Table K.1-1). Therefore, assuming a mix of replacement technologies impacts the estimated cost of alternatives. Similar to the sensitivity analysis that was performed for ancillary service assumptions (Section K.1.10.8), the GTMax-Lite model was used to estimate the range of LTEMP alternative capital and fixed O&M costs. This modeling method was selected because it runs more rapidly with far fewer resources than AURORA, yet it produces similar results in terms of both differences in total NPV among

alternatives and alternative ranking.[5] To roughly estimate costs under the mixed capacity replacement assumption, GTMax-lite was run for the two cases under consideration—replacement capacity provided by new CT plants only or a mix of 60% NGCC/40% CT plants. The difference between the two cases represents the higher cost of replacing lost Glen Canyon Dam capacity via a mix of thermal technologies instead of adjusting only CT capacity additions.

Table K.1-16 shows that using a mix of CT and NGCC replacement technologies at the 90% exceedance level would increase costs for all alternatives except for Alternative B which has a higher benefit (shown as a negative cost) of approximately $11.0 million. The costs for all other alternatives increase from $17.1 million under Alternative D (Preferred Alternative) to $93.4 million under Alternative F. Note that assuming a mix of capacity replacements does not change alternative rankings.

The estimated incremental cost shown in Table K.1-13 uses a simplified method and should therefore be viewed as an approximation of changes in costs between the CT only replacement case and the mixed technology replacement case. It does not capture the impact of capacity additions on the system dispatch and therefore changes in production costs. Because NGCC technologies are more efficient than CTs, the higher capital and fixed O&M costs for

TABLE K.1-16 Alternative Cost Increase Estimates for Mixed NGCC/CT Technology Capacity Replacement Relative to CT Only Replacement as Estimated Using GTMax-Lite

Alternative	Relative Cost of CT Only Replacement (million 2015$)[a]	Relative Cost of Mixed NGCC/CT Replacement (million 2015$)[b]	NGCC/CT Cost Increase (million 2015$)	Rank
A	0.0	0.0	0.0	2
B	-46.2	-57.2	-11.0	1
C	133.8	175.9	42.0	5
D (Preferred)	81.3	98.4	17.1	3
E	93.2	125.0	31.8	4
F	395.0	488.4	93.4	7
G	260.7	317.1	56.4	6

[a] Costs are relative to those of Alternative A. Assumes natural gas combustion turbines would be used to replace all capacity from Glen Canyon.

[b] Costs are relative to those of Alternative A. Assumes a 60% natural gas combined cycle/40% natural gas combustion turbine mix would replace lost capacity.

[5] The GTMax-lite expansion approach produced rankings that are identical to the AURORA model except that Alternative D (Preferred Alternative) has a slighter higher power systems ranking (i.e., lower cost) using GTMax-lite, and Alternative E has a slightly lower one.

NGCCs are partially offset by lower system production costs. Compared to an advanced CT, the advanced NGCC technology would be operated more frequently, generates more energy, and displaces more generation from expensive energy producing resources. Also, the GTMax-Lite methodology immediately replaces lost capacity compared to the AURORA method that, under most alternatives, replaces capacity 2 to 3 years after the start of the study period. As a result, the GTMax-Lite method tends to overestimate the incremental cost associated with replacing lost capacity with a mix of technologies.

K.1.10.10 Summary of Economic Ranking

Power systems analysis results show that there are three distinct groups of outcomes. Alternatives A and B are clearly the most favorable for hydropower economics, while Alternatives F and G are the least favorable. Alternatives C, D, and E rank between these two extremes. As shown in Table K.1-17, the ranking of alternatives is very consistent regardless of changes in assumptions that were made in the sensitivity runs. Alternatives D and E switched ranking under only two sets of assumptions. This order switch between the third and fourth rank is mainly attributed to the lumpy nature of capacity expansion paths. Among the sensitivity analyses conducted the discount rate assumption had the largest impact on absolute economic costs, but in terms of percent changes in total system costs that were tracked, it had negligible effects.

It is noteworthy that as the exceedance level increased from 50% to 99% the cost of the alternatives decreased, but the rankings did not change except for the aforementioned switching of Alternatives D and E. Although cost differences among alternatives decrease, higher exceedance levels increase overall SLCA/IP market system costs for all alternatives; however, system reliability improves with higher exceedance levels since there is more capacity built in the system.

Last, the rankings of alternatives are also in general agreement with those found in the structured decision analysis (SDA). The SDA report shows that the value of GCD hydropower production is the highest under Alternative B followed closely by Alternative A. Alternatives F and G have the least value, respectively, and the remaining alternatives are between these bookends.

K.2 WAPA'S SLCA/IP FIRM ELECTRIC SERVICE RATE IMPACTS[6]

The SLCA/IP firm electric service (FES) rate is the price paid per unit of product sold by WAPA's CRSP Management Center to its SLCA/IP FES customers. Two SLCA/IP commodities are sold, namely firm capacity and firm energy. Each has a separate price. This section

6 New terms and acronyms used in this section are defined at first use, and definitions of those terms are provided at the end of the section.

TABLE K.1-17 Summary of Economic Rankings for Baseline and All Sensitivity Scenarios

Assumptions					Alternative Rank (lowest to highest total cost)						
Exceedance Level (%)	Excess Capacity Sales	Hydrology	Base Expansion Path	Discount Rate (%)	A	B	C	D	E	F	G
90	No	Representative Trace	CT & NGCC	3.375	2	1	5	4	3	7	6
90	Yes	Representative Trace	CT & NGCC	3.375	2	1	5	3	4	7	6
50	No	Representative Trace	CT & NGCC	3.375	2	1	5	3	4	7	6

90	Yes	Representative Trace	NGCC	3.375	2	1	5	3	4	7	6

documents the methods and calculations used to determine the impact of the LTEMP EIS alternatives on the SLCA/IP capacity and energy rates.[7] The analysis was performed by WAPA CRSP Management Center staff with assistance from Argonne.

The analysis in this section begins with the calculations of economic impact performed and described in Section K.1. Section K.1 describes the economic impact on electrical power production, which is the impact—measured in dollars—on the economy. It includes the system cost of changing the timing and routing of water releases at Glen Canyon Dam. It also includes the expense of constructing (or savings resulting from forgoing construction of) additional electrical generators because of changes in firm SLCA/IP hydropower capacity.

Several calculations were performed to determine the impact of the LTEMP EIS alternatives on the SLCA/IP rates. Three rates were calculated for each of the seven alternatives: (1) a firm energy rate, (2) a firm capacity rate, and (3) a composite rate. This section describes the methods and assumptions used to determine these financial rate impacts.

7 The term "rate" will be used rather than "price." This is the standard convention for wholesale electrical commodities. Rate is the price charged for an energy unit, whether capacity or energy. Rate is often used to describe wholesale prices because it is the price of wholesale units and not necessarily the units used for retail sales.

This analysis is a financial study. It uses the economic estimates described in Section K.1 as input values to conduct a financial analysis. Because existing FES contracts are firm obligations to deliver electrical power, the economic impact described in Section K.1 will affect the SLCA/IP rates through the period specified under contract. This analysis describes how the economic impacts are "stepped down," through changes in the SLCA/IP rate, to utilities that purchase Glen Canyon Dam electrical power. The analysis assumes that WAPA's contractual obligation to deliver power to its current FES customers remains unchanged from current levels through the end of the marketing period.

K.2.1 Relationship between the Economic Impacts of LTEMP Alternatives and Impacts on SLCA/IP FES Rates

It is important that this analysis of the impacts of LTEMP alternatives on SLCA/IP FES rates be compatible with the economic analysis of the impacts of alternatives on Glen Canyon Dam power production and value (as presented in Section K.1). Economic impacts are changes in the value of power systems resources. The power system economic analysis described in Section K.1 determines the economic loss (or gain) of changing the operation of Glen Canyon Dam. The economic information resulting from the analysis presented in Section K.1 is used as input values for the SLCA/IP rate analysis. This financial analysis is a "step down" from the economic analysis described in Section K.1. It demonstrates how the economic impact of alternative-specific differences in Glen Canyon Dam electric power generation affects the per-unit cost of electricity to FES customers through changes in the SLCA/IP rate.

K.2.2 Temporal Scope of the Analysis and Input Data

The SLCA/IP rate analysis is a 20-year analysis encompassing the CY 2015 through CY 2034 time period. It is assumed that the SLCA/IP rate associated with the alternative does not change throughout the power repayment study (PRS) repayment period, which extends beyond CY 2034.

As explained in Section K.2.3, the SLCA/IP rate is required to be sufficient to repay authorized irrigation projects, which have construction and repayment periods that extend for another 50 years. Therefore, although the analysis includes LTEMP EIS alternative-specific costs that differ by alternative over the 20-year time frame of the LTEMP EIS, the rate study continues with other operations and repayment expenses for many years thereafter.

Rate changes as a result of alternative operating criteria for Glen Canyon Dam impact all FES customers.[8]

8 "FES customers" and "SLCA/IP LTF customers" are used synonymously.

Data described in Section K.1 are key input data for the SLCA/IP rate impact analysis. These data include:

- The hourly SLCA/IP electrical production under each alternative for the representative 20-year trace[9] that is simulated by both the GTMax-Lite model and the Small SLCA/IP Powerplant Spreadsheet that is produced for the economic impact analysis;

- The hourly FES customer requests for energy and capacity under the terms of their contractual agreements with WAPA; and

- The estimated capacity cost for each alternative that is set equal to the AURORA model's capacity expansion plan multiplied by the technology-specific levelized cost of capital plus annual fixed O&M expenses.

K.2.3 SLCA/IP Rate Setting

A typical regulated electrical utility sets a rate based on a "test year" using a formula that recoups its estimated operations expenses and allows a fair return on its capital investment. For electrical utilities regulated by State Commissions, their rates are reviewed and approved by the Commission. This approach is quite different from the rate setting process required of WAPA.

WAPA sets SLCA/IP rates in order to repay all costs associated with power generation. WAPA must establish power rates sufficient to recover operating, maintenance, and purchase power expenses. In addition, WAPA sets rates in order to repay the federal government's investment in building these generation and transmission facilities within 50 years. Outside of the 50-year repayment period, this is similar to a regulated electrical utility. The biggest difference lies in the requirement that WAPA's rates must also be set to cover certain non-power costs Congress has assigned to power users to repay. These are authorized irrigation costs in excess of water users' ability to repay. For the CRSP, authorized irrigation projects have repayment periods that extend for another 50 years. WAPA must demonstrate to the Federal Electrical Regulatory Commission (FERC) that its SLCA/IP rate is set appropriately to make required repayment of all authorized projects. Even though FERC approves a SLCA/IP rate that expires in 5 years, it is a rate that has been demonstrated to make all required repayment of all authorized projects.

Another approach to this analysis would be to add LTEMP EIS alternative-specific expenses for 5 years, estimate a SLCA/IP rate based on that, do it again for another 5 years, and again and again. The LTEMP EIS alternative-specific impact would then show four SLCA/IP rates that cover the 20-year temporal scope of the EIS. We could then do a net present value

9 The basis for selection of a representative trace is described in Attachment K-3 of Appendix K.

calculation to 2015. This approach would have made the SLCA/IP rate analysis more comparable to the approach used in Sections K.1 and K.3. This approach would be a straight-forward calculation similar to that of a regulated utility that uses a "test year" to set rates. The expenses related to a "test year" would be available for each of the 20 years included in the LTEMP EIS time frame from the analysis in Section K.1. As explained in the previous paragraph, this approach would be significantly different from WAPA's required method of setting SLCA/IP rates. In addition, the schedule for completion of this analysis did not allow for the added time required

K.2.4 Calculation of Net Electrical Energy Expense

Figure K.2-1 illustrates the method used to determine the yearly expense of electrical energy over the 20-year study period.

K.2.4.1 SLCA/IP Electrical Production

Data on the combined amounts of electrical energy produced by all of the SLCA/IP federal hydropower plants under each alternative were generated for the economic analysis described in Section K.1, and were used as input to the SLCA/IP wholesale rate analysis. The data are hourly over the 20-year study period. There is one set of these hourly data for each LTEMP EIS alternative.

K.2.4.2 Sustainable Hydropower (SHP) and Available Hydropower (AHP) Capacity and Energy

WAPA's Energy Management and Marketing Office (EMMO) schedules electrical capacity and energy to serve FES customer energy requests. Each FES customer requests energy according to the terms and conditions of CRSP Management Center FES contracts. An FES customer can schedule an amount of energy to be delivered up to a specified capacity amount. This is known as the SHP capacity.[10] SLCA/IP FES customers also have a monthly amount of electrical energy that WAPA is obligated to deliver. A customer schedules the monthly allocation of electrical energy within the capacity limit mentioned above. This is known as the SHP energy allocation. Both capacity and energy amounts differ by customer and by month. Table K.2-1 shows CRSP Management Center current total SHP contractual obligations and project use required deliveries by month.

[10] Specific descriptions of the terms and conditions of FES contracts will not be discussed here. The abbreviated descriptions provided here are intended only to explain the process of calculating the impact of the LTEMP DEIS alternatives on the SLCA/IP wholesale rate.

TABLE K.2-1 SHP Contractual Obligations and Project Use Required Deliveries by Month

	Firm Electric Service			Project Use		Total	
Month	Capacity (kW)	Energy (kWh)	CROD[a] (kW)	Capacity (kW)	Energy (kWh)	Capacity (kW)	Energy (kWh)

[a] CROD = Contract Rate of Delivery

Because SLCA/IP FES customers are allowed to schedule SHP energy according to their individual needs, the hourly shaping of energy differs from day to day and from customer to customer. Therefore, it is necessary to estimate the aggregate daily shape of electrical energy schedules submitted to the EMMO by all FES customers. WAPA used average weekday, Saturday, and Sunday shapes for each month of WY 2014 to represent these schedules. When a holiday occurs, the load shape for Sunday is used. These SHP loads are provided in Table K.2-2.[11] In addition, the EMMO must serve project use loads that vary over time. WAPA used WY 2014 data, rather than averaging several years of loads or projecting different load shapes for future years, because the SHP daily shape does not differ substantially from year to year.

[11] In some situations, it is difficult to separate customer SHP and project use loads that are submitted to Western's EMMO. For this analysis, it is assumed that the loads in Table K.2-2 are only SHP loads even though small amounts of project use loads are included. This assumption will have minimal impact on the results, since the same hourly loads are used for all alternatives.

When seasonal SLCA/IP federal hydropower resources are significantly greater than combined SHP commitments and project use loads plus the energy required to cover delivery losses,[12] the CRSP Management Center offers its FES customers capacity and/or energy above the SHP levels. These additional offers plus SHP are referred to as available hydropower (AHP). The methodology applied for the wholesale rate analysis offers a seasonal AHP, which is distributed monthly. The seasons that met the AHP offer criteria were largely a function of hydrological condition rather than of the alternative. Each of the seven alternatives had the same number of seasons that met the AHP criteria. The alternatives differed, however, in the amount of AHP that was offered.

Based on the sequence of hydrological conditions contained in the representative trace, AHP offers were calculated for any season that met the 20% excess AHP offer criterion; that is, an AHP offer is made only if hydropower resources in a season are at least 20% greater than the seasonal SHP level.

WAPA is required under its FES contracts to provide AHP, by season, when available. However, the contracts do not specify how much energy above SHP is required to make a seasonal AHP offer. There are no set criteria for offering AHP. It is the current practice of the CRSP Management Center to review and release information for the upcoming season and decide whether to offer AHP. CRSP Management Center power marketing managers confer with EMMO managers and consider anticipated release information, market prices, the amount of anticipated energy and capacity above SHP, and other factors in making an AHP offer for the upcoming season.

For the purposes of completing this analysis, CRSP Management Center managers and staff that are involved in the seasonal determinations were surveyed to establish a criterion based on past practices. The 20% trigger represents a reasonable amount of additional available hydropower that could be efficiently and equitably offered to WAPA's more than 135 customers. Offers to FES customers are made prior to the beginning of the season.[13] If the predicted energy production above AHP levels did not occur, and an AHP offer was made, the resulting short position must be resolved by energy market purchases. When available seasonal hydropower is less than 20% it is assumed that the excess energy would be offered to the market. The 20% trigger used for this analysis is for modeling purposes only and does not represent an established policy or practice.

The amount of AHP offered in a particular month was the smaller of the percent energy above the SHP energy and the percent capacity above the SHP capacity. Once this was determined, the SLCA/IP hourly energy delivery obligation (i.e., SHP load) was scaled by the

---

12 Energy delivery losses were conservatively set equal to 8.5% of the total SLCA/IP hourly federal hydropower generation when computing FES rates and seasonal customer offers above AHP levels. This level is consistent with historical levels used for ratemaking, but somewhat higher than the 5% loss rate used for power systems economic analyses presented in Section K.1.

13 SLCA/IP power is marketing in two seasons: the "summer" season is April through September, the "winter" season is October through March.

appropriate percentage for each hour in the months that offer seasonal AHP. Project use loads were not adjusted.

AHP is sold to SLCA/IP FES customers at the FES energy rate. Since the FES energy rate is typically lower than the hourly spot market price, the addition of AHP tends to reduce CRSP Management Center revenues when compared to selling this excess (or long) energy to the spot market. There is typically a relatively minor (if any) financial impact on WAPA from offering AHP capacity. All SLCA/IP FES customers are billed monthly for the CROD capacity allocation, regardless of the particular SHP or AHP capacity allocation for the month. However, there is a financial impact on WAPA when SHP capacity offers exceed the amount available from SLCA/IP federal hydropower resources (due to, for example, the aforementioned forecast error), because WAPA must purchase capacity to fill the deficit.

Seasonal SLCA/IP federal hydropower generation is almost always either above or below the SHP obligation. The logic that is used to model this energy imbalance is shown in Figure K.2-1. If generation is below the SHP obligation, it is assumed that WAPA will be a net seasonal power purchaser and cover the short energy position via the spot market at spot market prices.[14] If generation is above the SHP obligation, the excess seasonal energy is sold to the spot market at spot market prices, unless it is a season in which the AHP offer criteria are met, in which case the seasonal excess energy is sold to SLCA/IP customers at the FES energy rate.

Although WAPA may be short during a specific season, on an hourly basis it may produce SLCA/IP federal hydropower in excess of FES SHP loads (i.e., FES customer energy requests). For example, during the middle of the night, under a steady flow alternative, loads may be less than generation. Likewise, there are some hours when hydropower resources produce less energy than loads when there is excess seasonal energy. Therefore, the wholesale rate analysis uses a methodology in which long and short positions along with associated costs and revenues are computed hourly under each alternative. Spot prices are the same scaled AURORA Western Interconnection LMPs at the Palo Verde hub that are used for power system economic analyses.

K.2.5 Calculation of Capacity Expenses and Total Net Costs

In addition to the annual net expense related to electrical energy for each alternative, WAPA will have a cost related to electrical capacity purchases or, in the case of Alternative B,

[14] Western's CRSP Management Center has several decades of experience with the vicissitudes of hydrological conditions in the Colorado River basin. There have been years in which electrical production from the SLCA/IP was inadequate to meet SHP commitment levels. Western once hedged its risk of dealing with this condition by making a long-term capacity and energy purchase. Outside of one instance, Western's firming purchases have only been on the day-ahead market or for a season when conditions were forecasted to require this.

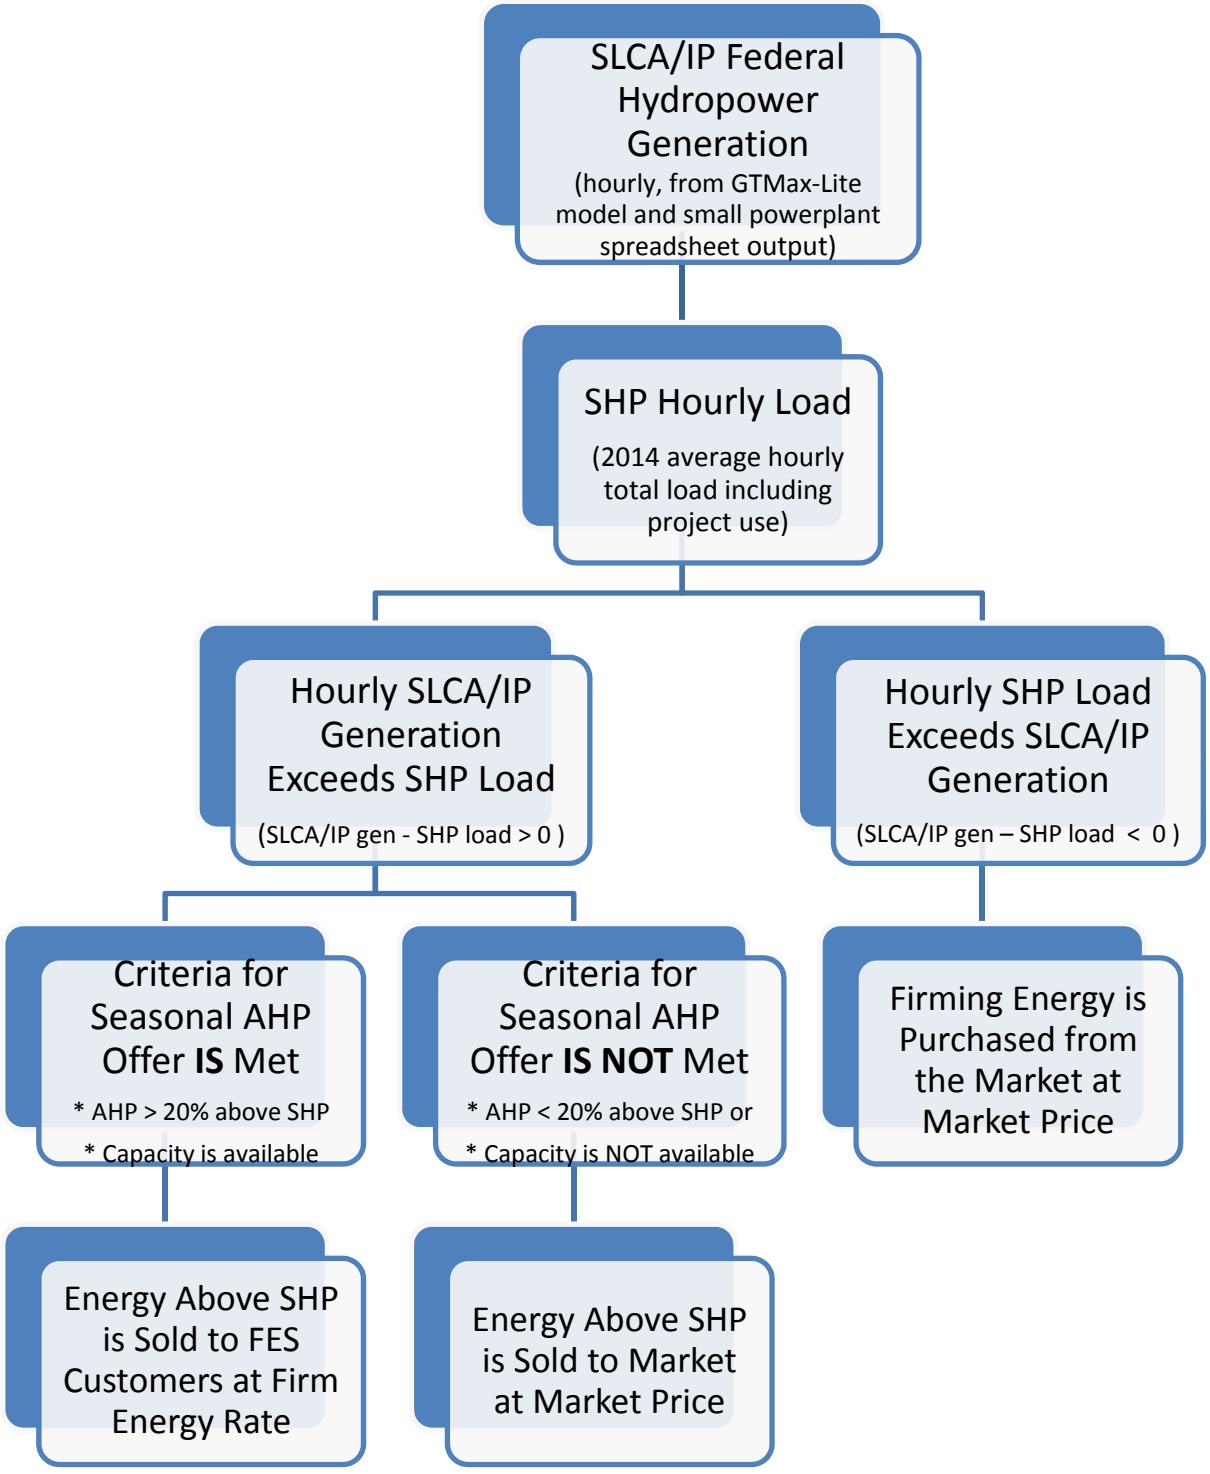

FIGURE K.2-1 Determination of Energy Hourly Expense or Revenue

capacity cost avoided.[15] As explained in Section K.2.1, an important requirement of this SLCA/IP wholesale rate analysis is to maintain compatibility with the economic analysis presented in Section K.1. The AURORA capacity expansion module applied in the analysis indicated that additional capacity facilities (construction of new generation) would be required over the 20-year LTEMP period. Table K.2-3 contains the same costs that were used in the power systems economic analysis described in Section K.1. It shows the capacity expense required over the 20-year period for each alternative.

The net energy expense for each alternative is computed as described above and illustrated in Figure K.2-2. Added to this figure is the capacity cost, by year, for each alternative. The sum of these two numbers is the total WAPA expense that is incorporated into the computation of wholesale rates (Figure K.2-2).

[15] Capacity in this context is LTF capacity that Western must acquire as a result of a reduction in Glen Canyon Powerplant output that is caused by a change in operating criteria specified under an LTEMP alternative. It is distinctly different from the short-term capacity discussed in the previous section that is dependent on natural short-term hydrological variability.

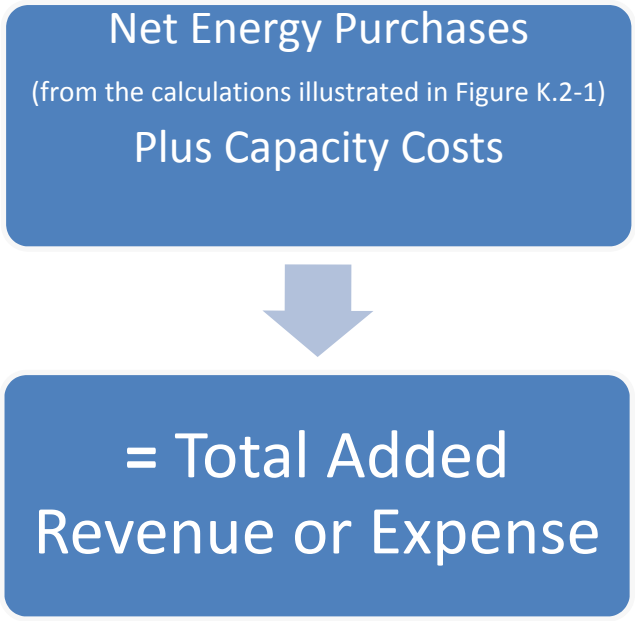

FIGURE K.2-2 Determination of Total Net Expense or Revenue by Year for Each Alternative

Table K.2-3 is a reproduction of a table from Section K.1. It is the estimated expense of capacity construction under each alternative. Alternative A includes capacity expenses, not because of a changed operation at Glen Canyon Dam or a change in SLCA/IP commitment levels by WAPA, but because of growth in electrical demand and the need for SLCA/IP customers to have to build new generating units to meet growing electrical demand. Based on the analysis described in Section K.1, existing generating units are sufficient to meet electrical demand until 2017.

The difference between the capacity expenses under Alternative A and the other alternatives is a function of how the LTEMP EIS alternatives affect the available capacity at Glen Canyon Dam. Differences in capacity expenses from Alternative A are a result of implementing the alternative. Table K.2-4 shows the differences in capacity expenses from Alternative A. The numbers in Table K.2-4 (differences from Alternative A) were used in this analysis. Notice that no capacity expense is required until 2018 under all alternatives except for Alternative F, which requires a capacity expense in 2017.

K.2.6 WAPA Replacement Resources

Using AURORA capacity expansion path modeling, the power systems analysis identified lost Glen Canyon Dam Powerplant capacity that would result from alternative-specific differences in operations and changed system capacity expansion paths. However, WAPA's FES power obligations are unaltered over the time period of this analysis, at least through FY 2024. Therefore, it is assumed for this analysis that WAPA purchases this capacity and incurs capacity firming costs.

When capacity in the region is in short supply, WAPA's firming purchases either include a capacity premium or WAPA makes a capacity purchase. For this analysis, it is assumed that WAPA purchases the electrical capacity projected by the AURORA capacity expansion module. The capacity expenses included in this analysis are the differences from those for Alternative A.[16]

16 See Section K.1 for details on the generation types, years in which construction occurs, and pricing assumptions.

WAPA's purchase of electrical power to meet contractual obligations is a common occurrence. It is quite typical for WAPA to make these purchases during drier years with low release targets. Even in average years, WAPA purchases firming energy on some days or for some hours. Typically, WAPA purchases electrical energy on an hourly basis for the days or months ahead. However, WAPA's CRSP Management Center has also purchased firming energy for a future season or year. WAPA has also once contracted for electrical power and energy over a multi-year period.

It is also assumed that, when electrical capacity in the region is in short supply, utilities that buy electricity at a price that covers the average cost, including the cost of capital and fixed O&M. For this analysis, it is assumed that WAPA purchases the capacity needed to make up for losses in capacity that results from alternative-specific changes in Glen Canyon Dam operations (i.e., the difference between FES capacity and the alternative-specific SLCA/IP federal hydropower firm capacity that is based on a 90% exceedance level).

Electrical capacity additions by WAPA's FES customers are required under Alternative A over the 20-year analysis period, with existing SLCA/IP contractual obligations in place. These additions are required because of growth in electrical demand. However, if there is a change in the operation of Glen Canyon Dam that reduces the powerplant's firm capacity—as would occur under most of the LTEMP alternatives—additions to electrical capacity would be required.[17] The assumption used for this analysis is that WAPA purchases the capacity identified as the amount lost under each alternative, costing the amounts specified in Table K.2-3. The differences in total costs include levelized capital and fixed O&M between each alternative and Alternative A.

To be clear, Table K.2-3 is a duplication of the power economic analysis (Section K.1). WAPA would not incur the capacity expansion costs for Alternative A. Added capacity costs needed for load growth in Alternative A are not included. Only the differences in capacity costs between Alternative A and the other alternatives are included in the analysis.

K.2.7 Post-2024 Marketing Period

WAPA markets SLCA/IP electrical power under firm, long-term contracts. Under these contracts, WAPA is required to deliver this electrical power to federal points of delivery regardless of hydrological conditions or changes in the operational criteria of the SLCA/IP hydropower plants. The current FES marketing contracts expire on September 30, 2024. For the period following 2024, WAPA is currently engaged in developing a marketing plan. This requires a formal public process in compliance with applicable federal law.

[17] This is not the case for Alternative B. Under Alternative B, Glen Canyon Dam marketable capacity is increased over that of Alternative A. Fewer capacity additions are required.

For the purpose of completing this analysis, certain assumptions had to be made. First, it was assumed that WAPA will continue with its current SLCA/IP obligations until the current marketing period ends and the existing contracts expire.[18] This requires that WAPA deliver the same amount of electrical power and energy to SLCA/IP customers until the end of FY 2024, regardless of the alternative analyzed. Second, recognizing that there is a period of uncertainty between 2025 and 2034, net firming expenses for the post-2024 time period were analyzed under two sets of assumptions. These are as follows:

- A continuation of existing SLCA/IP FES contract commitments between FY 2025 and FY 2034 (no change); and

- A reduction in SLCA/IP FES contract commitments so that net firming expenses are equal to $0 between FY 2025 and FY 2034. This means, for the numbers included in the SLCA/IP power repayment study, zero dollars of firming expense and zero additional dollars of revenue from market sale or from AHP sales (resource available).

These two assumptions constitute "bookends" regarding the outcomes possible in the development of the post-2024 marketing plan.[19]

These bookends are for modeling purposes only. They represent a very broad range of possible FES obligations of electrical power in the post-2024 marketing period.

Obligations of electrical capacity under the current marketing plan were based on a 90% exceedance level (i.e., the amount of hydropower capacity available 90% of the time). This level of marketable capacity is consistent with marketing plans established by other WAPA regional offices. In establishing power obligations for the post-2024 marketing period, WAPA will consider the capacity and energy available from the SLCA/IP units including those at the Glen Canyon Dam Powerplant and will establish, through a public process, an appropriate and reasonable amount of marketable capacity and energy to provide to FES customers. The range of SLCA/IP impacts described for these bookends will almost certainly encompass the actual rate impact, once the post-2024 marketing plan is completed.

---

18 There is a provision in the existing SLCA/IP contracts to modify the FES obligations upon a 5-year notice to SLCA/IP customers. However, considering the probable timing of new operating criteria for the Glen Canyon Dam following the completion of the LTEMP DEIS and the issuance of a ROD, a 5-year notice would not be significantly different than the end of the current marketing period.

19 Western could choose a post-2024 SLCA/IP FES obligation of electric power that exceeds its current obligation. However, prior to completion of the required public process it would be difficult to determine what the higher obligation would be that could be considered a reasonable bookend. Moreover, the time-frame available to complete this analysis required that the analysis be simplified. The assumption that the post-2024 SLCA/IP FES obligation continues existing commitments was easier to accomplish since much of the data related to this assumption was produced in Section K.1.

It should be noted that the establishment of these bookends is not an attempt to predict or to anticipate WAPA's choice prior to the conclusion of the required public process. This is an analysis, not a description of policy or attempt to predict WAPA's post-2024 marketing plan. This set of bookends is intended to reflect the range of reasonable possibilities. It is reasonable that WAPA would continue existing commitment levels to ensure continued customer access to the transmission associated with the energy. Moreover, it is also reasonable to believe that WAPA would establish post-2024 marketing plan commitments that exactly follow the power resource available at the SLCA/IP power system.

K.2.8 Power Repayment Studies to Determine Rate Impacts

WAPA sets rates as low as possible consistent with sound business principles to repay the federal government's investment in generation and transmission facilities in addition to specific non-power costs that power users are legislatively required by Congress to repay, such as irrigation costs that are beyond the irrigators' ability to repay. Sales of federal electric power and transmission repay all costs (including interest) associated with generating and delivering the power. WAPA prepares a PRS for each specific power project to ensure the rates are sufficient to recover expenses, including O&M, transmission, interest, replacement/upgraded equipment, purchased power, and wheeling. The PRS consists of two parts: historical data and future forecasted data. The historical data is a record of project repayment from the beginning of the project to the most recent year for which audited financial data are available. The first future year in the PRS is the first year for which forecasts, rather than actual data, are used. The last future year in the PRS must cover the final year allowed for repayment of historical investment.

Although the tool used to calculate the PRS has changed many times in the past, the principles underlying project repayment have not. These principles are summarized in U.S. Department of Energy (DOE) Order RA 6120.2 that governs project repayment and financial reporting for the DOE Power Marketing Administrations. In addition to Order RA 6120.2, WAPA's PRSs must meet the Federal Energy Regulatory Commission's rate filing requirements and procedures in 18 CFR Part 300.

K.2.8.1 PRS Expenses

All annual costs that are to be repaid by power customers must be included in the PRS. These costs include O&M, purchased power, transmission and other expenses, and interest expense. Interest expense is calculated by multiplying each investment's prior year unpaid balance by the appropriate interest rate.

Tables K.2-5 and K.2-6 show the total net purchase power costs for each year for each alternative. These tables show net purchase power expenses only. They do not include other O&M expenses, interest or principle payments. Positive numbers indicate net purchase power

TABLE K.2-5 Total Net Purchase Power Expenses (thousand 2015$) by Year and Alternative for the Continuous Current Obligations Scenario[a]

2034	35,900	31,240	48,130	46,830	46,230	71,540	72,020

[a] These numbers are compared to a condition in which generation is just equal to SHP obligations. Positive numbers indicate net firming purchases. Negative numbers indicate revenues collected above a condition in which generation is just equal to SHP obligations.

expenses. Negative numbers indicate that generation from SLCA/IP power plants is sufficient to meet SHP obligations and include additional sales of electricity to FES customers (AHP) or additional sales to the market. The numbers in these tables are net purchase power expenses compared to a condition in which electrical generation is just sufficient to meet SHP obligations without firming expenses and without sales of surplus electricity to FES customers or to the market. Note that the negative numbers occur in the years 2023-2025 and carry across all the alternatives in these years. These are the wettest years of the representative trace used for this analysis.

Table K.2-5 is purchase power for the scenario in which the existing SLCA/IP commitment levels for energy and capacity are maintained. Table K.2-5 is purchase power for the scenario in which WAPA reduces its commitment levels, post-2024, to just the amount of

TABLE K.2-6 Total Net Purchase Power Expenses by Year and Alternative for the Reduced Obligations to Match Resource Scenario[a,b]

Year	Alternative A (No Action Alternative)	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G

[a] These numbers are compared to a condition in which generation is just equal to SHP obligations. Positive numbers indicate net firming purchases. Negative numbers indicate revenues collected above a condition in which generation is just equal to SHP obligations.

[b] Zeroes indicate that no purchase power expenses are required to firm contract obligations; however, other expense, such as operations, maintenance, repayment of investment and interest payments would continue.

energy and capacity provided by the resource. These data were developed as described above and include the following:

- Purchase power expense net of additions to revenue from the sale of AHP, and
- Cost of capacity including capital and fixed O&M expenses relative to Alternative A.

K.2.8.2 PRS Revenue Distribution

The CRSP Management Center uses a balloon payment methodology for repayment of project costs. This means that principal payments for capital costs are not due until the end of their repayment period. For example, if an investment has a repayment period of 50 years, the total principal payment can be made in the 50th year. The revenue distribution described in this section, and the PRS calculations described in the next section, pertain to the balloon payment methodology.

Within the PRS, electrical power revenues within the year must first be applied to the annual O&M costs. Interest expense is considered an operational cost, but it is the last in priority. After all annual costs are paid, capital costs must be repaid in the following order: (1) required principal payments, (2) deficits, and then (3) the highest interest-bearing investment. Required payments are payments on those investments that still have an unpaid balance at the end of their repayment period.

K.2.8.3 The SLCA/IP PRS

The SLCA/IP PRS includes the revenue requirements for the CRSP, Collbran, and Rio Grande projects, which were integrated for marketing and ratemaking purposes on October 1, 1987, in addition to two participating projects of the SLCA/IP system that have power facilities, the Dolores and the Seedskadee Projects. The CRSP Management Center forecasts 5 years of firming purchased power in the PRS. This reflects the firming purchase power requirements between projected generation and FES contract obligations. For the remaining future years, a forecast of $4 million per year is projected to cover operational purchase power costs for the EMMO located in Montrose, Colorado.

WAPA used the FY 2015 preliminary SLCA/IP PRS as the template to calculate the rate impacts for all the alternatives. The generation, project use, energy, and capacity values for each alternative were updated in the PRS, and the rate was computed for each alternative. The rate-setting period in the PRS is determined by calculating the revenue requirement from the first future year through the year with the highest revenue requirement, which is referred to as the pinch-point year. For this rate analysis, the first future year used in the template is FY 2018. The pinch point used in the template is FY 2025 and is driven by a multi-million dollar Aid-to-Participating-Projects required payment due that year. Consequently, the rate-setting period for the template, from the first future year to the pinch point, is FY 2018 through FY 2025. The revenue requirements are recovered through a 50/50 split between the energy and capacity rates. Three rates calculated in the PRS are energy, capacity, and composite.

The energy rate is the rate that sets forth the charges for energy. It is expressed in mills/kWh and is applied to each kilowatt-hour delivered to an FES customer. The energy rate is estimated by a rates specialist and manually entered in the PRS, and a study is run to determine if the rate is sufficient to cover costs without creating a deficit. If the study produces a deficit balance, a new rate is entered into the PRS and the study is run again. The estimated rate is increased until the study no longer produces a deficit.

The capacity rate is the rate that sets forth the charges for capacity. It is expressed in $/kW-month and applied to each kilowatt of the CROD. The formula for the capacity rate is linked to the energy rate and is simultaneously updated to ensure the revenue requirement is recovered through a 50/50 split between the capacity and energy rates.[20]

The composite rate is the rate for firm power, which is the total annual revenue requirement for capacity and energy divided by the total annual energy sales. It is expressed in mills/kWh and used for comparison purposes only. The composite rate is calculated after the energy rate is computed and the rate-setting period is established. The composite rate, in mills/kWh, is calculated as the ratio of the total revenue required during rate-setting period to the total projected sales during the rate-setting period.

K.2.8.4 Standard PRS Rate-Setting Method Versus the Method Used in This Analysis

In order to accurately compute the impact of each alternative in terms of energy and capacity rates, projected power purchases for the entire rate-setting period of 2015 through 2034 were used. This deviates from WAPA's normal 5-year forecast in order to accurately capture each alternative's rate impacts. Table K.2-4 shows power purchase costs, assuming that current FES obligations would continue after FY 2024, and Table K.2-5 shows results for the marketing structure that would incur zero firming expenses after 2024. Table K.2-6 shows the SLCA/IP rate impact for each alternative.

K.2.9 Results

Table K.2-6 shows the estimated SLCA/IP energy and capacity rates by alternative. This reflects WAPA's current method of billing. SLCA/IP FES customers are billed monthly for the amount of energy used and for their capacity allocation. A composite rate is an index number that includes the energy and capacity rates together and may be useful for comparison purposes.

Table K.2-7 shows that there is a significant difference between the "bookend" assumptions. Comparing the composite rate, the No Change condition results in higher SLCA/IP rates across all alternatives compared to the Resource Available condition. For the No Change condition, the highest rate occurs under Alternative G (38.75 mills/kWh). The lowest SLCA/IP

[20] The production of hydropower that Western markets requires the construction of a dam and water storage. The fuel for these hydropower facilities is water, which is costless. Under the law, Western is required to set "cost-based" rates. If Western used production costs to set capacity and energy rates, the energy rate would be zero or near zero. It has been Western's practice to set FES rates so that 50% of the revenues collected through the sale of power are through the capacity rate and 50% of the revenues collected are through the energy rate. Other Federal power marketing agencies use different rate-setting strategies, but their rates are also required to be cost-based. The "50/50 split" is not a legal requirement, but, rather, a common Western practice.

TABLE K.2-7 SLCA/IP Rate Impact by Alternative[a]

	Alternative A (No Action Alternative)		Alternative B		Alternative C		Alternative D (Preferred Alternative)		Alternative E		Alternative F		Alternative G	
	NC[b]	RA[c]	NC	RA	NC	RA	NC	RA	NC	RA	NC	RA	NC	RA
Pinch-Point FY	2031	2055	2031	2055	2031	2055	2031	2055	2031	2055	2025	2057	2031	2055
Composite (mills/kWh)	32.64	25.19	32.69	25.07	33.77	25.65	33.65	25.22	33.41	25.16	37.79	27.53	38.75	26.65
Energy (mills/kWh)	13.52	13.40	13.54	13.22	13.99	14.55	13.94	13.78	13.84	14.01	15.67	16.86	16.07	15.22
Capacity ($/kW-month)	5.74	5.69	5.75	5.62	5.94	6.18	5.92	5.85	5.88	5.95	6.66	7.16	6.83	6.50

[a] Rate impacts in this table are in part based on net purchase power costs shown in Tables K.2.5 and K.2.6 which include the impacts of LTEMP experiments

[b] NC = No change from current FES commitment levels.

[c] RA = Resource available. Commitment level equals available SLCA/IP federal hydropower resource.

rate occurs under Alternative A (32.64 mills/kWh), although Alternative B is almost the same rate (32.69 mills/kWh). The range is 6.11 mills/kWh, with Alternative G producing a rate that is 19% higher than Alternative A (the no action alternative). The Resource Available condition produces similar results. The lowest SLCA/IP rate occurs under Alternative B (25.07 mills/kWh), almost identical to Alternative A (25.19 mills/kWh). Under this condition, the highest SLCA/IP rate occurs under Alternative F (27.53 mills/kWh). The range is smaller under this condition with Alternative F producing a rate that is 2.46 mills/kWh or 10% higher than Alternative B.

It is worth noting that under either of the post-2024 "bookend" conditions, Alternatives A, B, C, D, and E produce similar SLCA/IP rates. Alternatives F and G produce significantly higher SLCA/IP rates.

As described previously, the no change and resource available bookends are used for modeling purposes only and do not represent estimates or indications of the post-2024 commitment levels that may result from the public process. Alternative impacts on SLCA/IP rates illustrated in Table K.2-7 are indications of the rank order of the alternatives and the direction of impacts (positive or negative), and they encompass a reasonable range of the actual future rate impacts once the post-2024 marketing plan has been implemented. For the final LTEMP EIS, assumptions concerning post-2024 commitment levels may be revised to duplicate the range examined in the economic analysis described in Section K.1. This would be a SLCA/IP capacity obligation based on the 99th, 90th, and 50th percentile exceedance levels. The resulting

range will likely be somewhat narrower than the results of the bookend analysis presented in this draft.

K.2.9.1 Pinch-Point Year

Table K.2-7 includes pinch-point year information. The pinch point is the year in which the largest revenue requirement occurs in the future and is influential in setting the SLCA/IP rate.

There were three common pinch points that occurred when determining alternative-specific rates:

- 2025, caused by a required Aid-to-Participating-Projects Payment (Duchesne);
- 2031, caused by purchase power expense; and
- 2055, caused by a required Aid-to-Participating-Projects Payment (Starvation Reservoir).

As described in Section K.2.3, WAPA's SLCA/IP rates are set to assure repayment of all authorized water projects. In the current PRS, repayment of existing projects and repayment of yet-to-be constructed water projects will be completed in 50 years. The pinch-point is the year in which the largest future revenue requirement occurs. These pinch-points occur when a large water project – or "block" of a large water project – requires a repayment. After this pinch-point year, revenues are sufficient to complete repayment of remaining water projects. Therefore, it is said that the pinch-point year drives the rate.

Higher purchase power requirements require increasing the revenue requirement in the pinch-point year. Because the amount of purchase power is not consistent across alternatives, neither is the revenue requirement. The pinch-point year varies among alternatives because of the variation of purchase power amounts by alternative. It is not possible to use a consistent pinch-point year because each alternative produces different annual revenue requirements, and therefore a different schedule for completing repayment. The only way to have a consistent pinch-point year is to have consistent revenue requirements across each alternative.[21] With a fixed rate, the lower the purchase power, the more revenue available for discretionary repayment of investments which reduces annual interest and ultimately the annual revenue requirements. Conversely, increases in purchase power reduce the amount available for repayment on investment which leads to higher interest payments and subsequently, higher annual revenue requirements.

[21] One could argue that the SLCA/IP rate analysis should "force" the SLCA/IP rate to have the same pinch-point year for each alternative so that the impact of the alternatives is a more "apples to apples" comparison. This was considered as an approach, but it was decided that forcing such a condition would require a significant change in the rate-setting process. Moreover, it may be useful to the reader to know how alternatives differ in terms of their effect on setting a pinch-point year.

K.2.10 Definitions Used in Section K.2

Available Hydropower (AHP): The amount of SLCA/IP electrical energy and/or capacity available to FES customers for either the summer or winter seasons. This is designated for each month of the season.

Aid to Participating Projects: This is the part of an authorized irrigation/water project that is assigned to power for repayment. There is an assigned amount in the PRS for each authorized project.

Composite Rate: This is not a rate that is used for billing purposes. It is for comparisons. One takes the capacity rate and the energy rate, assumes a load factor and calculates the average rate per kilowatt-hour.

Contract Rate of Delivery (CROD): the amount of capacity allocated to an FES customer, by season, for the marketing period. It represents the "ceiling" obligation. An FES customer can utilize AHP capacity up to this amount.

Colorado River Storage Project (CRSP): Federal hydropower facilities in the Upper Colorado River Basin including Glen Canyon, Flaming Gorge, Fontenelle and the Aspinall Units.

CRSP Management Center: WAPA's Colorado River Storage Project Management Center. This is the WAPA office that has the responsibility for marketing the SLCA/IP power resources and for setting SLCA/IP FES rates.

Federal Energy Regulatory Commission (FERC): A federal commission that regulates the interstate transmission of electricity, natural gas, and oil. FERC also reviews proposals to build liquefied natural gas terminals and interstate natural gas pipelines as well as licensing hydropower projects. The FERC has limited jurisdiction over WAPA's rates, but must ensure that WAPA's project rates are sufficient to repay authorized projects.

Load Factor: A proportion of average energy used over a specified time period compared to peak demand for the same time period.

No Change Scenario (NC): This scenario represents a post-2024 condition where WAPA continues its current obligations to provide capacity and energy from the SLCA/IP resources.

Pinch Point Year: In setting the SLCA/IP FES rate, this is the year in which the highest payment obligation exists. It is said to "drive" the rate.

Project Use: Electrical capacity and energy reserved to power authorized water projects.

Power Repayment Study (PRS): this is the name of the model used by WAPA to set rates. PRS models are project specific.

Resources Available Scenario (RA): This scenario represents a post-2024 condition where WAPA reduces its current commitment of SLCA/IP energy and capacity to exactly match the production of power from the SLCA/IP resources.

Sustainable Hydropower (SHP): The amount of SLCA/IP electrical energy and capacity available to FES customers over the course of the marketing plan. This is the "firm" commitment that WAPA, in low release conditions, must firm up. There is an SHP capacity and energy amount for each month of the season.

Salt Lake City Area Integrated Projects (SLCA/IP): The Collbran, Rio Grande, and the Colorado River Storage Projects were integrated by WAPA in 1986 for marketing and rate-setting purposes.

K.3 IMPACTS ON RETAIL ELECTRICITY RATES

This section documents the effects of LTEMP alternatives on retail electricity rates and bills. Retail rate impacts measure how LTEMP alternatives affect electricity bills paid by household and business consumers who buy electricity from utility systems that directly or indirectly receive power from the SLCA/IP through WAPA. These impacts are documented in three sections that first explain the methodological approach, then summarize results, and finally present the impacts. The measured rate impacts do not use the wholesale rate impacts described in Section K.2 as an input, meaning that there is no direct connection between Section K.2 and this section. Instead, the rate impacts are directly computed from wholesale power costs that are derived directly from the power systems analysis. The retail rates are directly impacted by the LTEMP experiments and include both capacity and energy cost impacts. The wholesale costs that are measured directly from the power systems analysis using the carrying charge analysis described below are greater than the measured wholesale rates discussed in Section K.2, with the exception of Alternative G. This implies that the rate impacts would be lower had the wholesale rates from Section K.2 been used rather than the wholesale costs explained in this section (again, with the exception of Alternative G).

K.3.1 Analysis Approach

Retail rate and residential bill impacts are derived from the power systems analysis (described in Section K.1), SLCA/IP allocations, and publicly available retail rate and sales data using various allocation formulas. The foundation of the analysis is a database of retail sales, retail rates, and SLCA/IP energy allocations for utility systems that are given preference in power allocation from the SLCA/IP (referred to here as preference power). Rate impacts are based on the assumption that the capital, operating, and administrative costs of Glen Canyon Dam do not substantively change under different LTEMP alternatives when the energy output from the dam changes. Because these operating and administrative costs are not affected by the LTEMP alternatives, rate impacts result from changes in the cost associated with replacing capacity and/or energy with changes in dam operations. The wholesale power costs associated with changes in dam operations are labeled "grid costs" and include costs of replacement

capacity, changed production costs (fuel costs, purchased power costs, and variable operation and maintenance [O&M] costs), and differential fixed O&M costs. Using the retail data along with aggregate grid costs, the retail rate impacts of the LTEMP alternatives were determined for the vast majority of municipal, cooperative, and other entities that directly or indirectly receive preference power from SLCA/IP. A separate analysis was made for American Indian Tribes using SLCA/IP allocations to the Tribes combined with contract price data for special arrangements that are made with Tribes for SLCA/IP energy and capacity. The special contract arrangements imply that rate impacts for Tribes are generally greater than the rate impacts for non-Tribal systems. This analysis is presented in Section K.4.

The primary output from the rate impact analysis is a set of figures and tables that present the percent increase or decrease in electric rates and the changes in monthly electricity bills paid by residential consumers of municipal utilities, cooperative distribution utilities, Tribal authorities, and irrigation districts. (Retail consumers include businesses households and other institutions, while residential only includes households.) The rate impacts of different LTEMP alternatives are presented relative to Alternative A (the no action alternative). Rate impacts were estimated for all of the utility systems that have available retail energy sales data published by the Energy Information Agency (EIA) and incorporated more than 90% of entities that receive power from the SLCA/IP in terms of energy allocation. Entities for which rate impacts cannot be measured directly because of a lack of publicly available data include direct retail consumers such as military bases, universities, and the DOE Albuquerque office. In addition to computing rate impacts for companies with available data from the EIA, retail rate impacts for American Indian Tribes were calculated. This calculation used data from utility systems that serve the Tribes at a retail level combined with the effects of net benefit contracts between the Tribes and wholesale utility systems that directly compensate for wholesale power. Contracts between Tribes and wholesale systems to provide benefits are termed net benefit contracts. This analysis is presented in Section K.4.

Four primary tasks were undertaken to compute the rate impacts on retail consumers. These tasks were:

1. Compiling retail energy sales ($), rate ($/MWh), and residential bill ($/month) data for each utility system directly or indirectly receiving an allocation of SLCA/IP federal preference power;

2. Computing year-by-year grid costs under LTEMP alternatives from the power systems analysis and analyzing how the capital cost of new capacity is translated into retail revenue requirements (the capital recovery factor or carrying charge rate);

3. Allocating the aggregate grid cost impacts under LTEMP alternatives to individual retail utility systems; and,

4. Presenting the disparate retail rate and residential bill impacts over time for different systems.

Three information sources, as illustrated in Figure K.3-1, were used to compute the rate impacts of LTEMP alternatives. The first set of inputs for the analysis was a database of sales, rates, and SLCA/IP allocations for utility systems that receive federal preference power from the SLCA/IP. The second set of inputs consisted of the aggregate grid cost combined data from the power systems analysis with capital recovery charge analysis that represents the wholesale power costs. The third set was macroeconomic data from the Energy Information Administration (EIA) (EIA 2015b,c). These inputs were used to determine the relative rate impacts for individual systems from different LTEMP alternatives. Varying impacts on individual systems were largely driven by (1) the amount of preference power allocated to each system relative to the total generation resources of the system, and (2) the current retail rate, which influences the percentage change calculation (a higher rate results in a smaller percent change).

Explanations of analytical methods for determining rate impacts are organized around Figure K.3-1. The next three sections explain the data input items listed on the left side of Figure K.3-1. Section K.3.1.4 describes details of the calculation process referenced in the middle of Figure K.3-1, and Sections K.3.2 and K.3.3 describe the rate impacts that are cited on the right side of the figure. Additional description of the process to compute rate impacts for American Indian Tribes appears in Section K.4.

K.3.1.1 Database of Sales, Rates, and SLCA/IP Allocation for Retail Utility Systems

The explanation of the database is separated into two parts that address: (1) how a list of utility systems that receive federal preference power from SLCA/IP and distribute power to retail

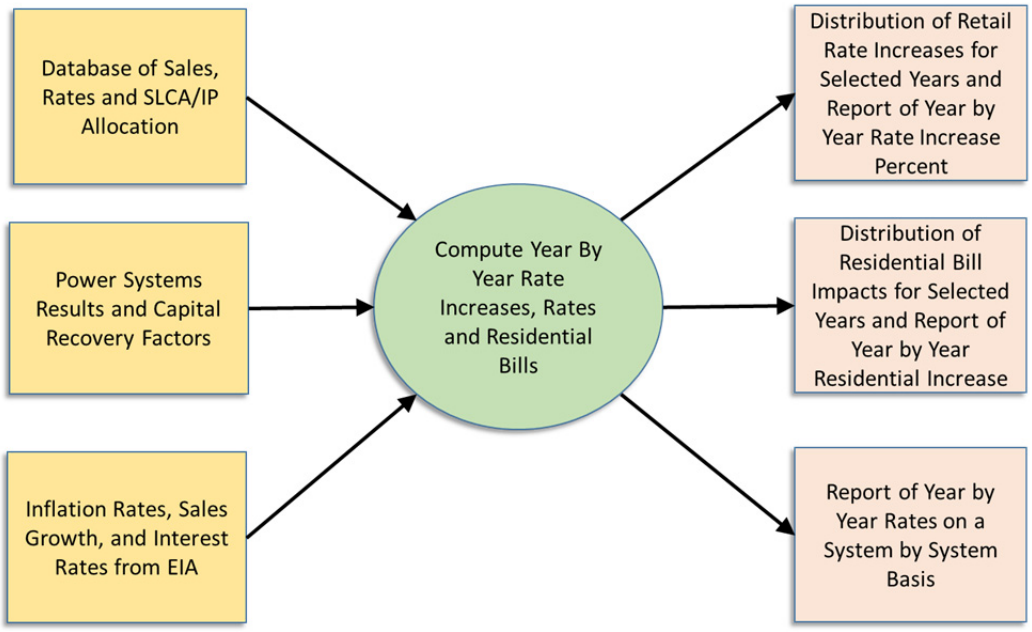

FIGURE K.3-1 Flowchart Diagram of Rate Impact Analysis Process

residential, commercial, industrial and other consumers was compiled; and (2) how retail statistics are gathered for utility distribution systems from Form EIA-861 detailed data files (EIA 2015a).

List of Utility Systems that Distribute Power to Retail Consumers

Developing the database for retail rate analysis involved arranging a list of utility systems that sell electricity on a retail basis and that directly or indirectly receive SLCA/IP federal preference power allocations. The starting point for this list is tabulating utility systems that receive federal preference power from SLCA/IP. WAPA provided this information in a spreadsheet of allocations for the period October 1, 2008, through September 30, 2024 (Osiek 2014). The allocation data included information for 154 different systems that receive separate preference power allocations.

Some of the utility systems listed in the Allocation Report do not sell power on a retail basis to residential and business retail consumers. Five systems including (1) the Wyoming Municipal Power Agency (WMPA), (2) the Utah Municipal Power Agency (UMPA), (3) the Platte River Power Authority (Platte River), (4) the Colorado River Commission of Nevada (CRCN), and (5) Tri-State Generation and Transmission Cooperative (Tri-State) receive preference power allocations from SLCA/IP and then re-allocate power to distribution systems. Table K.3-1 shows that these five indirect systems comprise 47% of the total SLCA/IP federal preference power. Deseret Generation and Transmission Cooperative and the Utah Associated Municipal Power Systems are not included in the five indirect allocation entities because for these two systems, each of their member distribution systems receives distinct direct allocations.

TABLE K.3-1 Energy Allocations for Systems Receiving Indirect SLCA/IP Allocations

System	Annual SLCA Energy Allocation (MWh)	Percent of Total Allocation
Systems Receiving Indirect Allocation		
Wyoming Municipal Power Agency	24,753	0.50%
Utah Municipal Power Agency	290,604	5.87%
Platte River Power Authority	502,467	10.15%
Colorado River Commission of Nevada	88,212	1.78%
Tri-State Generation and Transmission	1,424,012	28.76%
Subtotal Systems with Indirect Allocation	2,330,048	47.05%
Systems Receiving Direct Allocation	2,621,739	52.95%
Total Energy Allocation	4,951,787	100.00%

For the systems with indirect allocation listed in Table K.3-1, it is necessary to compile retail sales and rate data on all of the individual systems that sell power to retail consumers because the larger wholesale systems do not sell to retail consumers. A list of retail entities that are members of indirect retail systems (e.g., distribution cooperatives [co-ops] that are members of Tri-State) have been obtained from Websites for the five indirect allocation utility systems (CRCN 2015; Platte River Power Authority 2015; Tri-State 2015; UMPA 2015; WMPA 2015). After including the retail systems that are members of indirect allocation utilities, the total number of retail utility systems in the database increases from 154 to 226.

Retail Statistics for Distribution Utility Systems from the Form EIA-861 Database

Rate impact calculations for each entity required data for residential and nonresidential sales revenues and sales quantity. The primary source for the existing retail rates and retail residential, commercial, industrial, and other energy sales is the Form EIA-861 database (EIA 2015a). Data for direct retail consumers such as military bases and most American Indian Tribes are not included in the primary EIA database. After adjusting for complications associated with differences in system names, historical data availability, and systems that operate in multiple states, 91% of the preference power can be associated with retail sales data available in the EIA 861 database as shown in Table K.3-2. This table does not include additional data that has been separately gathered for the American Indian Tribes and is described in Section K.4. Additional data for American Indian Tribes is derived from utility companies that serve the Tribal Reservation along with wholesale utility systems that are the SLCA/IP benefit crediting partners (see Section K.4). Tribal entities that provide data to the EIA 861 database (representing the figure of 44.19% in Table K.3-2) included Ak-Chin, Tohono O'odham Reservation, and the Navajo Tribal Utility Authority. These three systems operate their own utilities and do not have special contracting arrangements to secure their SLCA/IP allocation. After accounting for special net benefit contracts used by Tribal Authorities combined with retail utilities that serve the Tribes, the coverage of Tribes is 100%. The 44.19% shown in Table K.3.2 does not include the additional data that is described in Section K.3.2.

K.3.1.2 Incorporation of Power Systems Analysis and Capital Recovery Factors

The second category of information input to the rate impact analysis shown in Figure K.3-1 is projected grid cost data derived from the power systems analysis and capital recovery factors. The amount of annual aggregate capacity (in MW) that is added on an annual basis, the total annual variable production cost, and the fixed O&M costs for new capacity are obtained from the power systems analysis described in Section K.1. The amount of capacity that needs to be added under each LTEMP alternative due to changes in operations is converted to revenue requirements using a carrying charge analysis combined with the projected cost of constructing new generating plants.

TABLE K.3-2 Coverage of Retail Information from EIA Database Relative to SLCA/IP Preference Power Allocation[a]

System	SLCA Annual Energy Allocation (MWh)	Percent of Total Energy Allocation	SLCA Energy with Retail Sales	Percent of Energy With Retail Sales
WMPA, UAMPS, UMPA, CRCN, Platte River	1,231,926	24.87	1,229,054	99.77
Tri-State, Deseret	1,840,470	37.15	1,840,470	100.00
Co-ops not Included in Larger Entities	210,951	4.26	210,951	100.00
Electric Districts and Irrigation Districts	123,588	2.49	108,401	87.71
Municipalities not in JAAs (including SRP)	921,408	18.60	921,408	100.00
Military Bases	70,550	1.42	0	0.00
Tribal Authorities	464,030	9.37	205,051	44.19
Universities and DOE Office	91,401	1.84	0	0.00
Total	4,954,323	100.00	4,515,334	91.14

[a] Note: CRCN = Colorado River Commission of Nevada; JAA = Joint Action Agency; SRP = Salt River Project; UAMPS = Utah Associated Municipal Power Systems; UMPA = Utah Municipal Power Agency; WMPA = Wyoming Municipal Power Agency.

To integrate power systems analysis with the rate impact calculations, selected results are summed together over the different systems that are simulated. Aggregating data from the power systems analysis across the large systems that were modeled and then allocating those costs to individual systems means that, in terms of the rate impact analysis, there is no difference in treatment between the small systems and the other eight utilities modeled in the power systems analysis. Equations used to convert the generation cost and capacity expansion data to aggregate grid cost impacts are listed below, where *t* represents the annual period, *i* represents the LTEMP alternative, and *c* represents the capacity type. The summation is over the new capacity type:

$$\text{Capacity Cost}_{t,i} = \sum \text{New Capacity}_{t,i,c} \times \text{Capacity Cost}_{t,i,c} \times \text{Carrying Charge Rate}_{t},$$

$$\text{Fixed O\&M}_{t,i} = \sum \text{Accumulated Capacity}_{t,i,c} \times \text{Fixed O\&M Cost/kW-yr}_{c}, \text{ and}$$

$$\text{Grid Cost}_{i,t} = \text{Production Cost}_{i,t} + \text{Capacity Cost}_{t,i} + \text{Fixed O\&M}_{t,i}.$$

Carrying Charge Factors Applied to New Capacity That Account for Ownership and Financing Structures of Municipal and Cooperative Systems

Rate impacts cannot be directly calculated from outputs generated by the power systems analysis because of the manner in which plants are financed. The annual cost of new capacity that is charged to consumers is established from dollar amounts that are paid to bondholders who lend money for constructing a new plant. Annual funds collected to compensate for the cost of building new capacity is termed the "capital recovery factor" or the "carrying charge rate." A detailed analysis has been made of carrying charges for individual municipal and cooperative

systems as part of the rate impact analysis. The carrying charges used data from financial reports and derived revenue requirements from changes in the quantity of generating capacity. The analysis includes effects of municipally financed debt, debt service requirements, the tenor of debt, and other assumptions including the interest rate. Some of the considerations in deriving the carrying charge analysis include:

- The carrying charge for purposes of the rate impact depends on the debt structure used to finance the investment. If the bond repayment period is not the same as the plant life and/or the bond repayment does not increase with inflation (both of which are generally true) then the capital recovery for purposes of the rate impact analysis is different than the economic carrying charge used in the power system analysis;

- The carrying charge for rate impact analysis does not reflect differences in risks associated with generating alternatives that are borne by consumers (for example, the capacity from Glen Canyon Dam already exists, while the ultimate cost of capacity from new generation plants has uncertain capital and operating costs);

- The carrying charge for rate impact analysis is affected by the debt service coverage and other specific features of bonds issued to finance construction for municipal and cooperative systems;

- The year-by-year carrying charge measured using actual interest rates relevant for measuring rate impacts is flat over the prospective tenor of the debt (by contrast, the real carrying charge used in economic analysis in the initial year of the plant life is lower than subsequent years);

- The carrying charge for generation and transmission cooperatives may be affected by patronage capital that is generally part of the financing of a new powerplant;

- The interest rate used in the calculation of carrying charges for rate impact analysis should reflect the credit rating and the tax status of entities that will finance the new construction; and

- The interest rate used for the carrying charge analysis changes over time when interest rates change (as projected by the EIA).

The carrying charge rates implemented in the rate impact analysis are shown on Figure K.3-2. The carrying charges applied in the rate impact simulation are a weighted average of the carrying charges for taxable (e.g., co-op) and municipal financing. The weighted average is derived from the energy allocations for (1) systems that issue taxable debt (co-ops and irrigation districts), and (2) systems for which the interest is exempt from federal income taxes (municipal systems). The weighted average carrying charge that converts one-time capital costs for construction of new capacity into projected annual revenue requirements begins at a level of

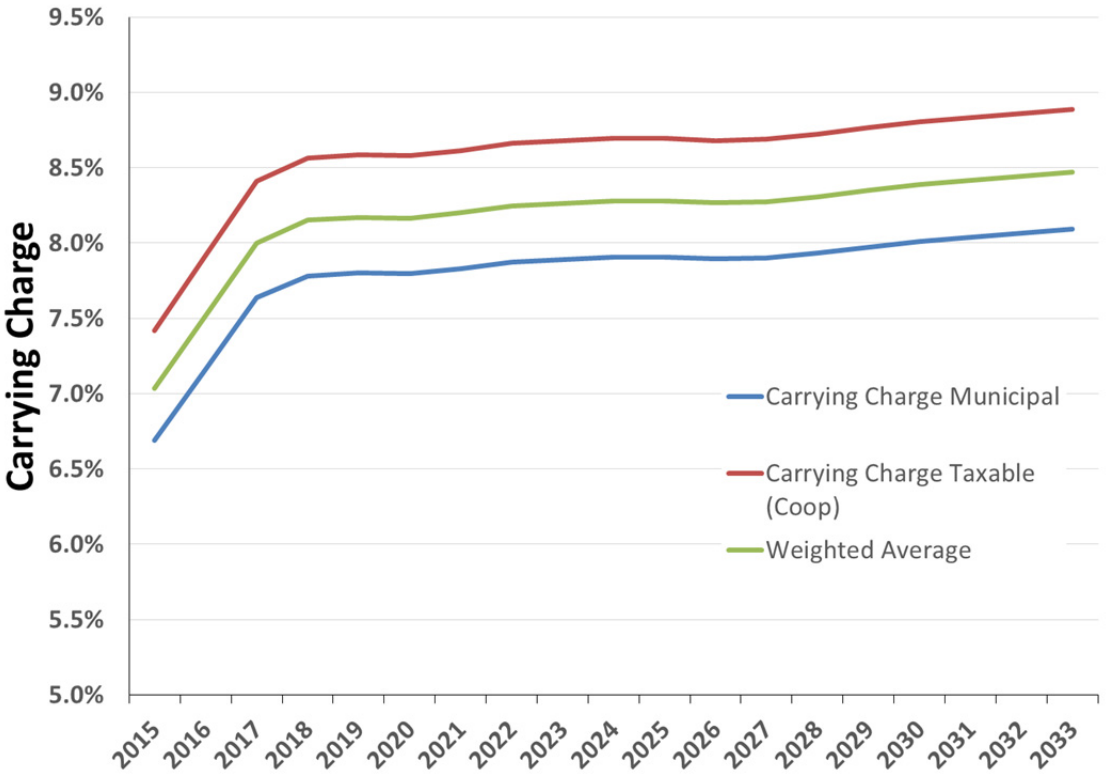

FIGURE K.3-2 Projected Carrying Charge Rates Used in Rate Impact Analysis

7.03% in 2015 and eventually increases to 8.50% (the middle line in Figure K.3-2). By contrast, if the same interest rate and inflation assumptions were applied to computing economic carrying charges, the real capital recovery factor would only be 4.38% in 2014. This higher carrying charge increases measured rate impacts.

K.3.1.3 Inflation Rates, Sales Growth, and Interest Rates from EIA

The third set of input data presented on the left side of Figure K.3-1 consists of general macroeconomic variables that drive the prospective level of base retail rates for each utility system. Macroeconomic factors include the expected level of electricity rates and the expected level of retail sales growth in the southwest region, as well as future interest rates for the municipal and cooperative systems. Data for these items has been derived from information provided in EIA regional forecasts presented in the 2015 Annual Energy Outlook (EIA 2015b). Projections from the EIA annual outlook (EIA 2015c) are also used for macroeconomic data including prospective inflation rates and interest rates.

K.3.1.4 Calculation Process for Computing Rate and Bill Impacts

The middle of Figure K.3-1 represents calculations made for computing rate impacts after the inputs are established. The computations of rate impacts for individual systems involve a series of allocations under each LTEMP alternative. Figure K.3-3 shows three allocation procedures that were part of calculating rate impacts. The first allocation involved attributing total grid cost to individual utility systems using SLCA/IP allocation data (shown in red in Figure K.3-3). For the indirect allocation systems defined in "List of Utility Systems that Distribute Power to Retail Consumers" above, a second allocation involved attributing SLCA/IP power from the Generation and Transmission Cooperative or the Joint Action Agency to individual members (shown in yellow in Figure K.3-2). These two allocations define impacts measured by the percent change in retail rates. The only allocation that involves assumptions with respect to utility-specific ratemaking processes is the computation of residential bill impacts. To compute the residential bill impact, costs must be allocated between residential and nonresidential consumers (shown in green in Figure K.3-2). For this allocation, the assumption is made that capacity and energy costs are allocated in the same proportion as existing overall rates.

Then next five sections describe the allocation process used to compute the rate impacts. The first section explains why wholesale rates were not needed in the allocation process and how

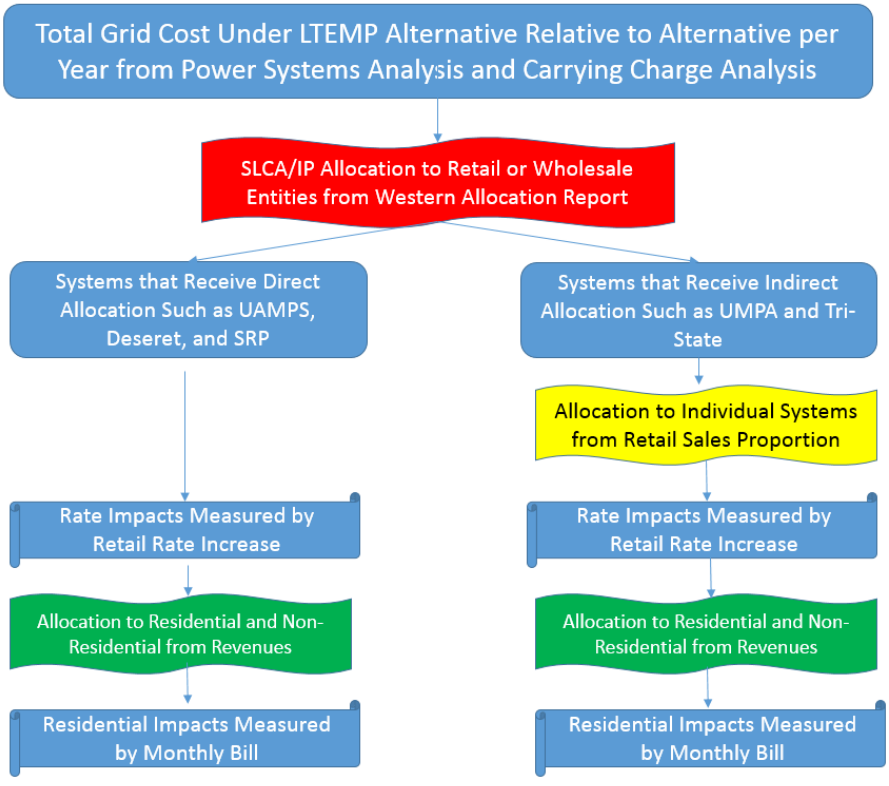

FIGURE K.3-3 Flowchart Diagram of Allocation Process

the aggregate grid cost impacts can be compared to SLCA/IP wholesale revenues. The second section describes the allocation of aggregate grid costs to different systems, and the third section describes the allocation process for indirect systems. The fourth section explains the allocation process for residential rates, and the final section demonstrates the process with a case study.

Using Grid Costs Rather than SLCA/IP Wholesale Rates for Computing Retail Rate Impacts

A fundamental concept underlying the rate impact analysis is that rate impacts of LTEMP alternatives occur because of differences in alternatives with regard to capacity that is lost and energy that must be purchased during different periods, not WAPA's cost structure. WAPA must collect the same amount of revenue to cover its costs under all of the LTEMP alternatives, even though marketable capacity has declined and timing of energy production has changed. For LTEMP alternatives that increase grid cost relative to Alternative A, retail consumers of entities that receive SLCA/IP capacity and energy in one way or another pay for replacing capacity and more expensive energy. (It is assumed that consumers who are not associated with entities that receive SLCA/IP capacity do not incur added costs.) This implies that rate impacts can be computed directly from grid costs rather than WAPA wholesale tariffs. For benchmarking purposes, the average annual production, fixed O&M, and investment costs on SLCA/IP customers are presented relative to the dollar amount of revenues collected by WAPA presented in Sections K.1 and K.3.2.2. Wholesale grid costs used as the basis for computing rate impacts have been compared to the aggregate wholesale amounts that would be paid under projected SLCA/IP rates described in Section K.2. This analysis evaluated the aggregate incremental grid cost for each alternative as compared to the aggregate wholesale power cost that would be paid under the wholesale SLCA/IP rates computed in Section K.2. The analysis demonstrates that for LTEMP alternatives other than Alternative G, the SLCA/IP wholesale rates would result in lower measured impacts than the aggregate grid costs.

The fact that retail rate impacts can be computed without separate calculations of WAPA wholesale rates can be demonstrated with a hypothetical example of three rate calculation approaches, the first of which does not include wholesale rate calculations, while the second and third apply different possible changes in wholesale tariffs that result from various LTEMP alternatives. All three of the wholesale rate techniques result in the same retail rate impact. The first method does not require measurement of SLCA/IP wholesale rates and is consistent with the approach illustrated in Figure K.3-3. Using this approach, rate impacts are computed by directly allocating grid costs under different LTEMP alternatives. The second method assumes that WAPA increases wholesale capacity charges to cover the fixed costs associated with lower amounts of capacity from changes in Glen Canyon Dam operations. This method assumes that the utility systems themselves procure the capacity and energy to make up for the changes in dam operations. The total amount of wholesale revenues received by WAPA does not change in this second method, and the utility systems themselves incur the increased grid costs in this scenario. Because WAPA's revenues do not change and utilities procure the capacity and energy deficits created from the LTEMP alternatives, the second scenario produces the same revenues as the first method, in which wholesale rates are not considered. The third approach assumes that WAPA, instead of the utility systems, procures the deficient capacity and energy. This means the

grid cost impacts are included in the WAPA wholesale rates and, from the perspective of the utility systems, the capacity quantity does not change. The same amount of capacity and energy must be procured by WAPA as would be procured by the individual utility systems. Ultimately, SLCA/IP rates change in different LTEMP alternatives to cover changes in the cost of capacity and energy.

Allocation of Aggregate Grid Costs to Retail Systems

The primary allocation formula applied to compute rate impacts involves allocating total grid costs to different systems using the annual SLCA/IP energy as reported in Osiek (2015). This allocation process, illustrated in red in Figure K.3-3, is represented by the following equation (recall that retail rates include rates to residential, business, and other consumers served by the utility system):

Retail Change for Individual System Relative to Alternative A ($) =
[SLCA/IP Energy Allocation to Individual System (MWH) /
Aggregate SLCA/IP Energy Allocation to All Systems (MWH)] ×
Aggregate Grid Cost Impact of LTEMP Alternative Relative to Alternative A ($).

SLCA/IP energy allocation in the above formula is applied by summing the summer and winter energy allocation for each system listed in Osiek (2015). The actual allocation that determines the amount each system pays for SLCA/IP power involves both energy and capacity and is differentiated by season. This raises the question of whether summer capacity, winter capacity, summer energy, and winter energy should be applied in a more complex allocation process. The question is resolved because the allocation shares to individual systems would be virtually identical if either the capacity or energy allocation were used. This is demonstrated by the fact that the annual load factor in SLCA/IP allocations is similar across different systems. If the load factor across systems is the same, then allocation of total grid costs using either capacity or energy will result in the same percentage of aggregate grid cost being attributed to each individual system. The similarity of annual load factors (average hourly energy for the winter and summer divided by the average summer and winter capacity) is illustrated in Figure K.3-4. Because the load factor is nearly identical for almost all distribution systems in Figure K.3-4, the use of capacity or energy does not influence the allocation process.

Given total retail revenues attributed to individual systems, the calculation of percent change in retail rates from LTEMP alternatives can be represented by the two formulas shown below. In these formulas, *t* is a subscript for the year and *i* represents the individual system. The term Retail $\text{Change}_{t,i}$ shown in the equation is the result of the equation presented at the beginning of this section.

$$\text{Rate Change Percent}_{t,i} = \text{Retail Change}_{t,i} / \text{Retail \$ Revenue under Alternative A}_{t,i}$$

Retail Revenue under Alternative $A_{t,i}$ comes from retail revenue for each individual system that is part of the database. Increases in retail revenues from sales growth and from price increases

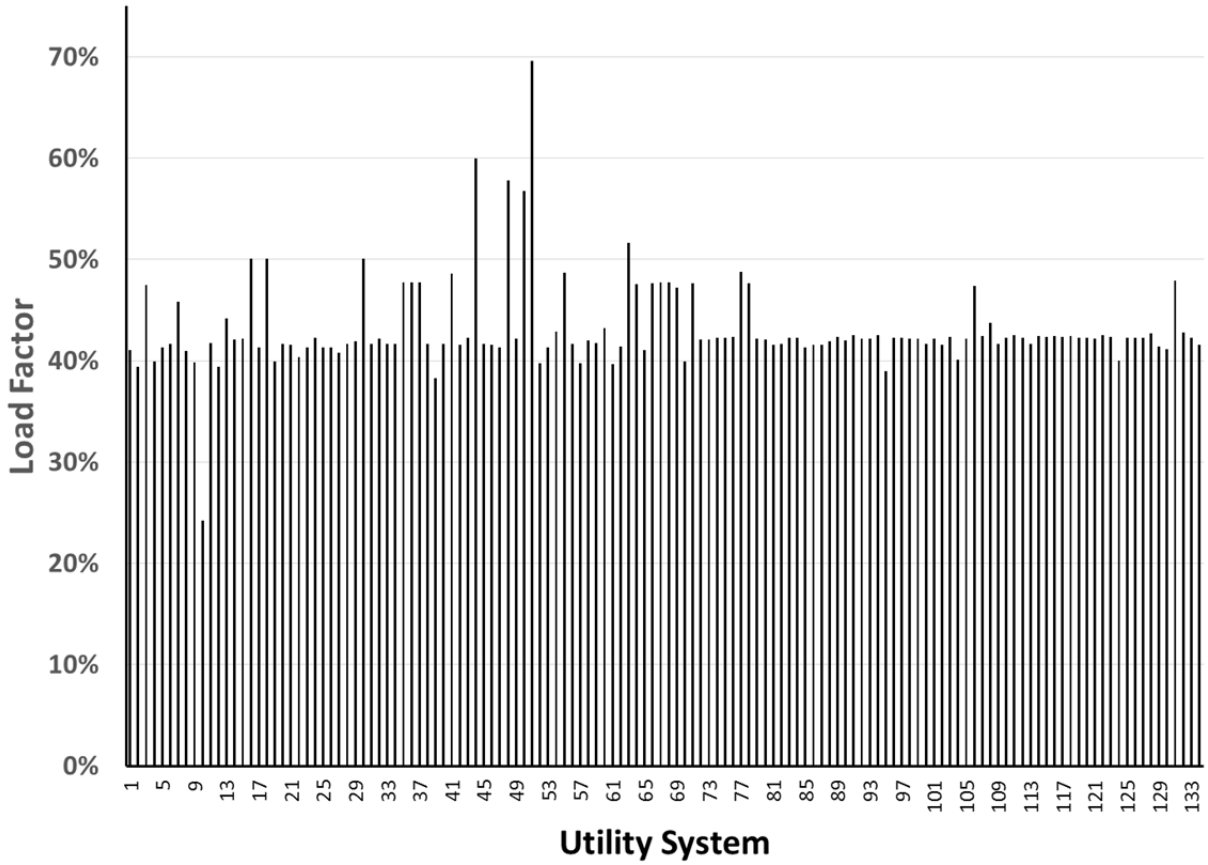

FIGURE K.3-4 Load Factors of SLCA/IP Power (Source: Osiek 2015)

after the base period are calculated from the EIA energy outlook for the Southwest region as represented by the following equation:

Retail Rate ($/MWh) under Alternative $A_{t,i}$ = Retail Rate under Alternative $A_{t-1,i}$ × (1 + Electricity Price Inflation from EIA_t) × (1+1 + Sales Growth from EIA_t).

SLCA/IP Energy for Indirect Allocation Systems

The second allocation issue highlighted in Figure K.3-3 involves allocation of SLCA/IP energy and capacity to individual retail entities from systems that receive indirect allocations. For the indirect allocation systems other than Tri-State (WMPA, UMPA, Platte River, and CRCN), the allocation of SLCA/IP energy to individual member utility systems is made on the basis of the retail sales proportion. Retail sales of the individual member system are divided by aggregate retail sales accumulated for the wholesale system (e.g., WMPA). The percentage of retail sales is multiplied by the aggregate SLCA/IP allocation to the large system reported in Osiek (2015). For Tri-State, the same general process was used, with the exception that

distribution cooperatives in Nebraska are not assumed to receive any SLCA/IP preference power and are not included in the aggregate sales calculation. The method for allocating SLCA/IP energy to individual distribution systems that are part of the larger indirect allocation systems can be represented by the following equation:

Allocation of SLCA/IP to Distribution Entity (MWh) =
[Annual Retail Sales of Distribution Entity (MWh) /
Total Aggregate Retail Sales of Distribution Systems in Group (MWh)] ×
Total SLCA/IP Allocation to Group (MWh).

Allocation Process from Computing Residential Bill Impacts

The final allocation process illustrated in Figure K.3-3 is the allocation of overall retail revenues (residential and non-residential revenues) to residential consumers and computation of residential bills. Calculation of residential bills involves two steps. The first step is to allocate a portion of the total retail increase for the system to residential consumers. This allocation is made with the ratio of residential revenues to total retail revenues for each system. Using the residential revenue percent, the dollar amount of change in residential revenue under LTEMP alternatives relative to Alternative A can be represented by the following equation:

$$\text{Residential Revenue Change } \$_{t,i} = \text{Change in Grid Cost}_{t,i} \times \text{Residential Percent}_{i}.$$

The second step is computing the monthly residential bill change from residential revenue change. The change in monthly residential bill relative to Alternative A is computed by dividing the total residential revenue change by projected residential consumers and then by 12. The number of residential consumers is projected through dividing the overall sales growth by 2 (implicitly assuming half of the growth is from increased use per customer). Calculation of monthly residential bills relative to the Alternative A is demonstrated in the equations below:

$$\text{Residential \$ Bill Increase}_{t,i} = \text{Residential \$ Increase}_{t,i} / \text{Residential Customers}_{it} / 12,$$

where:

$$\text{Residential Customers}_{it} = \text{Residential Customers}_{i,t-1} \times (1+\text{Sales Growth EIA}_{t}/2).$$

Case Study Illustration of the Allocation Process

The process of calculating rate impacts can be demonstrated by considering a case study. Tri-State is used to show how aggregate grid costs are allocated to determine rate impacts and why wholesale rates are not necessary in computing retail rate impacts. To demonstrate how rate changes are established, the grid cost impact under Alternative F in the highest impact year is used. On an aggregate basis, grid costs in this case increase by $41 million (in real 2015 dollars) relative to Alternative A. Tri-State members had retail revenues of $1.476 billion (computed from aggregating revenues for the Tri-State systems excluding the Nebraska members using the

database).[22] Tri-State energy allocations represent 29.0% of the total SLCA/IP (derived from the allocation report and recorded in the database). The amount of grid cost increase allocated to Tri-State can be computed as 29.0% multiplied by the aggregate grid cost change of $41 million, or $11.89 million. Note this calculation is made without any wholesale rate calculations. This calculation implies that the increase in average retail rates for Alternative F in the high-impact year across Tri-State member systems is $11.89 million/$1,476 billion = 0.81%.

The same retail rate calculation can be made by first computing impacts on SLCA/IP wholesale rates. Using the current capacity and energy allocations, WAPA revenues collected from SLCA/IP power are current published rates multiplied by aggregate allocations. Total revenues from multiplying capacity charges by total SLCA/IP capacity and energy charges by total SLCA/IP energy, sum to approximately $143 million. The total increase in wholesale rates would then be 28.67%, or $41 million/$143 million, if WAPA did not change capacity and energy allocations in the SLCA/IP tariff. Tri-State payments for wholesale power without the increase are the Tri-State allocation percent multiplied by total SLCA/IP revenues or 29.0% × $143 million = $41.47 million. For Tri-State, the increase in wholesale costs is 28.67% × $41.47 million = $11.89 million. Thus, the wholesale cost increase is the same whether it is calculated directly from aggregate grid costs as in the last paragraph or whether it is computed using wholesale rates as in this paragraph, and the $143 million of revenues collected from wholesale rates is not necessary for computing retail rate impacts. The wholesale impact of $11.89 million translates into the same retail impact of 0.81% discussed above. The example demonstrates that a large wholesale rate increase of 28.87% translates to a much smaller retail rate impact.

Rate Impact Measurement for American Indian Tribes

A detailed retail rate impact analysis has been prepared for American Indian Tribes. The analytical approach and results are described in Section K.4.

K.3.2 Results

Retail rate and residential bill changes are affected by the aggregate grid costs that occur under the various LTEMP alternatives relative to Alternative A. Once grid cost changes are established (that correspond to SLCA/IP wholesale rate changes), differential retail rate changes experienced by individual systems are affected by the amount of power that a system receives from SLCA/IP relative to total generation resource requirements of the system. The ratio of SLCA/IP allocation to retail sales for a particular system is termed the "preference ratio." Measurement of aggregate grid cost and the effect of SLCA/IP allocation guide presentation of the rate analysis in this section. The first part measures the aggregate grid cost change relative to

[22] By comparison, Tri-State's wholesale revenues were $1.019 billion in 2013, as reported in its Financial Report (Tri-State 2015).

wholesale revenues that are currently collected for SLCA/IP capacity and energy. Second, differential retail rates for individual systems are explained in the context of the preference ratio.

K.3.2.1 Grid Cost Changes Relative to WAPA Wholesale Revenues

Retail rate impacts of LTEMP alternatives relative to Alternative A are relatively small for individual utility systems. This is because grid cost impacts are spread over a wide consumer base and because SLCA/IP is only one out of a multitude of generating resources for the retail utility systems. Given the small rate impacts on retail systems, changes in annual grid costs relative to the total SLCA/IP revenues are introduced to provide a benchmark for comparing LTEMP alternatives. Table K.3-3 presents the average annual real grid cost increases per year from 2015 through 2035 (the LTEMP period) for LTEMP alternatives relative to Alternative A. (Grid costs that include capacity costs and production costs are defined in Section K.3.1.) Table K.3-3 shows that using the benchmark of wholesale revenues collected for SLCA/IP federal preference power, the increase in annual real grid costs divided by current wholesale revenues is as much as 20% for Alternative F. The grid cost increase is between 4% and 5% of current SLCA/IP wholesale revenues for Alternatives E and D. Capacity differences between the respective LTEMP alternatives and Alternative A, presented as the capital recovery of capacity costs, are the most important drivers of grid cost changes. The average annual capacity that is constructed under Alternative A that corresponds to the two right-most columns in Table K.3-3 is 2,701 MW.

TABLE K.3-3 Average Annual Grid Cost Relative to SLCA/IP Wholesale Revenues Relative to Alternative A

Alternative	Average Annual Grid Cost Increase Relative to Alternative A (in thousands of 2015$)	WAPA Revenues from SLCA/IP Capacity and Energy Charges (in thousands of 2015$)	Percentage Change Relative to WAPA Revenues	Average Capacity Differential Relative to Alternative A After 2017 (MW)	Maximum Capacity Differential in Single Year Relative to Alternative A (MW)
A		143,000	0.00%		-
B	(976)	143,000	–0.68%	(13.53)	(230.00)
C	9,820	143,000	6.87%	189.41	230.00
D	6,831	143,000	4.78%	121.76	230.00
E	6,392	143,000	4.47%	135.29	230.00
F	28,751	143,000	20.11%	392.35	460.00
G	17,218	143,000	12.04%	230.00	230.00

K.3.2.2 Retail Rate Changes for Individual Systems and SLCA/IP Power Relative to Total Resources

Variation among retail rate changes for individual utility systems under different LTEMP alternatives are driven in large part by the ratio of SLCA/IP energy allocation compared to the total generation resources required for the system. Using the database described in Section K.2.1.2, the proportion of SLCA/IP power to total resources can be measured by computing the ratio of SLCA/IP annual energy allocation to total retail sales. If this preference ratio is low for a retail utility system, then even a relatively large increase in SLCA/IP costs will probably have a small rate impact. Figure K.3-5 displays the range in preference ratios for individual systems, together with the size of the systems, in a scatter plot. The size of the system on the x-axis is represented by annual retail sales. The y-axis of the graph demonstrates that the range in preference ratio varies from less than 1% to more than 60% for different systems in the database. Points in the upper left corner of Figure K.3-5 demonstrate that most of the systems with high preference ratios are small. This is likely due to the history of allocations for preference power. If a system was small when it originally received a preference power allocation, but has subsequently grown large, it will have a relatively lower ratio of SLCA/IP allocation to retail sales (sales have increased and the SLCA/IP allocation has remained the same). On the other hand, if a system has not grown much since the original allocation was made (i.e., it is a small system with relatively low retail sales), the preference ratio could remain relatively high.

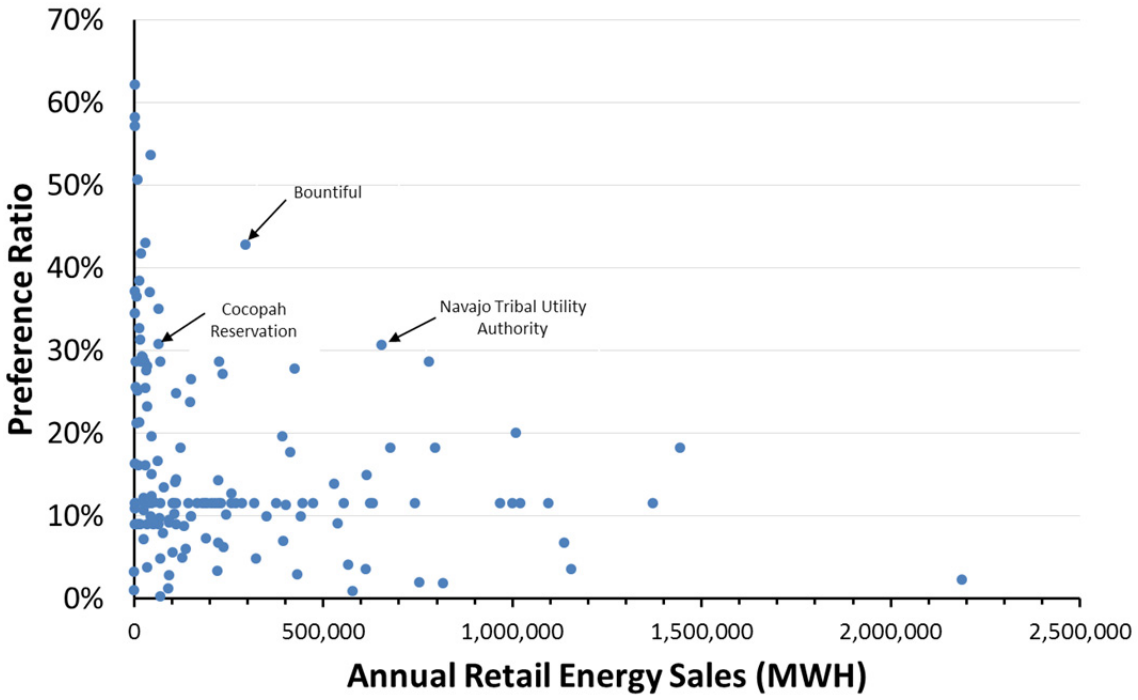

FIGURE K.3-5 Scatter Plot of Preference Ratio and Annual Retail Sales

Two of the Tribes that provide data to the EIA 861 database are highlighted in Figure K.3-5 as background for the rate impacts that are discussed in Section K.3.4.[23] The Navajo Tribal Utility Authority represents a large proportion (about 40%) of the SLCA/IP allocation to Tribes.[24] Figure K.3-5 shows that the Tribes with EIA data do have relatively high preference ratios. The only other utility system with a relatively high preference ratio that is not a very small system is the City of Bountiful, a member of UAMPS (highlighted in Figure K.3-5).

The relationship between the preference ratio and rate changes for individual systems is demonstrated by scatter plots of the percentage retail rate change and the preference ratio. In the scatter plots, the retail rate change is measured relative to Alternative A, implying that a scatter plot for Alternative A is not meaningful. Figure K.3-6 presents scatter plots of the preference ratio and the percent rate change relative to Alternative A for Alternatives B through G. In displaying the scatter plots for each LTEMP alternative relative to Alternative A, a single year is selected so that each system represents a single point. In each panel of Figure K.3-6, the year shown is the year with the highest rate impact for the respective LTEMP scenario. Because the highest rate changes do not occur in the same year for the various LTEMP alternatives, as explained in Section K.3.3.2, the scatter plots use different years.

The scatter plots shown in Figure K.3-6 demonstrate that much of the rate impact on individual systems is driven by the preference ratio. For each of the panels in Figure K.3-6, a regression equation of the percent retail rate change versus the preference ratio is displayed. The R^2 statistic displayed on each of the panels is 0.87. This indicates that 87% of the variation in percentage rate change can be explained by variation in the preference ratio. The 13% of variation in percentage retail rate changes that is not explained by the preference ratio represents other factors that include the level of retail rates, the load factor of the system, distribution costs, and the capacity and energy costs paid for non SLCA/IP power.

Scatter plots displayed in Figure K.3-6 have differently scaled y-axes. The y-axes represent the range in possible rate changes for the respective LTEMP alternative in the year with the highest (absolute value) percent change. The upper end of the y-axis therefore represents the absolute maximum retail rate percent increase for the LTEMP alternative across systems. Finally, regression equations are presented in each panel of Figure K.3-6 that shows the relationship between the preference ratio and the percent retail rate change in the year with the maximum change for each LTEMP alternative. These regression equations can be used to approximate rate impacts for systems that are not included in the database, as explained in the next section.

---

23 Fifty-three different Tribal entities receive capacity and energy allocations from SLCA/IP, representing 8.85% of the total energy allocation. Because the Tribes do not report sales and revenues as part of Form EIA-861 database, accessing sufficient data to make individual rate impact assessments was not possible. Instead, the analysis focused on two Tribal systems: Navajo Tribal Utility Authority and the Cocopah Reservation.

24 Retail data for the Navajo Tribal Utility Authority was derived from its Integrated Resource Plant (IRP) and Website (https://ww2.wapa.gov/sites/western/es/irp/Documents/NTUA2012.pdf) rather than from the EIA-861.

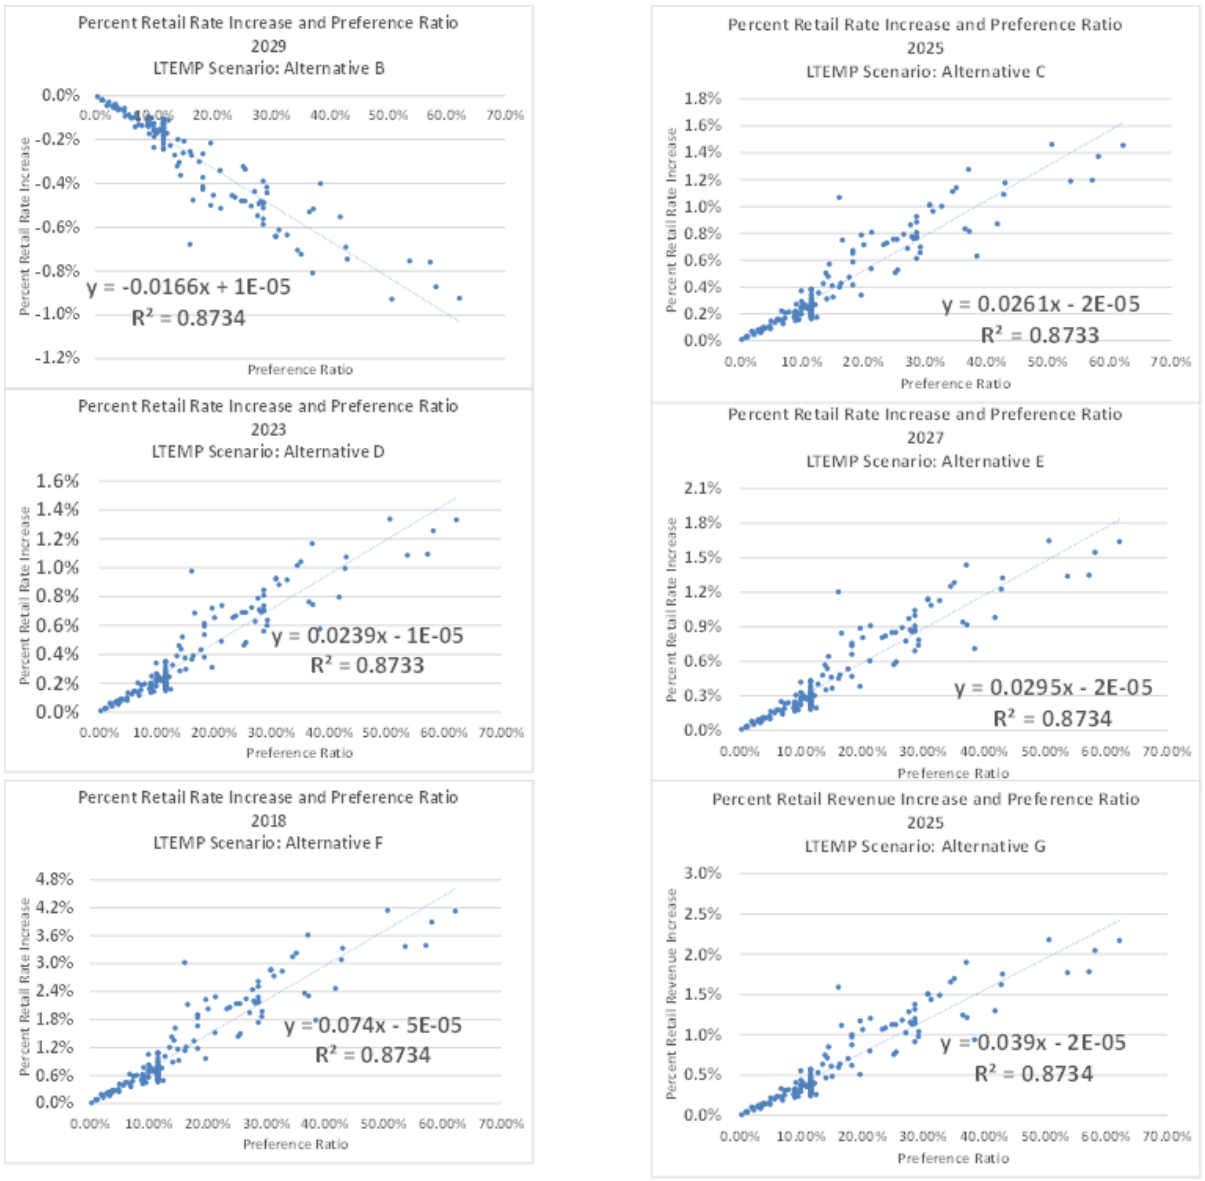

FIGURE K.3-6 Scatter Plots of Percent Retail Rate Change and the Preference Ratio

K.3.2.3 Using Regression Equations to Approximate Retail Rate Changes for Systems Not Included in the Database

For small Tribal systems and other entities that do provide retail sales and rate data to the EIA, the rate impacts can be approximated using the regression equations shown in Figure K.3-6. To compute rate impacts for systems that are not directly evaluated in the database, the preference ratio should be computed first through dividing annual SLCA/IP energy allocations by the retail electricity usage of consumers for the system. This preference ratio can then be multiplied by the coefficient shown in each of the panels of Figure K.3-6. For example, under Alternative F in the high-impact year, the coefficient is 0.074. If the ratio of SLCA/IP energy to

total energy consumption is 50% for an entity such as a U.S. Air Force base or for a Tribe that does not report to the EIA, the estimated rate increase would be 3.7% (0.074 × 50%).

K.3.3 Summary of Impacts

Retail rate and residential bill impacts under the LTEMP alternatives were compiled for 147 different utility systems during the LTEMP period, 2015 to 2035, on an annual basis. The retail rate impacts and the residential bill impacts under Alternatives B–G are presented relative to Alternative A. Due to the large number of retail utility systems that receive federal preference power and the number of LTEMP alternatives, various different techniques were used to summarize the rate impact results.

Rate and bill impacts are presented in four parts. First, the aggregate impacts are averaged across all systems and across the entire LTEMP period. Second, the impacts of LTEMP alternatives are presented on a year-by-year basis averaged across all systems. This section also includes a summary comparison of maximum-impact-year rate and bill impacts across different LTEMP alternatives. Third, rate and bill impacts for specific utility systems are listed under different LTEMP alternatives and the impacts under each LTEMP alternative are discussed. Fourth, the rate impacts on small systems and Tribes are explained.

K.3.3.1 Average Rate Impacts under LTEMP Alternatives over the 20-Year LTEMP Period

To demonstrate the general magnitude of rate impacts and evaluate the relative impact of different LTEMP alternatives on retail electricity rates, impacts are presented in terms of average impacts across utility systems and the LTEMP period. Before introducing the rate and bill impacts for Alternatives B, C, D, E, F, and G relative to Alternative A, retail rates and residential bills for Alternative A are described. The retail rates and residential bills under Alternative A provide a benchmark for gauging impacts of other alternatives. For example, a monthly residential bill increase of $1.00 under a particular LTEMP alternative relative to Alternative A can be evaluated relative to the average and median monthly residential bills in Alternative A.

Figures K.3-7 and K.3-8 display retail rates in $/MWh and residential bills in $/month under Alternative A. Note that none of the tables and figures in this section include the impacts on Tribes that have special net benefit contracts. Rate impacts for Tribes with net benefit contracts are addressed in Section K.3.4.2. Figure K.3-7 shows the distribution of retail rates across the utility systems. Retail rates are computed by dividing retail revenues collected from residential, business and other consumers by retail sales for the consumers. Rates and bills are represented in Figures K.3-7 and K.3-8 with distribution analyses. The increments on the x-axes demonstrate the highest and lowest ranges for rates and bills across different systems. The average and the median statistics, as well as the ranges, are shown in the graph titles. The range in retail rates under Alternative A varies from $55/MWh to $177/MWh, with an average rate of $104/MWh. The level of retail rates influences the reported rate increase percent in subsequent

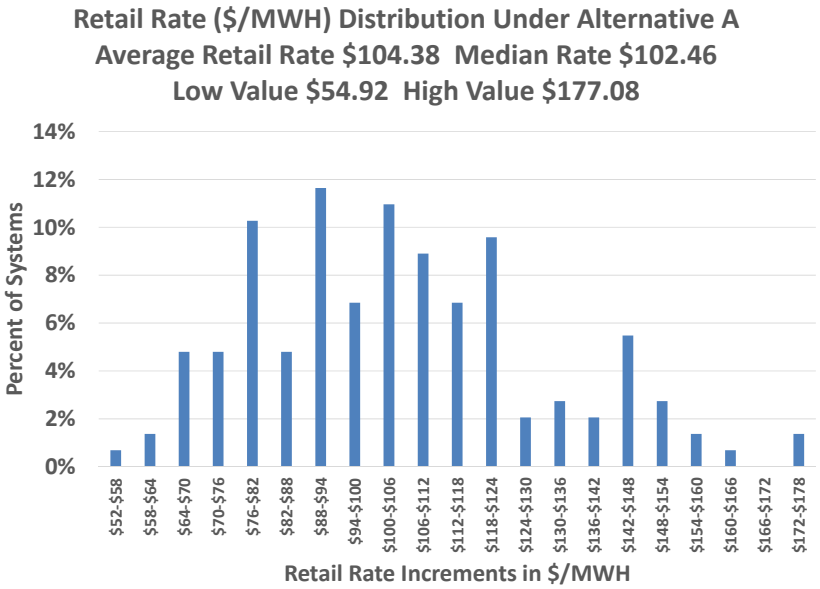

FIGURE K.3-7 Retail Rate Distribution under Alternative A

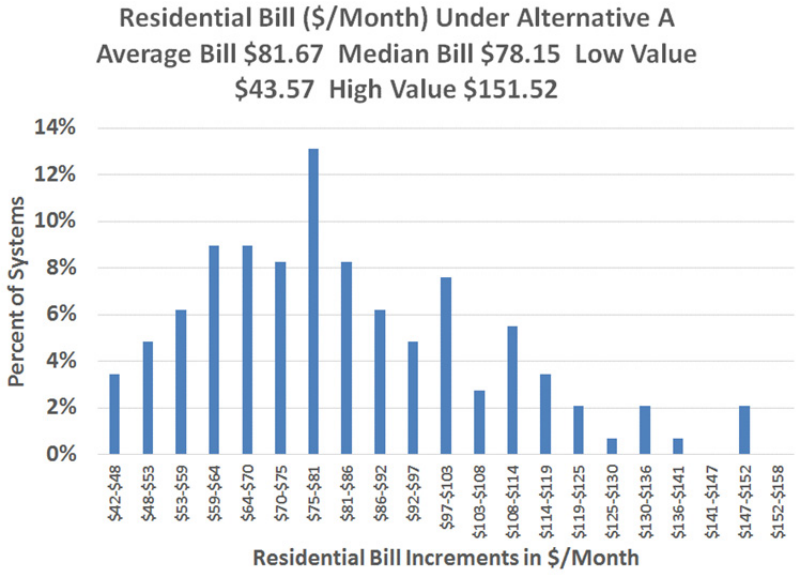

FIGURE K.3-8 Monthly Residential Bill Distribution under Alternative A

presentation of rate impacts. For example, a lower retail rate for a particular system results in a higher percent increase, all else being equal, because the allocated aggregated cost increase is divided by the retail rate. On the other hand, a lower retail rate does not influence the residential bill calculation because bill impacts are measured on an absolute basis.

Figure K.3-8 presents monthly residential bills that are calculated by dividing annual residential revenues of a system by the number of residential consumers and then dividing the product by 12. Average monthly bills under Alternative A range between $44 and $151 per month, with an average of $82 per month. This implies that an increase of $1 from an LTEMP alternative other than Alternative A results in a typical percent increase in monthly bills of somewhat more than 1%.

Figures K.3-9 and K.3-10 illustrate the average impacts on retail rate changes and on monthly residential bills across different systems relative to Alternative A. Residential bill impacts in Figure K.3-10 and in the rest of the subsequent rate impact presentation are measured in real 2015 dollars. The graphs in Figures K.3-9 and K.3-10 display averages across systems that are not weighted by the size of the systems. This means that a small system with less than 1,000 consumers is given the same weight as a large system with hundreds of thousands of customers (such as SRP). Because rate impacts tend to be greater for small systems, evaluating impacts using averages weighted by the sales size results in lower increases (about half of the unweighted average). Weighted average impacts are discussed in Section K.3.3.3 and presented in Table K.3-4. Figure K.3-9 demonstrates that even the most extreme LTEMP alternative in terms of changing dam operations (Alternative F) results in rate changes for retail consumers below 1%. Under Alternative F, there is an average rate increase of 0.75% relative to Alternative A. Figure K.3-10 shows that the highest average residential bill impact is 69 cents per month. Alternatives E and D have much lower retail rate impacts that are approximately 20% of the rate impact under Alternative F. (Note that individual rate impacts on particular systems can be higher than the average impacts.)

K.3.3.2 Average Year-by-Year Rate Impacts

Rate impacts presented in the previous paragraphs, which average rate and bill changes across the entire LTEMP period, mask the year-to-year rate impacts. Impacts in a single year can be different than average impacts across years because of the manner in which capacity changes occur and the effects of dam operations on production costs. Maximum rate impacts in a single year may be of concern to stakeholders. Therefore, the average annual retail rate and bill impacts from year to year are presented in this section. Figures K.3-11 and K.3-12 show the year-by-year averages for the overall retail percent changes and residential bill changes under different LTEMP alternatives. Year-by-year impacts for LTEMP alternatives are measured relative to Alternative A and the averages are not weighted by system size. Figure K.3-11 demonstrates that in terms of average percent changes in retail rates across all of the utility systems, the changes are not constant from year to year. Retail rate impacts from Alternative F are above the other alternatives, except in 2 of the years. The largest percent changes other than under Alternative F are under Alternative G, which has relatively constant changes over the LTEMP period. The

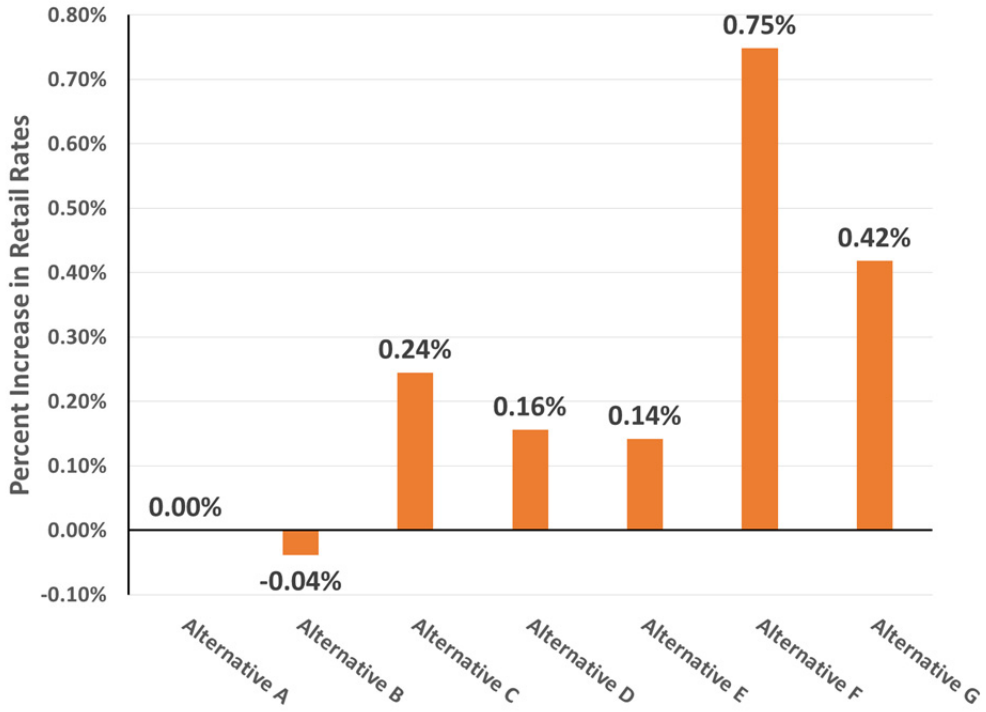

FIGURE K.3-9 Average Retail Rate Impacts under LTEMP Alternatives Relative to Alternative A

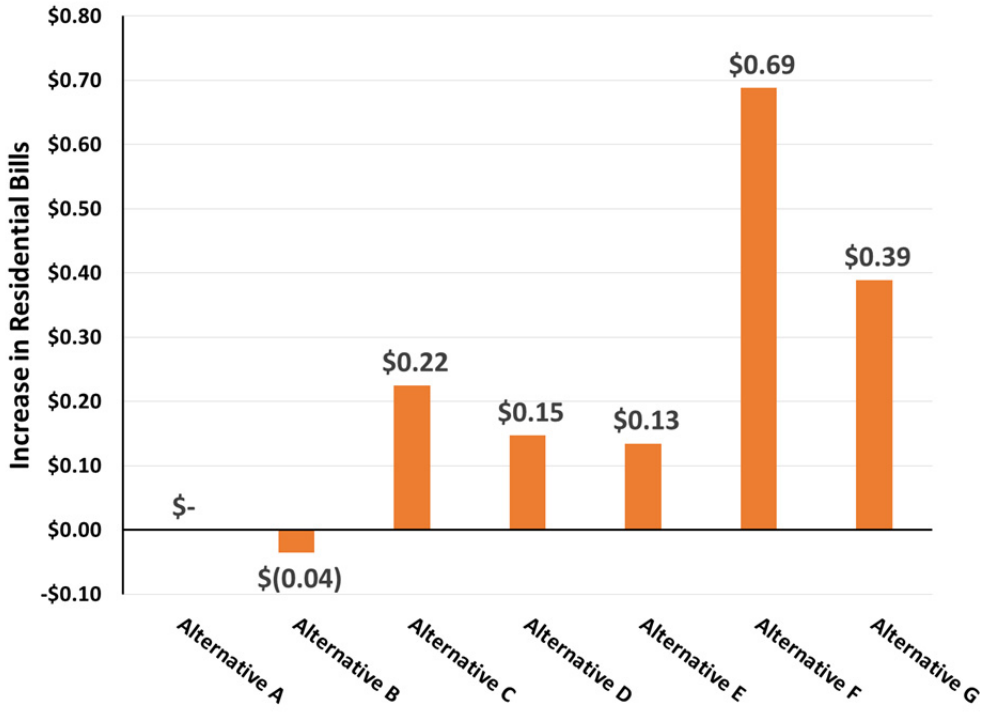

FIGURE K.3-10 Average Residential Bill Impacts under LTEMP Alternatives Relative to Alternative A

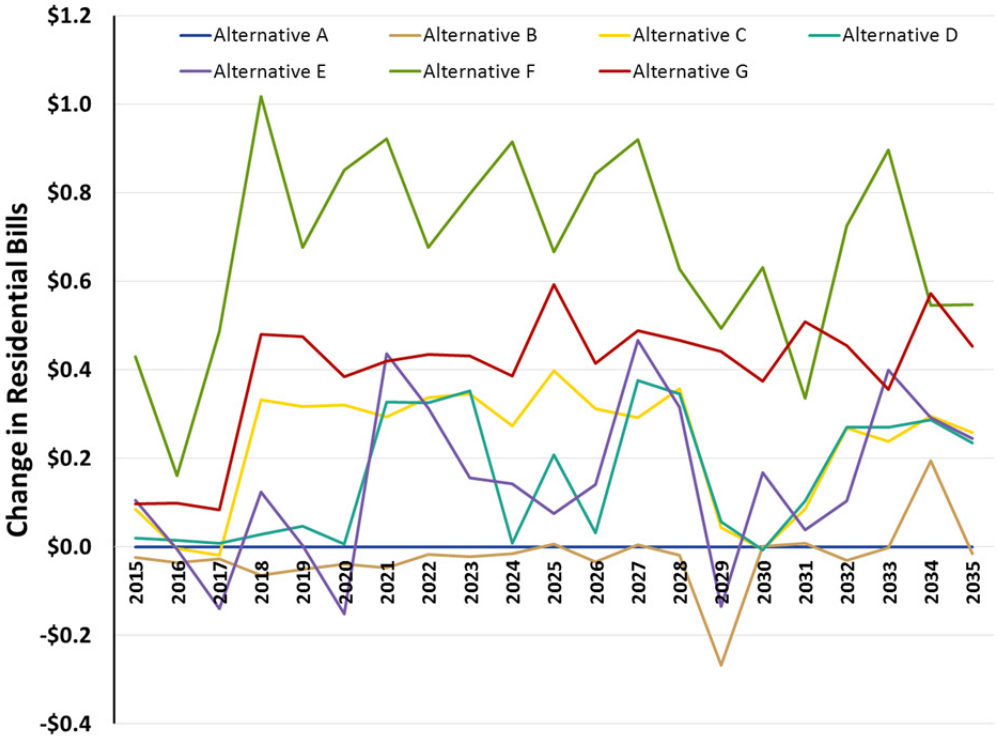

FIGURE K.3-11 Average Retail Percent Revenue Increase Relative to Alternative A

third-highest rate impacts are from Alternative C; these are constant until 2028, after which the impacts decline. Alternatives D and E have varying impacts from year to year that are driven by differences in construction of new capacity. Alternative B has impacts below zero (bill reductions relative to Alternative A), except in 2034, when construction of new capacity is accelerated relative to Alternative A. All of the tables and figures in this section include the Ak-Chin, Tohono O'odham Reservation, and Navajo Tribal Utility Authority Tribes but do not include the impacts on Tribes that have special net benefit contracts. Rate impacts for Tribes with net benefit contracts are addressed in Section K.3.4.2.

Figure K.3-12 shows that in terms of monthly bill changes from year to year, the annual patterns are similar to the trends in retail bill changes. The highest monthly bill impact in a single year is just above $1.00 per month under Alternative F, relative to Alternative A in 2018. The year 2018 for Alternative F is termed the maximum impact year. For Alternative G, the maximum residential monthly impact is just below 60 cents per month in the year 2025. Impacts for the maximum year are presented in Table K.3-4. Figure K.3-11 also demonstrates that monthly bill impacts are more variable from year to year under Alternative E than other LTEMP alternatives. Alternative E has bill changes below zero in the years 2017, 2020, and 2029. The bill impacts are higher for Alternative E than Alternative D, but Alternative D does not have any impacts that are below zero.

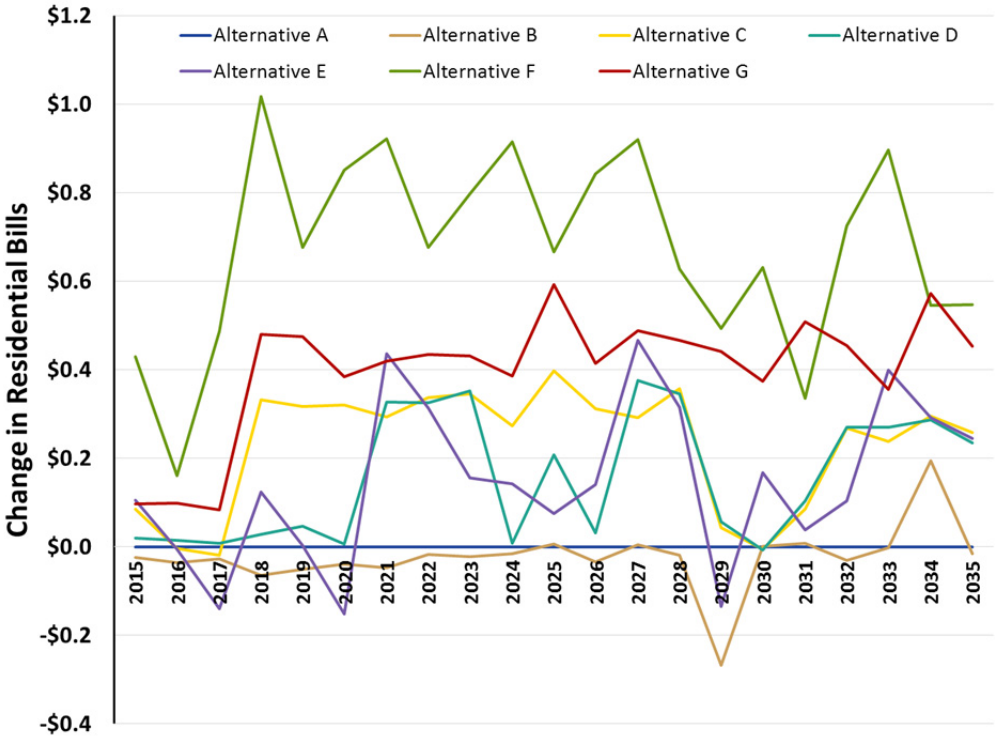

FIGURE K.3-12 Average Monthly Residential Bill Changes Relative to Alternative A

Maximum and average rate and bill impacts are recorded in Table K.3-4, which summarizes the average impacts across systems in the maximum impact year and over the LTEMP period. Unlike the impacts presented up to this point, Table K.3-4 also presents the averages and maximum impacts using an alternative weighting method where the size of different systems is considered. The weighting method places a higher weight on larger systems by multiplying all of the impacts by the ratio of retail sales for a system to aggregate retail sales across all systems. When averages are weighted by sales, the rate and bill impacts are approximately half of the amount without weighting. For example, the maximum monthly bill impact of $1.02 per month under Alternative F in 2018 is reduced to 50 cents when small systems are given lower weight and larger systems are given higher weight. The large reduction in impacts from weighting by sales comes about in part because SRP and the City of Colorado Springs have low rate impacts and a very high level of sales relative to other systems. The sales of these two systems alone represent 45% of the total sales for all systems in the analysis. When weighting by sales, the weighting calculation shown in Table K.3-4 excludes SRP and the City of Colorado Springs in the aggregate sales tabulation.

In addition to displaying average impacts across years and average rate impacts in the maximum change year, median impacts are also shown in Table K.3-4. Median statistics show the rate or bill change for which 50% of companies are above the value and 50% are below the value. The median values are less affected by extreme high values or low values and result in

TABLE K.3-4 Summary Table of Comparative Values

Impact	Alternative A (No Action Alternative	Alternative B	Alternative C	Alternative D (Preferred Alternative)	Alternative E	Alternative F	Alternative G
Percent change in average grid cost relative to WAPA revenues	No Change	–0.68	6.87	4.78	4.47	20.11	12.04
No Weighting by size							
Percent change in retail rates (average across years)	No Change	–0.04	0.25	0.15	0.14	0.75	0.42
Average percent change in retail rates (maximum impact year)	No Change	–0.27	0.43	0.39	0.50	1.21	0.64
Median percent change in retail rates (maximum impact year)	No Change	–0.20	0.27	0.25	0.30	0.76	0.40
Change in monthly residential bill (average across years)	No Change	–$0.04	$0.22	$0.15	$0.13	$0.69	$0.39
Average change in monthly residential bill (maximum impact year)	No Change	–$0.27	$0.40	$0.38	$0.47	$1.02	$0.59
Median change in monthly residential bill (maximum impact year)	No Change	–$0.23	$0.31	$0.27	$0.09	$0.78	$0.46
Weighting by size with adjustments for SRP and Colorado Springs							
Percent change in retail rates (average across years)	No Change	–0.03	0.19	0.12	0.11	0.59	0.33
Percent change in retail rates (maximum impact year)	No Change	–0.21	0.34	0.31	0.39	0.96	0.50
Median percent change in retail rates (maximum impact year)	No Change	–0.19	0.26	0.24	0.30	0.75	0.39
Change in monthly residential bill (average across years)	No Change	–$0.03	$0.18	$0.12	$0.11	$0.56	$0.32
Change in monthly residential bill (maximum impact year)	No Change	–$0.25	$0.32	$0.31	$0.38	$0.83	$0.48
Change in monthly residential bill (average across years)	No Change	–$0.22	$0.31	$0.27	$0.10	$0.79	$0.46

lower observed impacts because a few systems with high rate impacts skew the averages. The top half of Table K.3-4 shows data on an unweighted basis that have been shown above. The lower half shows weighted averages, including the median. The top part of Table K.3-4 demonstrates that the maximum impact is lower when measured by the median instead of the average. For example, under Alternative F, the maximum residential bill impact of $1.02 that is averaged for all systems is more than 20% less (78 cents) when the median is used to measure the typical impact. The impact is further reduced when the impacts are weighted by sales size, as shown at the bottom of the table. Weighting by sales reduces the measured rate impact. For example, under Alternative G, the average retail rate increase is reduced from 0.64% to 0.50% when the average is weighted by adjusted sales size. When the median sales weighted statistic is measured, the number for the maximum year under Alternative G falls to 0.39%.

K.3.3.3 Individual System Impacts and Summary Descriptions of LTEMP Alternatives

This section addresses individual rate and bill impacts on particular systems rather than presenting results in terms of averages. Detailed rate impacts on selected individual utilities are presented separately for systems that experience relatively large and relatively small impacts. Four tables, Table K.3-5 through Table K.3-8, demonstrate the large and small individual impacts on different systems. The tables show the year with the maximum retail rate and monthly bill impact for each alternative relative to Alternative A. Using the lists of systems with the highest rate impacts and the graphs and tables from previous sections, each alternative is summarized.

Lists of Individual Systems with Largest and Smallest Impacts

Table K.3-5 lists the 30 systems with the largest percentage retail rate impact (in absolute value) for the LTEMP alternatives. Given the aggregate grid cost change from an LTEMP alternative, the retail rate impact for a particular system depends on the SLCA/IP energy allocation, the preference ratio, and the current retail rate. None of these three items change with different operations of the dam. This means the ranking of systems does not change under different alternatives and lists of systems with the largest and smallest impact can be presented on a single table. The percentage rate impact is shown under the letter of the respective alternative. The year of the maximum impact for which the retail rate impact is displayed is shown below the alternative title. Table K.3-6 displays the 30 systems with the smallest percentage retail rate impact in a similar format. The size of systems as measured by the number of residential consumers and the preference ratio is presented for each system. The year for which the impact is measured is also shown on Table K.3-5.

Many of the entities that experience the largest impacts are part of the UAMPS system and have a high ratio of preference power to sales. The systems with the highest rate impacts generally are relatively small, such as the City of Enterprise (with 517 consumers). The systems that experience the smallest impact are often large systems and have relatively low preference power ratios.

TABLE K.3-5 Individual Systems with the Largest Percent Retail Rate Impacts Relative to Alternative A

Number	Utility System	Preference Ratio	Number of Residential Consumers	Percent Rate Impact Relative to Alternative A					
				Alternative B 2029	Alternative C 2025	Alternative D 2023	Alternative E 2027	Alternative F 2020	Alternative G 2025

[a] NA = Not applicable.

Tables K.3-7 and K.3-8 list the systems with the highest and lowest residential monthly retail bill impacts in a similar format to the percent retail rate change tables. As with Tables K.3-5 and K.3-6, the impacts are shown for Alternatives B–G relative to Alternative A. The ranking of residential bill impacts is not the same as the rank of the retail percent increase. One of the reasons for differences in ranking is due to residential use variation among individual systems. Systems with lower residential use have a higher bill impact because grid costs are spread over a smaller base, all else being equal. Differences in residential usage are evidenced by the fact that the median average usage across the different systems is 730 kWh per month, while the maximum use for a single system is 1,680 kWh per month, and the system with the lowest annual residential usage is 391 kWh per month.[25] The ranking of retail percent impacts and monthly residential bill impacts also differs because residential bills are measured in absolute rather than in percentage terms. If two utility systems have the same overall percentage rate increase, but one system has a higher level of prices and higher residential bills, that system will have a higher residential bill impact relative to the percentage impact. For example, Ak-Chin has a higher ranking for bill impacts than for retail rate change impacts. This utility system has a small number of residential customers and a relatively high level of consumer bills. In 2012, the average monthly bill of Ak-Chin was about $140, which is 69% higher than the average bill across all systems of $84 per month.

K.3.4 Impacts on Small Systems

Two groups of utilities that are allocated a large fraction of their generation resources from SLCA/IP projects are Tribes and some small utilities, implying that the rate and bill impacts on these two groups tend to be relatively large. Impacts on small systems are presented separately in this section. Impacts on Tribes are presented in Section K.4.

To demonstrate the effect of system size on rate impacts, statistics were computed for the 20 systems with the largest impact and the 20 systems with the smallest impacts. Table K.3-9 demonstrates that, as measured by the number of residential consumers, the average size of systems with the largest rate impacts (1,680 consumers) is much smaller than the typical size of utility systems. Without adjusting for SRP and Colorado Springs, utilities with the smallest rate impacts are on average 38 times the size of the systems that have the largest rate impacts. When the two large systems are removed, the systems with the smallest impacts are still about 10 times larger than the systems with the largest percent rate increases.

The comparatively high retail rate increases on some small utility systems under the LTEMP alternatives are shown in Table K.3-10. This table shows average retail rate impacts under different alternatives relative to Alternative A for the selected groups of utility systems. In comparing rate impacts, the maximum impact year is used. The 20 systems with the largest impact have an average rate increase that is 2.52 times the average rate increase percent across all systems. On the other hand, the 20 systems with the smallest impact have an average rate

25 These figures are averages for a system and do not account for the distribution of usage within the systems.

TABLE K.3-9 Size and Preference Ratio for Utility Systems with Large Rate Impacts

Statistics for Impact Analysis on Small Systems					
Group of System	Rate Impact Relative to Average	Residential Customers	Size Relative to Large Impact Systems	Preference Ratio	Preference Ratio Relative to Average
Utilities with Largest Rate Impact[a]	2.52	1,680	1.00	38.83%	2.36
Utilities with Smallest Impact[b]	0.18	69,099	41.13	3.24%	0.20
Utilities with Smallest Impact Excluding SRP and CS	0.20	17,096	10.18	3.81%	0.23
Average of All Systems	1.00	16,567.69	9.86	16.43%	1.00

[a] Includes 20 systems with largest impact except Tribes.

[b] Includes 20 systems with smallest rate impact.

TABLE K.3-10 Rate Impacts for Selected Groups in Maximum Impact Year

Alternative	Largest Retail Rate Change Group in Maximum Impact Year (%)	Smallest Retail Rate Change Group in Maximum Impact Year (%)	Average Retail Rate Change Across All Systems in Maximum Impact Year (%)	Rate Impact for Largest Group/ Average Rate Impact ($)
A	0.00	0.00	0.00	–
B	–0.56	–0.09	–0.27	2.08
C	1.08	0.09	0.43	2.52
D	0.98	0.07	0.39	2.52
E	1.21	0.09	0.50	2.44
F	3.05	0.22	1.21	2.52
G	1.60	0.12	0.64	2.52

increase that is a small fraction of the average rate increase for the entire population of systems. Finally, Table K.3-10 illustrates that the preference ratio is highly correlated to the rate increase.

K.3.5 Alternative-Specific Impacts

K.3.5.1 Alternative A

Under Alternative A, SLCA/IP marketable capacity is 737.2 MW using an assumed water flow rate that is low enough that one can be 90% confident that the rate will be exceeded. Average annual daily generation and hydropower value at Glen Canyon Dam and SLCA/IP marketable capacity would not change under Alternative A. Rate impacts for each LTEMP alternative are computed relative to this alternative, meaning that the difference between two cases must be used to evaluate the change in rates.

Retail rates and residential bills are computed for Alternative A using inflation rates and sales growth from EIA forecasts (Figure K.3-13). Production costs, fixed O&M costs associated with new capacity, and the cost of new capacity from Alternative A are used as the basis for evaluating aggregate grid cost impacts for the other LTEMP scenarios.

K.3.5.2 Alternative B

Under Alternative B, rates and bills would be lower than under all other alternatives. Production costs are lower under Alternative B than under Alternative A, and there is a minor difference in the amount of capacity added for 1 year. Although the total amount of capacity added over the 20-year LTEMP period is the same as in Alternative A, a 1-year delay in constructing a new natural-gas-fired combustion turbine is projected in the power systems analysis for the year 2029. This delay in capacity additions and the difference in production cost accounts for the slightly lower annual average grid cost for Alternative B compared to Alternative A. The difference in annual grid costs averages $976 thousand per year (real 2015$).

When the annual grid cost reduction is translated to impacts on electric bills, the average retail rate decrease over the LTEMP period is -0.039%. The maximum rate decrease occurs in the year of the capacity deferral, 2029. The percent decrease in this year with the deferred capacity (the maximum impact year) is -0.27%. Table K.3-5 shows that the individual systems with the maximum impact have decreases that range between -0.48% and -0.93%. The average decrease in monthly residential bills over the LTEMP period is 4 cents per month, while the decrease in 2029 is 27 cents per month.

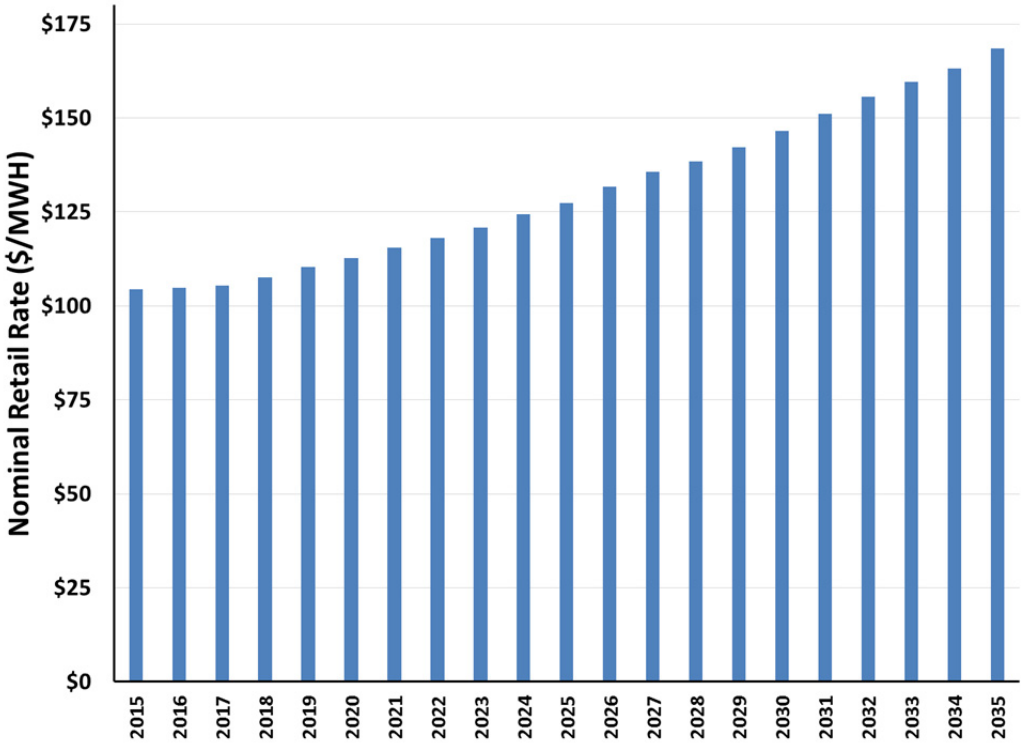

FIGURE K.3-13 Retail Rates under Alternative A

K.3.5.3 Alternative C

Retail rate increases under Alternative C relative to Alternative A are primarily driven by an increase in capacity of 230 MW that occurs for most years after 2018. This capacity increase is more than the reduction in marketable capacity of 129.1 MW. Replacement of the lost capacity and increased production costs results in varying grid cost impacts over the LTEMP period. Average grid impacts in real 2015 dollars are $9.8 million per year relative to Alternative A. These impacts are less than under Alternative F and Alternative G, but more than under Alternatives D, E, or B. The increase of $9.8 million in grid costs represents an increase of 6.87% relative to the annual wholesale revenues currently collected from SLCA/IP capacity and energy charges. When the wholesale grid cost of 6.87% is converted into retail rates, the averages across all systems and years range from a low of 0% to a high of 0.428% in 2025. The average percent retail rate increase across all systems for the LTEMP period is 0.245%. For the year 2025, which is the year with the maximum percent rate impact shown in Table K.3-5, individual systems experience percentage impacts ranging from less than 0% up to 1.46%.

Monthly residential bill impacts under Alternative C relative to Alternative A range from 0 to 40 cents for the LTEMP period. The average increase in residential bills is 22 cents per month. Detailed residential bill impacts under Alternative C for the maximum year are shown in Table K.3-6. Residential bill impacts in the highest impact year (2025) are not much higher than the results from Alternative D discussed in the next section. However, the average impacts under

Alternative C are 43% greater than the impacts under Alternative D. For the maximum impact year 2025, the range in residential bill impacts ranges between approximately $0 (4 cents for SRP consumers) and $2.07 per month (Ak-Chin Electric Municipal).

K.3.5.4 Alternative D

Retail rate increases under Alternative D relative to Alternative A are primarily driven by a reduction in capacity of 230 MW in most years. Replacement of capacity and increased production costs result in varying grid cost impacts on a year-by-year basis. Average grid impacts in real 2015 dollars are $6.8 million per year. When translated to retail rates, the impacts as an unweighted average across all systems range from 0% to a high of 0.391% in 2023. The average retail rate increase across all systems for the LTEMP period is 0.156%. For the maximum impact year 2023, individual systems experience percentage impacts ranging from 0% to 1.38%, as shown in Tables K.3-5 and K.3-6. The maximum impact retail rate increase is lower for Alternative D than for any other alternative analyzed except Alternatives B and A.

The impacts measured in terms of residential bills for individual systems in the maximum impact year are shown in Tables K.3-6 and K.3-7. Residential bill impacts under Alternative D relative to Alternative A, measured in 2015 dollars per month, range from 0 to 38 cents over the LTEMP period. The bill increase of 38 cents per month in the high-impact year is less than the bill increase in the high-impact year of 47 cents under Alternative E. The average increase in residential bills over the LTEMP period is 15 cents per month. For the year 2023, with the maximum bill impact, the range in residential bill impacts is between 0 and $1.83 per month.

K.3.5.5 Alternative E

Retail rate increases under Alternative E relative to Alternative A are primarily driven by an increase in capacity of 230 MW that occurs in 10 out of the 20 years of the evaluation, the average of which is more than the reduction in marketable capacity change of 90.21 MW. Replacement of the lost capacity and increased production costs results in varying grid cost impacts over the LTEMP period, some of which are lower than rates and bills under Alternative A. Average grid impacts are $6.4 million per year, which is lower than any of the LTEMP alternatives except Alternatives A and B. When the grid cost is converted into retail rates, the average across all systems and years range from changes that are below zero in years with no capacity change, to a high of 0.497% in 2027. The average percent retail rate increase across all systems for the years 2015 to 2035 is 0.142%. When compared to Alternative D, the average increase across the LTEMP period is slightly less, but the impact in the maximum year is slightly more. For the year 2027, which is the year with the highest rate impact, individual systems experience percentage impacts ranging from 0.03% (SRP) to 1.65% (City of Enterprise).

Residential bill impacts under Alternative E relative to Alternative A range from amounts that are below zero to 47 cents over the LTEMP period. The average increase is 13 cents per month. For the year 2027 with the maximum bill impact, the range in residential bill impacts is between 5 (SRP) and $2.42 per month (Ak-Chin Municipal Electric).

K.3.5.6 Alternative F

Retail rate increases under Alternative F relative to Alternative A are driven by increases in capacity of either 230 MW or 460 MW in various years, as well as varying amounts of production cost increases. The increase in capacity compares to the reduction in marketable capacity of 314 MW. The average grid cost increase under Alternative F is $28.7 million per year. This is much higher than any of the other LTEMP alternatives and equates to 20.11% of the $143 million in SLCA/IP wholesale revenues. The average retail rate increase reaches a high of 1.21% in 2018 and the average percent retail rate increase over the LTEMP period is 0.75%. When compared to the next highest impact scenario, Alternative G, the average impact is almost double. For the year 2018, the year with the maximum rate impact, individual systems experience percentage impacts ranging from 0.08% (SRP) to 4.14% (City of Enterprise, a member of UAMPS), as shown in Tables K.3-5 and K.3-6.

Residential bills under Alternative F that result from the grid cost increases are higher than bills under Alternative A in all years and are $1.02 in the maximum impact year. The average increase in residential bills over the LTEMP period is 69 cents per month. For the year 2018, with the maximum bill impact, the range in residential bill impacts is between 11 cents (SRP) and $5.29 (Ak-Chin Municipal Electric) per month.

K.3.5.7 Alternative G

Retail rate increases under Alternative G relative to the Alternative A are driven by an increase in capacity of 230 MW that occurs from the year 2018 forward, as well as production cost increases. The increase in capacity of 230 MW is more than the reduction in marketable capacity of 179 MW. Average grid cost increases by $17.2 million per year, which is higher than any of the LTEMP alternatives except Alternative F. The average retail rate increase across all systems and years is above zero in all years and reaches a high of 0.638% in 2025. Across the LTEMP period and all systems, the rate increase is 0.418%. When compared to Alternative C, the average increase is almost double and the impact in the maximum year is also higher because of higher production costs. For the year 2025, which is the year with the highest rate impact in this scenario, individual systems experience percentage impacts ranging from 0.04% (SRP) to 2.18% (City of Enterprise).

Residential bill impacts under Alternative G have a high of 59 cents, while the average increase in residential bills is 39 cents per month over the LTEMP period. For the year 2025, with the maximum bill impact, the range in residential bill impacts is between 6 cents (SRP) and $3.08 (Ak-Chin Municipal Electric) per month as shown in Tables K.3-7 and K.3-8.

K.4 FINANCIAL IMPACTS OF LTEMP ALTERNATIVES ON AMERICAN INDIAN TRIBES

The purpose of this section is to estimate the financial impact of LTEMP alternatives on American Indian Tribes that receive an allocation of SLCA/IP electrical power. This section also

compares the estimated financial impacts on these Tribes to the estimated financial impacts on other WAPA FES customers in the SLCA/IP marketing area to see how Tribal financial impacts compare with the financial impacts on others.

WAPA's post-2004 marketing plan purposely provided SLCA/IP power allocations to over 50 Tribes in its marketing area who historically had not been able to receive the financial benefits of federal hydropower. WAPA normally requires its customers to operate electric utilities, and most Tribes do not meet that requirement. Tribes are preference power customers. In order to encourage widespread use of federal hydropower, WAPA made administrative changes to allow numerous Tribes to receive an allocation of power and the associated financial benefits. There are 57 Tribes or Tribal entities who currently receive an allocation of SLCA/IP power (directly or indirectly) from WAPA.

The impact of the alternatives ranges from almost no impact to over $3 million in financial costs for the Tribes, with the average financial impact of all the alternatives being $1.345 million per year. Tribes may be financially impacted in three ways by the LTEMP alternatives:

- Tribes that operate their own utilities may see a change in the rate they pay for SLCA/IP power.

- Tribes that do not operate their own electric utility and have entered into benefit crediting arrangements with another utility to take their allocation, and instead receive an economic benefit from that utility, may see a change in the economic benefit, essentially a change in payment received from that other utility.

- Tribes that have entered into an economic benefit with a utility that also receives SLCA/IP power may see their economic benefit crediting payments change and may experience changes in the retail rates charged to Tribal members.

There are currently 57 Tribes and Tribal entities that received a power allocation from the SLCA/IP resources. The analysis in this report assumes that each of these Tribes will continue to receive its current allocation under each alternative of the LTEMP EIS. Nine of these Tribes operate electric utilities and receive power directly from WAPA. The remaining 48 Tribes are not electrical utilities but still receive the benefits of federal hydropower through benefit crediting arrangements with SLCA/IP customers or other electric utilities.

The purpose of benefit crediting is to provide a Tribe with the financial benefits associated with SLCA/IP power—a low-cost capacity and energy resource. This benefit is usually provided to the Tribe by an electrical service provider (supplier) that serves the area in which the Tribe is located. The benefit received by the Tribe is in lieu of a direct delivery of power by WAPA. It is intended to be the financial equivalent of a direct delivery. Because the SLCA/IP rate is generally lower than the supplier's production cost of electrical power, the difference between these costs is considered the benefit per megawatt-hour received by the

Tribe. This cost difference is multiplied by the Tribe's megawatt-hour allocation of SLCA/IP power. The product of these two numbers is the dollar benefit to the Tribe for an SLCA/IP allocation. The supplier provides the Tribe with a dollar benefit. The equation used to determine the benefit is similar to the following:

$$Benefit = SLCA/IP\ Allocation \times (Supplier\ rate - SLCA/IP\ rate) \quad \text{(Eq. 1)}$$

Where:

Benefit	=	the financial benefit received by the Tribe from the electric service provider ($),
SLCA/IP Allocation	=	SLCA/IP allocation to the Tribe in the post-2004 marketing period (MWh),
Supplier rate	=	average production cost (i.e., large customer retail rate) or purchase cost of the electrical supplier ($/MWh), and
SLCA/IP rate	=	the composite SLCA/IP FES rate ($/MWh).

K.4.1 Contractual Requirements for Calculating and Delivering Benefits to Tribes

In order to accommodate the post-2004 allocations of SLCA/IP electrical power to Tribes, WAPA contracted with seven electrical wholesale utility customers (suppliers) to establish benefit crediting arrangements, which would allow the Tribes that did not operate electric utilities to benefit from a federal hydropower allocation. WAPA and the individual Tribes made arrangements with one of the following entities:

- Public Service Company of New Mexico,
- Navajo Tribal Utility Authority,
- Page Electric Utility,
- Tri-State Generation and Transmission Association,
- Salt River Project,
- Ak-Chin Indian Community
- Deseret Generation and Transmission.

Each of these suppliers calculates the financial benefit of a Tribe's SLCA/IP power allocation according to language in three-party contracts among WAPA, the supplier, and the Tribe. The contractual language varies somewhat for each supplier. The contract for Tribal payment is typically based on the economic cost savings for the primary load serving entity. These savings are based on formulas in contracts between WAPA and the entities that compute the avoided cost of supplying the Tribal load that is ultimately served by WAPA. Essentially, the benefit each Tribe receives is the difference between the supplier's value of electrical energy and the SLCA/IP wholesale rate multiplied by the Tribe's SLCA/IP allocation. These benefit crediting arrangements are intended to capture the approximate benefit a Tribe would receive from an allocation of SLCA/IP power if it were able to receive it directly to serve its own electric load.

K.4.2 Calculation of Tribal Benefit Baseline under Alternative A (No Action Alternative)

Attachment K.11 lists the Tribes that receive an allocation of SLCA/IP electrical power, the amount of electrical capacity and energy the Tribe is currently allocated (by season), and the utility that serves the Tribal reservation or Tribal lands.

The Tribal benefit was calculated for Alternative A. Note that this benefit calculation differs somewhat from the benefit currently received by the Tribe for two reasons:

- The SLCA/IP rate developed by WAPA for Alternative A is marginally higher than the actual current SLCA/IP rate.

- The electrical rate of the supplier is estimated in several cases. WAPA's contracts may refer to "average generation cost" or to the "Class A rate," but the rate of the supplier is typically not quantitatively specified in the contract language. Therefore, the published rates for the seven suppliers that best conformed to the current contract description were used.

With these data, the calculation of the Tribal economic benefit was determined by inputting the relevant rates and Tribal allocations into Equation 1. It includes both capacity and energy components. This calculation was performed for each Tribe that has entered into a benefit crediting contract. This was not done for the nine Tribes that operate utilities; they do not receive a benefit credit because they directly receive an SLCA/IP allocation.

K.4.3 Calculation of Change in Tribal Benefit as a Result of LTEMP EIS Alternatives

Figure K.4-1 illustrates the method that was used for evaluating the impacts of LTEMP alternatives on the benefit for each Tribe.

The power economic impacts for the EIS are described in Section K.1. WAPA used these data to estimate the SLCA/IP FES rate for each alternative. The method used the results that are described in Section K.2. The financial benefit was computed for each Tribe for each alternative using the estimated SLCA/IP rate for each alternative, the estimated supplier's rate, and the Tribal allocations listed in Attachment K.11.

A simplifying assumption was used in this analysis. The Tribal allocations used for the analysis (and listed in Attachment K.11) are SLCA/IP commitment levels from the current marketing plan. This plan expires at the end of FY 2024. It was assumed that these commitment levels would continue through the LTEMP period, which extends through 2035. It should be emphasized that this is an analysis, not a description of policy or attempt to predict WAPA's post-2024 marketing plan. Although it is a reasonable assumption for the purposes of this analysis that WAPA will continue existing commitment levels after 2024, the reader should not assume that WAPA will or will not maintain these levels when the new marketing plan is finalized.

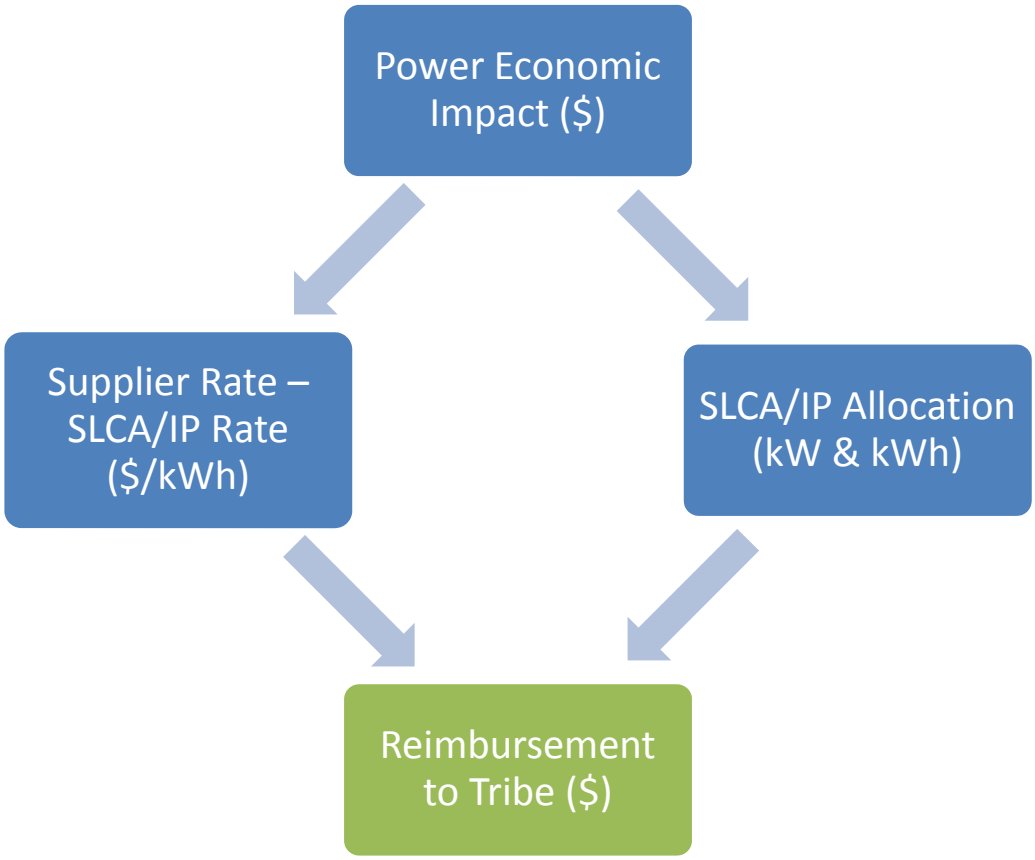

FIGURE K.4-1 Calculation of Change in Tribal Benefit Resulting from LTEMP EIS Alternatives

K.4.4 Impacts on Tribes through a Change in the Retail Rate of the Electrical Supplier to Tribal Lands

In addition to the economic impact of the LTEMP alternatives on Tribal benefits, some Tribes receive retail electric service from suppliers (such as rural cooperatives) that are SLCA/IP customers themselves. This means that Tribal households and commercial establishments on Tribal lands could pay a different retail rate for their electricity. If an alternative operating criterion at Glen Canyon Dam causes a change in the SLCA/IP rate, a utility supplying retail service to a Tribe could change its retail rate for electricity as a result of that alternative. Tribal members and commercial establishments on Tribal lands (households and businesses) could incur a change in their electrical utility bills as a result.

Attachment K.11 includes the list of the Tribes receiving their SLCA/IP allocation from a supplier along with the name of the electrical supplier that serves the Tribal reservation or Tribal lands. Section K.3 includes the estimated retail rate change for SLCA/IP customers by alternative. The financial impacts on the Tribes based on changes in the SLCA/IP rate were calculated using the following equation:

$$\textit{Financial Loss/Gain} = \textit{Total Reservation Electricity Consumption}^{26} \times \textit{Change in Retail Rate}^{27} \quad \text{(Eq. 2)}$$

Attachment K.12 is a list of Tribes receiving SLCA/IP allocations and the estimated total electrical use by Tribe. These data were partly gathered and required by WAPA as part of the development of the post-2004 marketing plan. They are referred to as applicant profile data.

These applicant profile data are believed to be out of date because they are based on electrical use by Tribes in 1998. However, more current data on Tribal electrical use were not readily available or published. Therefore, the amounts of electrical energy shown in Attachment K.12 were escalated by 2.5% per year to 2015.[28] The estimated Tribal electricity use calculated with Equation 2 is therefore an escalated amount and represents an estimate of the current electrical use by Tribes.

The estimated 2015 total electrical use by Tribal households and commercial establishments on Tribal lands was multiplied by the change in the retail rate estimated for the electrical service supplier—which is an SLCA/IP FES customer—as derived from the analysis described in Section K.3. This results in an estimated increase (or decrease) in the retail electrical utility costs paid by each Tribe annually under each alternative (via the Tribal members who live on Tribal lands).

K.4.5 Calculation of Tribal Impacts for Tribes That Are Direct SLCA/IP Recipients

For the Tribes that operate electrical utilities and receive SLCA/IP power directly from WAPA, the impacts of LTEMP alternatives were calculated. This calculation is the difference in the SLCA/IP FES rate between each of the action alternatives and the No Action alternative multiplied by the total escalated electrical use for each Tribe. Multiplying the change in SLCA/IP rate (from Section K.2) by the escalated Tribal electrical use yields the estimated financial impacts for each of the LTEMP EIS alternatives on each of the nine Tribes that receive SLCA/IP allocations directly from WAPA.

---

26 This estimate is for the year 2015. It is therefore an annual amount of electrical energy used. The financial loss or gain should be interpreted as an annual financial impact.

27 These estimated changes in retail rates by alternative are taken directly from Section K.3.

28 Based on data reported by the EIA, 2.5% is the approximate average annual increase in electrical energy use over the last decade in states where Tribal entities reside.

Table K.4-1 is the result of the retail-rate impact analysis for the average household on a Tribal reservation or on Tribal lands. The estimates, by Tribe, presented in Table K.4-1 describe how a residential household might be impacted by the LTEMP EIS alternatives due to a changed retail rate. The numbers in Table K.4-1 are taken from the retail rate impact analysis described in Appendix K.3. That analysis computed the monthly change in an electric utility bill for an average residence across the SLCA/IP market footprint. Table K.4-2 shows this change. It is extracted from similar information in Section K.3. It assumes that residences on Tribal lands incur the same change in residential monthly electrical utility bills as other residences in the same electrical service area.

For example, the reservation of the Ute Tribe is electrically served by Moon Lake Electric. According to the estimate in Section K.3, Moon Lake Electric residences will pay slightly over a dollar a month more for electricity under Alternative F. It was assumed that the residences of the Ute Tribe on the Ute reservation, served by Moon Lake Electric, will also pay slightly over a dollar a month more for electricity under Alternative F. Remember that the information in Table K.4-1 is one of two financial impacts on the Tribes caused by the alternatives. The total financial impact on Tribes is presented in Table K.4-2.

K.4.6 Total Impact of LTEMP EIS Alternatives: Benefit Change and Rate Effect

Table K.4-2 lists the estimated Tribal financial impact by alternative relative to the impact under Alternative A. Table K.4-2 lists the total annual financial impact, which is (1) the change in Tribal benefit plus (2) the increase in the electrical utility bill of Tribal households and businesses due to a change in the SLCA/IP FES customers' retail rate.[29] Negative numbers indicate a positive financial benefit (this only occurs under Alternative B). Note that:

- Tribes whose electrical service is provided by a non-SLCA/IP FES customer have no retail rate change, but do experience a change in Tribal benefits;
- The Tribes that operate their own utility have no change in Tribal benefits, but do experience a change in retail rates; and
- Tribes whose lands are served by SLCA/IP customers are impacted by both a change in retail rate and a change in Tribal benefits.

[29] Table K.4-2 shows the total financial impact. The separate financial impacts from a change in Tribal benefits and from a change in the electrical utility payments made by Tribal households and businesses were calculated but not shown here because of space limitations.

Alternative impacts listed in Table K.4-2 include the sum of both types of financial impacts.[30] Alternative impacts included in Table K.4-2 are indications of the rank order of the alternatives and the direction of impacts (positive or negative), and they describe an estimated financial impact under current contractual obligations. These financial impacts would continue beyond 2024 if contract commitments to all FES customers including Tribes and Tribal entities do not change. They represent one possible outcome of the post-2024 marketing plan. For the final EIS, assumptions concerning post-2024 commitment levels may be revised to duplicate the range examined in the economic analysis described in Section K.1.

30 The Tribal benefit calculation is the difference the Supplier's average production cost and the SLCA/IP rate multiplied by the Tribe's SLCA/IP allocation. For simplicity, the authors assume that the supplier's average production cost does not change as a result of an LTEMP DEIS alternative. It is more likely that an increase in a SLCA/IP rate will result in a lesser increase in the average production cost of a SLCA/IP FES customer. Therefore, the calculations of Tribal benefit change are overestimates for those Tribes that are served by SLCA/IP FES customers.

K.4.7 Total Impact on Tribes and Tribal Members Versus Retail Rate Changes to Households

Figures K.4-2 through K.4-7 illustrate the difference between the total financial impact of the alternatives on Tribes as compared to the financial impact on non-Tribal households and businesses that receive retail service from utilities that are SLCA/IP customers.

The financial impacts on non-Tribal households and businesses are, for illustrative purposes in this analysis, the percentage change in the electrical retail rate for the SLCA/IP FES customer (or their utility system member that provides retail electrical service in a service area). This information is a duplication of the analysis included in Appendix K.3, which is the retail rate analysis of the alternatives. In Figures K.4-2 through K.4-7, the blue lines illustrate non-Tribal SLCA/IP FES customers or member systems and are the same data that are included in Section K.3.

An increase (decrease) in the retail rates of an SLCA/IP FES customer or member system causes a financial effect (positive or negative) on households and businesses in the utilities' service area by increasing (decreasing) the electrical utility cost paid. This change in the utility bill and the resulting financial effect at the household/business level is approximately equivalent to the financial impact on Tribes and Tribal members.

Figures K.4-2 through K.4-7 present the percentage difference (compared to Alternative A) of financial impacts on Tribes and non-Tribes[31] for each alternative. Alternative B is the only alternative that results in a reduction in impacts relative to Alternative A (Figure K.4-3). The financial impacts of Alternatives C, D, and E are relatively similar (Figures K.4-3 through K.4-5), but greater than under either Alternative A or Alternative B. The financial impacts of Alternatives F and G are relatively similar to each other (Figure K.4-3), and higher than under any of the other alternatives. Alternative F has the highest financial impacts of any alternative.

K.4.8 Conclusions

Several conclusions can be drawn from this analysis:

- LTEMP alternatives are estimated to have a financial effect on Tribes that receive an SLCA/IP allocation. Compared to Alternative A, the impact is negative for Alternatives C, D, E, F, and G. These impacts are larger for Alternatives F and G. The financial impact on Tribes under Alternative B is largely positive.

[31] The total percentage change is measured on the y-axis. For Tribal entities, this percentage change is the sum of the retail rate impact and the Tribal benefit impact. For non-Tribal SLCA/IP customers or members systems, it is the percentage change from the retail rate impact.

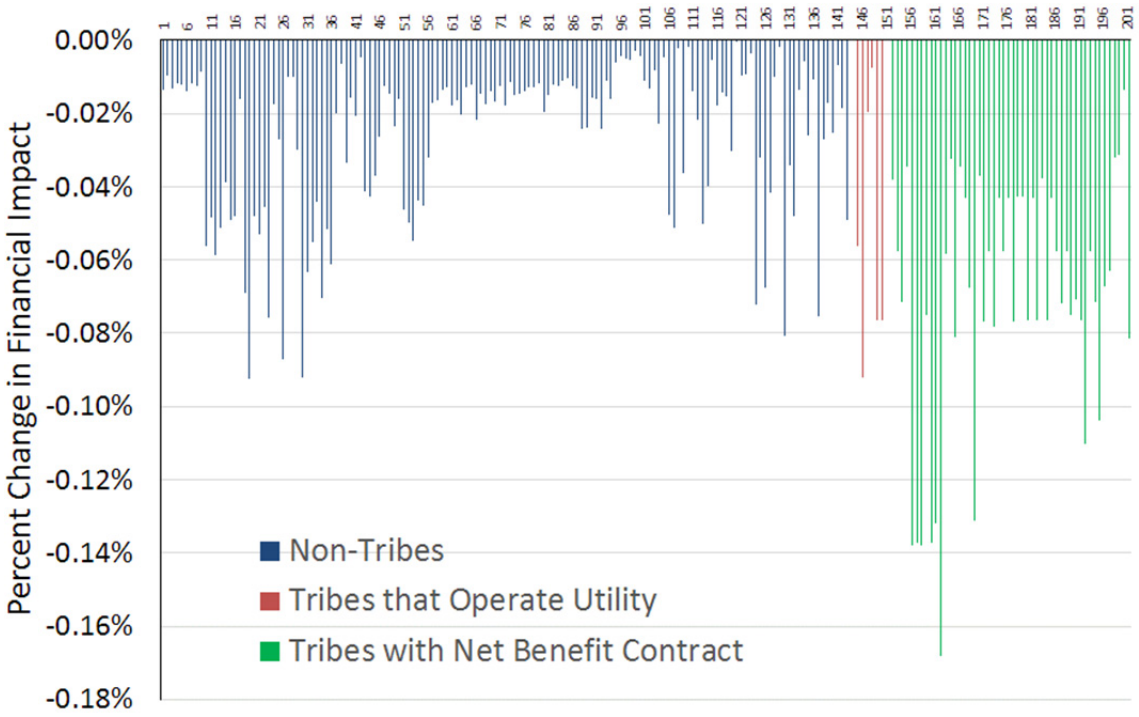

FIGURE K.4-2 Financial Impacts under Alternative B Relative to Alternative A for Tribal and Non-Tribal Entities

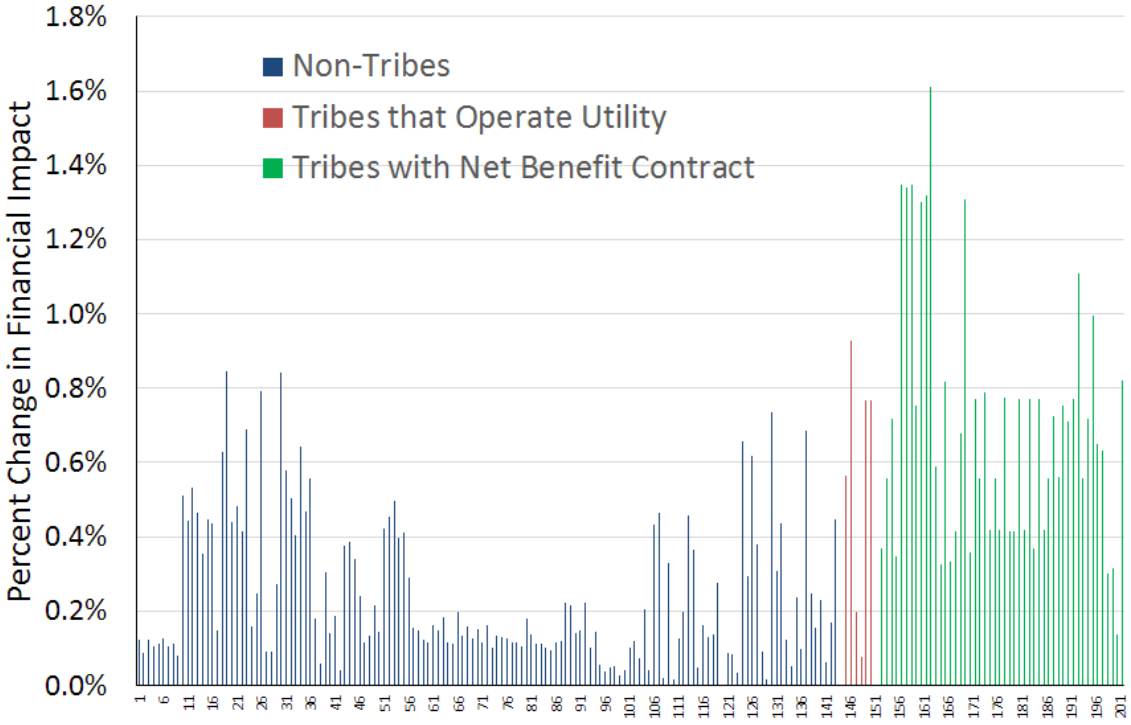

FIGURE K.4-3 Financial Impacts under Alternative C Relative to Alternative A for Tribal and Non-Tribal Entities

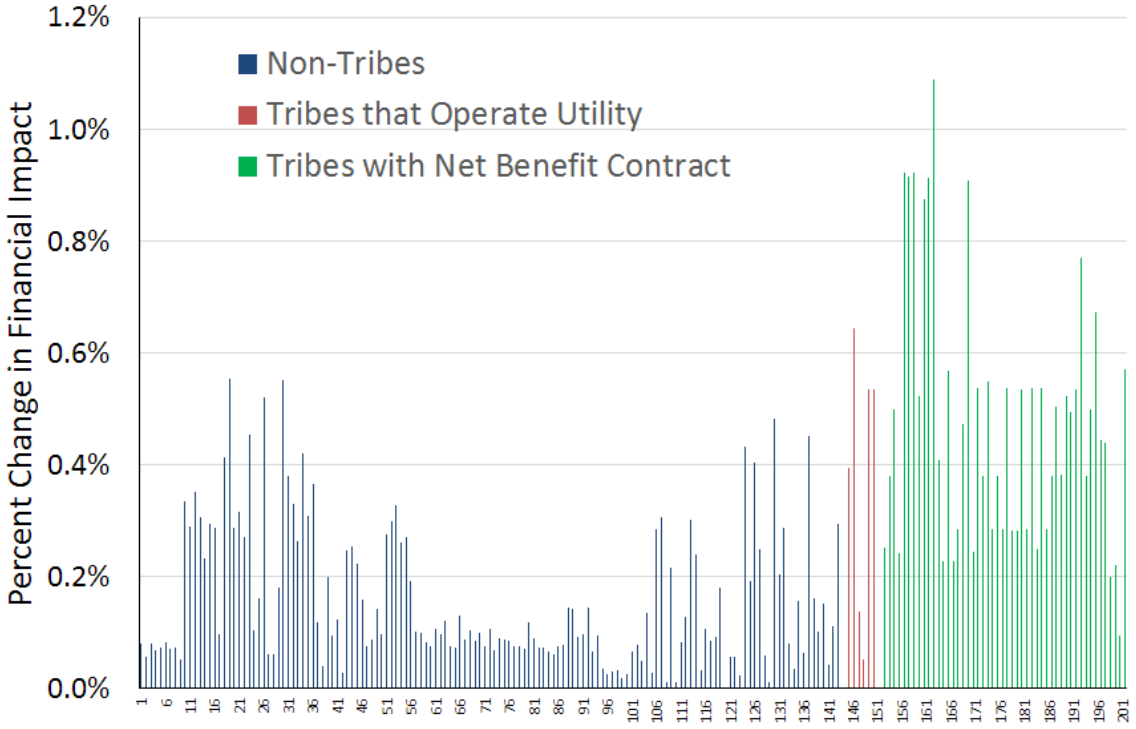

FIGURE K.4-4 Financial Impacts under Alternative D Relative to Alternative A for Tribal and Non-Tribal Entities

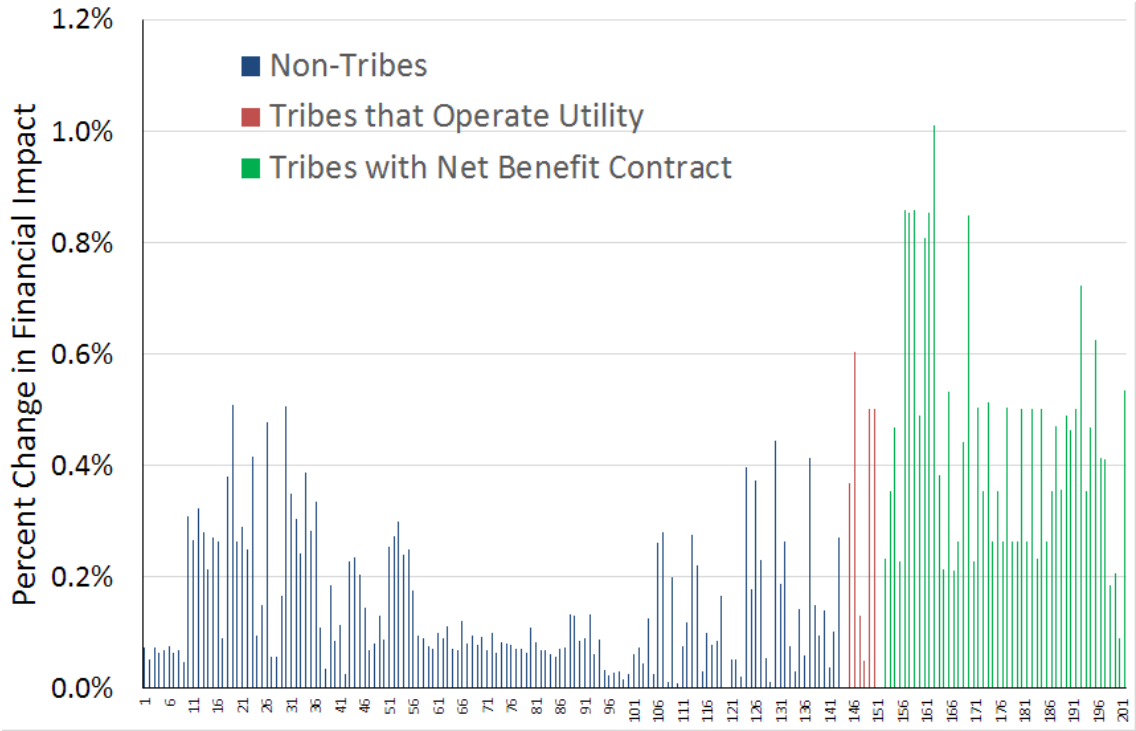

FIGURE K.4-5 Financial Impacts under Alternative E Relative to Alternative A for Tribal and Non-Tribal Entities

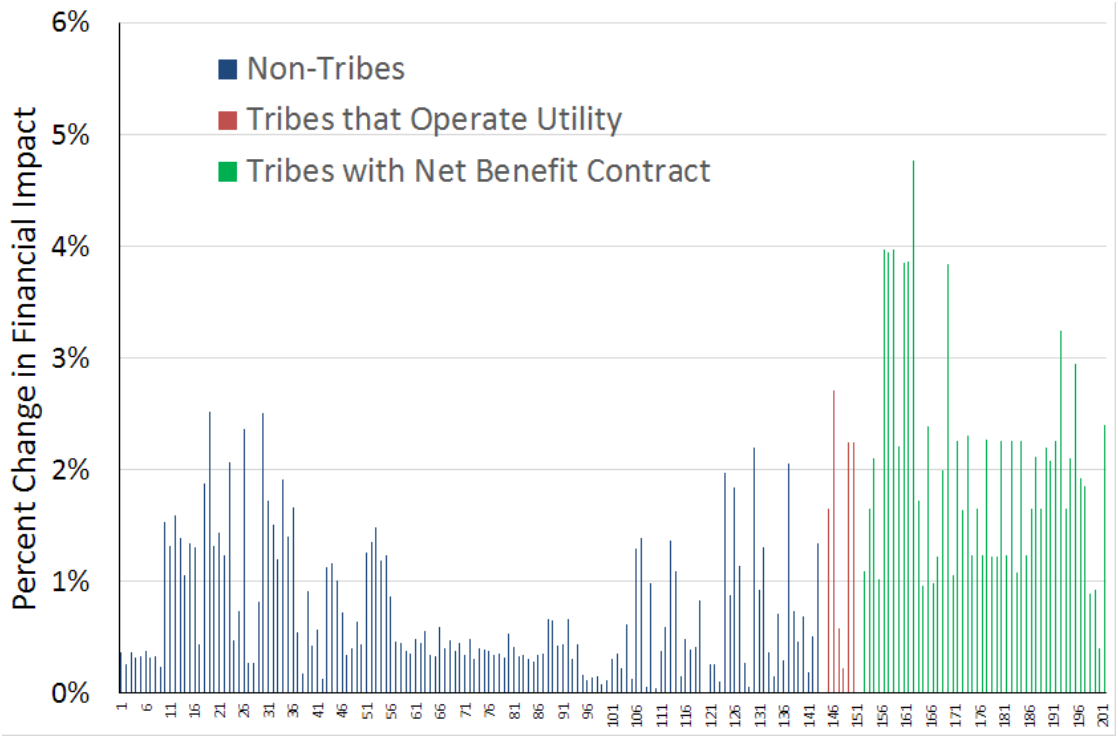

FIGURE K.4-6 Financial Impacts under Alternative F Relative to Alternative A for Tribal and Non-Tribal Entities

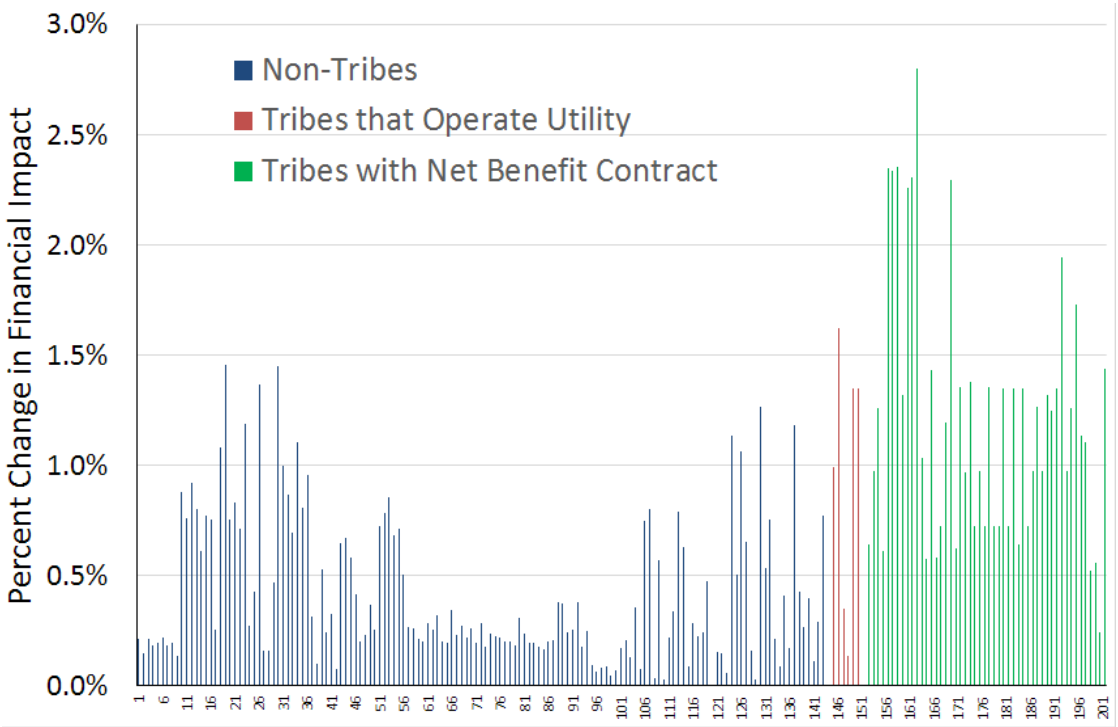

FIGURE K.4-7 Financial Impacts under Alternative G Relative to Alternative A for Tribal and Non-Tribal Entities

- The financial impacts on Tribes are from two sources:
  - A change in the Tribal benefits provided to the Tribes under benefit crediting contracts; and
  - A change in the electrical utility bills paid by Tribal members and businesses that receive retail service from a supplier that receives an SLCA/IP allocation.

- These two sources of financial impact are additive for some Tribes—those who receive Tribal benefits and whose reservation or Tribal land is served by electrical utilities that are SLCA/IP FES customers.

- Tribal financial impacts for Alternatives C, D, E, F, and G, relative to Alternative A, are larger than the financial impacts on non-Tribes.

K.5 IMPACTS OF LTEMP ALTERNATIVES ON LAKE MEAD AND THE HOOVER DAM POWERPLANT

The Hoover Dam Powerhouse has 17 turbines that have a combined hydropower nameplate capacity of 2,074 MW (https://www.wapa.gov/About/Pages/power-projects.aspx). Both the energy production and operating capacity of this large hydropower resource is affected by LTEMP EIS alternatives. Released water from Lake Powell through the Glen Canyon Dam travels down the Colorado River through the GCNP and then into the Lake Mead Reservoir. Monthly water release volumes from Lake Powell, however, differ by LTEMP alternative and will therefore impact pool elevations in Lake Mead, and, in some rare situations water releases from Hoover Dam, when Lake Mead's operating condition is changed as a result of differences in projected December month-end elevations. Alternatives B, D, and E have the same Glen Canyon Dam October through December total release volumes as Alternative A, and therefore do not affect the Lake Mead operating condition, and thus the release volumes from Hoover Dam.

For example, Figures K.5-1 and K.5-2 show that under Alternative F, Lake Powell monthly water releases from late winter through spring are higher than for Alternative A (dotted orange line), thereby raising the pool elevation (solid orange line) at Lake Mead above levels projected under Alternative A from April through November. Because Glen Canyon Dam annual release volumes under all alternatives are nearly identical, the impacts of changed operations are within an annual time frame. Note that all alternatives, except for Alternative F, have very similar pool elevations when comparing end of the water year values.

Monthly differences in Lake Mead reservoir elevations among alternatives may impact Hoover Dam's generation economic value. The primary factors include changes in (1) the

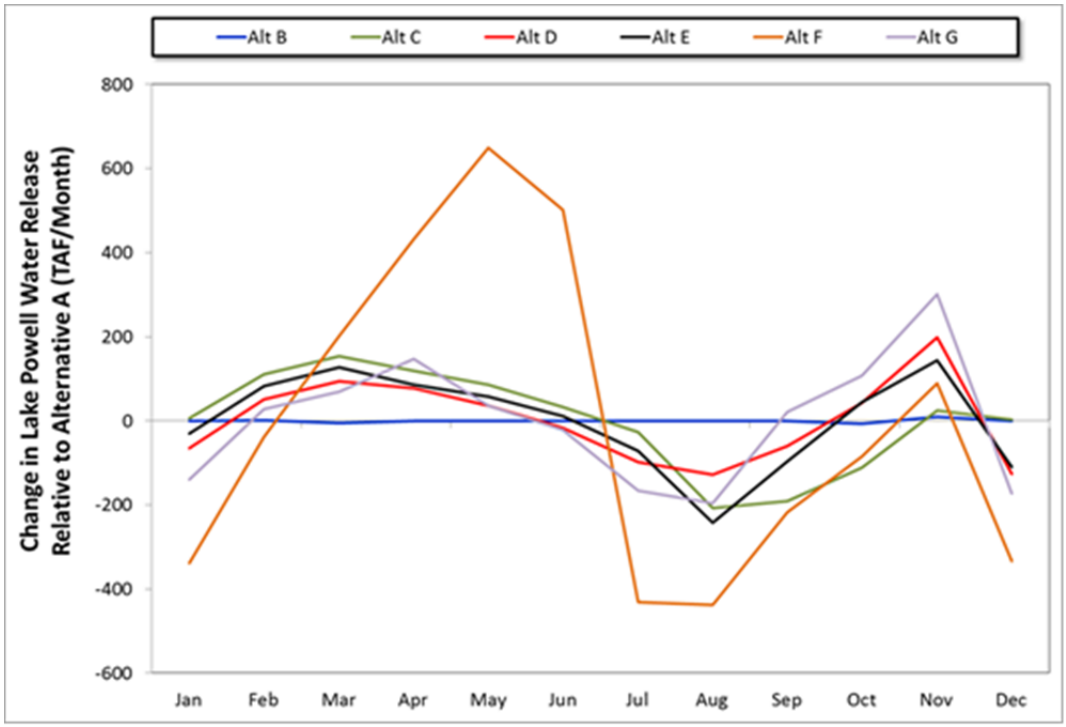

FIGURE K.5-1 Change in Lake Powell Monthly Water Release Volumes under LTEMP Alternatives

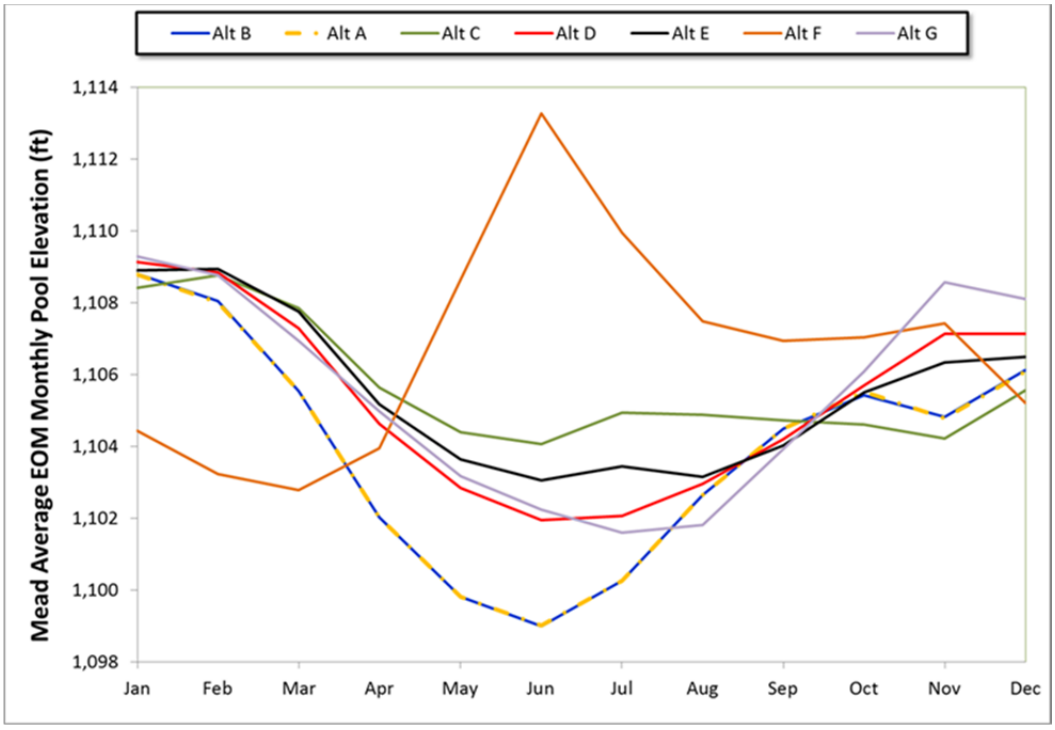

FIGURE K.5-2 Average Lake Mead EOM Pool Elevations under LTEMP Alternatives

percentage of time Lake Mead elevation is below minimum power pool[32]; (2) monthly differences in power head and resulting electricity (i.e., energy) production[33]; (3) maximum operating capacity; and (4) in some infrequent situations, but only for Alternatives C, F and G, differences in water release volumes from Lake Mead. In terms of the economic impacts of alternatives on the Hoover Powerplant, the first two are much larger than the latter two.

Hoover powerplant economics are composed of firm capacity and energy components. For the purpose of evaluating the economic value of the Hoover Powerplant, a distinction is made between the powerplant's nameplate capacity and its maximum operational capacity, which varies as a function of power head. This maximum operational capacity is referred to in this section as the Hoover derated capacity.

This study also refers to firm capacity, which is distinctly different from both nameplate and derated capacities. Firm capacity in this report is defined as the Hoover Powerplant derated capacity level (output potential) during the time of the regional peak electricity demand (load) at a specified probability level of occurrence. To be consistent with the definition of firm capacity used elsewhere in this EIS, Hoover firm capacity is set equal to the Hoover derated capacity at a 90% exceedance level during August. It is based on numerous forecasts of derated capacity using an ensemble of future hydrology and Lake Mead pool conditions. Note that the 90% exceedance level means that the derated capacity is lower than the firm capacity only 10% of the time, and is therefore based on a very low hydropower condition. Firm capacity is assumed to be the capacity level that would be used in either regional or utility-specific studies of current and future capacity needs such as an IRP.

At Hoover Dam, power is scheduled by WAPA's Desert Southwest Office customers, each of which is allocated a portion of the available real-time derated capacity of the Hoover powerplant. It is therefore at the discretion of each entity that receives Hoover capacity how it utilizes this capacity for long-term planning purposes; that is, how it credits Hoover as "firm" capacity. Under these contracts, the utility customer bears the risk of not meeting its firm capacity targets and system reliability goals. The utility may therefore need to acquire additional firm capacity. Marketed capacity levels are rooted in the amount that is projected to be physically available.

Hoover economic metrics for both firm capacity and energy are measured in terms of NPV and are computed for each alternative. The following sections describe the methods, model, and comparative impacts of LTEMP alternatives on Lake Mead, Hoover Powerplant operations, and power system economics.

---

32 For this analysis, a distinction is made between water that is routed through the powerplant turbines and water that bypasses the dam and powerplant.

33 Turbine water releases convert the kinetic energy of falling water into mechanical energy which is then converted to electricity by a generator. The volume of water needed to generate 1 MWh of electricity is a function of several factors.

K.5.1 Hoover Analysis Methods, Model, and Supporting Data

The purpose of this analysis is to determine if impacts to Hoover Dam hydropower exist, the direction of impact, and some sense of the magnitude of that impact. A model of Hoover Powerplant operations was developed to analyze potential LTEMP impacts on Hoover Powerplant economics. Compared to the modeling of Glen Canyon Dam hydropower resources, it is a simpler representation of dam and hydropower operations because it is less detailed and it operates on monthly time steps instead of hourly. *Its purpose is to provide rough estimates of the direction, magnitude, and ranking of LTEMP alternative impacts on the Hoover Powerplant under a given set of assumptions.* As will be discussed in more detail later, model results are highly sensitive to assumptions, some of which are not yet precisely known. Because of the uncertainties of the assumptions, the magnitude of these estimates for Hoover Dam hydropower resources is not directly comparable to the results for Glen Canyon Dam hydropower resources. The above factors should be taken into consideration when interpreting model results.

The Hoover Powerplant Model utilizes monthly Lake Mead water release volumes projected by the CRSS model for 21 hydrology traces over the 20-year LTEMP study period. These water releases sometimes vary by alternative. Releases are primarily driven by the operating criteria that were established under the *Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead* ROD that was signed on December 13, 2007 (Reclamation 2007b). Under Alternatives C, F, and G, changes in Lake Mead monthly releases may, in rare occasions, occur when Lake Mead's operating condition is changed as a result of differences in projected December end of month (EOM) elevations. Because monthly water release decisions for the upcoming year are made at the beginning of the calendar year and forecasts of the future are uncertain, Hoover releases sometimes differ from the ones that would have occurred had the future been known with perfect foresight.

Lake Mead EOM reservoir elevations projected by the Sand Budget Model (SBM) are also input into the Hoover Powerplant Model. For each alternative and 21 hydrology traces over the 20-year study period, the SBM schedules HFEs at Glen Canyon Dam. Scheduling is based on CRSS model results for Glen Canyon Dam and initial results from the GTMax-lite model. Because an experiment typically requires a large water release volume, the SBM reallocates CRSS Glen Canyon Dam monthly water releases within a WY in order to provide the HFE with a sufficient amount of water. Based on this reallocated monthly water and a water mass-balance equation, Lake Mead pool elevations are computed. The SBM primarily reallocates water within the same WY, not among WYs.

The SBM does <u>not</u> alter CRSS Hoover Dam monthly water releases, allowing the Hoover Powerplant Model to directly use CRSS water releases. The SBM does, however, change CRSS monthly inflows into Lake Mead and thus projected, water storage volumes, and reservoir elevations.

AURORA model monthly average market on-peak and off-peak prices projected for the Palo Verde hub are used by the Hoover Powerplant Model to compute economic energy values. These are the same hourly prices used elsewhere in this EIS. Also identical to the GTMax-Lite

methodology, firm hydropower capacity is based on a 90th percentile exceedance level during the month of August. Other factors such as unscheduled unit outage probabilities and unit maintenance schedules can also factor into powerplant maximum operational capacity and firm capacity computations, but were not included in this relatively simple model.

The economic value of Hoover firm capacity is based on the same replacement costs as those used for GTMax-lite and very similar to the average costs used in the power systems economic analysis. It is based on the levelized cost of capital plus annual fixed O&M costs to construct a new advanced combustion turbine (CT), which amounts to $51,300/MW-yr. As discussed later, these capacity replacement costs are irrelevant to the final economic cost computation. The time series of Hoover economic costs are discounted at the same 3.375% annual rate used in GTMax-Lite and the power systems analysis.

K.5.2 Hoover Monthly Energy Production and Water-to-Power Conversion

The Hoover Powerplant Model projects powerplant monthly energy production over the 20-year LTEMP study period based on SBM monthly projections of Lake Mead EOM pool elevation and CRSS-projected Hoover Dam monthly water releases for each of the 21 hydrology traces. A model-derived water-to-power conversion factor[34] is multiplied by the monthly turbine water release volumes to project Hoover Powerplant energy production. The operating characteristics of the Hoover Powerplant were based on and derived from information provided by Reclamation.

Argonne derived a water-to-power conversion equation and its coefficients based on historical Lake Mead pool elevations and Hoover generation data, as recorded in Form PO&M-59. The equation has two components. The first component is a linear relationship between historical conversion factors and the pool elevations. The second component relates the conversion factor to monthly water release volumes in the form of a third-order polynomial function. Due to the implementation and application of new software at Hoover Dam that optimizes the powerplant unit dispatch to increase plant-level power conversion efficiency, equation coefficients in the period prior to March 2011 differ from the coefficients used after this date.[35]

To assess the accuracy of the derived equation, a back-casting exercise was conducted. Lake Mead pool elevation and water-to-power conversion factors have a similar pattern and can be used to explain most, but not all, of the changes in power conversion over time. Monthly turbine releases yield additional accuracy to the Argonne power conversion equations, but relatively small inaccuracies remain. Average absolute conversion errors during both the

---

34 The water-to-power conversion factor, expressed in terms of MWh/ac-ft equals the monthly turbine water release (ac-ft) divided by monthly generation. Note that this conversion factor only includes turbine releases; that is, bypass water is excluded.

35 McManes (2014) discusses the change in Hoover Powerplant efficiency (3.4% improvement) that results from using unit dispatch software to guide power operations.

historical pre- and post-2011 periods are less than 0.005 ac-ft/MWh; that is, the equation estimated power conversion factors are on average within 1.2% of the actual values. The simple average of the errors equals zero. For comparative analyses such as this one, this level of accuracy was judged to be sufficient.

Projections of future monthly water-to-power conversion factors use equation coefficients derived for the post-2011 time period. In reality, conversion efficiencies (and therefore water-to-power conversion factors) will change in the future as equipment ages and changes are made to the powerplant. One such change that is partially implemented involves the replacement of old turbines with ones that can be operated over a wider range of hydraulic heads and have a narrower operating rough zone.

When the SBM projects that the Lake Mead elevation is below the minimum power pool, the Hoover Powerplant Model assumes the entire projected monthly water volume bypasses the Hoover Powerplant. Therefore, both the monthly derated capacity and generation of the Hoover Powerplant are set equal to zero. These non-power water releases are referred to in this report as "bypass" water.

Based on information and guidance from Reclamation, at the time this analysis was conducted, it was conservatively assumed that the minimum pool elevation for energy production at the Hoover Powerplant was 1,050 ft above sea level. It should be noted that at the time the final LTEMP EIS was being written, the official minimum power pool required to generate power was being revised. It appears that Hoover turbines will be capable of operating below a 1,050-ft pool elevation. This is in part supported by turbine performance curves for new wide-head turbines that are installed at some of the units. Since none of the Hoover turbines have actually been operated below this level, derated capacities and power conversion factors below 1,050 ft are somewhat speculative.

The monthly average turbine water release at Hoover Dam over the 21 traces and 20-year study period differ by alternative. As shown in Figure K.5-3, the greatest difference in turbine releases among alternatives relative to Alternative A is about 81 thousand acre-feet (kaf) (roughly 11.7% more) in June under Alternative F. In almost all cases, the difference in turbine water release among alternatives is nearly counterbalanced by differences in bypass water releases. In the example above, 69 kaf more water is bypassed under Alternative A than under Alternative F. This is due to a higher occurrence of reservoir elevations below the minimum power pool elevations under Alternative A. There is also a greater average total water release (turbine and bypass); about 12 kaf, in June under Alternative F due to the differences in the frequency of Lower Basin shortages that are projected to occur in the future. The greater water release in June is offset by lower water releases in the winter and early spring. Also note in Figure K.5-3 that on average Lake Mead turbine water releases are nearly identical in Alternatives A and B, and Alternative D has the next smallest deviations from Alterative A.

Multiplying monthly turbine water releases by the water-to-power conversion factor yields an estimate of the generation produced by the Hoover Powerplant. As shown in Figure K.5-4, Alternatives A and B have the lowest generation levels, while Alternative F typically has the most generation. The range of generation among alternatives is the largest from

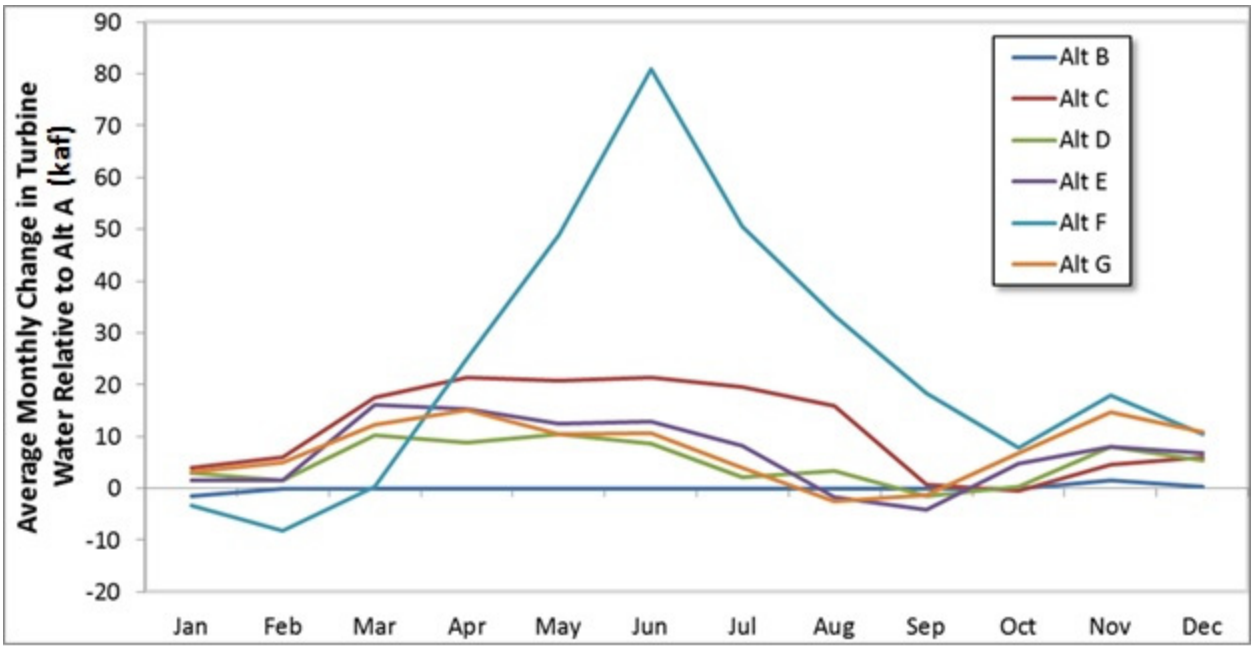

FIGURE K.5-3 Average Monthly Difference in Turbine Water Releases Relative to Alternative A

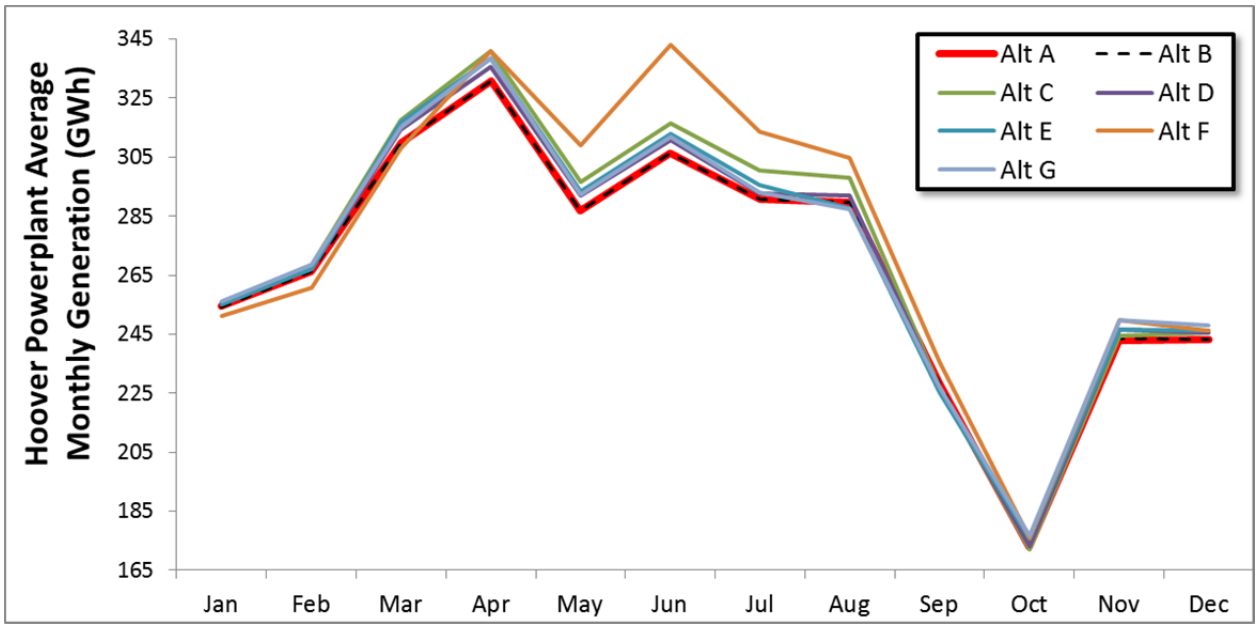

FIGURE K.5-4 Average Monthly Hoover Powerplant Generation for All Power Systems under Primary LTEMP EIS Alternatives

late spring through the end of summer, while the range in autumn and winter tends to be relatively small.

K.5.3 Hoover Maximum Operational Capacity and Firm Capacity

In addition to water-to-power conversion factors discussed in the preceding section, the derated capacity of the Hoover Dam Powerplant is also affected by the pool elevation of Lake Mead. Argonne derived a curve of derated capacity as a function of pool elevation based on information provided by Reclamation. Historically, at pool elevations of 1,205 ft and above, the maximum net output is 2,074 MW. It decreases as the pool elevations drops below the 1,205-ft level. As discussed previously, below the minimum power pool elevation of 1,050 ft, the derated capacity is zero.

This analysis assumed that the firm hydropower capacity of Hoover is based on a 90th percentile exceedance. Results of this analysis, however, show that under all alternatives, Lake Mead's elevation in August is projected to be below the minimum power pool level (where no generation is assumed to be possible) more than 10% of the time. Because the maximum operational capacity is zero under all alternatives, the powerplant is credited with no firm capacity despite projections that indicate that the derated capacity for the Hoover Powerplant is expected to be greater than zero most of the time. It therefore follows that LTEMP alternatives have no impact on Hoover Powerplant's firm capacity and economic value.

K.5.4 Economic Value of Hoover Powerplant Energy

The change in the economic value of Hoover Powerplant energy production under each alternative is computed by multiplying the change in monthly energy production by monthly market prices of energy as projected by the AURORA model. Estimates are made for each month of the 20-year LTEMP period for all 21 hydrology traces. For this analysis, it was assumed that the powerplant generates 95% of its total energy production during hours of the week that have relatively high market prices.[36] The remaining 5% is generated during times when prices are lower.

To compare the economic impact of alternatives on a consistent basis, the net present value (NPV) of Hoover Powerplant economic benefits were computed using a 3.375% annual discount rate, the same rate used for computing the NPV elsewhere in this EIS. The result of NPV calculations for the Hoover Powerplant is shown for each alternative in Figure K.5-5. The NPV benefit for Hoover ranges from nearly zero for Alternative B to about $89 million for Alternative F.

[36] The 95% assumption is based on discussions with Reclamation staff.

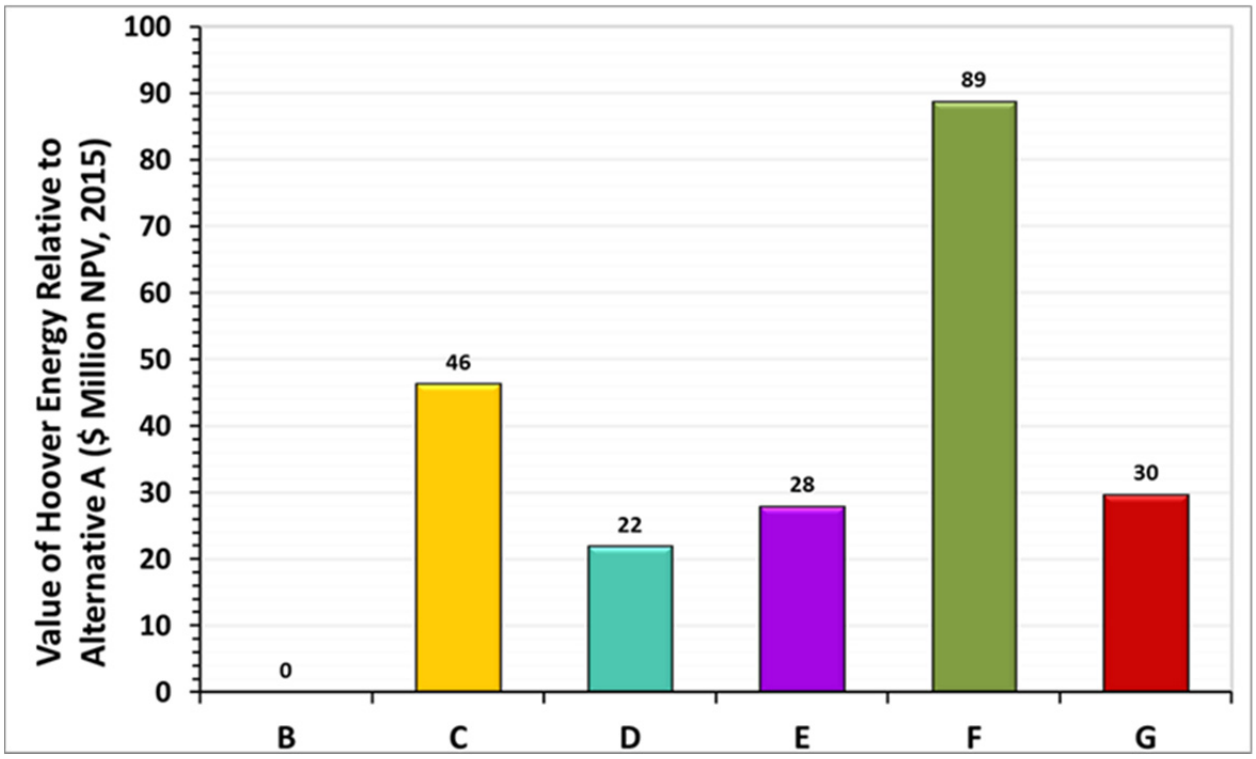

FIGURE K.5-5 NPV of Hoover Powerplant Benefits Relative to Alternative A Resulting from LTEMP Alternatives

K.5.5 Sensitivity of Model Results

Model results are highly sensitive to assumptions, some of which are not yet precisely known. In particular, the assumption regarding minimum power pool elevation has a large bearing on the results discussed above because most of the estimated benefits are due to lower bypass releases under LTEMP alternatives. If a lower minimum pool elevation was assumed, results would be significantly different. For example, at an assumed minimum power pool of 950 ft the Hoover Powerplant Model projects zero bypass releases because SBM pool elevations are always above that level. Energy economics would therefore be significantly different.

On the other hand, the economic impacts of firm capacity discussed above are zero because pool elevations are lower than 1,050 ft more than 10% of the time under all alternatives. If a 950-ft minimum power pool had been assumed. Firm capacity levels and economic values would always be greater than zero and most likely vary among alternatives. This lack of precise information about Hoover should be taken into consideration when interpreting model results.

ATTACHMENT K.1:

GEOGRAPHIC SCOPE OF THE ANALYSIS

The geographic scope of the economic effects of the operations of Glen Canyon Dam has long been a topic of discussion among staff at the Western Area Power Administration (WAPA), Bureau of Reclamation (Reclamation), National Park Service (NPS), Grand Canyon Monitoring and Research Center (GCMRC), and Argonne National Laboratory (Argonne). The method described herein assumes that the effect of changes to the operation of the Glen Canyon Dam is limited to the Salt Lake City Area Integrated Projects (SLCA/IP) system; that is, SLCA/IP federal hydropower resources and WAPA's SLCA/IP long-term firm (LTF) customers. Figure 1 shows the extent of the study area considered in this analysis. This assumption became essential when the scope and timing of the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) power systems analysis were re-evaluated in June 2014 as a result of funding and schedule considerations. Several proposed options for proceeding were developed at that time to offer different levels of analytical detail, costs, and completion dates. The option selected (middle ground relative to detail, funding, and timing) defined the geographic scope as WAPA's SLCA/IP marketing area with ties to the rest of the Western Interconnection for market transaction at the Palo Verde hub. Budget and timing factors have determined the scope of this initial analysis.

This analysis assumes that there is little, if any, economic effect at electricity hubs outside the SLCA/IP system of hydropower plants and WAPA's firm customers in terms of changes in locational marginal prices (LMPs) as a result of alternative operations at Glen Canyon Dam. Argonne undertook a study that verified this limited regional influence. A report documenting this study will be written and peer reviewed. A final, peer-reviewed version of this report will not be available until sometime after the final LTEMP Environmental Impact Statement (EIS) has been published. Therefore, when simulating the operation of Glen Canyon Dam, the region of detailed modeling is restricted to the SLCA/IP system. Spot market transactions conducted at points between this system and the rest of the Western Interconnection will be represented as a static set of market prices for the Palo Verde hub.

Western Interconnection Energy Transactions

The SLCA/IP system is directly connected with other private or invest-owned electric utilities (IOUs) in the geographic area. Among these are Rocky Mountain Power, Excel Energy, and Public Service Company of New Mexico. An electrical market exists such that the SLCA/IP system can exchange with these utilities and others to which they are indirectly connected in order to lower operating costs. To approximate these economic energy exchanges, the AURORA model was run to simulate the dispatch of the entire Western Interconnection. Resulting prices from this run are then input into the more geographically limited, but more detailed, model of the SLCA/IP powerplants and its firm customers. It is assumed that these prices are static and do not change as a result of alternative operating criteria at Glen Canyon Dam. Glen Canyon Dam is a

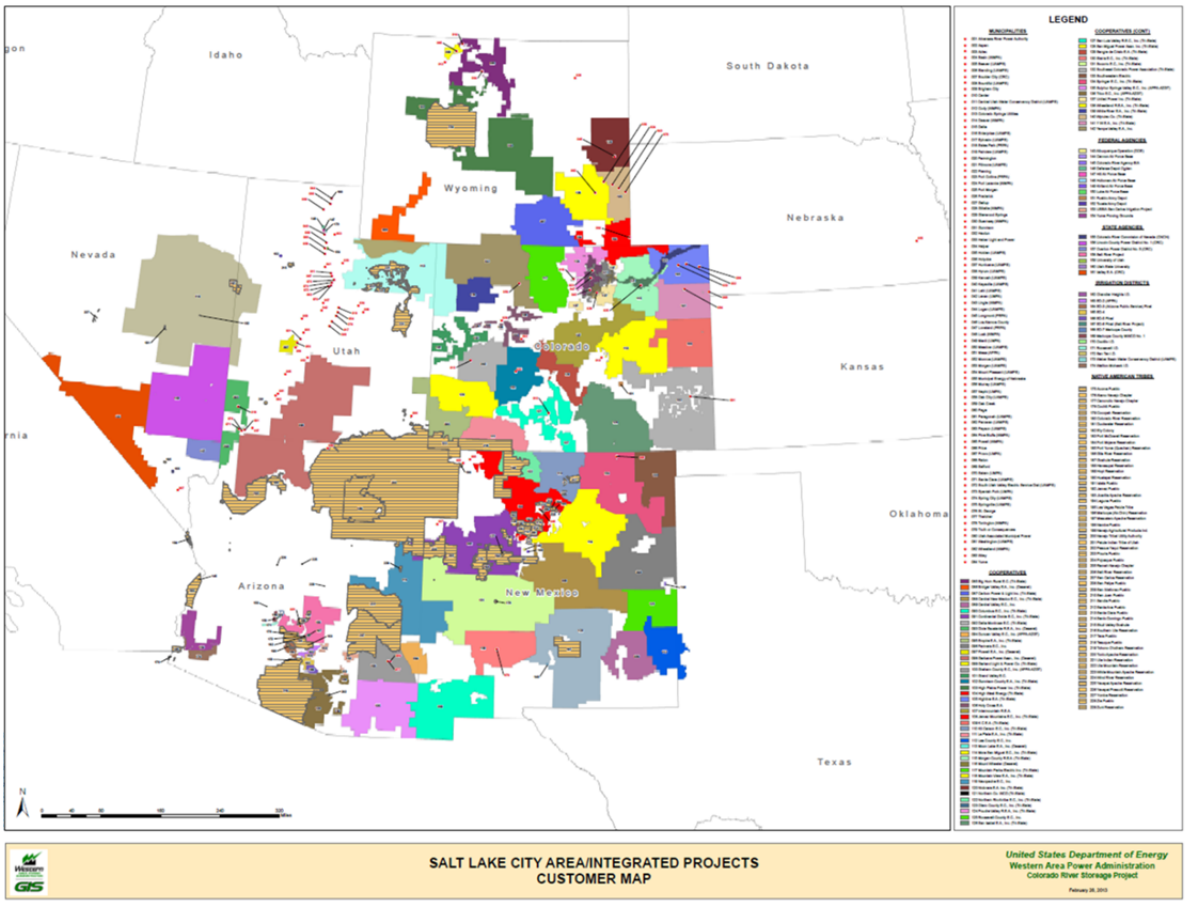

FIGURE 1 Study Area Considered in the LTEMP Power Systems Analysis

very small resource compared to the total Western Interconnection generating capacity and is thought to have only a miniscule impact on Western Interconnection market prices.

Western Interconnection Capacity Transactions

For this analysis, we make the simplifying assumption that no capacity exchange or joint expansion planning occurs—economic impacts of changes in Glen Canyon Dam capacity are limited to WAPA's eight large SLCA/IP LTF customers. Note that smaller customers do not have significant supply resources. It is therefore assumed that small customers will not build capacity in the future. All lost Glen Canyon Dam capacity as a result of operational changes at Glen Canyon Dam would be replaced by the eight larger utility systems, and any resulting capacity losses for the small customers would be replaced via LTF capacity agreements with the larger utilities.

This assumption that the SLCA/IP system will replace lost capacity through its own initiatives can be justified if there is no accessible excess capacity in the larger region. Therefore,

a capacity loss at Glen Canyon Dam cannot be replaced via the purchase of excess capacity from a surrounding utility; for example, from IOUs with whom they are connected. If this assumption is true, the methodology described here will provide a very good approximation of the true economic impact, since the loss of Glen Canyon Dam capacity will require the construction of new capacity somewhere in the grid.

In order to properly assess the strength of this assumption, an examination of relevant regional data, such as integrated resource plans (IRPs) of WAPA's large customers that own generating facilities and large IOUs in the geographic and "electrical" area was conducted. In general, all IRPs examined revealed that utilities are expanding capacity with both renewable and thermal technologies in the near future. In addition, some utilities are increasing Demand Side Management programs to reduce the need for expanding capacity. It was also discovered that the loss of capacity in one large IOU (namely, NVEnergy) from a mandated shutdown of coal-fired powerplants will be replaced with natural gas-fired generation about a year after the first group of coal-fired units are shut down (see Figure 7 in Attachment K.9). Summaries of key IRPs are provided in Attachment K.9. The conclusion drawn from the review of the IRPs is that there is very little, if any, excess capacity in the Balancing Authorities in which WAPA's customers are located and in the broader power pool areas that are defined in the AURORA "out-of-the-box" model configuration. Therefore, loss in capacity at Glen Canyon Dam would need to be replaced soon after the loss was incurred. This loss could be replaced by new capacity that is either built by WAPA's customers or alternatively by another utility and sold via LTF capacity contracts. In this analysis, it is assumed that the replacement capacity would be directly built by the customers. From a purely economic viewpoint, there is little difference if the pool of eight large customers builds the capacity or if it is built by another utility.

Analysis Fidelity

Although in reality WAPA and its customers operate in the Western Interconnection, the approach used by Argonne power system analysts emphasizes performing high-fidelity analyses on a smaller network topology as opposed to analyzing system response of the entire Western Interconnection to changes in operating criteria dictated by LTEMP EIS alternatives. By accurately modeling a smaller system, it is possible to track and explain with a relatively high level of confidence both system- and component-level reactions to alternative operating criteria and to trout management flow (TMF) and HFE operation schedules. SLCA/IP system interactions with the broader Western Interconnection are also represented, but in far less detail. As described in this attachment, power systems analysts were able to fairly closely match historical 2013 generation levels for the eight large utility systems.

It should also be noted that unit commitments, system dispatch, and capacity expansion decisions are not made by a single entity that makes decisions for the entire interconnect. Instead autonomous decisions under uncertainty are made by many entries in the Western Interconnection using market price signals such as the ones reported by the Intercontinental Exchange (ICE) to take unit commitment, dispatch, and energy market transaction decisions. Therefore, the AURORA model of the Western Interconnection tends to "over optimize" system operations. Low 2012 Palo Verde market prices computed by AURORA may be in part due to

the "single decision maker" approach that is employed. Another difficulty in modeling Western Interconnection operations is that hydropower operating constraints for the multitude of hydropower plants within the interconnection are extremely challenging. The approach used in this analysis represents a middle ground between simulating each utility individually and optimizing Western Interconnection operations. It also allows the modeler to represent hydropower operations at a level of detail that cannot be simulated at an adequate level of fidelity by AURORA.

ATTACHMENT K.2:

AURORA WESTERN INTERCONNECTION SPOT MARKET ENERGY PRICES ADJUSTMENTS

The power systems analysis uses a representation of the spot market at the Palo Verde hub where SLCA/IP market system participants buy and sell energy at a set of given hourly prices. The methodology applied in this study uses this price set to represent the economic value of energy; that is, the marginal cost to produce energy that serves the last megawatt of load. This includes both fuel costs and variable operation and maintenance (O&M) expenses. Historical economic values are extremely difficult to accurately estimate because the Western Interconnection is composed of numerous independent entities that operate in a geographically large and very complex grid. Difficulties associated with modeling the Western Interconnection for long-term analyses consist of but certainly not limited to the following (http://www.ipd.anl.gov/anlpubs/2012/04/73032.pdf):

1. The interconnection includes multiple U.S. states and three countries;

2. Part of the system operates in an organized central market (i.e., CAISO) and other portions operate in a bilateral market;

3. A large fraction of Western Interconnection loads are supplied by hydropower plants, many of which are subject to complicated and difficult to model environmental operating criteria (even on a site-specific level);

4. A lack of unit-specific information on fuel prices and heat rate curves ;

5. Insufficient data on bus-level loads;

6. A large and complicated transmission system;

7. Lack of information on resource availability (e.g., unit outage and transmission line outages);

8. Forecast errors associated with loads, hydropower inflows, and variable resource (wind/solar) output; and

9. Complex interactions among entities that make decisions under uncertainty based on limited information about the interconnection.

All power systems models, including AURORA, must therefore make many simplifying assumptions about the grid and the mathematical representation of each grid component. These assumptions lead to an imperfect representation of reality.

In the study, spot market prices modeled for 2013 by the default Western Interconnection AURORA model were significantly different from day-ahead market (DAM) prices published by the ICE and the CAISO. The Palo Verde hub was chosen to represent prices for the spot market in the AURORA network topology for the LTEMP analysis because it is the hub closest to Glen Canyon Dam and is often used as the benchmark price for Western Area Power Administration (WAPA) energy transactions.

The ICE publishes day-ahead weighted average peak, off-peak, and Sunday off-peak electricity price for every day each year. Sunday off-peak hours are the 16 daytime hours that have the highest loads; they correspond to the 16 hr classified as peak in the other 6 days of the week. Hourly prices generated by the AURORA model were subdivided into 7 categories; namely, holiday, Sunday daytime, Sunday nighttime, Saturday peak, Saturday off-peak, weekday peak, and weekday off-peak. The monthly averages were computed for each category and compared against the monthly average of the ICE prices in these categories.

In order to bring AURORA model hourly prices in line with these ICE prices, AURORA model results were scaled to match ICE averages. A scalar (ratio of the ICE to AURORA prices) was generated for each month and each category. In this preliminary investigation, it was discovered that prices generated by the AURORA model were generally lower than the ICE prices. Prices in off-peak hours were lower by about 5 to 15% and prices in peak hours were lower by as much as 20 to 50%. To adjust for this discrepancy in prices, future AURORA model runs for the LTEMP network topology, AURORA prices at the Palo Verde hub were multiplied by the aforementioned scalar. The scalars derived from ICE prices are shown in Table 1.

TABLE 1 Scalars Used to Adjust Spot Market Prices in the AURORA Model

		Sunday		Saturday		Weekday	
Month	Holiday	Daytime	Nighttime	Peak	Off Peak	Peak	Off Peak
January	1.053	1.032	1.110	1.068	1.042	1.058	1.019
February	NA[a]	1.145	1.221	1.123	1.083	1.093	1.140
March	NA[a]	1.133	1.175	1.119	1.126	1.105	1.120
April	NA[a]	1.319	1.297	1.257	1.132	1.163	1.183
May	0.943	1.143	1.126	1.156	1.046	1.165	1.053
June	NA[a]	1.210	1.241	1.241	1.067	1.200	1.066
July	1.100	1.222	1.204	1.343	1.009	1.538	1.094
August	NA[a]	1.175	1.142	1.231	1.004	1.230	1.060
September	1.088	1.133	1.251	1.218	1.051	1.170	1.116
October	NA[a]	1.134	1.235	1.156	1.118	1.094	1.142
November	1.079	1.084	1.208	1.166	1.159	1.098	1.113
December	1.082	1.279	1.470	1.233	1.265	1.228	1.299

[a] NA = not applicable.

The scaled AURORA prices were used as a surrogate for the economic value of energy based on the premise that the ICE data adequately reflects actual market prices and those market prices are a good measure of economic costs. In economic theory, a perfect market will produce prices that reflect economic costs. However, no market is perfect, including those in the Western Interconnection. Therefore, due to the complexities associated with modeling actual economic costs at the margin, power system modeler used the aforementioned scaling methodology. This not ideal, but it appears that market mechanisms in the Western Interconnection are working reasonably well and market monitors (such as those in the CAISO) help to ensure that participants do not unduly take advantage of market imperfections.

ATTACHMENT K.3:

SELECTION OF REPRESENTATIVE TRACE

Introduction

This paper briefly describes the process that was used for selecting a representative hydrology trace for use in the Long-Term Experiment and Management Plan (LTEMP) power systems modeling task. A single representative trace was required to balance the complexity and time requirements for power system simulations with task completion timelines. Goals in selecting a trace included considerations for (a) matching the probability distribution of annual water releases as exhibited in the full set of 21 hydrology traces developed by the Bureau of Reclamation, (b) representing the variability in monthly releases, (c) avoiding significant numbers of non-power release events (where monthly volumes and elevations lead to water releases not being fully utilized for power generation), and (d) providing reasonably close matches (across all six alternatives and long-term strategies) for end-of-year elevations and release volumes. The following sections describe several metrics that were developed to characterize these goals and provided the basis for selecting a representative trace.

Six alternatives and long-term strategies,[1] including a no action alternative, were originally proposed for study in the LTEMP Draft Environmental Impact Statement (DEIS). A seventh alternative, Alternative D, was proposed after this analysis for choosing a representative trace was performed, and is not included in this analysis. The alternatives have been assigned a letter designation and will be referenced in this document by that letter: Long-Term Strategies B1, C1, and E1, and Alternatives F and G. Alternative A, the no action alternative, is the current operating regime and is known as modified low fluctuating flow (MLFF) as defined in the 1996 Record of Decision.

Annual Powell Outflows—Exceedance Curves

A priority in selecting a single representative 20-year hydrology trace for power modeling is to capture the range and distribution of water conditions that occur across all 21 of the original 20-year hydrology traces. To address that objective, we constructed time-independent exceedance curves (basically representing probability distributions) for the annual Powell outflows for each of the 21 traces and six alternatives and long-term strategies. As a metric for comparing the closeness of fit for those 21 distribution profiles as compared with the full set of traces, we calculated the least-squares differentials between each trace-specific

[1] It should be noted that at the time the representative trace was chosen, the LTEMP DEIS had only 6 alternatives and long-term strategies. A hybrid or 7th alternative was subsequently added. The hybrid is a combination of the C1 and E1 long-term strategies; however, the choice of the representative trace would not be affected by the addition of the hybrid alternative.

TABLE 1 Powell Outflow Exceedance: Rankings of Traces by Least-Squares Differentials as a Measure for Matching the Distribution of Releases for All Traces[a]

	Alternative A (No Action Alternative)		Long-Term Strategy B1		Long-Term Strategy C1		Long-Term Strategy E1		Alternative F		Alternative G

18	Trace 1	11,249	Trace 1	11,249	Trace 10	11,557	Trace 10	11,601	Trace 1	11,491	Trace 1	11,408
19	Trace 5	11,262	Trace 5	11,262	Trace 5	12,662	Trace 5	12,816	Trace 5	12,712	Trace 5	12,113
20	Trace 9	13,003	Trace 9	13,003	Trace 9	14,797	Trace 9	14,807	Trace 9	13,982	Trace 9	14,046
21	Trace 11	14,321	Trace 11	14,321	Trace 11	16,284	Trace 11	16,349	Trace 11	15,433	Trace 11	15,501

[a] Trace 14, the selected representative trace, is highlighted in green.

[b] Note: Sq. Diff. = least squares differential between the trace-specific exceedance curve and the all-traces exceedance curve.

exceedance curve and the all-traces exceedance curve. These differentials were calculated separately for each of the six alternatives and long-term strategies (Table 1).

Table 2 shows that hydrology Trace 14 provides a distribution of annual water releases that closely mimics the full set of releases for all traces. We also observed that differences in the rankings when examining Powell outflows versus estimated power releases were minor and relatively insignificant to the selection of a single representative trace. Thus, the illustrations used in this summary focus primarily on Powell outflows.

Trace 13 also provides a good match with all-trace outflows, especially for Alternative G and Long-Term Strategies C1 and E1, where the least-squares differences are less than those for Trace 14. However, a large portion of the least-squares difference between Traces 13 and 14 is accredited to the closer match to near-peak releases for some alternatives in Trace 13 versus Trace 14, whereas Trace 14 exhibits a closer fit over other portions of the flow distributions (illustrated in figures that follow). Additionally, alternative-to-alternative inconsistencies in end-of-year Powell elevations and annual water releases were significantly greater for Trace 13 than Trace 14.

Trace 19 represents another possible contender with a good match to the all-trace variability. It is not considered further, though, because it includes numerous occurrences of Powell elevations below the top of the penstock within the 20-year modeling period (4 months for each alternative except Alternative F). The below-penstock occurrences across the 21 traces and 20 years are listed below:

- Alternative A—Trace 8: 3 in 2032; Trace 19: 12 in 2016 to 3 in 2017 inclusive.
- Long-Term Strategy B1—Trace 8: 3 in 2032; Trace 19: 12 in 2016 to 3 in 2017 inclusive.
- Long-Term Strategy C1—Trace 8: 3 in 2032; Trace 19: 12 in 2016 to 3 in 2017 inclusive.
- Long-Term Strategy E1—Trace 8: 3 and 4 in 2032; Trace 9: 3 in 2027; trace 19: 12 in 2016 to 3 in 2017 inclusive.
- Alternative F—none; all elevations above 3,490 ft.
- Alternative G—Trace 8: 2 in 2032 to 4 in 2032 inclusive; Trace 19: 12 in 2016 to 3 in 2017 inclusive.

Figures 1 through 5 illustrate the close match between Trace 14 and all-traces exceedance curves for annual Powell outflows. For comparison purposes, we also show: (1) Trace 14 exceedance curve for Long-Term Strategy C1, where Trace 14 ranked third instead of first in the distribution match (this represents the worst-case match for Trace 14); and (2) the Trace 19, 13, and 16 exceedance curves for the No Action Alternative (Alternative A) to illustrate the

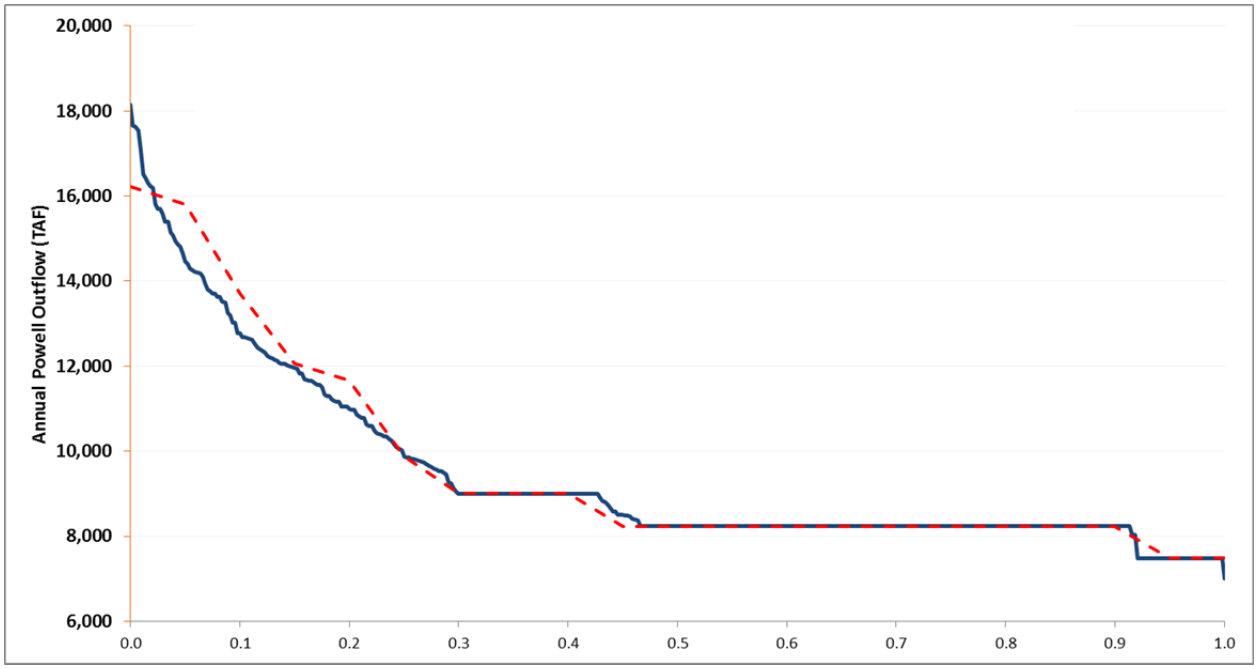

FIGURE 1 Exceedance Curve Comparing Outflows of Trace 14 (red dotted line) and the All-Trace Average (blue line) for the No Action Alternative

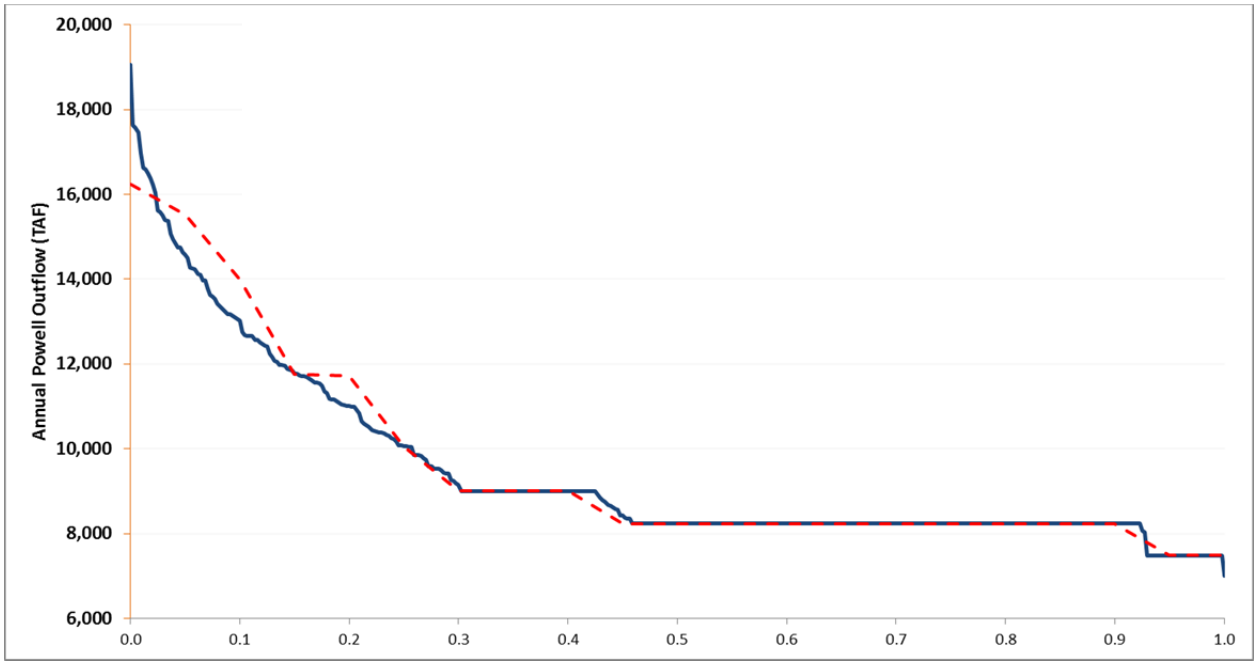

FIGURE 2 Exceedance Curve Comparing Outflows of Trace 14 (red dotted line) and the All-Traces Average (blue line) for Long-Term Strategy C1

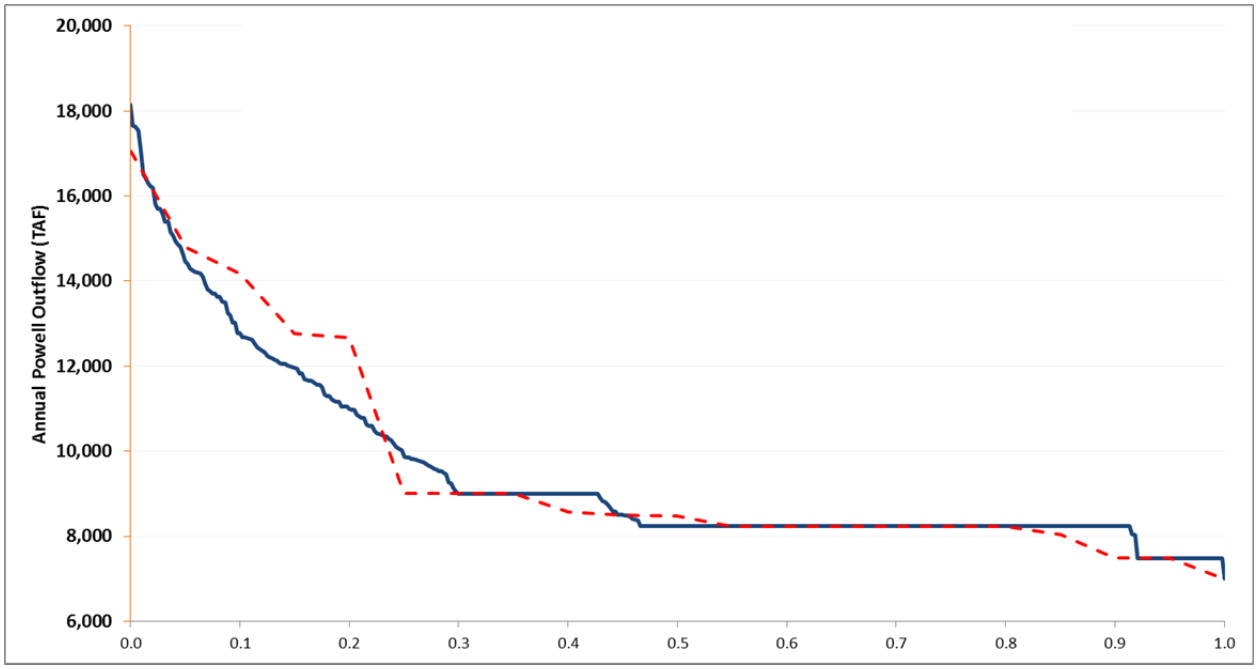

FIGURE 3 Exceedance Curve Comparing Outflows of Trace 19 (red dotted line) and the All-Traces Average (blue line) for the No Action Alternative

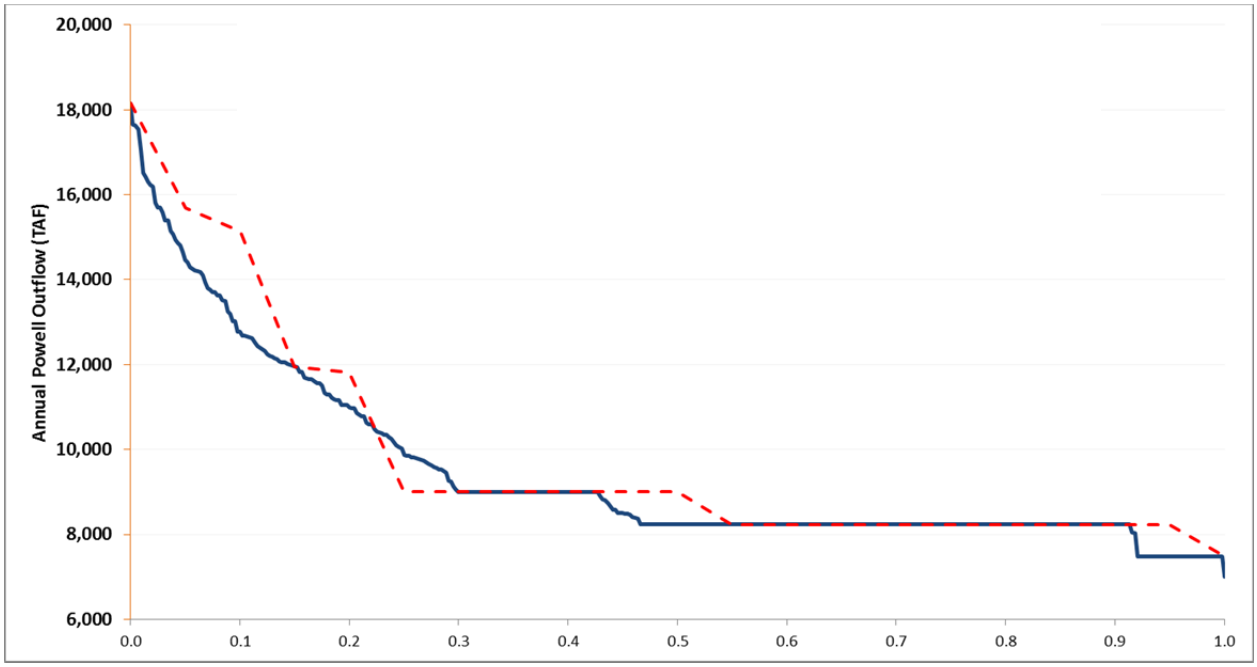

FIGURE 4 Exceedance Curve Comparing Outflows of Trace 13 (red dotted line) and the All-Traces Average (blue line) for the No Action Alternative

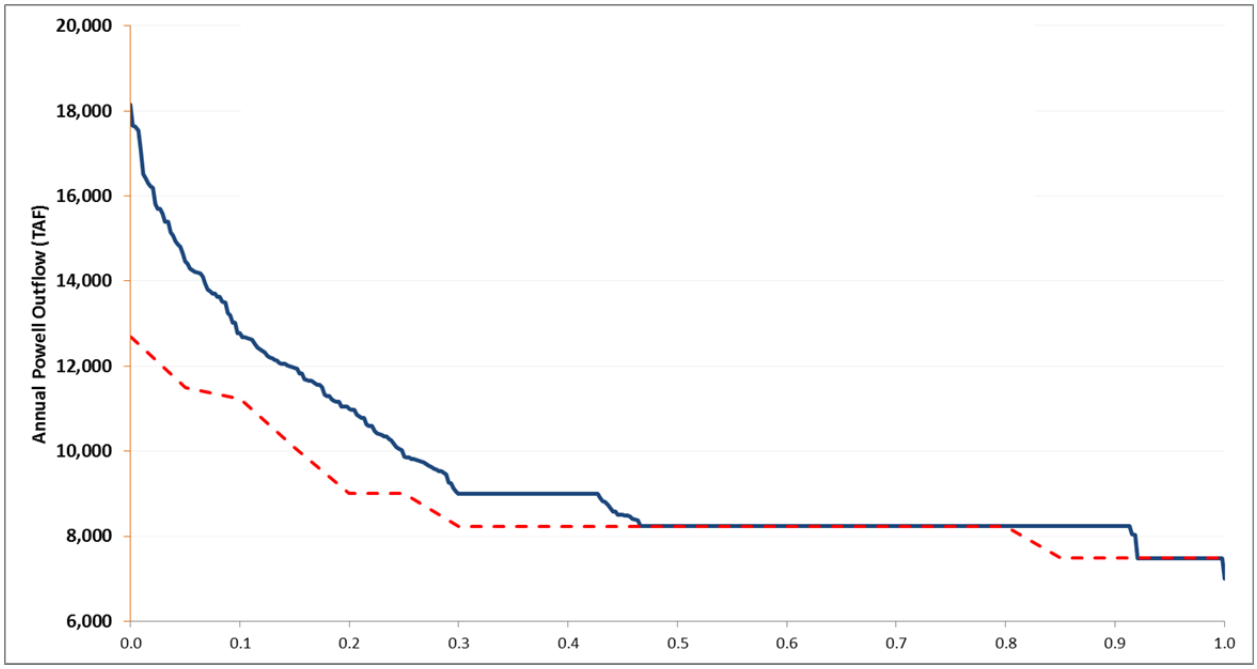

FIGURE 5 Exceedance Curve Comparing Outflows of Trace 16 (red dotted line) and the All-Traces Average (blue line) for the No Action Alternative

difference in fit between the top and middle-ranked traces (rankings for Alternative A are: Trace 19 = 2nd; Trace 13 = 3rd; and Trace 16 = 11th).

Comparison of Monthly Water Releases and Powell Elevations to Averages

Complementing the probability distribution analysis, monthly Powell elevations and water releases for each trace were compared to the associated averages for each month in the 20-year study period for all traces. Again, these comparisons were made separately for each alternative and long-term strategy. The objective in these examinations is to provide "representative variability" over the 20-year spans relative to average outcomes (i.e., the goal is to include conditions that are sometimes "wet," sometimes "dry," and sometime "average," rather than conditions that are uniformly "average" across the entire study period).

Results of monthly outflow and end-of-month elevations for Trace 14 and the all-trace averages are plotted in Figures 6 to 11. Table 3 shows the number of HFEs and the amount of water bypassed during all HFEs for Trace 14 and the all-trace average. Trace 14 is characterized by lower-than-average water outflow through 2019, higher water outflow through 2026, followed by lower-than-average water outflow through 2033. As seen from these figures, the monthly Powell elevations and water releases averaged over the 21 traces are significantly less variable than observed for a single trace.

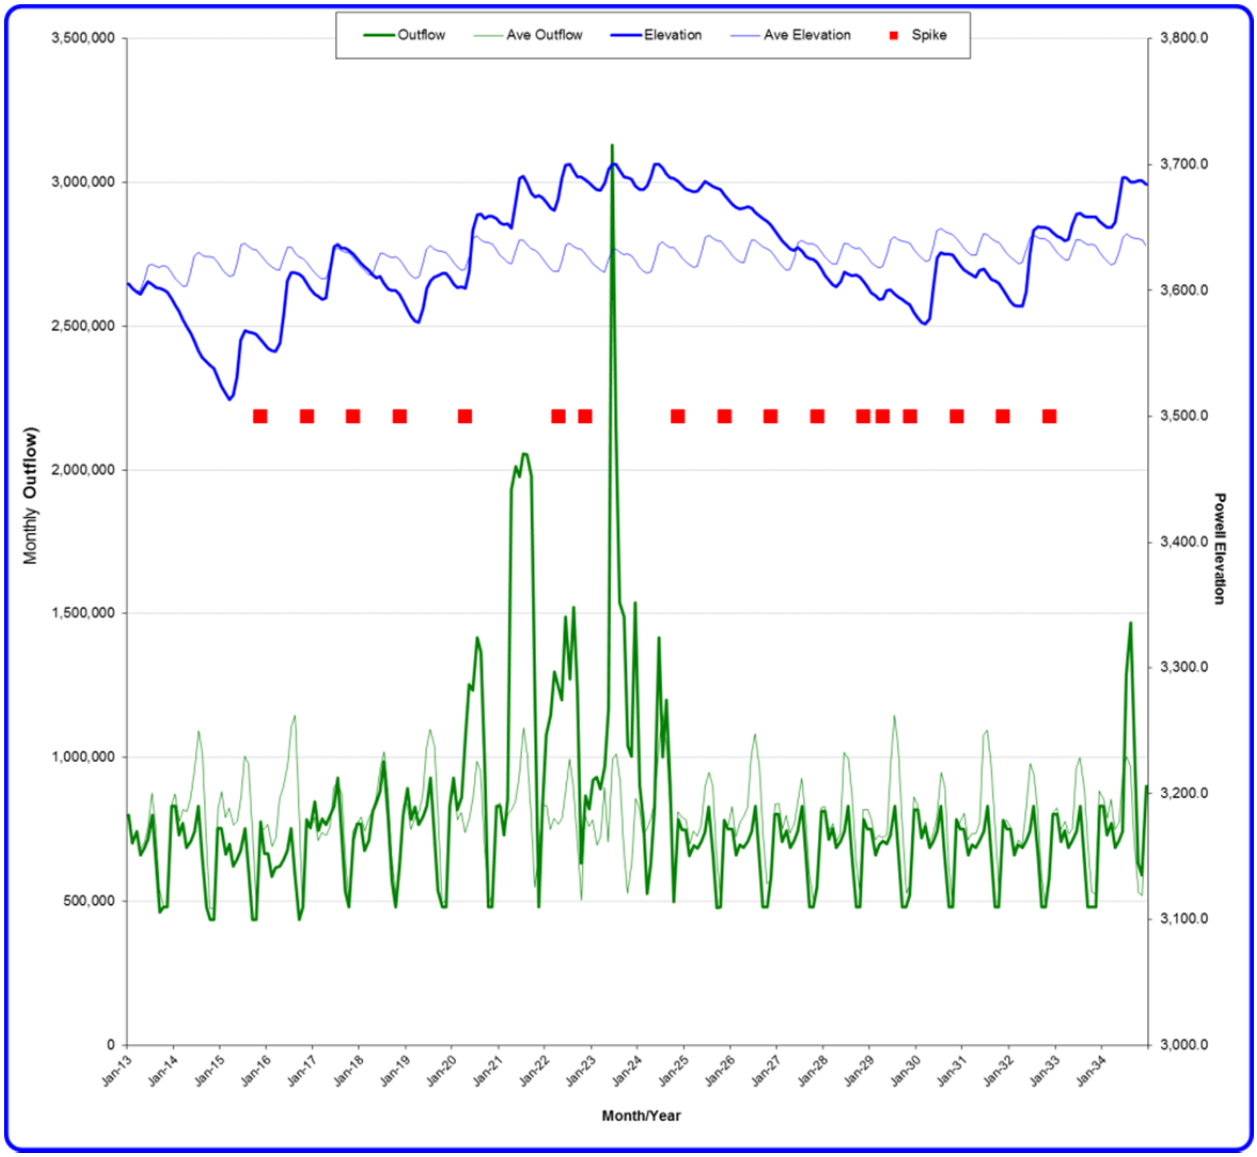

FIGURE 10 Comparison of Monthly Outflow and End-of-Month Elevation of Trace 14 and the All-Trace Average for Long-Term Strategy C1

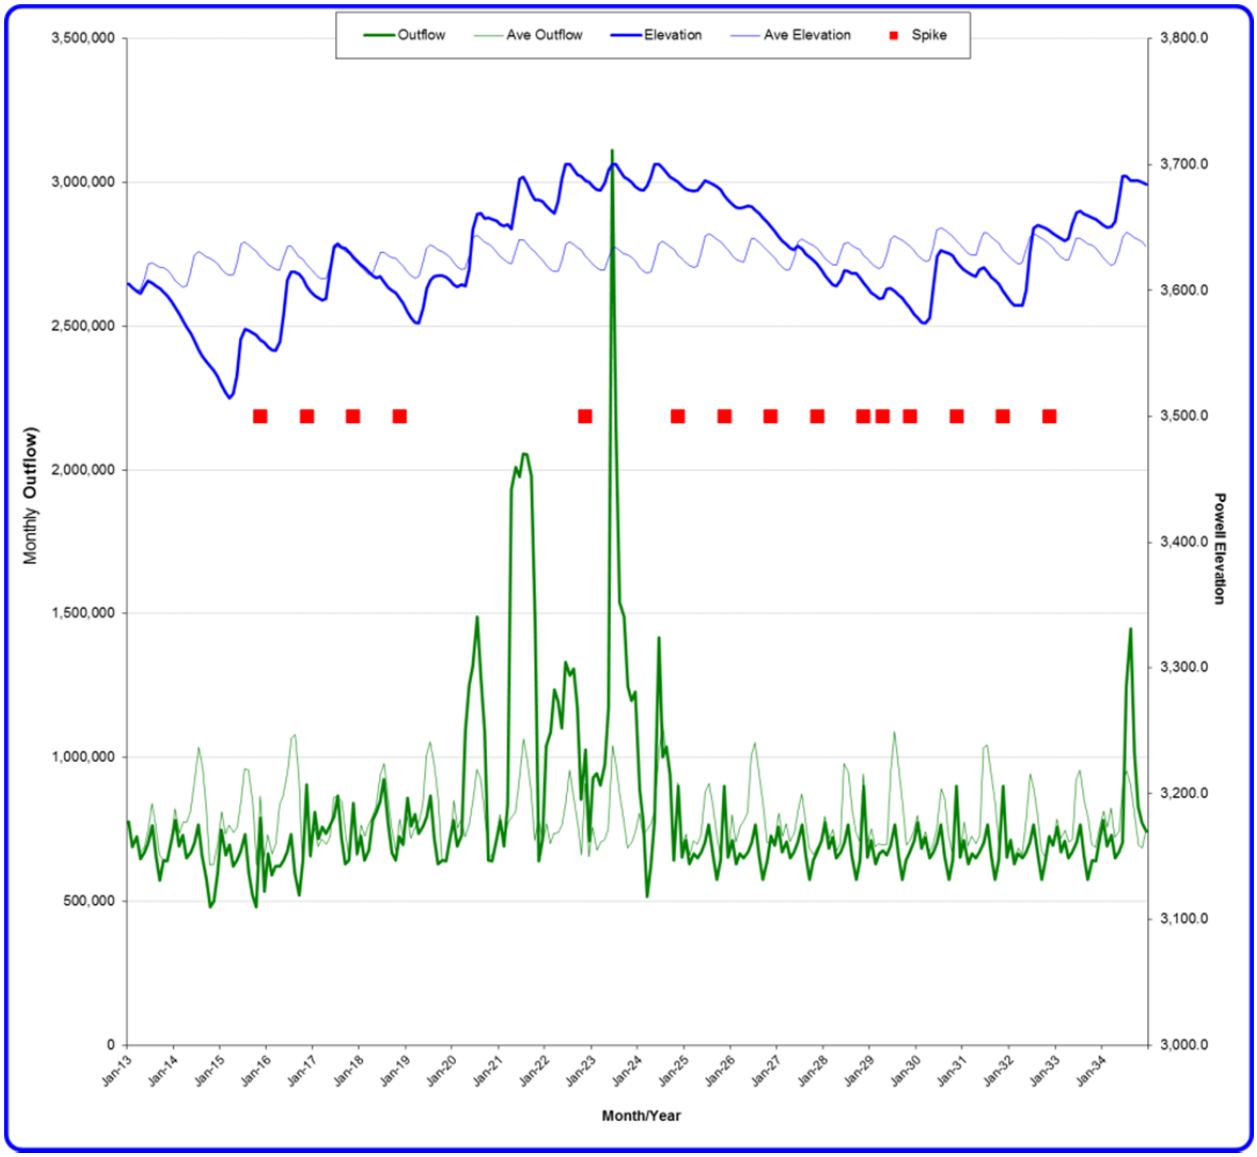

FIGURE 11 Comparison of Monthly Outflow and End-of-Month Elevation of Trace 14 and the All-Trace Average for Long-Term Strategy E1

TABLE 2 Number of HFEs and Amount of Water Spilled Bypassed during HFEs in Trace 14 and the All-Trace Average

Alternative/ Long-Term Strategy	Characteristic	Trace 14	21 Traces Average
A (No Action Alternative)	Number of HFEs	4	4
	Amount of bypassed water spilled during HFEs (kaf)	262	346
B1	Number of HFEs	6	7
	Amount of bypassed water spilled during HFEs (kaf)	472	553
C1	Number of HFEs	17	19
	Amount of bypassed water spilled during HFEs (kaf)	1,329	1,522
E1	Number of HFEs	15	16
	Amount of bypassed water spilled during HFEs (kaf)	1,236	1,211
F	Number of HFEs	18	19
	Amount of bypassed water spilled during HFEs (kaf)	1,734	1,853
G	Number of HFEs	22	22
	Amount of bypassed water spilled during HFEs (kaf)	3,188	2,591

TABLE 3 Rankings of Hydrology Trace 14 in Matching Average Elevations and Outflows Compared to the 21-Trace Average

Alternative/ Long-Term Strategy	Powell Elevation Trace 14 Rank	Powell Outflow Trace 14 Rank
A (No Action Alternative)	11	13
B1	11	13
C1	11	13
E1	10	13
F	12	13
G	10	13

Because capturing variability is an important objective for this study, an exact match to the 21-trace averages is not desirable. Table 4 illustrates how Trace 14 ranks near the middle of variability for all of the 21 traces; it is neither too close to the average during all years, nor the most extreme divergence from the average over all years.

To assess the 21 traces on a common metric, rankings were calculated based on the least-squares differences by rank relative to the monthly average of all 21 traces: Rank = 1 is the closest match to the average (smallest least-squares difference); Rank = 21 represents the largest difference relative to the average. Table 4 demonstrates that Trace 14 is in the mid-range for both elevation and outflow. The point of this comparison is to illustrate that the selected trace contains neither excessive variability, nor insufficient variability relative to all of the traces under consideration.

Evaluation of Differentials in End-of-Year Powell Elevations and Annual Water Releases

For the representative hydrology trace selection, we also examined how closely each trace's end-of-year Powell elevations and annual water releases match when compared across all six alternatives and long-term strategies. In theory, these values should match closely, but we found that this is not the case for a majority of the traces. To generate a common metric for trace-specific comparisons, we first calculated the differences in both end-of-year elevation and annual outflow between Alternatives A and F; A and G; A and Long-Term Strategy B1; A and Long-Term Strategy C1; and A and Long-Terms Strategy E1 for each of the 20 years and each hydrology trace (using Alternative A [no action alternative] as a reference point). Since these values should ideally all be zero, we calculated the least-squares differentials and ranked the traces according to the sum of the least-squares differences for the five comparisons listed above. Table 5 shows that for these criteria, Trace 14 ranks near the middle of all traces, indicating that it does not represent an extreme case for deviations in end-of-year elevations or annual water releases. In contrast, Trace 13 exhibits the worst match (21st) in annual outflows and ranks 18th in Powell end-of-year elevations.

Examining this same issue through graphical depictions, Figures 12 and 13 compare the differentials for Traces 14 and 13 side by side, in year-by-year plots of the pairwise end-of-year differentials. Trace 14 is preferred over Trace 13 because of the more consistent end-of-year Powell elevations and annual water releases across the six alternatives and long-term strategies.

Evaluation of HFE Bypasses

As a final comparison, Figure 14 shows quantities of water bypassed during the HFEs for Trace 14 (highlighted as enlarged red diamond) compared to other traces for each of the six alternatives. These comparisons show that Trace 14 exhibits outcomes that span the range of possible rankings relative to other traces. That is, Trace 14 exhibits HFE bypass volumes that are low, medium, and high, for various alternatives, in comparison with other traces. These observations make Trace 14 a favorable candidate for representative bypass characteristics across all alternatives.

TABLE 4 Rankings of Hydrology Traces Compared to All-Trace Average for End-of-Year Elevations and Annual Water Releases

Rank (1 = least differential)	Powell Elevation		Powell Outflow	
	Trace Number	Square Differential	Trace Number	Square Differential
1	Trace 4	6.51	Trace 9	0.000
2	Trace 9	20.05	Trace 4	0.000
3	Trace 11	26.91	Trace 11	0.000
4	Trace 6	32.63	Trace 6	0.001
5	Trace 0	43.05	Trace 8	0.003
6	Trace 20	47.32	Trace 12	0.006
7	Trace 3	47.95	Trace 15	0.006
8	Trace 1	54.64	Trace 14[a]	0.007
9	Trace 2	59.81	Trace 0	0.008
10	Trace 7	64.72	Trace 20	0.010
11	Trace 12	127.00	Trace 2	0.015
12	Trace 15	192.56	Trace 1	0.015
13	Trace 14[a]	235.30	Trace 3	0.016
14	Trace 17	326.53	Trace 17	0.018
15	Trace 19	354.81	Trace 7	0.019
16	Trace 16	458.47	Trace 5	0.029
17	Trace 8	583.18	Trace 19	0.060
18	Trace 13[a]	838.12	Trace 10	0.071
19	Trace 5	914.47	Trace 18	0.086
20	Trace 18	1085.39	Trace 16	0.099
21	Trace 10	2363.07	Trace 13[a]	0.112

[a] Traces 13 and 14 are highlighted to illustrate their relative rank with respect to end-of-year elevations and annual water releases.

Summary

The observations and comparisons described above were used to select hydrology Trace 14 as the representative trace. Characteristics such as annual water release distributions, monthly water release variability, bypass events, and end-of-year elevation/volume consistency were considered and a majority of these factors favor Trace 14. While a few other traces show comparable strengths in certain comparison categories, each of those candidate traces show less favorable rankings in other categories.

ATTACHMENT K.4:

DISCOUNTING PROCEDURES

The costs and benefits of most environmental policies are incurred at different times over what are frequently long time horizons. A fundamental concept in finance and economics is that the timing of benefits and costs makes a difference in the attractiveness of an investment. All other things being equal, one would prefer to receive the benefits of an investment as soon as possible and to pay the costs as far out in the future as possible. Given the choice between receiving $100 today or $100 a year from now, most people would prefer $100 today. Alternatively, if given the choice between paying out $50 today or one year from now, most of us would prefer the latter.

Because the timing of these costs and benefits differs across alternatives, the responsible policy choice requires the use of appropriate techniques to allow for commensurate comparisons. Typically, the present value of the future stream of costs and benefits for each alternative is computed and the results arrayed for decision-makers.

Discounting is the method used for identifying the present value of a cost or benefit that occurs at some time in the future. The process of "discounting" is used to make costs or benefits that occur at different points in time commensurate with each other.

Although the mechanics of the discounting process are very straightforward, the magnitude of the discount rate greatly influences the degree to which future costs and benefits "count" in the decision. As a result, the choice of discount rate is the subject of much controversy.

The literature on discounting and the choice of a discount rate is vast. Many modern economics texts contain synopses of this literature (e.g., Field 2008; Tietenberg and Lewis 2009). A more lengthy assessment can be found in the Environmental Protection Agency's, *Guidelines for Preparing Economic Analyses* (EPA 2010) and Burgess and Zerbe (2011).

Federal water resource agencies, including the Bureau of Reclamation (Reclamation), are required to employ an administratively determined discount rate known as the federal plan formulation and evaluation rate when undertaking economic analyses of water resource and related matters (see 42 U.S.C. 1962d–17, Public Law 93-251-March 7, 1974 Sec. 80 (a)). This requirement and more specific analysis procedures are described in the *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* (U.S. Water Resources Council 1983). This document is often referred to as the "P&Gs."

A new set of water resource planning guidelines have been announced which will ultimately supersede the P&Gs (Council on Environmental Quality 2014). In March 2013, the *Principles and Requirements for Federal Investments in Water Resources* (referred to as the P&Rs) were released and in December 2014 a set of *Interagency Guidelines* (IGs) were released by the President's Council on Environmental Quality. Reclamation is now drafting agency-

specific procedures. These ongoing efforts will lead to production of a consolidated document, the *Principles, Requirements and Guidelines* (PR&Gs). Finalization of this effort is slated for calendar year 2016.

Two procedural points are relevant to this analysis. First, the forthcoming PR&Gs do not alter the statutory requirement of the Bureau of Reclamation to employ the federal plan formulation and evaluation rate in their water resource analyses. Second, this environmental impact study was initiated well-prior to completion of these new guidelines, and the PR&Gs are not applicable to the analysis reported here.

As prescribed by law and described in the P&Gs, federal water resource agencies must use an administratively determined discount rate for cost-benefit analysis. This rate is known as the federal discount rate for plan formulation and evaluation. The plan formulation and evaluation rate is calculated annually by the Secretary of the Treasury pursuant to 42 U.S.C. 1962d-1 (see the *Code of Federal Regulations* [CFR] at 18 CFR Part 704 for a description of the methodology) and then is officially transmitted to the water resource agencies. The plan formulation and evaluation rate for fiscal year (FY) 2015 is 3.375% (Reclamation 2014a,b).

Table 1 summarizes the inflation, escalation, and discounting procedures used in this analysis. As illustrated, the base year chosen for this economic analysis is 2015. The period of analysis is 21 calendar-years, spanning the period 2013 to 2033. All economic value estimates reported in this document are measured in 2015 dollars, unless otherwise stated.

The prices and values employed as input data for the economic modeling were reported at various times. To create a common input baseline, these prices and values were inflated from the year in which they were reported to 2014 dollars, using the annual Western Regional Consumer Price Index (CPI) (Bureau of Labor Statistics 2015).

TABLE 1 Discounting Procedures

Parameter	Value
Base year for reported results	2015
Period of analysis 2013 through 2033	21 years
Price escalation rate (2014 through 2015)	2.2126%
Price escalation rate (2015 through 2033)	0.0%
Discount rate[a]	3.375%

[a] Federal Water Resource plan formulation and evaluation rate for FY 2015.

Modeling output was inflated from 2014 to 2015 dollars for reporting purposes. The equivalent annual CPI rate during the most recent 10-year (2004 to 2014) period was calculated to be 2.2126 percent (rounded to 4 decimal places). Price inflation from 2014 to 2015 was assumed to be the same as it was during this 10-year period. All 2014 values and prices were escalated from 2014 to the base year of 2015 using an escalation rate of 2.2126 percent.

To summarize, consistent with applicable federal law, the procedures described in the *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* (U.S. Water Resources Council 1983), all costs and benefits that occur after 2015 are reported in constant 2015 dollars (they are not escalated). Costs and benefits that occur in 2015 are not discounted, given that 2015 is the base year for this analysis. All costs and benefits that occur after 2015 are discounted back to the 2015 base year using the FY 2015 federal discount rate for plan formulation and evaluation (3.375%).

ATTACHMENT K.5:

FORCED OUTAGE SCENARIO GENERATION FOR HYDROELECTRIC POWER FACILITIES

The following is a description of the methodology used in creating a forced outage scenario for hydroelectric power facilities.

Requirement

1. Generate a reasonable forced outage scenario consistent with industry average for hydro units.

2. The forced outages should be multiple of 24 hr.

3. The forced outage always starts at the beginning of a day.

Inputs

1. Planned maintenance schedule for the hydroelectric power facility being modeled (from Reclamation)

2. Cause code statistics from the North American Electric Reliability Corporation (NERC)

3. Forced outage rate distribution from NERC

NERC publishes generating availability data system (GADS; http://www.nerc.com/page.php?cid=4|43|47). These reports contain aggregate statistics for various unit types. The cause code group statistics provides the number of forced outages and the number of hours under forced outage per unit per year. Tables 1 and 2 contain the relevant data extracted from GADS 2010.

Methodology

1. For each year and for each unit, randomly assign a forced outage rate (FOR) based on the distributions in Table 2.

2. Compute the forced outage hours based on the assigned FOR and service hours. Service hours are the number of hours the unit is not on planned maintenance schedule (i.e., available for generation).

3. Sum forced outage hours across all the units for a given year (TOTSYS)

TABLE 1 Cause Code Statistics for Hydro Plants >30 MW 2006–2010

9	13	0.9	0.9971
9	14	1	1

4. Using cause code statistics, calculate average outage length in hours for each cause code (column 6 divide by column 5 in Table 1).

5. Compute the total forced outage hours for each cause code across all units (column 6 * no. of units) and also the total forced outage hours across all units and all cause codes (TOTFOH).

6. Total outage hours based on cause codes are typically much lower than the hours out for units since cause codes outages are based on actual data and reflect only those hours that the unit is in service or called into service. Compute a "SCALE" as the ratio of TOTFH and TOTSYS.

7. Compute the total number of outages for each cause code across units using the "SCALE", column 5 from Table 1 and the total number of units.

8. For each cause code, loop through the number of outages. Randomly select a unit and a random start time that the unit is not on planned maintenance. Assign the forced outage for the duration of average outage length for the given cause code (from step 4 above).

9. Adjust the length of forced outage to be a multiple of 24 hr and move to the beginning of the day, if necessary.

ATTACHMENT K.6:

FORECAST OF MONTHLY PEAK LOADS AND ENERGY BY SLCA/IP LONG-TERM FIRM CUSTOMER

The development of hourly load projections over the study period is based on the 2006 representative nominal load profile and monthly projections of utility-level peak and total loads. Implementation of this method differs from utility to utility depending upon data availability. The primary source of forecast information was the utility's integrated resource plan (IRP). If these data are not available in the IRP, then generation and capacity projections from the Energy Information Administration's (EIA's) 2014 Annual Energy Outlook (EIA 2014) are used instead. The method for developing the hourly load forecast for each of the eight utilities plus Western Area Power Administration's (WAPA's) remaining small customers is described in more detail in Section K.1.6.3 of Appendix K.

Figures 1 and 2 show monthly peak loads and total monthly load projections, respectively, for each of the eight large customers and the two aggregate small customer groups. This data was used to generate the graphs shown in Figures K.1-15 and K.1-16 in Section K.1.6.3 of Appendix K.

ATTACHMENT K.7:

ANALYSIS OF THE TIMING OF THE PEAK LOAD

In the recent past, Western Area Power Administration's (WAPA's) coincidental peak load has occurred in the summer, but it does not consistently occur in a specific month. A study was performed to determine the month in which the peak occurred in recent history.

Hourly load data was obtained for 2006 to 2012 from Federal Energy Regulatory Commission (FERC) Form 714 for WAPA's eight largest customers: Salt River Project (SRP), Tri-State Generation and Transmission Association (Tri-State), Colorado Springs Utilities (CSU), Platte River Power Authority (PRPA), Navajo Tribal Utility Authority (NTUA), Utah Associated Municipal Power Systems (UAMPS), Utah Municipal Power Agency (UMPA), and Deseret Generation and Transmission Cooperative (Desert). These customers account for 75% of WAPA's energy and capacity, so the aggregate load of these customers would determine when WAPA's peak occurs.

Table 1 shows the peak load in each month of the year from 2006 to 2012. Data was not available for NTUA and Deseret from 2010 to 2012, so those utilities were not included in those years. However, Figure 1 shows that NTUA and Deseret only account for 1% and 3% of the peak load from 2006 to 2009, respectively, so not having their data in the last 3 years of the study would not alter the occurrence of the coincidental peak.

The peak load occurs in July in 3 of the 7 years and in August in 4 of the 7 years (as indicated by the shaded areas in Table 1). Therefore, the peak occurs in either July or August

TABLE 1 Aggregate Monthly Peak Load of WAPA's Eight Large Customers for 2006 to 2012[a]

Month	2006	2007	2008	2009	2010	2011	2012
1	7,470	8,089	8,411	7,983	7,426	7,836	7,160

ATTACHMENT K.8:

ANALYSIS OF CAPACITY DETERMINATIONS— COMPARING RESULTS USING A RANGE OF EXCEEDENCE LEVELS AND TWO SUMMER PEAK MONTHS

Marketable capacity is very sensitive to the assumed exceedance level and the timing of the annual peak load. This attachment will describe that sensitivity. In the Western Interconnection annual peak loads almost always occur in either July or August; in fact, the study described in Attachment K.7 shows the peak occurs in either July or August with nearly equal frequency.

The graphs on the left side of Figure 1 show the marketable capacity for the six major alternatives and long-term strategies at exceedance levels from 10% to 99% for the three hydropower resource components combined. Marketable capacity was also shown for three different times when the peak load was assumed to occur, namely, July, August, and July/August combined. All alternatives have less marketable capacity at all exceedance levels than the no action alternative, except for Long-Term Strategy B1, which is expected because it has the least restrictive environmental constraints of any alternative.

The graphs on the right of Figure 1 show the difference in marketable capacity compared to Alternative A, which is the the no action alternative. The graphs show that the greatest difference in capacity occurs at the 50% exceedance level and the smallest at the 99% exceedance level.

There is also a noticeable difference in marketable capacity for some alternatives compared to the no action alternative depending upon the month chosen. Long-Term Strategies C1 and E1 have a much smaller difference in marketable capacity compared to Alternative A in July than in August at all exceedance levels.

The choice of the peak month and exceedence level used for Glen Canyon Dam capacity availability is a policy choice by the Western Area Power Administration (WAPA) and is related to the degree of risk WAPA chooses to take when marketing long-term capacity. There have been variations in level of risk chosen by WAPA when marketing long-term capacity from various projects. For the Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS), an exceedance level of 90% and a peak month of August were selected. The exceedance level was chosen based on an analysis of the current post 2004 WAPA marketing plan that demonstrated that WAPA has sufficient SLCA/IP resources to meet its firm capacity obligations 90% of the time (67 FR 5113). Results were presented in Section K.1.10.4 for exceedance levels of 50% and 99%.

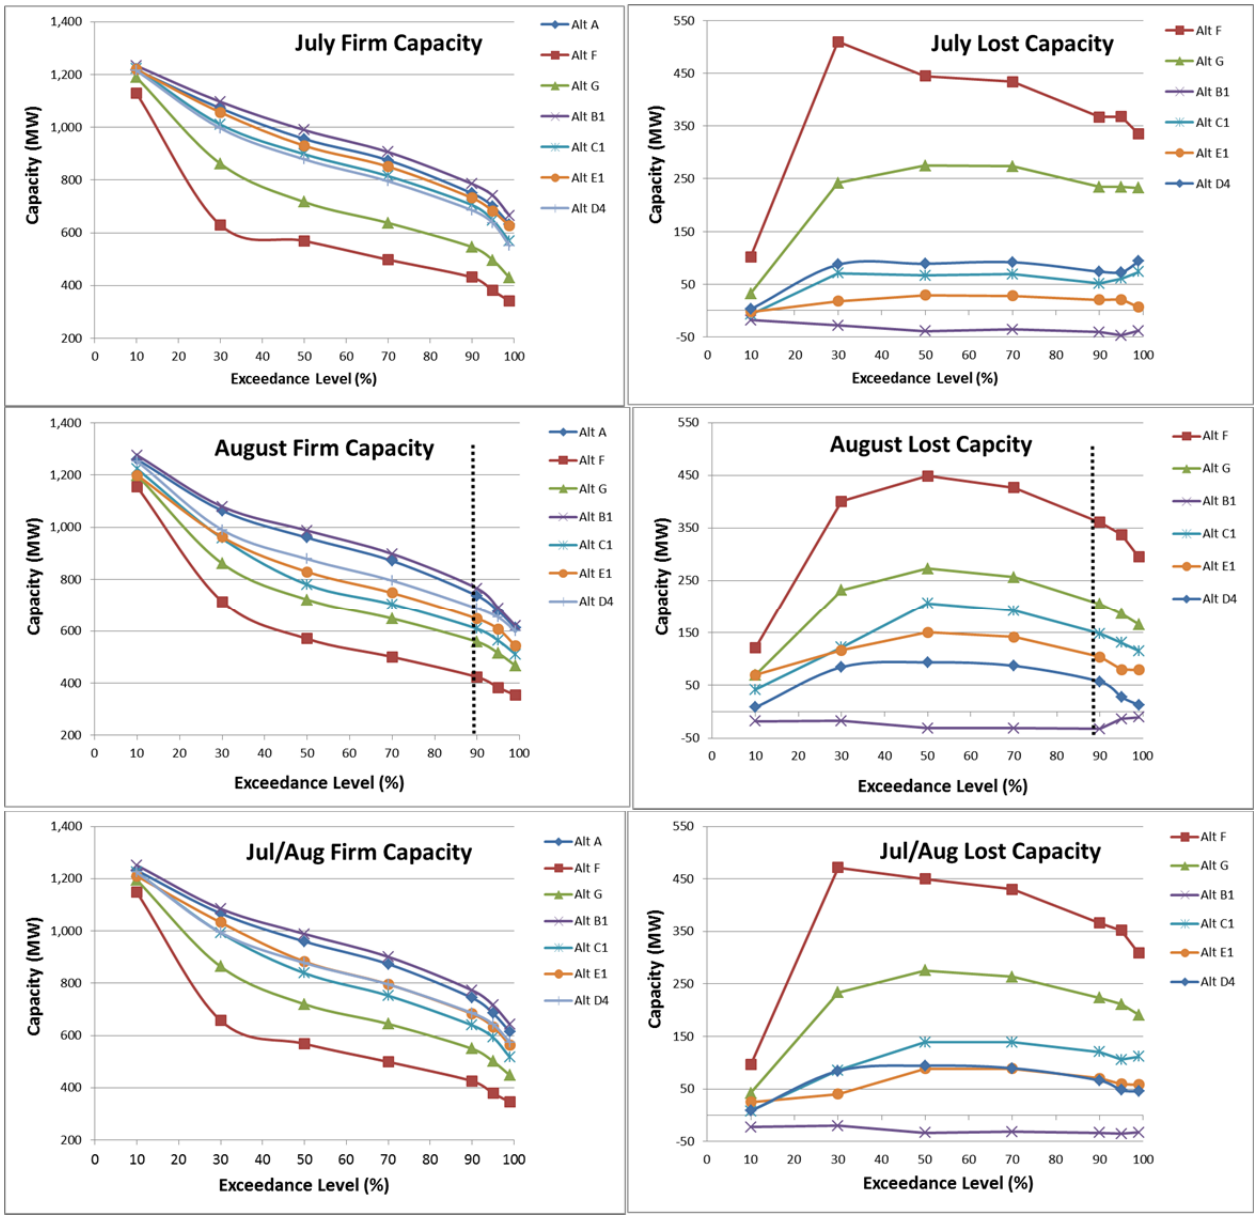

FIGURE 1 Comparison of SLCA/IP Federal Hydropower Firm and Lost Capacity Determinations across Alternatives, Exceedance Levels, and Summer Peak Months

ATTACHMENT K.9:

RESULTS OF A SURVEY OF ELECTRIC UTILITY INTEGRATED RESOURCE PLANS

An integrated resource plan (IRP) is a comprehensive decision support tool and roadmap for meeting an electric utility's objective of providing reliable and least-cost electric service to all of its customers. It is typically developed with considerable involvement from state agencies and regulators, customer and industry advocacy groups, project managers, and other stakeholders. Key elements of an IRP include determining the need for resources over a specific planning period, such as the next 10 to 20 years; the preferred portfolio of supply-side and demand-side resources to meet this need; and an action plan identifying the steps to implement the plan, such as the timing of bringing new resources online.

A survey of IRPs of Western Area Power Administration's (WAPA's) large customers that own generating facilities and large investor-owned utilities (IOUs) in the geographic and "electrical" area was conducted to determine the timing and type of resources these utilities were planning to reliably meet future electric demand. The results of this IRP survey could be compared to the results of the AURORA expansion model to see how well the AURORA prediction matched against the utility's best estimate. WAPA's customers surveyed included Platte River Power Authority (PRP), Colorado Springs Utilities (CSU), Tri-State Generation and Transmission Association (Tri-State), and Salt River Project (SRP).

Large IOUs surveyed included Public Service of Colorado (PSCO; now part of Xcel Energy), Public Service Company of New Mexico (PNM), Rocky Mountain Power (RMP; the eastern business unit of PacifiCorp or PACE), Arizona Public Service Company (AZPS), Tucson Electric Power Company (TEPC), Nevada Power Company (NEVP; the southern subsidiary of NV Energy), and Sierra Pacific Power Company (SPPC; the northern subsidiary of NV Energy). All IRPs were obtained from company websites and were all published between 2011 and 2014. These IOUs were chosen because they have contracts to supply generation to some of WAPA's customers and are also located in the same power pools in the AURORA model as WAPA's customers. Figure 1 shows the approximate service territories of these IOUs in the Western Interconnection.

If the timing and type of new generation predicted by our AURORA expansion model runs are similar to what is planned in the IRPs, then the limited scope in our model is a good surrogate for modeling the larger system.

Figure 2 shows the least-cost baseline expansion plan for PSCO in its most recent IRP, which was published in October 2011. The plan predicts that several combustion turbines will come online between 2018 and 2022 followed by a combined-cycle gas turbine in 2023. Expansion plans from the 2014 PNM IRP shown in Figure 3 forecasts a small 40-MW gas turbine in 2016 followed by a 177-MW gas turbine in 2018. Rocky Mountain Power's expansion plans from its 2013 IRP are shown in Figure 4. A 645-MW combined-cycle unit was just brought

online in 2014 as forecast by the IRP. RMP also plans to bring a combined-cycle combustion turbine and wind turbines online in 2024.

Figure 5 shows a future capacity addition plan from the APS IRP. The capacity it obtains from long-term contracts is steadily decreasing from over 2,800 MW in 2014 to less than 350 MW by 2029. ASP plans to bring over 1,000 MW of natural gas–fired generation online in 2019 followed by 2,000 MW more in 2024 and 1,000 MW in 2029. ASP also plans to rely more heavily on customer energy efficiency beginning in 2019. Additional generation from renewables will begin in 2019.

Figure 6 shows a future capacity addition plan from the TEP IRP. New natural gas generation of over 370 MW is planned for 2015 followed by another 640 MW in 2019. All short-term market resources will be phased out by 2019.

Figure 7 shows capacity addition plans from the NEVP IRP for four scenarios. To comply with a Nevada law phasing out certain coal-fired generation, a combination of new solar photovoltaic and natural gas-fired generation will be brought online between 2016 and 2021. To satisfy future demand, additional combined-cycle generation of 597 MW is planned to come online as early as 2020 and another 273 MW of capacity in 2022.

Figure 8 shows capacity addition plans from the SPP IRP for four scenarios. Depending upon the scenario, combustion turbines with a total capacity of from 273 MW to 536 MW are planned as early as 2022 and 2023. By 2025, an addition of over 570 MW of combined-cycle generation is planned followed by over 300 MW of combustion turbine capacity in 2029.

The IRPs of four of WAPA's large customers that own generation were also surveyed; namely, PRP, CSU, Tri-State, and SRP. The PRP IRP states that new peaking capacity may be needed as early as 2020 because that is when its reserve margin is forecast to drop below 15%. The CSU IRP shows capacity expansion plans for a number of future scenarios. Depending on the scenario, new renewables are expected to begin coming online beginning in 2017 to 2023. New combustion turbines of approximately 40 MW will start coming online from 2029 to 2031. The Tri-State IRP also examines numerous future scenarios. Depending on the scenario, new combined-cycle powerplants with a capacity of 588 MW will start coming online as early as 2019 to 2022; new renewable generation in multiples of 50 MW blocks will come online steadily from 2015 to 2029. Finally, SRP expects to bring new natural gas-fired peaking generation online between 2020 and 2022.

In conclusion, the survey of new capacity additions shown in IRPs for both WAPA's customers and large IOUs show that new capacity, both thermal and renewable generation, is scheduled to be brought online as early as 2017 to 2018. This means that there is very little excess capacity in the power pools in which WAPA's customers are located. Therefore, any capacity lost at Glen Canyon due to changes in operations from the Long-Term Experimental and Management Plan alternatives might cause new generation to be brought online earlier than the current IRPs indicate.

ATTACHMENT K.10:

INDICES USED FOR CONVERTING DOLLARS FROM ONE YEAR TO ANOTHER

The Argonne National Laboratory Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS) power systems team has data that are expressed in terms of various nominal dollars. However, it is important that model runs and analysis be performed on a consistent dollar year basis. The range of nominal dollars that was used ranges from 2010 dollars to 2013 dollars. In addition, the LTEMP EIS co-lead team has also decided that results presented to the public should be expressed in terms of 2015 dollars. For all power systems analyses, the gross national product (GNP) implicit price deflator (IPD) was used for converting nominal dollars from one year to another. Argonne staff used the Federal Reserve Economic Data (FRED) for the IPD with the series ID of the Gross Domestic Product: Implicit Price Deflator (GDPDEF) found on the St. Louis Federal Reserve Bank (Fed) website (http://research.stlouisfed.org/fred2/data/GDPDEF.txt).

The IPD is a good measure of the rate of price change in the economy as a whole. However, the last data point available from the St. Louis Fed is for October 2014. Therefore, the index was projected through January 2015. Based on a simple trend analysis using a third-order polynomial to fix the GNP price deflator over the January to October 2014 time period, the projected IPD was approximately 107.7 in January 2015 (January 2010 index = 100); that is a decline of about 0.3% from the October 2014 level. Figure 1 and Table 1 below show results of the trend analysis.

As shown in Figure 2, there is a similar, but somewhat more pronounced, decline when a trend analysis was conducted using monthly data for the seasonally adjusted (SA) consumer price index (CPI) for all U.S. cities/all items (series ID: CUSR0000SA0) (see http://download.bls.gov/pub/time.series/cu/cu.data.1.AllItems) and also for producer price index (PPI) data for total final demand (series ID: WPUFD4) from January 2014 through December 2015 (see http://www.bls.gov/news.release/ppi.nr0.htm). Both the CPI and PPI are about 1.0% lower in December 2014 relative to September 2014.

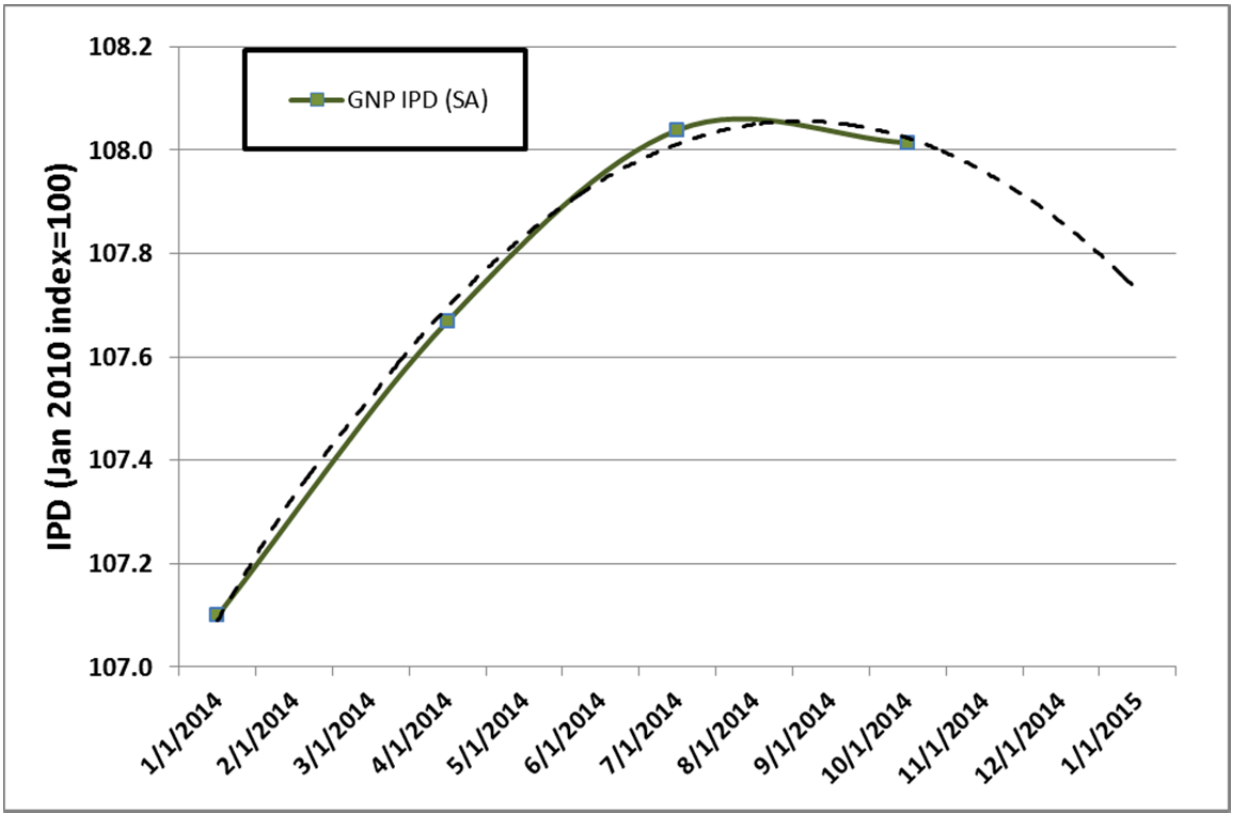

FIGURE 1 Results of Trend Analysis to Project Implicit Price Deflator (IPD) to January 2015 (SA = seasonally adjusted)

A downward trend in future producer prices through January 2015 is also in line with projections made by the Financial Forecast Center, which projects a 1% lower PPI for all commodities in January 2015 compared to December 2014 levels (see http://www.forecasts.org/ppi.htm).

The lower, but not as dramatic decrease in the IPD is further supported by Figure 3 below that shows both the CPI and PPI compared to the IPD. Both roughly follow the same trend in the January 2010 and October 2015 time period. However, the IPD tends to follow a smoother, less jagged track, implying that in general it may be somewhat less responsive to short-term economic drivers.

TABLE 1 Historical Quarterly Implicit Price Deflators and Projection for January 2015

Date	IPD
1/1/2010	100.0

APPENDIX L:

SOCIOECONOMIC TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX L:

SOCIOECONOMIC TECHNICAL INFORMATION AND ANALYSIS

The socioeconomic analysis of changes in Glen Canyon Dam operations conducted for the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS) included a number of parts:

- Analysis of changes in recreational activity in Lake Mead, Lake Powell, and the Colorado River in terms of recreation use values, non-use (passive use) values, and regional economic impacts; and

- Analysis of the regional economic impacts of changes in retail electricity prices resulting from changes in Western Area Power Administration (Western) wholesale electricity rates, and the analysis of the impacts of the construction and operation of additional Western customer utility generating capacity.

L.1 RECREATION ECONOMIC ANALYSES

L.1.1 Recreation Use Values

Estimation of use values associated with potential changes in recreational resources under each of the alternatives used benefits transfer methods; this involves applying existing use value data or estimates for a particular time period, site, level of resource quality, or combination thereof at an original or study site to a policy site for which data are not available. The benefits transfer method involves choosing study and policy sites with similar socioeconomic and environmental characteristics, similar recreational activities, and similar ranges of change in recreational quality.

Benefits transfer studies involve either the transfer of use values from a study site or the transfer of a statistical model used to estimate use values. The traditional benefits transfer approach to valuing recreation has been to employ existing use values from either travel cost or contingent valuation studies conducted at a study site, adjusting estimates to account for inflation by converting the original values to current dollars using the consumer price index (CPI) or some other price index, and applying them to analysis at the policy site. Given improvements in valuation techniques over time, however, the preferred approach is to employ statistical recreation models developed for a study site at a policy site. Proposed alternative-specific information about variables in the model can be gathered for the policy site. This information is used in conjunction with coefficients from the study site to estimate recreation visitation and/or value at the policy site, allowing the model transfer technique to improve the validity of the results compared to the use value transfer approach.

Benefits transfer methods present a reliable alternative to conducting original research when the analysis is not expected to be controversial, when time and budget constraints prevent the pursuit of original research, or when original research efforts have already been conducted at most of the geographic areas of interest. Because statistical models have been developed for estimating recreation value per trip for two of the three river reaches in the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) study area—Glen Canyon and Upper Grand Canyon—and models estimating recreation use have been developed for Lake Powell and Lake Mead, while other studies have estimated values per trip for recreation use of Lake Powell and Lake Mead, the benefits transfer methods provides a useful and reliable approach to estimating river use values and lake visitation. More information on the background literature, data, and assumptions in applying the benefits transfer method to the analysis undertaken for the EIS can be found in Reclamation (2014).

For the EIS, the net economic value of recreation was estimated for Lake Powell, Lake Mead, and three reaches of the Colorado River—Glen Canyon (from Glen Canyon Dam to Lees Ferry), Upper Grand Canyon (from Lees Ferry to Diamond Creek), and Lower Grand Canyon(from Diamond Creek to Lake Mead)—using two utility programs:

- The Lake_Full program was used to estimate recreation economic value for Lake Powell and Lake Mead.

- The GCRec_Full utility program was used to estimate the economic value for recreation on the Colorado River.

L.1.1.1 Lake_Full Utility Model

The Lake_Full utility model incorporates the recreation-use relationships for Lake Powell and Lake Mead described in Neher et al. (2013). The model operates on a monthly time step and was designed to use all years and all traces of monthly data supplied by the Colorado River Storage Simulation (CRSS) model. The utility uses the end-of-month (EOM) reservoir contents to predict recreation use at the specified reservoir. The user supplies a unit economic value per trip and the utility employs the predicted recreation use in a given month and the unit economic value to calculate the monthly economic value of recreation. This calculation is repeated for each month in the period of analysis and for each hydrologic trace or sequence. The major analytical modeling steps are shown in Figure L-1.

The user also supplies appropriate inflation, escalation, and discount rates for the intended analysis. The Lake_Full utility program employs these economic inputs to compute the present economic value of recreation for each hydrologic trace present in the dataset. The results of these computations are reported for each reservoir as summary metrics computed from the distribution of trace present economic values. Current versions of the utility model output the 5% exceedance, 10% exceedance, 25% exceedance, mean, median (50% exceedance), standard deviation, 75% exceedance, 90% exceedance, and 95% exceedance.

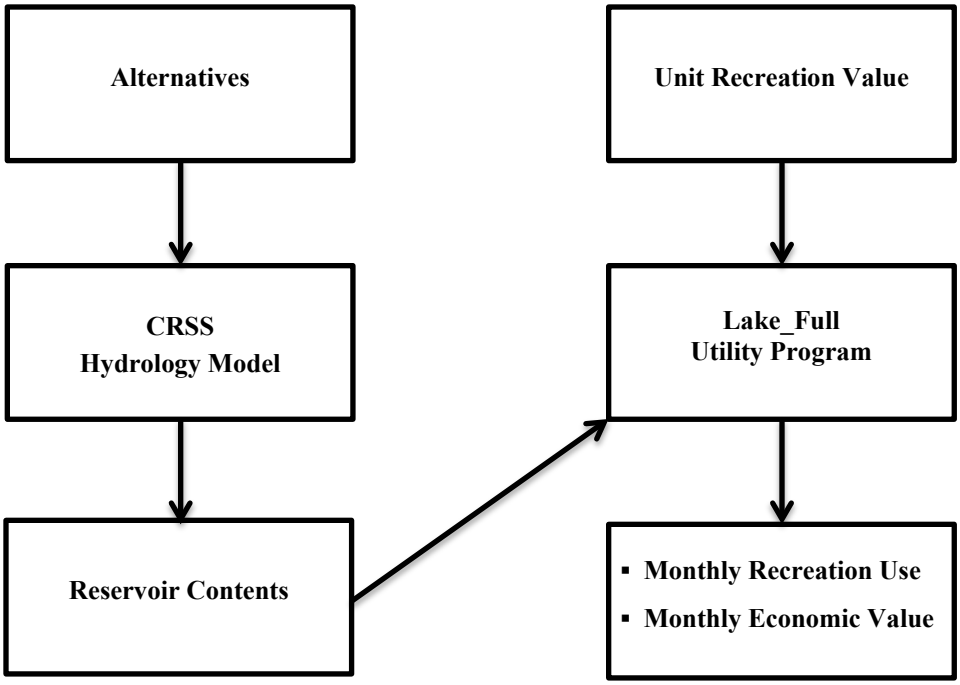

FIGURE L-1 Elements of the Lake_Full Utility Model

L.1.1.2 GCRec_Full Utility Model

The GCRec_Full utility model uses the recreation value relationships for Glen Canyon and Upper Grand Canyon estimated by Bishop et al. (1987). For purposes of this study, these relationships are extended to the Lower Grand Canyon. The model operates on a monthly time step and was designed to use all years and all traces of monthly data supplied by the CRSS model. The utility uses the mean monthly release from Glen Canyon Dam and the presence or absence of daily fluctuations exceeding 10,000 cfs per day during the month to predict the economic value of day-use rafting and angling in Glen Canyon and the economic value of commercial and private whitewater boating in the Upper Grand Canyon. The user also supplies the monthly recreation use, by activity. The utility employs the recreation use in a given month and the estimated economic value per trip to calculate the monthly net economic value of recreation for each activity. These calculations are repeated for each month in the period of analysis and for each hydrologic trace or sequence in the supplied dataset. The major analytical modeling steps are shown in Figure L-2.

The analyst also supplies appropriate inflation, escalation, and discount rates for the intended analysis. The GCRec_Full utility program employs these economic inputs for computing the present economic value of recreation for each hydrologic trace in the dataset. The results of these computations are aggregated and then reported as summary metrics computed from the distribution of trace present economic values. Current versions of the utility model output the 5% exceedance, 10% exceedance, 25% exceedance, mean, median (50% exceedance), standard deviation, 75% exceedance, 90% exceedance, and 95% exceedance levels.

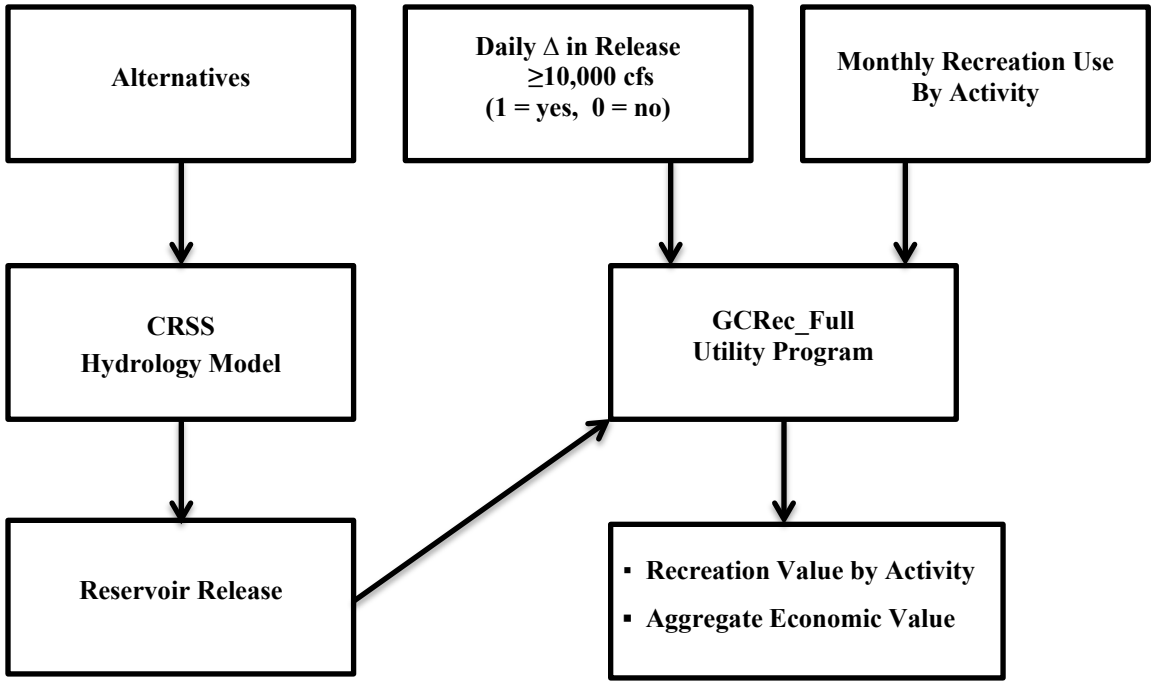

FIGURE L-2 Elements of the GCRec_Full Utility Model

More information on the background literature, data, assumptions, and output for these two models can be found in Reclamation (2014).

L.1.2 Recreation Non-Use Values

Non-use values are values that may be placed on the status of the natural or physical environment by non-users, or individuals who may never visit or otherwise use a natural resource that might still be affected by changes in its status or quality, and may assign a non-use or passive-use economic value to a resource. Although there are two approaches for measuring non-use values—revealed preference and stated preference methods—stated preference methods are typically used.

Stated preference valuation techniques include contingent valuation (CV), which is a means of eliciting the maximum dollar amount an individual would be willing to pay for a resource of a specified quantity and quality. CV methods use surveys to ascertain value by asking people about their willingness to pay (WTP) for a carefully specified change in environmental amenities. The dichotomous choice CV methodology is frequently employed in non-use valuation studies to estimate the net economic value for natural resource amenities. Respondents are presented with a hypothetical situation, including a price that they may be willing to pay for a change in an environmental condition, and they are then asked to respond to a dichotomous choice (yes or no) question. Using the data obtained from these surveys, the probability that an individual will respond "yes" is estimated using logistic regression analysis;

estimated regression coefficients are used to estimate the consumer surplus or net economic value associated with a particular resource.

Stated preference methods also include conjoint analysis, where respondents are presented with the characteristics or attributes of different hypothetical situations, and are then asked to either rank them or choose between them. Using the resultant survey data, the probability that an individual will rank or choose any particular scenario is then estimated, with data used to estimate households' total value for outcome changes associated with each alternative. There is a growing body of work that suggests that CV models and discrete choice methods can yield valid measures of willingness to pay (see, for example, Vossler and Evans [2009], and Vossler et al. [2012]).

Contingent valuation and conjoint methods have been applied widely in policy analysis, in particular in studies relating to measuring non-use values associated with river and lake resources associated with Grand Canyon National Park, Lake Mead National Recreation Area, and Glen Canyon National Recreation Area. Government agencies have also begun to use contingent valuation methods in benefit-cost analyses. The Bureau of Reclamation (Reclamation), for example, used contingent valuation to place a value on the impact of removing dams and restoring river habitat within the Klamath River Basin (RTI International 2012). The non-use values were used in a subsequent benefit-cost analysis (U.S. Department of the Interior 2012).

Contingent valuation surveys have been applied widely in the published economics literature to estimate passive-use values associated with preserving river and lake resources. Sanders et al. (1990), for example, estimated the total value of preserving 15 wild and scenic rivers in Colorado. They reported that Colorado residents expressed a use value of $19.15 and a non-use value of $81.96 per household per year. The total (use and non-use) value of protecting 15 Colorado rivers aggregated over these 12 million households was estimated at approximately $120 million annually, approximately four times the recreation use value. Welsh et al. (1995) estimated the willingness to pay to improve native vegetation, native fishes, game fish, river recreation, and cultural sites in Glen Canyon National Recreation Area and Grand Canyon National Park. Value estimates varied between $17.74 and $26.91 for a U.S. sample, and between $29.05 and $38.02 for a western U.S. sample.

Other studies indicate that the range of values per household or respondent can be large, producing larger ranges in aggregated values. For example, Duffield and Patterson (1991) estimated a willingness to pay $2.24 per licensed angler to maintain fisheries resources, based on a one-time cash donation, while Hanemann et al. (1991) estimated $181 per California household per year. Large ranges in value have also been found in lake studies, with values ranging from about $45 per household annually for the preservation value of Flathead Lake in Montana (Sutherland and Walsh 1985) to about $60 per year for an increment of lake elevation at Mono Lake, California (Loomis 1989). In a 2010 survey, the annual value (in 2011 dollars) of Klamath River Basin restoration after the removal of dams, water sharing agreements, and improved fish habitat was estimated at $122 for households in a 12-county area, $213 by households in the rest of Oregon and California, and $213 in the rest of the United States (RTI International 2012).

Understanding nonmarket values affected by proposed operational changes at Glen Canyon Dam (GCD), for both recreational use and environmental non-use values, has been the topic of a considerable number of prior investigations (e.g., Bishop et al. 1987; Welsh et al. 1995). These studies have been important in bringing nonmarket values into consideration for managing the resources of the Colorado River Basin (Harpman et al. 1995; Loomis et al. 2005). In that regard, two additional studies (Loomis 2014 and Jones et al. 2016) have been conducted regarding nonmarket values.

Loomis (2014) concluded that there is a theoretical basis for nonmarket values associated with hydropower and water. He used the example of how people can place value on maintaining the ranching and farming way of life associated with western rural communities as irrigated agriculture landscapes are correlated with open space. In addition, people may place value on the existence and well-being of farming communities. Indirect empirical support for altruism toward farmers is cited in this report. Nonmarket values associated with hydropower and water resources may also exist to the extent that hydropower and developed water assist in the maintenance of Native American Tribe cultural values and social well-being. Loomis (2014) concluded that research on this subject is limited and that additional research may be warranted.

The National Research Council (2005) has concluded that the results of studies using contingent valuation methods are of high quality; however, the results and findings of studies relating to the Colorado River Corridor are considerably outdated. Others have emphasized the need for additional or updated research on the sources and magnitudes of values associated with operational goals (see National Research Council 1999). To address these concerns, the National Park Service (NPS) has conducted a survey to determine non-use values associated withthe impacts of each of the six action alternatives on the endangered humpback chub, sandbars in the Grand Canyon, and populations of large trout in Glen Canyon. The survey used a discrete choice model to estimate household and aggregate willingness to pay for the six action alternatives based on data collected from two household samples, a national sample including all U.S. households, and a regional sample, consisting of all households receiving power from Western Area Power Administration, and including all utilities receiving power from the Glen Canyon Dam. The study involved a repeat contact mail-back survey method (Dillman 2007) in three phases.

The first phase was a survey of a subsample (n = 200) of the total sample population to pretest the survey instrument (24% response rate). These responses were used to conduct preliminary analysis on the data to determine whether the levels were adjusted up or down to create greater differences between the LTEMP alternatives. If more than 80% (n = 160) of individuals in the subsample selected the No Action Alternative, then the cost of the alternatives was adjusted downward. The results from this sample inform the choice of attribute levels in the final conjoint version of the survey mailed to the respondents in the second phase of the study. Once the attributes were evaluated and adjusted, the final mail survey was used to collect data. Two survey instruments, both of which use identical sampling methods, were used. All respondents received the same instructions and answered a series of common introductory questions to determine general socio-demographic background, visitation patterns, recreational preferences, values, and other information. Then 75% (n = 4,668) of individuals in the sample received Survey A with a section that included conjoint questions. The remaining 25%

(n = 1,500) received Survey B, which included contingent valuation questions. The local survey received an 18% reponse rate, the national survey, 12%. The final phase included a short nonresponse phone survey that was used to help test for any nonresponse bias. The results are presented in Neher et al. (2016) and include discussion of the survey, data collection, response rates, analysis of the results, and nonresponse corrections.

Respondents to the survey were given two discrete choice valuation questions relating to different impacts on the endangered humpback chub, sandbars, and large trout populations under each alternative. The effects of changes in hydropower operations were also included in the survey to incorparate a trade-off between improved resource conditions and their costs. In addition to the physical canyon attributes, respondents were asked to choose between current management at no cost and a changed outcome management plan that would cost between $12 and $280 per year per household over a 20-year period. The levels of the cost parameter and the management outcome attributes were varied among 12 versions of the survey to provide an efficient sampling design.

To estimate the parameters of the conjoint model, a standard conditional logit (CL) model was utilized, which used maximum-likelihood methods to estimate the attribute parameters. The parameter estimates from the CL model were then used to estimate the average marginal value of each noncost attribute.

A recently published study (Jones et al. 2016) offers an alternative Total Economic Value analysis to that presented by Neher et al. (2016). The Jones et al. analysis relied on the contingent valuation methodology, which is similar to the methodology used by Welsh et al. (1995) but different from the methodology used by Neher et al. The Neher et al. analysis relied on the choice experiment methodology, which incorporates recent methodological advances in nonmarket valuation. However, the Jones et al. analysis is also different from the Neher et al. analysis because it included two additional attributes: (1) impacts to Native American and rural western communities that depend on hydroelectric production, and (2) increases in air pollution by switching to nonrenewable fossil fuels in the power generation system. The Jones et al. study concludes that including these additional attributes will "significantly decrease WTP for changing Glen Canyon Dam operations, and demonstrate a significant fraction of the population with a positive WTP for maintaining dam operations."

The Jones et al. (2016) study was a pilot study that relied on an internet panel rather than a randomized mail survey; the Tribe and rural western community attributes did not identify specific causal relationships or quantified values to ensure consistent respondent interpretation, and potential air quality impacts associated with increased fossil fuel use may be overstated for the range of alternatives analyzed for LTEMP (see Sections 4.15 and 4.16). While this study created a new framework that provided a different way to evaluate some of the attributes that would not have been analyzed otherwise, the issues discussed above limit the application of this study to the LTEMP EIS.

L.1.3 Regional Recreation Economic Impacts

Economic impacts of changes in recreational activity are measured by changes in visitor expenditures associated with various types of recreational activities, including angling, rafting, and boating. Visitor expenditures in the river corridor may include spending on food and beverages, fishing and boating equipment, gasoline for vehicles and boats, camping fees or motel expenses, guide services, and fishing license fees. Economic impacts also include the secondary effects of changes in expenditures that may occur on income, employment, and tax revenues. The major analytical modeling steps are shown in Figure L-3.

Analysis of these effects was undertaken in the six-county region in which the majority of current Glen Canyon, Grand Canyon, and Colorado River recreational expenditures occur:

- Coconino County and Mohave County, Arizona; and
- Garfield County, Kane County, San Juan County, and Washington County, Utah.

The following data were used in the analysis:

- Changes in visitation rates, by alternative and river reach, from the analysis of changes in activity resulting from changes in lake and river water levels for a range of river and lake segments using the Net Economic Valuation (NEV) model (see Section L.1), and
- Typical per-capita expenditure data by type of activity, based on studies of typical visitor spending patterns reported in existing technical and academic literature.

Data from these sources are combined to produce changes in expenditure by activity type, by year, and by alternative.

Two types of effects result from changes in recreational expenditures: (1) direct effects are employment and income effects in sectors of the economy in which recreational expenditures occur, while (2) indirect effects are employment and income effects in sectors providing materials, equipment, and services to sectors in which recreational expenditures occur. Indirect effects occur when suppliers to local businesses increase or decrease their purchases of equipment, materials, and services from other businesses, and those businesses in turn change their level of purchases. For food and beverages, for example, indirect effects occur when local food manufacturers purchase additional produce from local farmers, and the farmers then purchase additional supplies in order to grow products necessary to meet this demand. Additional, induced effects result from wages paid to households by both directly and indirectly affected businesses.

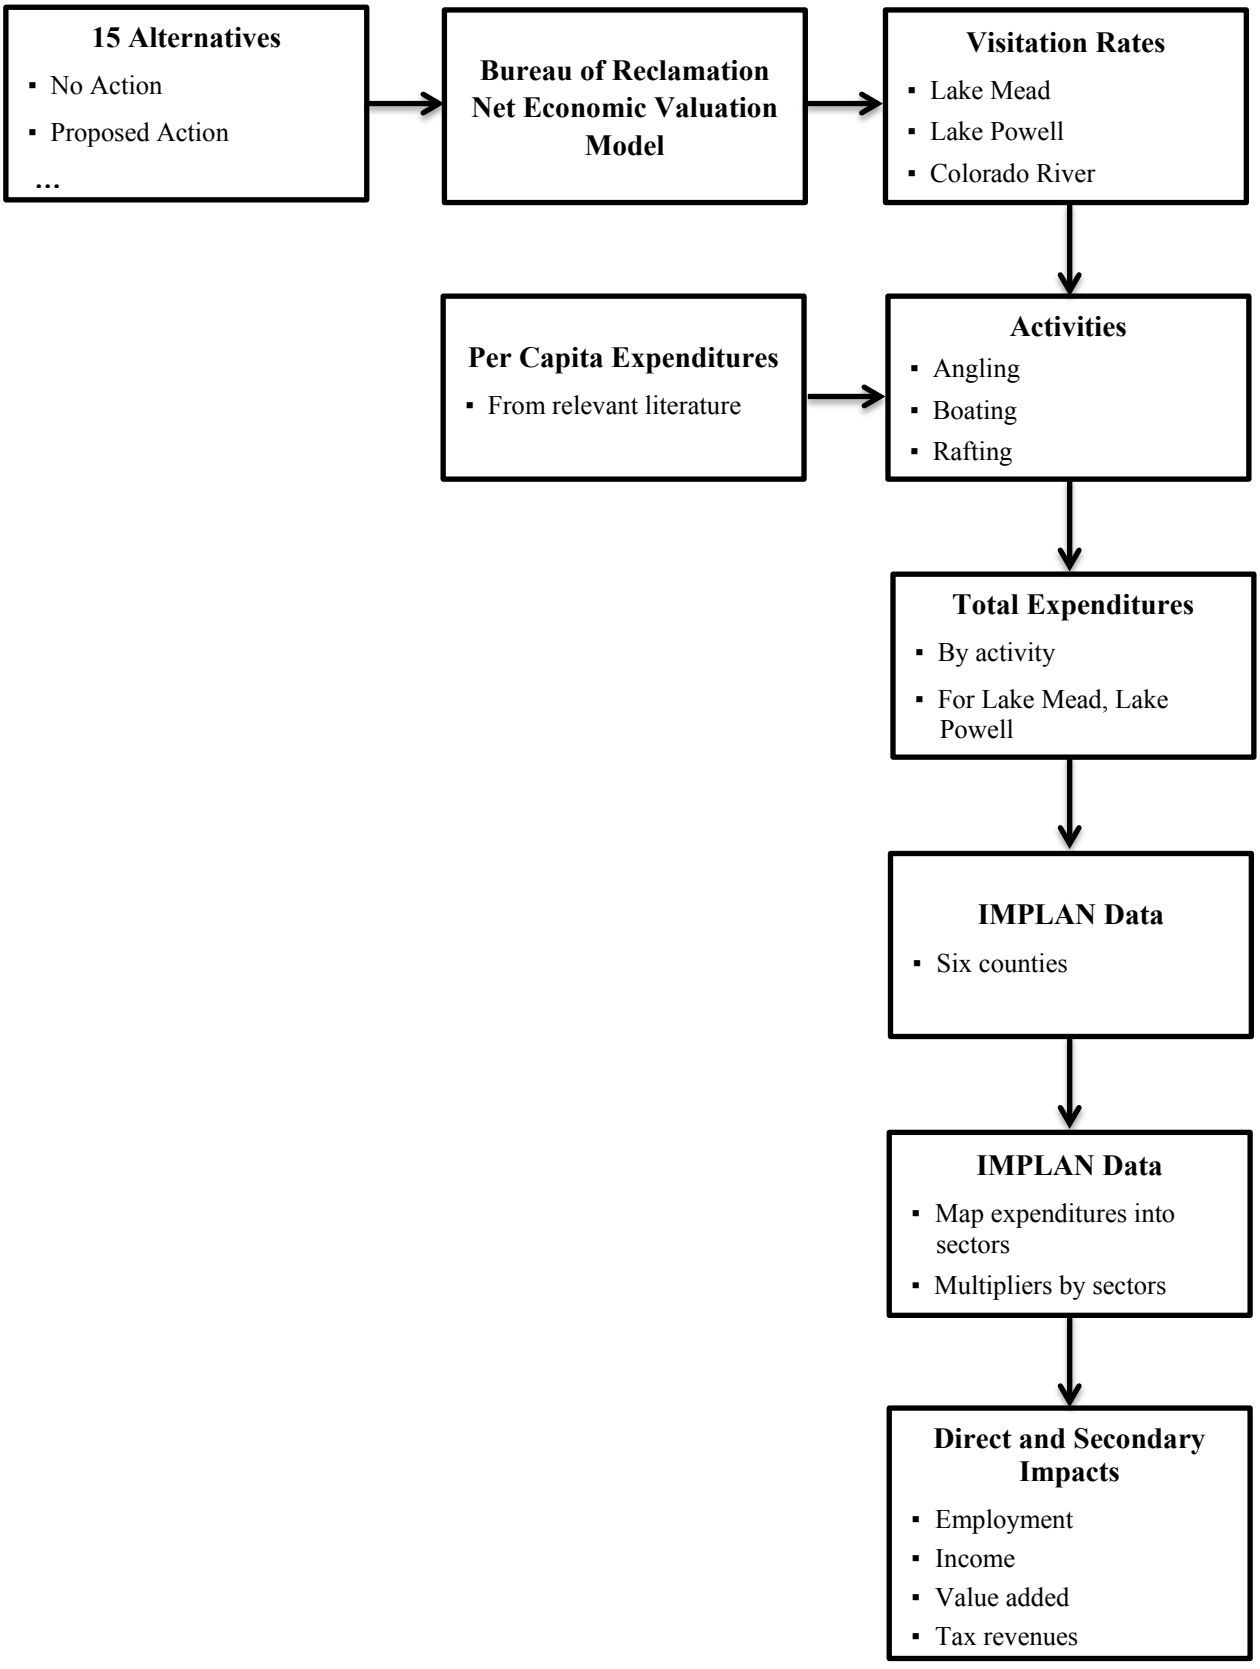

FIGURE L-3 Elements of the Regional Recreation Impacts Analysis

Input-output data and the associated multipliers can be readily used to determine the impact of changes in recreational expenditures through the estimation of multipliers for each sector in the multi-county region in which recreational expenditures occur. These multipliers typically give the total (direct plus indirect plus induced) benefits to the region in terms of employment, income, and taxes. Input-output data includes information for 440 separate North American Industry Classification System (NAICS) industries used by the U.S. Department of Commerce, Bureau of Economic Analysis. These accounts show the flow of commodities between industries and institutional consumers. Industries represented are those in agriculture, mining, construction, manufacturing, wholesale and retail trade, utilities, finance, insurance and real estate, and consumer and business services. Each industry is described in terms of its purchases from, and sales to, all other industries in the local economy.

Input-output accounts also provide information on value added by industry, and sales by industry, to final demand. Value added includes employee compensation (wages and salary payments, benefits, life insurance, retirement, etc.), proprietary income (payments received by self-employed individuals as income), other property-type income (payments received from royalties and dividends), and indirect business taxes (primarily excise and sales taxes paid by individuals to businesses). Final demands include personal consumption expenditures (payments by individuals/households to industries for goods and services used for personal consumption), federal government (military and nonmilitary) purchases and sales, state and local government (public education and non-education) purchases and sales, inventory purchases (unsold annual output), sales (where inventory reduction exceeds additions from production), capital formation (expenditures made to obtain capital equipment), and exports outside the region and nation.

Estimates of the regional economic impacts of changes in recreation expenditure came from the IMPLAN model, an "off-the-shelf" model produced by IMPLAN Group, LLC, that provides county-level and state-level input-output data. The model allows detailed analysis of the impacts of changes in recreation expenditures by mapping changes in expenditures by item (gas, food, lodging, etc.) into the appropriate sectors in the model, and then using IMPLAN multipliers to provide estimates of indirect effects and total effects, by alternative, activity type, and year in terms of employment (full-time equivalent staff, or ftes), income ($m), and the various components of value added ($m), including employment compensation, proprietor income, and tax revenues.

L.1.4 Estimates of Recreational Economic Impacts

Glen Canyon and Grand Canyon attract large numbers of visitors every year (see Section 3.10), and expenditures on gas, food and drink, lodging, guide services, and outdoor equipment are substantial. They produce direct income and employment both in sectors of the economy in which expenditures occur, and in the remainder of the economy; wages and salaries, and dollars spent on the purchases of goods and services, in these sectors circulate through the regional economy, producing indirect effects (effects in other industries) and induced effects (household effects). In 2011, spending by visitors to the Glen Canyon National Recreational Area, Grand Canyon National Park, and Lake Mead National Recreational Area produced 10,301 direct, indirect, and induced jobs and $373.7 million in total income (Table L-1).

TABLE L-1 Total Regional Economic Impacts (Direct, Indirect, and Induced) of Non-Local Recreation Expenditures, 2013

Parameter	Glen Canyon National Recreation Area	Grand Canyon National Park	Lake Mead National Recreation Area	Total
Employment	1,435	6,238	2,628	10,301
Income ($m 2013 dollars)	39.3	235.9	98.5	373.7

Source: Thomas et al. (2014).

As part of the overall impact of recreational visitation, various studies have attempted to estimate the regional economic impacts of specific recreational activities. Douglas and Harpman (1995) estimated that Glen Canyon and Grand Canyon recreational use in the region comprised of Coconino and Mojave Counties supported approximately 585 jobs. More recently, Hjerpe and Kim (2007) estimated that Grand Canyon boating recreation spending supported approximately 394 jobs in Coconino County, with commercial boating producing the majority (357) of the jobs created; Douglas (2005) found that whitewater boating in Grand Canyon National Park supported 438 jobs.

In addition to the economic impacts of recreational visitation in Glen Canyon and Grand Canyon, recreation in the region also provides employment and income for Navajo tradespeople selling jewelry and souvenirs to the traveling public along various routes in the region; jewelry production and sales provides 400 to 700 jobs (Reclamation 2011). Jobs held by the Navajo people are especially important because wage earners usually support extended families.

L.2 REGIONAL ELECTRICITY ANALYSES

L.2.1 Regional Electricity Price Impacts

The analysis of increases in electricity rates considered (1) changes in customer utility electricity prices resulting from changes in Glen Canyon Dam operations; and (2) impacts of constructing and operating additional power plants with customer utility capacity expansion plans to replace energy and capacity previously provided by Western

Analyses were conducted in the seven-state region in which Western markets CRSP power: Arizona, Colorado, Nebraska, Nevada, New Mexico, Utah, and Wyoming. This includes the service territories of the eight major Western customer utilities:

- Colorado Springs Utilities,
- Deseret Generation and Transmission Cooperative,

- Navajo Tribal Utility Authority,
- Platte River Power Authority,
- Salt River Project,
- Tri-State Generation and Transmission,
- Utah Municipal Power Agency, and
- Utah Associated Municipal Power Systems.

Separate analyses considered the following:

- The effects changes in Glen Canyon operations and changes in power marketing by the Colorado River Storage Project (CRSP) would have on wholesale electricity rates charged to customer utilities, by state and customer utility, from the GTMax/GTMax Lite models (see Appendix H); and
- The impacts changes in Glen Canyon and CRSP electricity rates would have on commercial, industrial, and residential electricity rates charged by the eight largest Western customer utilities, by state and customer utility, from the ratepayer analysis (see Appendix K).

Data used to analyze the regional economic impact of increases in electricity prices consisted of the following:

- Current and forecasted electricity prices, by state, from Energy Information Administration (EIA) data and other sources; and
- Estimates of the response in customer demand to changes in electricity prices (elasticities) for each customer class—commercial, industrial, and residential—taken from the technical and academic literature.

IMPLAN input-output models (see Section L.1), were used to estimate the regional economic impacts of changes in electricity prices, with a separate IMPLAN model representing each of the seven states in the Western marketing area. The analysis involved a number of steps:

- Aggregation of sectors in each state input-output models into the three customer classes: commercial, industrial, and residential;
- Calculation of electricity expenditure shares for each customer class; and
- Calculation of IMPLAN multipliers for each customer class.

These data, combined with changes in prices and price elasticities, give the total (direct plus indirect plus induced) impact of changes in aggregate electricity prices on the economy of each state, by alternative, state, and year, in terms of employment (ftes), income ($m), and the various components of value added ($m), including employment compensation, proprietor income, and tax revenues. The major analytical modeling steps are shown in Figure L-4.

L.2.2 Regional Electricity Generating Capacity Expansion Impacts

Analysis of the effects changes in Glen Canyon operations would have on electricity rates and capacity expansion required data on capital and operating expenditures, by alternative, including the following:

- Capacity expansion requirements, by state and customer utility, from the GTMax/GTMax Lite models (see Appendix K); and

- Expenditures on materials, equipment, services, direct and indirect labor, by year, from appropriate projects (similar in terms of fuel type, technology, size, and location), from the Jobs and Economic Development Impact (JEDI) model (NREL 2015).

Capacity expansion capital and operating expenditures were mapped into the appropriate sectors in an IMPLAN input-output model for each state, which were then used to estimate the appropriate multipliers to provide estimates of indirect effects and total effects, by alternative and year, in terms of employment (ftes), income ($m), and the various components of value added ($m), including employment compensation, proprietor income, and tax revenues. The major analytical modeling steps are shown in Figure L-5.

L.3 ADDITIONAL SOCIOECONOMIC DATA

Table L-2 contains data pertaining to population, median household income, and poverty in each community in the six-county affected environment forming the basis of the regional recreational economy.

L.3.1 Urban Population in the Six-County Region

Within the six counties in 2010, there were 86 places identified by the U.S. Census Bureau in the region of influence (ROI), including incorporated cities and Census Designated Places CDPs (unincorporated areas). The population of the ROI in 2010 was 83% urban; the largest town, St. George, Utah, had a 2010 population of 72,897; other places in the ROI with more than 10,000 inhabitants include Flagstaff (65,870), Lake Havasu City (52,527), Bullhead City (39,540), Kingman (28,068), New Kingman-Butler (12,134), and Sedona (10,031), all of which are in Arizona. There were 27 smaller towns in the ROI with 2010 populations of between 1,000 and 10,000, and an additional 50 places with populations of less than 1,000.

[a] NA = data not available.

Source: U.S. Census Bureau (2013).

Urban population in the ROI grew at an average annual rate of 2.9% over the period from 2000 to 2010, although growth rates within the ROI varied considerably. Winslow West, Arizona, grew at an average annual rate of 12.8%; Spanish Valley, Utah, at 10.5%; and Arizona Village, Arizona, at 10.4% during this period, with higher than average growth also experienced in Washington, Utah (8.6%); Mesquite Creek, Arizona (7.3%); Mojave Ranch Estates, Arizona (6.4%); Golden Valley, Arizona (6.4%); Peach Springs, Arizona (6.2%); and Willow Valley, Arizona (6.1%). The remaining places experienced lower growth rates between 2000 and 2010, with 29 places experiencing negative growth rates during this period. Rural population in the ROI grew at an annual average rate of 7.5% between 2000 and 2010.

L.3.2 Urban Income in the Six-County Region

Median household incomes in 2010 varied considerably across places in the ROI. Ten places in the Arizona portion of the ROI had median incomes that were higher than the average for the state ($50,991); these included Doney Park ($79,457), Mountainaire ($67,333), Parks ($66,850), LeChee ($59,912), Munds Park ($59,620), Mohave Valley ($57,353), and Moenkopi ($56,229). Twenty-eight places in the Arizona portion of the ROI had median incomes lower than the state average, and two places, Cameron ($23,916) and Tonalea ($15,357), had incomes that were less than half that of the state average. In 21 places, more than 20% of individuals were living in poverty, with poverty particularly marked in four communities, Supai (48.0% of individuals), Tonalea (46.5%), Cameron (46.1%), and Winslow West (45.9%).

Nine places in in the Utah portion of the ROI had median incomes higher than the state average ($59,014) in 2010; these included Tselakai Dezza ($144,726), Enterprise ($104,585), Pine Valley ($81,015), Spanish Valley ($74,055), and Santa Clara ($73,078). Thirty-six places had median incomes lower than the state average, and three places, Aneth ($22,435), White Mesa ($21,100), and Halchita ($12,383), had incomes that were less than half the state average.

In 11 places, more than 20% of individuals were living in poverty, with higher poverty levels in four communities, Aneth (54.2% of individuals), Hildale (50.3%), Halchita (47.1%), and Oljato-Monument Valley (40.6%).

Median income growth rates within the ROI varied considerably over the period from 2000 to 2010. In the Arizona portion of the ROI, 39 places had annual average growth rates higher than the state rate (–0.7%), with high growth rates in Winslow West (12.1%) and Peach Springs (6.4%) during this period. The remaining places experienced lower growth rates between 2000 and 2010, with 15 places experiencing negative growth rates. In the Utah portion of the ROI, 24 places had annual average growth rates higher than the state rate (–0.6%), including Navajo Mountain (9.2%), Tselakai-Dezza (8.5%), and Enterprise (8.0%). The remaining places experienced lower growth rates between 2000 and 2010, with 16 places experiencing negative growth rates.

AIR QUALITY AND CLIMATE CHANGE TECHNICAL INFORMATION AND ANALYSIS

This page intentionally left blank

APPENDIX M:

AIR QUALITY AND CLIMATE CHANGE TECHNICAL INFORMATION AND ANALYSIS

This appendix provides a description of the analysis used to evaluate the impacts on air quality and climate change of the alternatives considered in the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS). Glen Canyon Dam hydropower generation does not generate air emissions. However, dam operations can affect air emissions and ambient air quality over the 11-state Western Interconnection, comprising Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming, because hydropower generation offsets generation from other non-hydropower-generating facilities in the Salt Lake City Area Integrated Project (SLCA/IP) and in the Western Interconnection. Differences among alternatives in the amount of Glen Canyon Dam generation at peak demand hours could affect regional air emissions, through differences in the technology mix of compensating generating facilities within SLCA/IP and, if SLCA/IP generation is insufficient to meet the Western Area Power Administration's (WAPA's) long-term firm contract obligations, through generation from combustion sources in the greater Western Interconnection.

Air quality issues within the 11-state Western Interconnection area include visibility degradation in Federal Class I areas. Coal, natural gas, and oil units emit sulfur dioxide (SO_2) and nitrogen oxides (NO_x), which are precursors to sulfate and nitrate aerosols, respectively. These aerosols play an important role in visibility degradation by contributing to haze. Among anthropogenic sources, sulfate is a primary contributor to regional haze in the Grand Canyon, and nitrate is a minor contributor. Effects on visibility are analyzed through a comparison of regional SO_2 and NO_x emissions under the various alternatives.

Differences among alternatives in the amount and timing of Glen Canyon Dam generation directly affect the generation needed from coal, natural gas, or oil units within the 11-state Western Interconnection region, of which the SLCA/IP system is a part, from the wholesale power market. As described in Section M.2, changes in generation from facilities within this interconnected system under various LTEMP alternatives result in small changes in total emissions because of similarly small differences in emissions from the contributing facilities.

Effects on visibility were analyzed through a comparison of SO_2 and NO_x emissions under the various alternatives. SO_2 and NO_x are also criteria air pollutants with limits on ambient concentrations under the National Ambient Air Quality Standards (NAAQS). Alternatives were compared on the basis of total emissions of these two pollutants from the contributing generation facilities in the interconnected system.

Electricity generation of combustion facilities in the system produces carbon dioxide (CO_2) and other greenhouse gases (GHGs). LTEMP alternatives can affect GHG emissions through changes in Glen Canyon Dam operations and related changes in GHG emissions of

interconnected combustion facilities, as for SO_2 and NO_x. For the purpose of this analysis, the principal GHG of concern is CO_2, which accounts for over 99% of GHG emissions related to power generation. However, facility- or technology-specific GHG emission factors also consider other GHGs, such as methane (CH_4) and nitrous oxide (N_2O), which may be emitted during facility operations.

M.1 ANALYSIS METHODS

To compute total air emissions under the LTEMP alternatives, emissions were summed from all generating facilities in the SLCA/IP system. This analysis was tiered off the power systems analysis (Section 4.13 of the EIS and Appendix K), which estimated electrical power generation for the same facilities under each alternative, including base operations and experimental flows, such as high-flow experiments (HFEs) and trout management flows (TMFs). Emissions were estimated using emission factor and corresponding generation level along with emission control efficiency for facilities equipped with a control system. Emission factors (either lb/MWh for power output or lb/MMBtu for heat input) were taken from standard references (EIA 2013; EPA 2014). Generation levels (either MWh/yr or MMBtu/yr) were the estimated electricity generation of each facility and the electricity traded on the spot market under each alternative by calendar year, which were obtained from the AURORA model outputs described in Appendix K. Emissions were then estimated by multiplying emission factors by electrical power generation. Emission controls were reflected in the emission factors used. Table M-1 presents emission factors used for SO_2, NO_x, and GHGs by plant for individual plants in the SLCA/IP system and the spot market. Table M-2 presents annual-average power generation for the same plants and for the spot market.

M.1.1 System Power Generation

Table M-1 presents emission factors by power generation type for (1) specific existing powerplants, (2) specific generating stations with multiple generating units under long-term contract, (3) power generation under long-term contract where no generating units are specified, and (4) future plants needed to provide additional capacity employing advanced gas technologies. For specific powerplants in the SLCA/IP system, pollutant emission factors (in lb/MWh) available in the *Emissions and Generation Resource Integrated Database* (eGRID)[1] with year 2010 data (EPA 2014) were used to estimate air emissions (Table M-1).

For advanced natural-gas-fired simple-cycle and combined-cycle generating units to be built in the future, emission factors for advanced combustion turbine (ACT) and advanced generation natural gas combined cycle (AG-NGCC) in EIA (2013) were used with the following

[1] eGRID is a comprehensive inventory of environmental attributes of electric power systems. The preeminent source of air emissions data for the electric power sector, eGRID is based on available plant-specific data for all U.S. electricity-generating plants that provide power to the electric grid and report data to the U.S. Government. eGRID plant-level emissions reflect monitored data, estimated data, or a combination of both.

values: 0.001 lb/MMBtu for SO_2 for both simple cycle (0.0098 lb/MWh) and combined cycle (0.0064 lb/MWh); 0.03 lb/MMBtu (0.29 lb/MWh) for simple cycle and 0.0075 lb/MMBtu (0.048 lb/MWh) for NO_x for combined cycle; and 117 lb/MMBtu for CO_2 for both simple cycle (1,141 lb/MWh) and combined cycle (752 lb/MWh).

Because emission factors for future plants and plants under long-term contract (Coolidge and Fort Lupton generating stations) are based on emissions per heat energy input (lb/MMBtu), conversion to lb/MWh is needed to produce the values shown in Table M-1 for these entities. Conversion factors were taken from the AURORA model outputs described in Appendix K and had the following values (in units of MWh/MMBtu): 6.43 for advanced combined cycle; 9.75 for advanced simple cycle; 9 for Coolidge; and 9.19 for Fort Lupton. For Brush 2 under long-term contract, emission factors in the eGrid database were used.

The Coolidge Generating Station under long-term contract has 12 simple-cycle natural-gas-fired peaking units with a total capacity of 575 MW, and began service in 2011. For this station, emission factors in lb/MMBtu for a conventional combustion turbine (CT) are assumed, which are the same as those for ACT (EIA 2013). The Fort Lupton Cogeneration Powerplant is a 272-MW combined-cycle natural-gas-fired station. For this station, emission factors in lb/MMBtu for conventional NGCC are assumed, which are the same as those for AG-NGCC (EIA 2013).

For unspecified powerplants under long-term contract, composite emission factors were employed that are representative of all types of powerplants (such as fossil-fuel-fired, hydroelectric, nuclear, and renewable resources) currently in operation over the 11-state Western Interconnection region. Composite emission factors were estimated to be 0.74, 1.07, and 963 lb/MWh for SO_2, NO_x, and GHGs in units of CO_2 equivalents (CO_2e),[2] respectively. Note that three plants (Kyrene, Rawhide, and Ray D. Nixon) have more than one type of generation, but only one plant-wide composite emission factor for each pollutant is given in the EPA's eGRID database (EPA 2014). The available emission factors were applied to all generation at these three plants.

M.1.2 Spot Market

For spot market purchases and sales, composite emission factors in Table M-1 that were used are representative of power generation from gas powerplants currently in operation over the Western Interconnection, based on the assumption that spot market generation is primarily to serve peak loads. Composite emission factors were estimated to be 0.0083, 0.266, and 888 lb/MWh for SO_2, NO_x, and GHGs, respectively (EIA 2013).

---

2 Emission factors for GHGs are expressed in CO_2e for the long-term contract (unspecified generation type) and power stations available in the EPA eGrid database. CO_2e is a measure used to compare the emissions from various GHGs on the basis of their global warming potential, defined as the ratio of heat trapped by one unit mass of the GHG to that of one unit mass of CO_2 over a specific time period (usually 100 years).

M.1.3 Generation Type

Tables M-1and M-2 group plants and other generation entities according to the type of generation technology used. Such grouping is for the purpose of understanding the differences in emissions under various LTEMP alternatives because of differences in generation from contributing generation technologies. Different operating regimes of Glen Canyon Dam under the various LTEMP alternatives supply different proportions of baseload or peaking power. Peaking power produced at the dam is assumed to displace power that would otherwise be produced by plants using gas turbine technologies, while baseload power produced at the dam is assumed to displace power produced by plants employing steam turbine technologies, most typically coal-fired plants. Gas- and coal-fired technologies have distinctly different emission profiles and levels. Gas-fired plants emit far less SO_2 and NO_x than coal-fired plants per unit of energy produced. Different mixes of these two types of technologies under various alternatives are related to the total levels of emissions. The technology groupings shown in Tables M-1 and M-2 are used below in the reporting and interpretation of results.

M.2 RESULTS

M.2.1 SO_2 and NO_x

The potential effects on visibility from emissions of SO_2 and NO_x, which are precursors of sulfate and nitrate aerosols, respectively, and which contribute to haze, are shown in Table M-3 for LTEMP alternatives. The geographic area of potential visibility impacts corresponds to the location of contributing powerplants in the SLCA/IP system and, to a small degree, the 11-state Western Interconnection and includes Grand Canyon National Park. Because the sources are geographically dispersed, effects would be similarly dispersed and low at any particular location. Further, because of very small differences in SO_2 and NO_x precursor emissions, negligible differences are expected among the alternatives with regard to visibility and haze in the region.

Emissions of SO_2 and NO_x under various LTEMP alternatives are compared with respect to air quality effects under NAAQS. Tables M-4 and M-5 show emissions of SO_2 and NO_x, respectively, under each LTEMP alternative, from contributing plants (35 primary facilities) and other contributing entities in the SLC/IP system, and present subtotals of emissions by generation technology type. These tables also show contributions from the spot market computed according to the level of electrical power generated at each plant and entity, using the emission factors in Table M-1.

Table M-6 presents a summary of total system emissions by type of generation technology drawn from Tables M-4 and M-5 for the generation facilities within the SCLA/IP system and from contributions from the spot market. The 35 generating facilities within the SLCA/IP system are categorized according to generation technology type, such as gas turbine or steam turbine (usually coal-fired), so that contributing emissions can be summed by technology type across the system to evaluate emissions from different technology mixes under alternatives.

With respect to the spot market entries in these tables, "sales" refers to sales of power by system utilities to non-system utilities within the Western Interconnection. Sales result in a net credit to total Western Interconnection emissions, because the sales result in a reduction in emissions from those non-system utilities that are purchasing the power. "Purchases" refers to purchases by SLCA/IP system utilities from other utilities within the Western Interconnection. Emissions related to these purchases are added to the total emissions in the Western Interconnection.

Total SO_2 and NO_x emissions in the system averaged over the 20-year LTEMP period under Alternative A are estimated to be about 42,465 tons/yr and 78,496 tons/yr, respectively, while emissions under other LTEMP alternatives are similar to those under Alternative A. Differences in emissions of SO_2 and NO_x under LTEMP alternatives relative to those under Alternative A are very small, at most −0.04%, and correspond to average annual emission differences that range from −18 to 5 tons/yr for SO_2 and from −10 to 6 tons/yr for NO_x, compared to those under Alternative A.

With respect to type of generation technology, SO_2 and NO_x emissions within the SLCA/IP system are dominated by steam turbine technologies, mainly coal-fired powerplants. Estimated differences among alternatives reflect slight differences in the contributions from various powerplant technologies; these are attributed to small differences in baseload and peaking energy generated by Glen Canyon Dam. As noted above, gas turbine peaking plant technologies produce lower SO_2 and lower NO_x emissions than baseload coal-fired plants. Thus, offsetting gas turbine peaking power with hydropower from Glen Canyon Dam has a potentially lower effect on total system emissions than offsetting coal-fired baseload with baseload energy from Glen Canyon Dam.

Table M-6 shows levels of electricity generation at Glen Canyon Dam in MWh/day that would be produced under each LTEMP alternative. Differences in generation at the dam affect the amount of power needed by other contributing generators in the system. Little difference exists in generation at the dam among alternatives, which ranges from 11,438 MWh/day to 11,650 MWh/day. Alternative A produces the most energy, while Alternatives F and G produce roughly 2% less hydropower energy than Alternative A (98.3% and 98.2%, respectively). This reduction in generation is a consequence of the more frequent HFEs under these alternatives, in which a portion of flows bypass the powerplant turbines.

Despite the facts that the steady-flow Alternatives F and G generate less power at Glen Canyon Dam than the fluctuating-flow Alternatives A–E and that this lost generation must be made up by additional generation at other facilities in the system, Alternatives F and G have the lowest total emissions of all alternatives. This result may be explained by the operational regime of the dam under these alternatives with respect to baseload or peaking power. Under steady-flow Alternatives F and G, the dam produces baseload power, which would displace baseload power from other facilities in the system, mainly coal-fired (steam turbine) facilities with relatively high emissions, while under fluctuating-flow Alternatives A–E, the dam produces a portion of peaking power, which offsets gas-fired peaking plants in the system, with relatively low emissions. A more detailed discussion of this interpretation of results is given in Section 4.14.2 of the EIS.

M.2.2 GHG Emissions

Table M-7 presents emissions in CO_2e for contributing plants (approximately 35 primary facilities) and other contributing entities in the SLC/IP system described above under each LTEMP alternative and presents subtotals of emissions by generation technology type and for contributions from the spot market. The spot market reflects the effects of Glen Canyon Dam operations on the larger Western Interconnection region and represents an offset of about 1% of system emissions. Emissions are computed from the level of electrical power generated at each plant and entity under each alternative using the emission factors in Table M-1.

Table M-8 summarizes emissions in Table M-7 by type of technology and presents total emissions under the LTEMP alternatives. Total CO_2e emissions in the system averaged over the 20-year LTEMP period under Alternative A are estimated to be 55,177,668 MT/yr (60,822,967 tons/yr), while emissions under other LTEMP alternatives are similar to those under Alternative A. Differences in emissions of CO_2e from Alternative A are very small, ranging from an increase of 0.011% (Alternative B) to 0.081% (Alternative F), and correspond to average emission increases ranging from 5,900 MT/yr (6,503 tons/yr) (Alternative B) to 44,522 MT/yr (49,077 tons/yr) (Alternative F), considering total emissions (system generation plus spot market sales and purchases) compared to those under Alternative A. Alternatives C, D, E, and G would have intermediate increases in CO_2e emissions of 18,161, 22,908, 16,503, and 40,960 MT/yr (0.033%, 0.042%, 0.030%, and 0.074%), respectively, compared to Alternative A.

With respect to type of generation technology, CO_2e emissions are dominated (about 87%) by steam turbine technologies within the system, mainly coal-fired powerplants, as is the case for SO_2 and NO_x (about 98%). Estimated differences among alternatives reflect slight differences in the contributions from various powerplant technologies providing baseload and peaking energy in conjunction with Glen Canyon Dam, as discussed above for SO_2 and NO_x. Since gas turbine peaking plant technologies produce about half the CO_2e emissions as baseload coal-fired plants per unit of energy produced (Table M-1), offsetting gas turbine peaking power with hydropower from Glen Canyon Dam has a potentially lower effect on total system emissions than offsetting coal-fired baseload with baseload energy from Glen Canyon Dam.

As shown in Table M-8, total CO_2e emissions are expected to be slightly higher for steady-flow Alternatives F and G than for the fluctuating-flow alternatives A–E. These increases in total emissions result mainly from relatively higher gas turbine emissions under Alternatives F and G. Higher gas turbine emissions are, in turn, attributable to the lack of peaking power from Glen Canyon Dam under the steady-flow alternatives, which require compensating peaking power from gas turbine peaking plants within the system. As for SO_2 and NO_x, Alternatives F and G have lower CO_2e emissions from steam turbine technologies than Alternative A and other fluctuating-flow alternatives, reflecting relatively greater offsets of baseload coal-fired plants from the steady-flow alternatives. However, total CO_2e emissions are greatest overall for Alternatives F and G because of a more-than-compensating increase in the gas turbine contribution under these alternatives. Alternatives F and G rank highest for CO_2e, but lowest for SO_2 and low for NO_x. This reversal in rank is due to smaller differences in emission factors between gas turbine and stream turbine technologies for CO_2e than for SO_2 and NO_x. CO_2e emission factors are lower for gas turbine technologies by roughly a factor of 2, while SO_2 is

lower by almost 2 orders of magnitude, and NO_x is lower by roughly a factor of 5 for gas turbines than for (coal-fired) steam turbines, as reflected in emission factors shown in Table M-1.

As shown in Table M-8, total system CO_2e emissions are a small fraction of total U.S. GHG emissions, totaling about 0.81% for all LTEMP alternatives.

TABLE M-1 (Cont.)

Generation Type	Plant Name	EIA Plant No.	Emission Factor (lb/MWh)		
			SO_2	NO_x	CO_2e[a]
Spot Market					
	Sales and purchases[f,g]	-	0.0083	0.266	888

[a] GHG emissions are expressed in CO_2e, except for advanced combined cycle, advanced simple cycle, and long-term contract emissions (Coolidge and Fort Lupton), which are expressed as CO_2 and shaded for clarity.

[b] Emission factors were originally given in lb/MMBtu but were converted into lb/MWh using conversion factors (MMBtu/MWh) from the AURORA model outputs described in Appendix K: 6.43 for advanced combined cycle; 9.75 for advanced simple cycle; 9 for Coolidge; and 9.19 for Fort Lupton.

[c] A hyphen denotes "not applicable."

[d] Generation type was not specified, so composite emission factors representative of all types of powerplants currently in operation over the 11 Western Interconnection states were used.

[e] These plants have more than one generation type, and only one plant-wide emission factor for each pollutant was given in the EPA's 2010 eGrid database.

[f] Composite emission factors representative of gas powerplants currently in operation over the 11 Western Interconnection states were used.

[g] "Sales" refers to sales of power by system utilities to non-system utilities within the Western Interconnection. Sales result in a net credit to total Western Interconnection emissions, because the sales result in a reduction in emissions from those non-system utilities that are purchasing the power. "Purchases" refers to purchases by system utilities from non-system utilities within the Western Interconnection. Emissions related to these purchases are added to the total emissions in the Western Interconnection.

Sources: EIA (2013); EPA (2014).

TABLE M-2 (Cont.)

[a] A hyphen denotes "not applicable."

[b] "Sales" refers to sales of power by system utilities to non-system utilities within the Western Interconnection. Sales result in a net credit to total Western Interconnection emissions, because the sales result in a reduction in emissions from those non-system utilities that are purchasing the power. "Purchases" refers to purchases by system utilities from non-system utilities within the Western Interconnection. Emissions related to these purchases are added to the total emissions in the Western Interconnection.

Data source: AURORA model outputs described in Appendix K.

TABLE M-3 Summary of Potential Impacts of LTEMP Alternatives on Visibility and Regional Air Quality

Air Quality	A (No Action Alternative)	B	C	D (Preferred Alternative)	E	F	G
Overall summary of impacts	No change from current conditions	Negligible increase in SO_2 and NO_x emissions compared to Alternative A	Negligible decrease in SO_2 emissions and no change in NO_x emissions compared to Alternative A	No change in SO_2 emissions and negligible increase in and NO_x emissions compared to Alternative A	Negligible increase in SO_2 and NO_x emissions compared to Alternative A	Negligible decrease in SO_2 and NO_x emissions compared to Alternative A	Negligible decrease in SO_2 emissions and negligible increase in NO_x emissions compared to Alternative A
Visibility[a]	No change from current conditions	No change from Alternative A	No change from Alternative A	No change from Alternative A	No change from Alternative A	No change from Alternative A	No change from Alternative A
Air Quality in 11-State Western Interconnection Region							
SO_2 emissions (tons/yr)[b]	42,465	42,471	42,463	42,465	42,466	42,448	42,453
	No change from current conditions	Negligible increase (0.01%) compared to Alternative A	Negligible reduction (−0.01%) compared to Alternative A	No change from current conditions from Alternative A	Negligible increase (<0.005%) compared to Alternative A	Negligible reduction (−0.04%) compared to Alternative A	Negligible reduction (−0.03%) compared to Alternative A
NO_x emissions (tons/yr)[b]	78,496	78,501	78,496	78,503	78,500	78,487	78,498
	No change from current conditions	Negligible increase (0.01%) compared to Alternative A	No change from current conditions from Alternative A	Negligible increase (0.01%) compared to Alternative A	Negligible increase (<0.005%) compared to Alternative A	Negligible reduction (−0.01%) compared to Alternative A	Negligible increase (<0.005%) compared to Alternative A

[a] Visibility effects are estimated from expected changes in the emissions of sulfate and nitrate precursors, SO_2 and NO_x.

[b] Total air emissions and percentage change in emissions (compared to Alternative A) from combustion-related powerplants in the Western Interconnection averaged over the 20-year LTEMP period.

Source: EPA (2014).

TABLE M-5 (Cont.)

[a] A hyphen denotes "not applicable."

[b] "Sales" refers to sales of power by system utilities to non-system utilities within the Western Interconnection. Sales result in a net credit to total Western Interconnection emissions, because the sales result in a reduction in emissions from those non-system utilities that are purchasing the power. "Purchases" refers to purchases by system utilities from non-system utilities within the Western Interconnection. Emissions related to these purchases are added to the total emissions in the Western Interconnection.

TABLE M-6 Summary of Impacts of LTEMP Alternatives on SO_2 and NO_x Emissions

Generation Type	A (No Action Alternative)	B	C	D (Preferred Alternative)	E	F	G
Total Glen Canyon Dam power generation relative to Alternative A (MWh/day) (% of Alternative A)	11,650 (100%)	11,616 (99.7%)	11,566 (99.3%)	11,525 (98.9%)	11,571 (99.3%)	11,449 (98.3%)	11,438 (98.2%)

GOVERNMENT-TO-GOVERNMENT AND NATIONAL HISTORIC PRESERVATION ACT CONSULTATION

This page intentionally left blank

APPENDIX N:

GOVERNMENT-TO-GOVERNMENT AND NATIONAL HISTORIC PRESERVATION ACT CONSULTATION

This appendix presents the correspondence pertaining to government-to-government and National Historic Preservation Act of 1966 (NHPA) Section 106 consultation for the Long-Term Experimental Management Program (LTEMP) Environmental Impact Statement (EIS). Attachment 1 provides copies of signed Memorandums of Understanding (MOUs), Attachment 2 provides official correspondence with Tribes, and Attachment 3 contains a copy of the letter to the Arizona State Historic Preservation Officer.

N.1 GOVERNMENT-TO-GOVERNMENT CONSULTATION

As detailed in Chapter 5 of the EIS, both the Bureau of Reclamation (Reclamation) and the National Park Service (NPS) coordinate and consult with all Tribal governments, American Indian communities and organizations, and Tribal individuals whose interests might be directly and substantially affected by activities within their jurisdiction. Both agencies strive to provide Indian Tribes with sufficient opportunities for productive participation in planning and resource management decision-making. In addition, Section 106 of the NHPA requires federal agencies to consult with Indian Tribes on undertakings on Tribal lands and on historic properties of significance to the Tribes that may be affected by an undertaking (36 CFR 800.2 (c)(2)) (see Section 4.8.1). Agency-specific guidance provides additional direction for American Indian consultations (see Section 5.2.3).

On January 21, 2011, an e-mail was sent to Tribes that were previous cooperators on the Glen Canyon Dam EIS (Reclamation 1995)—the Southern Paiute Consortium, the Hopi Tribe, the Hualapai Tribe, the Navajo Nation, and the Pueblo of Zuni—with an invitation to attend the initial "kickoff" meeting for the LTEMP EIS on February 11, 2011. Representatives from the Navajo Nation and the Pueblo of Zuni attended this meeting.

On October 17, 2011, an e-mail was sent to the Southern Paiute Consortium, the Hualapai Tribe, the Hopi Tribe, the Navajo Nation, and the Pueblo of Zuni indicating that Reclamation published in the *Federal Register* a Notice of Intent (NOI) to develop a LTEMP and prepare a LTEMP EIS. In this NOI, the public was notified of upcoming public scoping meetings and provided information on how to participate in the LTEMP public scoping process. A link to the project website and project lead contact information was provided.

On November 4, 2011, an e-mail was sent to the Hopi Tribe, the Southern Paiute Consortium, the Las Vegas Tribe of Paiute Indians, the Moapa Band of Paiute Indians, the Paiute Indian Tribe of Utah, the Havasupai Tribe, the Hualapai Tribe, the Navajo Nation, and the Pueblo of Zuni with an update on the LTEMP process. The e-mail summarized NOI publications and provided contact information for project leads. The e-mail also stated that several Tribes had already indicated their desire to participate as Cooperating Agencies and the joint leads would

soon be formally contacting all potentially interested American Indian Tribes to initiate consultation.

On November 30, 2011, 43 Tribes, bands, and organizations were formally invited to enter into government-to-government consultation on the LTEMP EIS. A letter, sent by the joint-lead agencies, provided notification of the intent to prepare the LTEMP EIS, initiated government-to-government consultation, and invited the Tribes to identify concerns related to historic properties, including traditional cultural properties and archaeological sites; natural resources; relevant Indian Trust assets; and other issues of importance.

On December 8, 2011, in accordance with Title 40 *Code of Federal Regulations*, Part 1501.6 (40 CFR 1501.6), concerning the Council on Environmental Quality (CEQ) regulations for implementing the procedural provisions of the National Environmental Policy Act (NEPA), and 43 CFR 46.225, concerning the Department of the Interior's (DOI's) regulations for implementing NEPA, Reclamation and NPS invited 11 Tribes to participate as Cooperating Agencies in the development of the EIS.

A total of 31 Tribes responded to the invitations. Six Tribes agreed to participate as Cooperating Agencies (the Havasupai Tribe, the Hopi Tribe, the Hualapai Tribe, the Kaibab Band of Paiute Indians, the Navajo Nation, the Pueblo of Zuni); three Tribes (the Fort Mojave Tribal Council, Pueblo of Zia, and the Gila River Indian Community) agreed to participate as Consulting Tribes; eight Tribes (Pueblo of Santa Clara, Ute Indian Tribe, Ute Mountain Ute, Pueblo of Nambe, Yavapai Apache, Paiute Indian Tribe of Utah, the Pueblo of Santa Ana, and the Fort Yuma Quechan) declined participation, but asked to remain on the mailing list; and 11 Tribes (Ak Chin Indian Community, Cocopah Indian Tribe, Fort McDowell Yavapai Tribal Council, Jicarilla Apache Nation, Ohkay Owingeh, Southern Ute Tribal Council, the Pueblo of Laguna, the Pueblo of Sandia, Yavapai-Prescott Indian Tribe, Tohono O'odham Nation, and the White Mountain Apache) declined participation in the LTEMP EIS. The joint-leads have yet to receive a response to the request for consultation from the remaining 15 Tribes (Colorado River Indian Tribes, Chemehuevi Tribal Council, Las Vegas Tribe of Paiute Indians, Moapa Band of Paiute Indians, Salt River Pima-Maricopa Indian Community, San Carlos Apache Tribe, San Juan Southern Paiute Tribe, the Pascua Yaqui Tribe, the Pueblo of Acoma, the Pueblo of Cochiti, the Pueblo of Jemez, the Pueblo of Pojoaque, the Pueblo of San Felipe, the Pueblo of Tesuque, and the Tonto Apache Tribe) despite follow-up phone calls and e-mails.

Although the Pueblo of Zia agreed to participate as a Consulting Tribe, there was little participation from the Pueblo. On February 11, 2014, an e-mail was sent to a Tribal representative asking if the Pueblo of Zia would like to remain a Consulting Tribe or be moved to the mailing list. A hard copy of this letter was also sent to the Tribe. No response was received and the joint-leads agreed to move the Pueblo of Zia to the mailing list. A summary of Tribal Participation Status is provided in Table N-1 and a summary of follow-up inquiries is provided in Table N-2.

Beginning in February 2012, the Tribes participating as Cooperating Agencies were invited to monthly conference calls to review progress and to reach agreement on major issues during the preparation of the EIS. Prior to these meetings, Tribes were sent an invitation to

TABLE N-1 Summary of Tribal Participation Status

Participating Tribes	Declined Participation	No Response
Cooperating Agencies	Ak Chin Indian Community	Chemehuevi Tribal Council
The Havasupai Tribe	Chemehuevi Tribal Council	Colorado River Indian Tribes
The Hopi Tribe	Cocopah Indian Tribe	Las Vegas Tribe of Paiute Indians
The Hualapai Tribe	Fort McDowell Yavapai Tribal Council	Moapa Band of Paiute Indians
The Kaibab Band of Paiute Indians	Jicarilla Apache Nation	Salt River Pima-Maricopa Indian Community
The Navajo Nation	Ohkay Owingeh	San Carlos Apache Tribe
The Pueblo of Zuni	Southern Ute Tribal Council	San Juan Southern Paiute Tribe
	The Pueblo of Laguna	The Pascua Yaqui Tribe
Consulting Tribes	The Pueblo of Sandia	The Pueblo of Acoma
The Fort Mojave Tribal Council	Tohono O'odham Nation	The Pueblo of Conchiti
Gila River Indian Community	White Mountain Apache	The Pueblo of Jemez
	Yavapai-Prescott Indian Tribe	The Pueblo of Pojoaque

Yavapai-Apache		

each meeting as well as a meeting reminder with an agenda, call-in number, and password. Monthly Cooperating Agency meetings are ongoing and will continue to be held throughout the length of the LTEMP.

Cooperating Agency Tribes were invited to sign a MOU defining the relationship and duties of the joint-lead and Cooperating Agencies in completing the NEPA compliance for the LTEMP. A draft copy of the MOU was sent to all Cooperating Agency Tribes on March 6, 2012, and Tribes were encouraged to make revisions and provide comments. Final copies of the MOU were distributed to each Tribe after revisions and comments were returned and incorporated into each MOU. Signed copies were returned to the joint-leads by all Cooperating Agency Tribes. Copies of the MOUs are provided in Attachment 1.

In addition to Cooperating Agency meetings, more than 30 meetings, workshops, and webinars were conducted with stakeholders and Cooperating Agencies to assist in the development of alternatives and performance criteria, explain the Structured Decision Analysis (SDA), conduct swing-weighting exercises, and provide general status updates. A series of Tribal-specific workshops, conference calls, and webinars were also held to identify Tribal resource goals and ways to measure the relative performance of alternatives against those goals. Prior to these meetings, inquiries were sent to Tribes to find a meeting time that would best suit

TABLE N-2 Summary of Tribal Correspondence

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Ak Chin Indian Community	February 2012: Steve Daron, Lake Mead National Recreation Area (LMNRA), attempted phone contact with the Ak Chin Indian Community three times in February. He was unable to reach anyone. May 4, 2012: Steve Daron spoke with Carol Antone and re-sent the November 30 letter. Phone call follow-up, but no response.	July 31, 2012: Letter from Louis J. Manuel, Jr., Chairman indicating that the Ak Chin Indian Community is not interested in participating in the LTEMP process at this time.
Chemehuevi Tribal Council	February 2012: Steve Daron, LMNRA, attempted to call the Chemehuevi Tribal Council three times in February. He was unable to reach anyone.	No response.
Cocopah Indian Tribe	January 23, 2012: John Halliday, DOI, called and was referred from the Chair Office to Tribal Administrator Christopher Nunez. John left him a message regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	January 25, 2012: Tribal staff member Barbera Mathias called Mr. Halliday and informed him that the Cocopah did not wish to participate in the LTEMP process.
Colorado River Indian Tribes	February 2012: Steve Daron, LMNRA, attempted to call Colorado River Indian Tribes three times in February and received no response. September 24, 2012: Jennifer Abplanalp, Argonne, called and left a message for Mr. Buma requesting an e-mail or mailing address to send LTEMP information.	August 10, 2012: Consulting and Cooperating Tribes meeting was held in Tempe, Arizona. Grant Buma, Acting Director of Water Resources Department, was in attendance. September 24, 2012: Mr. Buma called back with his e-mail address.
Fort McDowell Yavapai Tribal Council	January 23, 2012: John Halliday, DOI, called and left a message for Karen Ray regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday left a message with Ms. Ray asking if the Tribe wished to participate in the LTEMP process. January 27, 2012: Mr. Halliday left a message with Ms. Ray asking if the Tribe wished to participate in the LTEMP process. February 6, 2012: Mr. Halliday called and spoke to Tribal Cultural Representative Gary Loutenhizer. February 14, 2012: Mr. Halliday called and spoke to Mr. Loutenhizer.	February 6, 2012: Mr. Loutenhizer said that he would check with Karen Ray regarding participation in LTEMP and would get back to John soon. February 14, 2014: Mr. Loutenhizer indicated that the Ft. McDowell Yavapai did not want to participate in LTEMP process.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Fort Mojave Tribal Council	December 6, 2013: Steve Daron, LMNRA, spoke with Nora McDowell-Antone and asked if the Fort Mojave were still interested in participating as a consulting Tribe for the LTEMP EIS. January 30, 2014: Mr. Daron spoke with Ms. McDowell-Antone regarding the Fort Mojave participation as a consulting Tribe for the LTEMP EIS.	February 2012: Linda Otero, Director of the Aha Makav Cultural Society, called Steve Daron and indicated that the Fort Mojave were interested in participating in government-to-government consultation. April 24, 2012: Ms. Otero called Mr. Daron to schedule a meeting with the joint-lead agencies for an overview of the project. December 6, 2013: Ms. McDowell-Antone indicated that the Tribe is still interested. January 30, 2014: Ms. McDowell-Antone informed Mr. Daron that Ms. Otero had been temporarily assigned for 3 to 6 months but the Tribe would like to stay in the loop and receive information. Ms. McDowell-Antone requested the most recent documents.
Fort Yuma Quechan Tribe	February 2012: Steven Daron, LMNRA, spoke with John Bathke, Tribal Historic Preservation Officer (THPO), regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. Steve also sent Mr. Bathke an e-mail with information on the LTEMP website. May 8, 2012: Mr. Daron spoke with John Bathke, THPO, regarding LTEMP consultation. May 14, 2012: Mr. Daron sent Mr. Bathke an e-mail with some potential dates for a meeting. May 29, 2012: Mr. Daron informed Mr. Bathke that the LTEMP representatives would be available for a meeting on June 22, as requested. May 30, 2012: Mr. Daron spoke with Mr. Bathke regarding the LTEMP. April 4, 2013: Bruce Verhaaren, Argonne, called the new THPO, Arlene Kingery, Mr. Bathke's replacement, regarding the Tribe's continued involvement in the LTEMP process.	February 15, 2012: John Bathke, THPO, called and left a message for Steven Daron requesting LTEMP consultation. May 8, 2012: Mr. Bathke indicated that the Cultural Committee would like a presentation on the LTEMP project and asked Mr. Daron to provide dates when LTEMP representatives could come give a presentation. May 29, 2012: Mr. Bathke e-mailed Mr. Daron to request a meeting with LTEMP representatives on June 22, 2012, to discuss the LTEMP process. May 30, 2012: Mr. Bathke indicated that the Quechan are more interested in the impacts the project would have on cultural resources because the Tribe has heard that previous releases from Glen Canyon Dam have had impacts on sites. April 4, 2013: Ms. Kingery informed Bruce Verhaaren that the Quechan Cultural Committee had decided that they would no longer like to consult on the LTEMP but would like to remain on the mailing list.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Gila River Indian Community Council	January 9, 2012: Janet Cohen confirmed receipt of the Tribe's interest in consultation. February 2012: Steven Daron, LMNRA, attempted contact with the Gila River Indian Community Council May 14, 2012: Mr. Daron spoke with Larry Benallie, Archaeology Compliance Specialist, regarding the Tribe's participation in the LTEMP process. June 20, 2012: Bruce Verhaaren, Argonne, sent the draft copy of *American Indian Perspectives and Values Related to the Glen Canyon Dam Long-Term Experimental and Management Plan Environmental Impact Statement.*	January 3, 2012: Barnaby Lewis, THPO, sent a letter to John Wessels, NPS, and an e-mail to Ms. Cohen, NPS, indicating the Tribe's interest in consultation. May 14, 2012: Mr. Benallie informed Mr. Daron that the Gila River Indian Community Council did not want to schedule a meeting at this time, but would re-evaluate the decision after the alternatives have been chosen. Mr. Benallie also requested a copy of the draft copy of *American Indian Perspectives and Values Related to the Glen Canyon Dam Long-Term Experimental and Management Plan Environmental Impact Statement* and indicated that the Tribe would like to remain on the mailing list.
Havasupai Tribe	January 23, 2012: E-mail from Janet Cohen, NPS, to Chair and Vice Chair asking the Havasupai what their level of interest is in the project. Ms. Cohen attached a copy of the November and December 2011 letters and asked if they could get back to her by the end of the week regarding their involvement. January 27, 2012: Ms. Cohen tried to call Chairman Watahomigie and the Vice Chair regarding the November and December 2011 LTEMP letters asking if the Tribe wished to participate in the LTEMP process but was unable to reach anyone. January 30, 2012: Ms. Cohen called and spoke to Chairman Watahomigie regarding the November and December 2011 LTEMP letters asking if the Tribe wished to participate in the LTEMP process. Ms. Cohen resent the November and December 2011 letters and asked Chairman Watahomigie to return the Cooperating Agency form. February 7, 2012: Ms. Cohen sent copies of the November and December 2011 letters to the Tribal Secretary as per the Tribe's request. April 8, 2012: Sarah Rinkevich called and spoke with Margaret Vick, Attorney for the Havasupai, asking if they would like to submit a funding proposal and if they were still interested in participating in the LTEMP. July 2012: MOU signed by joint-leads.	January 30, 2012: Chairman Watahomigie said the Tribe is interested in participating but did not specify whether they wanted to be a Cooperating Agency or not. Chairman identified the Tribal secretary (Jaycee Manakaja) as the point of contact to send meeting information, etc. February 27, 2012: Cooperating Agency form returned indicating the Tribe would like to participate as a Cooperating Agency. July 6, 2012: MOU signed. April 8, 2013: Ms. Vick indicated that the Havasupai have not submitted any funding proposal for LTEMP, but she would ask the Chairman if the Havasupai were interested in funding. Ms. Vick indicated that the Havasupai may not be interested in sharing Grand Canyon cultural connections with the federal government but that the engineering and water quality departments may be interested in reviewing the alternatives. September 30, 2015: Havasupai Tribe submitted comments on the LTEMP DEIS.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Havasupai Tribe (Cont.)	December 17, 2014: Preliminary Chapters 1 and 2 sent to Havasupai Tribe for review. April 15, 2015: Preliminary Chapter 3 sent to Havasupai Tribe for review. July 1, 2015: LTEMP DEIS sent to Havasupai Tribe for review.	May 9, 2016: Havasupai Tribe submitted additional comments on the LTEMP DEIS.
Hopi Tribe	January 13, 2012: Janet Cohen, NPS, spoke with Mike Yeatts regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process February 15, 2012: Ms. Cohen spoke with Mr. Yeatts regarding Hopi participation as a Cooperating Agency in the LTEMP process. She asked him to return the Cooperating Agency form to Argonne as soon as possible. She e-mailed another copy of the November 2011 letter and the form to Mr. Yeatts. October 2014: MOU signed by joint-leads December 17, 2014: Preliminary Chapters 1 and 2 sent to Hopi Tribe for review. April 15, 2015: Preliminary Chapter 3 sent to Hopi Tribe for review. July 1, 2015: LTEMP DEIS sent to Hopi Tribe for review.	February 15, 2012: Mr. Yeatts indicated that he will follow up with Leigh Kuwanwiswima, THPO, to see if the Cooperating Agency form had been sent in. June 7, 2013: MOU signed. January 23, 2015: Hopi Tribe submitted comments on preliminary Chapters 1 and 2. September 30, 2015: Hopi Tribe submitted comments on LTEMP DEIS. April 29, 2016: Hopi Tribe submitted additional comments on the LTEMP DEIS.
Hualapai Tribe	November 16, 2012: Rob Billerbeck, NPS, called and spoke with Kerry Christiansen regarding the LTEMP project. January 5, 2012: The November 30, 2011, letter of invitation to become a Cooperating Agency letter was returned to Argonne. The letter was resent via e-mail to Loretta Jackson-Kelly, THPO. Ms. Jackson-Kelly was informed that the deadline for informing the lead-agencies if the Hualapai wished to be a cooperating agency was Friday January 6, 2012, and asked Ms. Jackson-Kelly to let her know if the Hualapai needed more time.	November 16, 2012: Mr. Christiansen expressed that the Hualapai Tribe may be interested in having LTEMP representatives meet with the Hualapai Tribal Council as they felt this has not happened enough on past processes. January 6, 2012: Ms. Jackson-Kelly returned the Cooperating Agency form via fax. The Hualapai would like to be a Cooperating Agency.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Hualapai Tribe (Cont.)	December 16, 2013: Jim May, Argonne, spoke with Peter Bungart and Earlene Havatone, Exec. Director of Grand Canyon West, about the impacts of Glen Canyon Dam releases on the Hualapai's river-running businesses. Mr. May encouraged Ms. Havatone to try to quantify the impacts and to include pictures of the kinds of damage and concerns that the Hualapai have. October 2014: MOU signed by joint-leads. December 17, 2014: Preliminary Chapters 1 and 2 sent to the Hualapai Tribe for review. April 15, 2015: Preliminary Chapter 3 sent to the Hualapai Tribe for review. July 1, 2015: LTEMP preliminary draft EIS sent to the Hualapai Tribe for review.	October 4, 2012: MOU signed. April 8, 2013: Mr. Bungart informed Ms. Rinkevich that the Hualapai already submitted their request for funding. Ms. Jackson-Kelly and he requested a presentation by LTEMP representatives at an open house at the next council meeting on May 3, 2013. August 16, 2013: Mr. Bungart sent a follow-up e-mail in response to a discussion held at the Tribal Values Workshop on Tuesday August 6, 2013, with suggested performance metrics that would be both practical and useful for Hualapai resources of concern. December 16, 2013: Major concerns expressed by Ms. Havatone include bank erosion, difficulty accessing docks, tougher navigation in a narrowing channel, difficulty in accessing the shoreline up steep banks and excessive wear and tear on outboard motors. Ms. Havatone indicated that she had not tried to quantify the effects of the impacts before, but she thought she could. April 16, 2015: The Hualapai Tribe submitted comments on preliminary Chapters 1, 2, and 3. September 30, 2015: The Hualapai Tribe submitted comments on the LTEMP DEIS. May 9, 2016: Hualapai Tribe submitted additional comments on the LTEMP DEIS.
Jicarilla Apache Nation	January 26, 2012: John Halliday, DOI, called Jeffrey Blythe regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	January 26, 2012: Mr. Blythe indicated that the Jicarilla Apache Nation did not wish to participate in the LTEMP process.
Kaibab Band of Paiute Indians	May/June/July 2012: MOU signed by joint-leads. December 17, 2014: Preliminary Chapters 1 and 2 sent to Kaibab Band of Paiute Indians for review.	February 15, 2011: The Cooperating Agency form as signed and returned. May 2, 2012: MOU signed.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Kaibab Band of Paiute Indians (Cont.)	April 15, 2015: Preliminary Chapter 3 sent to Kaibab Band of Paiute Indians for review. May/June/July 2012: MOU signed by joint-leads. December 17, 2014: Preliminary Chapters 1 and 2 sent to Kaibab Band of Paiute Indians for review. April 15, 2015: Preliminary Chapter 3 sent to Kaibab Band of Paiute Indians for review. July 1, 2015: LTEMP DEIS sent to Kaibab Band of Paiute Indians for review. November 2, 2015: Reclamation informed Charley Bulletts that the joint-leads had not received comments from the Kaibab Band of Paiute Indians as referenced in the September 29, 2015, letter and requested that Mr. Bulletts resend the comments.	January 6, 2015: Mr. Bulletts inquired as to when Chapter 3 would be available for review by Tribal Representatives. February 15, 2011: The Cooperating Agency form as signed and returned. May 2, 2012: MOU signed. January 6, 2015: Mr. Bulletts inquired as to when Chapter 3 would be available for review by Tribal Representatives. September 29, 2015: Kaibab Band of Paiute Indians submitted comments on the LTEMP DEIS. References a letter dated April 8, 2015, regarding comments on preliminary Chapters 1 and 2 that were never received by the joint-lead agencies. November 3, 2015: Mr. Bulletts sent comments on Chapters 1 and 2. Comments received by joint-lead agencies.
Las Vegas Tribe of Paiute Indians	January 23, 2012: Janet Cohen, NPS, sent an e-mail to Kenny Anderson with a copy of the initial November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 27, 2012: Ms. Cohen called Kenny Anderson to follow up on an e-mail containing copies of letters sent on January 23, 2012. February 15, 2012: Ms. Cohen sent an e-mail to Mr. Anderson with a copy of the initial November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. February 22, 2012: Ms. Cohen called Mr. Anderson and left a voicemail indicating that the NPS will have to assume that the Las Vegas Paiute are not interested in this project since they have not indicated otherwise.	January 27, 2012: Mr. Anderson indicated that the Las Vegas Tribe of Paiute Indians are likely interested in some level of consultation and would like to review the letters before saying for sure.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Moapa Band of Paiute Indians	January 23, 2012: Janet Cohen, NPS, sent an e-mail to Chairman Anderson containing copies of the initial November 2011 and December 2011 LTEMP letters asking if the Tribe wished to participate in the LTEMP process. January 27, 2012: Ms. Cohen called Chairman Anderson to follow-up on the e-mail sent out on January 23, 2012. Ms. Cohen asked Chairman Anderson to look at the e-mail and the letters and let the NPS know if the Moapa Band of Paiute Indians is interested in consultation or not. February 15, 2012: Janet Cohen, NPS, sent an e-mail to Chairman Anderson with the November 2011 and December 2011 LTEMP letters attached and asked if the Tribe was interested in consultation. The letter also indicated that if the NPS does not receive a response, the NPS will assume that the Moapa Band of Paiute Indians is not interested in consultation. February 22, 2012: Ms. Cohen called Chairman Anderson and left a voicemail indicating the NPS will have to assume the Moapa are not interested in the project since they have not indicated otherwise.	January 27, 2012: Chairman Anderson indicated he was very backed up on reviewing incoming e-mail and he wasn't sure if he had seen the letters or the e-mail.
Navajo Nation	January 13, 2012: Janet Cohen, NPS, spoke with Jason John regarding the proper contact person for LTEMP. It was confirmed that The Department of Water Resources will represent the Tribe in its Cooperating Agency status. Ms. Cohen will follow up with the Historic Preservation Department in regards to Section 106 and cultural resources. Ms. Cohen provided the web address for the LTEMP project. May 20, 2013: Bruce Verhaaren, Argonne, spoke with Jason John, Navajo Department of Water and Power (NDWP). Bruce advised Mr. John to call Sarah Rinkevich, DOI, to request a meeting. February 11, 2014: Mr. Verhaaren e-mailed a letter to Jason John, NDWP, and Tony Joe, Supervisory Anthropologist, from the joint-leads of the LTEMP EIS concerning the pending MOU between the Navajo Nation, the Bureau of Reclamation, and the NPS regarding the participation of the Navajo Nation as a cooperating agency for the EIS.	February 28, 2011: Letter from Tony Joe of the Navajo Nation with comments on the preliminary draft outline distributed at the kickoff meeting. January 9, 2012: Cooperating Agency form was submitted indicating the Navajo Nation would like to participate in the LTEMP as a Cooperating Agency. May 20, 2013: Mr. John requested a meeting or teleconference to discuss the LTEMP. February 21, 2014: Return receipt confirmation for the February 11, 2014, letter to Mr. John. February 21, 2014: Mr. John sent the joint-leads a letter from the Navajo Nation President Ben Shelly requesting government-to-government consultation.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Navajo Nation (Cont.)	February 13, 2014: A hardcopy of the February 11, 2014, letter was sent to Tony Joe and Jason John.	February 24, 2014: Return receipt confirmation for the February 11, 2014, letter to Tony Joe.
	February 28, 2014: Rob Billerbeck, NPS spoke with Mr. John regarding government-to-government consultation.	February 28, 2014: Mr. John indicated that there may have been a misunderstanding. The Navajo Nation would like LTEMP representatives to explain the LTEMP process before signing the MOU. The Navajo Nation will likely wait until summer for formal government-to-government consultation.
	March 17, 2014: Mr. Billerbeck sent an e-mail to Mr. John in reply to the February 21, 2014, e-mail and attached letter requesting to meet with the project managers of LTEMP. Mr. Billerbeck apologized for not being able to meet on the requested dates and proposed new dates for a meeting and attached some additional information on the LTEMP project for the Navajo to review in advance.	March 17, 2014: Mr. John requested a meeting at 2 p.m. on April 10, 2014, in Window Rock, Arizona.
	October 2014: MOU signed by joint-leads	June 9, 2014: MOU signed.
	December 17, 2014: Preliminary Chapters 1 and 2 sent to the Navajo Nation for review.	October 6, 2015: Navajo Nation submitted comments on the LTEMP DEIS.
	April 15, 2015: Preliminary Chapter 3 sent to the Navajo Nation for review.	May 4 and 5, 2016: Navajo Nation submitted additional comments on the LTEMP DEIS.
	July 1, 2015: LTEMP DEIS sent to the Navajo Nation for review.	
Ohkay Owingeh	January 23, 2012: John Halliday, DOI, called and left a message for Anthony Moquino regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	January 27, 2012: Mr. Moquino indicated that the Tribe did not wish to participate in the LTEMP process.
	January 26, 2012: Mr. Halliday left a message with Mr. Moquino asking if the Tribe wished to participate in the LTEMP process.	
	January 27, 2012: Mr. Halliday spoke with Mr. Moquino and asked if the Tribe would like to participate in the LTEMP process	
Paiute Indian Tribe of Utah	No follow-up needed. Tribe returned form and requested to be added to mailing list.	January 9, 2012: The Cooperating Agency form was returned. The Paiute Indian Tribe of Utah is not interested in being a Cooperating Agency, but would like to remain updated on the LTEMP.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Pascua Yaqui Tribe	January 24, 2012: John Halliday, DOI, called and left a message for Chairperson Peter Yucupicio regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday called and left another message for Chairman Yucupicio. January 27, 2012: Mr. Halliday called and left another message for Chairman Yucupicio. February 6, 2014: Mr. Halliday called and left another message for Chairman Yucupicio. February 14, 2014: Mr. Halliday called and left another message for Chairman Yucupicio.	No response.
Pueblo of Acoma	January 23, 2012: John Halliday, DOI, called and left a message for Theresa Pasquale regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday left another message for Ms. Pasquale. January 27, 2012: Mr. Halliday left another message for Ms. Pasquale. February 14, 2012: Mr. Halliday left another message for Ms. Pasquale.	No response.
Pueblo of Cochiti	January 23, 2012: John Halliday, DOI, called and left a message for Jacob Pecos, Director, Department of Natural Resources, regarding the LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday left another message for Mr. Pecos. January 27, 2012: Mr. Halliday left another message for Mr. Pecos. February 14, 2012: Mr. Halliday left another message for Mr. Pecos.	No response.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Pueblo of Jemez	January 23, 2012: John Halliday, DOI, called and left a message for Natural Resources Director Christopher Toya regarding the LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	No response.
	January 26, 2012: Mr. Halliday left another message for Mr. Toya.	
	January 27, 2012: Mr. Halliday left another message for Mr. Toya.	
	February 14, 2012: Mr. Halliday left another message for Mr. Toya.	
Pueblo of Laguna	January 23, 2012: John Halliday, DOI, called and was referred from the Governor's Office to Tribal Staff Member Adam Ringia and left a message for him regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	January 26, 2012: Mr. Ringia indicated that the Pueblo of Laguna does not wish to participate in the LTEMP process.
	January 26, 2012: Mr. Halliday called Mr. Ringia regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	
Pueblo of Nambe	January 23, 2012: John Halliday, DOI, called and left a message for Steve Romero regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	January 27, 2012: Ms. Carnevale informed Mr. Halliday that she is the new Tribal Environmental Officer. She indicated that the Tribe would like to schedule a consultation meeting.
	January 27, 2012: Mr. Halliday spoke with Nichole Carnevale regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	May 3, 2012: Mary Barger received an e-mail from Ms. Carnevale indicating that the Tribe would not like to actively participate in LTEMP but would like to remain on the mailing list.
Pueblo of Pojoaque	January 24, 2012: John Halliday, DOI, called and left message for Vernon Lujan, THPO, regarding the LTEMP letter asking if the Tribe wished to participate in the LTEMP process	March 29, 2012: Mr. Halliday received a message from Mr. Lujan indicating that the Tribe would like to participate in the LTEMP process.
	January 26, 2012: Mr. Halliday called and left another message for Mr. Lujan.	May 03, 2012: The Pueblo of Pojoaque indicated that they were interested in setting up a meeting and would get back to Ms. Barger, Reclamation, with a date to meet.
	January 27, 2012: Mr. Halliday called and left another message for Mr. Lujan.	
	February 14, 2012: Mr. Halliday called and left another message for Mr. Lujan.	May 14, 2012: Linda was not familiar with the project and gave Ms. Barger Mr. Lujan's cell phone number.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Pueblo of Pojoaque (Cont.)	May 14, 2012: Ms. Barger called Mr. Lujan to schedule a meeting time and spoke with Linda, a member of his staff. Ms. Barger left Mr. Lujan a message on his cell phone. May 16, 2012: Ms. Barger called and left a voicemail for Mr. Lujan. She offered to put them on the mailing list or schedule a meeting. May 17, 2012: Ms. Barger left another voicemail with Mr. Lujan. May 21, 2012: Ms. Barger called and spoke with Mr. Lujan. May 22, 2012: Adrianne Carr, Argonne, e-mailed a copy of the November 2011 LTEMP letter and the Draft Tribal Consultation Plan to Mr. Lujan for review. May 29, 2012: Ms. Barger called Mr. Lujan to follow-up on the documents sent on May 22 and see if the Pueblo was interested in participating in LTEMP. June 09, 2012: Ms. Barger spoke to Mr. Lujan regarding LTEMP participation. June 19, 2012: Ms. Barger left a message with Mr. Lujan regarding participation in the LTEMP. June 25, 2012: Ms. Barger left a message with Mr. Lujan. She stated that since she has not heard from him, the joint-leads are assuming that the Pueblo of Pojoaque is not interested in meeting on the EIS, and to contact her by June 29 if her assumption was incorrect.	May 21, 2012: Mr. Lujan requested more information so he could decide if the Pueblo of Pojoaque should consult. May 29, 2012: Mr. Lujan indicated that he did not have time to review the project information that Ms. Barger sent. June 9, 2012: Mr. Lujan indicated that he forwarded the information to the Governor's office and was awaiting a recommendation.
Pueblo of San Felipe	January 23, 2012: John Halliday, DOI, called and was referred from the Governor's Office to Tribal Administrator Daryl Candelaria. Mr. Halliday left him a message regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday called and left another message with Mr. Candelaria. January 27, 2012: Mr. Halliday called and left another message with Mr. Candelaria.	No response.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Pueblo of San Felipe (Cont.)	February 14, 2012: Mr. Halliday called and left another message with Mr. Candelaria.	
Pueblo of Sandia	January 23, 2012: Mr. Halliday, DOI, called and left a message for Environmental Director Frank Chavez regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday called and spoke with Mr. Chavez regarding Pueblo of Sandia participation in the LTEMP process.	January 26, 2012: Mr. Chavez indicated the Pueblo of Sandia did not want to participate.
Pueblo of Santa Ana	January 24, 2012: John Halliday, DOI, called and spoke with Tribal Liaison Ben Robbins regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 25, 2012: Mr. Halliday e-mailed copies of the November 2011 letter to Ben. February 06, 2012: Mr. Halliday called and left a message for Mr. Robbins regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. February 14, 2012: Mr. Halliday called and spoke with Mr. Robbins regarding Pueblo of Santa Ana participation in the LTEMP process.	January 24, 2012: Mr. Robbins asked Mr. Halliday to e-mail him another copy of the letter and he would ask the council and get back to John. February 14, 2012: Mr. Robbins indicated that the Tribe did not wish to participate in the LTEMP process, but would like to continue receiving information and updates.
Pueblo of Santa Clara	January 23, 2012: John Halliday, DOI, called to speak with Ben Chavarria, Native American Graves Protection and Repatriation Act (NAGPRA) Contact, regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 24, 2012: Mr. Halliday called and left a message for Mr. Chavarria regarding the Tribe's participation in the LTEMP process. January 26, 2012: Mr. Halliday called and left a message for Mr. Chavarria regarding the Tribe's participation in the LTEMP.	January 23, 2012: Mr. Halliday spoke with a Tribal staff member who informed John that the Tribe was closed for the day and he should call back the next day. January 26, 2012: Mr. Chavarria returned Mr. Halliday's phone call. He informed Mr. Halliday that the Tribe does not wish to participate, but would like to remain on the mailing list.

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Pueblo of Tesuque	January 23, 2012: John Halliday, DOI, called and spoke with Governor Mark Mitchell regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. February 6, 2012: Mr. Halliday left a message for Governor Mitchell regarding the Pueblo's participation in the LTEMP process. February 14, 2012: Mr. Halliday left a message for Governor Mitchell regarding the Pueblo's participation in the LTEMP process.	January 23, 2012: Governor Mitchell informed Mr. Halliday that he would ask the council and get back to him.
Pueblo of Zia	January 23, 2012: John Halliday, DOI, called and left a message for Mr. Peter Pino regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday called and left a message for Mr. Peter Pino regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 27, 2012: Mr. Halliday called and left a message for Mr. Peter Pino regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. February 6, 2012: Mr. Halliday called and left a message for Mr. Peter Pino regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. February 14, 2012: Mr. Halliday called and left a message for Mr. Peter Pino regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. May 3, 2012: Mary Barger spoke with the Pueblo of Zia. They will get back to her on a date for a meeting. May 14, 2012: Ms. Barger spoke with Tribal Administrator Peter Pino and a meeting was scheduled for May 23.	February 29, 2012: Mr. Pino called Mr. Halliday. He said that the Pueblo of Zia would like LTEMP Representatives to come out to the Pueblo and make a presentation on this subject. February 18, 2014: Delivery Confirmation of February 13 letter signed by Tammy L. Pino.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Pueblo of Zia (Cont.)	April 8, 2013: Sarah Rinkevich, Tribal Liaison, left a message for Mr. Peter Pino regarding the Tribe's participation in LTEMP. February 11, 2014: Bruce Verhaaren, Argonne, sent an e-mail to Governor David Pino regarding the Pueblo of Zia participation in the LTEMP process. The letter indicated that despite many attempts, Argonne and the joint-leads have not received a response from the Pueblo of Zia since January 2013 and advised that they would be moved to the mailing list unless otherwise instructed by February 28, 2014. February 13, 2014: Argonne sent a hardcopy of the above-referenced letter to Governor Pino.	
Pueblo of Zuni	November 10, 2011: Janet Cohen, NPS, presented information about the LTEMP to Kurt Dongoske and members of the Zuni Cultural Resources Advisory Team (ZCRAT). December 13, 2011: Ms. Heffernan met with the Zuni about another matter, but was advised by Mr. Dongoske that the Pueblo of Zuni will be a Cooperating Agency. January 9, 2012: Ms. Cohen confirmed the receipt of the Zuni's request to be a Cooperating Agency with Kurt Dongoske. August/September 2012: MOU signed by joint-leads. April 17, 2014: Bruce Verhaaren, Argonne, informed Mr. Dongoske that a draft copy of Chapter 3 should be available for Tribal review the week of April 21. April 30, 2014: Mr. Verhaaren informed Mr. Dongoske that Chapter 3 is still undergoing review by the joint-leads and he is not sure when the Tribes will be able to view it. May 5, 2014: Verhaaren informed Mr. Dongoske that text submitted by the Pueblo of Zuni was incorporated into the various technical areas of Chapter 3 and that the chapter will be ready for review upon approval of project management.	November 4, 2011: Mr. Dongoske called Beverly Heffernan, Reclamation, with some questions on the general LTEMP process. He asked why there was no public meeting in New Mexico and asked that Ms. Cohen provide information about the project. He indicated that Zuni would want a presentation sooner rather than later by John Wessels, NPS, and Larry Walkoviak, Reclamation. December 22, 2011: Governor Arlen Quetawki, Sr., sent a letter indicating that the Zuni would like to be a Cooperating Agency on the LTEMP. Mr. Quetawki advised that Mr. Dongoske is the primary representative of the Zuni for the LTEMP. The Cooperating Agency form was signed and enclosed. July 26, 2012: MOU signed. March 25, 2014: Mr. Dongoske requested a copy of Chapter 3 so that the ZCRAT could review how the Zuni information had been included. February 7, 2015: Pueblo of Zuni submitted comments on preliminary Chapters 1 and 2. June 24, 2015: Pueblo of Zuni submitted comments on preliminary Chapter 3.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Pueblo of Zuni (Cont.)	December 17, 2014: Preliminary Chapters 1 and 2 sent to Pueblo of Zuni for review.	September 29, 2015: Pueblo of Zuni submitted comments on the LTEMP DEIS.
	April 15, 2015: Preliminary Chapter 3 sent to Pueblo of Zuni for review.	May 4, 2016: Pueblo of Zuni submitted additional comments on the LTEMP DEIS.
	July 1, 2015: LTEMP DEIS sent to Pueblo of Zuni for review.	
Salt River Pima-Maricopa Indian Community	February 2012: Steve Daron, LMNRA, called the Salt River Maricopa Indian Community three times, but there was no response.	No response.
	May 14, 2012: Mr. Daron left a few messages with Shane Antone in the Cultural Resource Department but there was no response.	
San Carlos Apache Tribe	January 24, 2012: John Halliday, DOI, called the Tribal Administration staff regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. Mr. Halliday informed Reclamation about the name and address change of the Tribe.	January 24, 2014: A staff person informed Mr. Halliday that a new letter should be sent to the correct name and address.
	January 26, 2012: A copy of the November 2011 letter was sent to the new address.	February 14, 2012: Chairman Rambler requested that Mr. Halliday re-send the LTEMP letter via e-mail and he would get back to Mr. Halliday.
	January 30, 2012: A copy of the November 2011 letter was sent via e-mail.	No further response.
	February 14, 2012: Mr. Halliday called Chairman Terry Rambler regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. As requested, Mr. Halliday sent an e-mail to Chairman Rambler with the LTEMP letter attached.	
Southern Ute Tribal Council	January 23, 2012: John Halliday, DOI, called and left a message for NAGPRA Coordinator Neil Cloud regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	January 27, 2012: Mr. Naranjo informed Mr. Halliday that the Southern Ute Tribal Council did not wish to participate in the LTEMP process.
	January 26, 2012: Mr. Halliday called and left a message for Mr. Cloud regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Southern Ute Tribal Council (Cont.)	January 27, 2012: Mr. Halliday called and was referred to Mr. Alden Naranjo who was serving as the Acting Tribal NAGPRA representative. Mr. Halliday spoke to Mr. Naranjo regarding the LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	
Tohono O'odham Nation	January 24, 2012: John Halliday, DOI, called and left a message for Dr. Ned Norris, Jr., regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday left another message for Dr. Norris regarding the Tribe's participation in the LTEMP process. January 27, 2012: Mr. Halliday left another message for Dr. Norris regarding the Tribe's participation in the LTEMP process. February 06, 2012: Mr. Halliday left another message for Dr. Norris regarding the Tribe's participation in the LTEMP process.	May 03, 2014: Mary Barger, Reclamation, received an e-mail from Peter Steere, THPO, indicating that the Tribe does not wish to participate in the LTEMP process.
Tonto Apache Tribe	January 24, 2012: John Halliday, DOI, called and left a message for Chairman Ivan Smith regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday called and left a message for Chairman Smith regarding the Tribe's participation in the LTEMP process. January 27, 2012: Mr. Halliday called and left a message for Chairman Smith regarding the Tribe's participation in the LTEMP process. February 06, 2012: Mr. Halliday called and left a message for Chairman Smith regarding the Tribe's participation in the LTEMP process.	No response.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Ute Indian Tribe	January 23, 2012: John Halliday, DOI, called and left a message for Betsy Chapoose in the Cultural Rights and Protection Office regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday called and left a message for Ms. Chapoose, regarding the Tribe's participation in the LTEMP process. January 27, 2012: Mr. Halliday called and left a message for Ms. Chapoose, regarding the Tribe's participation in the LTEMP process.	February 1, 2012: Ms. Chapoose returned Mr. Halliday's phone call and informed him that the Tribe did not wish to participate in the LTEMP process, but would like to remain on the mailing list.
Ute Mountain Ute Tribe	February 29, 2012: Rosemary Sucec, Glen Canyon National Recreation Area (GCNRA), called and spoke with Lynn Hartman regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	February 29, 2012: Ms. Hartmann indicated that the Tribe did not wish to participate in the LTEMP process, but would like to remain on the mailing list.
White Mountain Apache	January 23, 2012: John Halliday, DOI, called and left a message for Chairman Ronny Lupe regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process. January 26, 2012: Mr. Halliday called and spoke with Chairman Lupe regarding the Tribe's participation in the LTEMP process. May 3, 2012: Mary Barger, Reclamation, spoke with Mark Altaha, THPO, about a consultation meeting. She also sent a follow-up e-mail to Mr. Altaha with the November 2011 LTEMP letter and requested Mr. Altaha let her know what kind of follow-up would be needed.	January 26, 2012: Mr. Lupe requested that LTEMP representatives meet with the Tribe to talk about the project and asked Mr. Halliday to coordinate the meeting with the Tribal Hydrologist, Cheryl Pailzot. May 3, 2012: Mr. Altaha informed Mary that it was not clear why the Chairman told Mr. Halliday that he wanted a meeting since the project was so far away. Mr. Altaha indicated he would look into the matter and get back to Ms. Barger. May 12, 2012: Mr. Altaha responded to Ms. Barger's e-mail and indicated he would forward her request to Ms. Pailzot as she was scheduled to meet with Chairman Lupe regarding the project. May 15, 2012: Ms. Pailzot e-mailed Ms. Barger and informed her she will recommend to Chairman Lupe that the White Mountain Apache do not need to be cooperators on the EIS.

TABLE N-2 (Cont.)

Tribe	Reclamation and NPS Communications with Tribes	Tribal Comment/Response
Yavapai-Apache Nation	May 15, 2012: Jan Balsom, GCNP, called Christopher Coder regarding the Yavapai-Apache Nation's interest in a meeting to discuss the LTEMP process. September 27, 2012: Bruce Verhaaren, Argonne, sent Christopher an e-mail asking him to confirm that the Yavapai-Apache Nation no longer wished to function as a Cooperating Agency due to the changing circumstances and only a peripheral interest, as stated in an earlier conversation. October 10, 2012: Mr. Verhaaren sent a follow-up e-mail to Christopher Coder asking him to confirm that the Tribe no longer wishes to act as a Cooperating Agency for LTEMP. October 23, 2012: Mr. Verhaaren sent a follow-up e-mail to Christopher Coder asking him to confirm that the Tribes no longer wishes to act as a Cooperating Agency for LTEMP.	January 9, 2012: Mr. Coder, Tribal Archaeologist, returned the Cooperating Agency form indicating that the Yavapai-Apache would like to be a Cooperating Agency. May 15, 2012: Mr. Coder returned Ms. Balsom's call and left a voicemail indicating that the Yavapai-Apache Nation would like to see the final set of alternatives before determining if they would like to have a meeting. October 10, 2012: Mr. Coder responded to Mr. Verhaaren's e-mail and indicated that he will confirm the position of the Yavapai-Apache Nation in regard to LTEMP participation at their next meeting and get back Mr. Verhaaren. October 24, 2012: Mr. Coder sent Mr. Verhaaren an e-mail confirming that the Tribe did not wish to participate as a Cooperating Agency anymore.
Yavapai-Prescott Indian Tribe	February 1, 2012: Steve Daron, LMNRA, called the Tribe and was directed to Greg Glassco. Mr. Daron left a message for Mr. Glassco regarding the November 2011 LTEMP letter asking if the Tribe wished to participate in the LTEMP process.	February 1, 2012: Mr. Glassco sent an e-mail to Mr. Daron indicating that the Tribe does not need to be consulted for LTEMP.

everyone. Every effort was made to hold a meeting when everyone was available; however, due to schedule conflicts there were instances when individuals could not attend and make-up meetings were held for these individuals. Tribes were sent an e-mail invitation prior to each meeting, as well as a meeting reminder with an agenda, call-in number, password, and any pertinent materials needed for review before the meeting. Meeting notes and presentations were distributed shortly after the meetings when requested. Meeting notes and other important documents related to the LTEMP EIS development process were also sent to those Tribes who wished to remain on the mailing list. Reclamation and NPS will continue to provide consultation opportunities for interested Tribes and keep all Tribal entities informed about the NEPA process for the EIS. A list of major face-to-face meetings, webinars, and conference calls involving Tribes is provided in Table N-3.

To date, the joint-leads have held individual Tribal consultation meetings with the Fort Mojave Indian Tribe, the Fort Yuma Quechan, the Havasupai Tribe, the Hualapai Tribe, the Hopi Tribe, the Kaibab Paiute Indian Tribe, the Navajo Nation, the Pueblo of Zia, and the Pueblo of Zuni. During these meetings, the background and overview of LTEMP process and was discussed, as well as specific Tribal concerns related to the LTEMP EIS. A summary of these meetings is provided in Table N-4.

Throughout the early stages of EIS development, many Tribes indicated the need for monetary assistance to be able to fully contribute Tribal knowledge to the EIS. The joint-leads recognized that in some cases it was appropriate to pay a fee for professional services to address the travel costs of Tribal representatives who possess special cultural knowledge or may experience a potential loss of income by being away from their regular jobs to attend a consultation meeting. At the March 14, 2013, Tribal Workshop, the joint-leads requested from the Tribes funding proposals detailing the cost of travel and compensation of Tribal Representatives for their participation in the LTEMP. The joint-leads agreed to fund—to the extent possible—reimbursement of Tribal representatives (elders, or experts not already being paid salaries by the Tribe) to participate LTEMP meetings by invitation and agreement in advance and the cost of deliverables for editing/preparing specific information such as the Affected Environment section of the EIS or requested data or reports regarding affected sites, if those materials are not already publically available. Tasks not funded included review of EIS chapters or drafts and fees for Tribal representatives (such as THPOs) who are being paid by the Tribes to participate in the cooperating agency meetings. Tribes submitted proposals and were funded as appropriate.

Throughout the course of developing the EIS, Cooperating Agency Tribes were asked to review and provide comments on the *Tribal Consultation Plan for the Glen Canyon Dam Long-Term Experimental and Management Plan Environmental Impact Statement, Draft Performance Criteria and Draft Objectives for the Glen Canyon Dam Long-Term Experimental and Management Plan, and the Preliminary Draft Alternatives*. Tribes submitted comments and suggestions and the joint-leads incorporated them as appropriate. Cooperating Agency Tribes were also afforded the opportunity for preliminary review of select chapters of the preliminary DEIS prior to distribution to other Cooperating Agencies. They were also sent revised copies of the DEIS when it was distributed to Cooperating Agencies. The joint-lead agencies also sent responses to the Tribes who submitted comments.

TABLE N-3 Summary of Major Face-to-Face Meetings, Webinars, and Conference Calls Involving Tribes

Date	Meeting	Meeting Type	Location
February 11, 2011	LTEMP EIS Kickoff Meeting	Face-to-Face	Tempe, AZ

September 8, 2016	Meeting—Discussion of the LTEMP Programmatic Agreement	Webinar	
September 22, 2016	Meeting—Discussion of the LTEMP Programmatic Agreement	Webinar	

At the start of the LTEMP, a document entitled *American Indian Perspectives and Values Related to the Glen Canyon Dam Long-term Experimental and Management Plan Environmental Impact Statement* was developed for inclusion as a chapter in the LTEMP EIS and distributed to the Cooperating and Consulting Tribes for review. After considering a number of comments received on the document and expressed at Tribal meetings, it was determined that Tribal concerns would best be incorporated throughout the EIS and would not be limited to one section. Instead, a Tribal Resources section (Section 3.9) was added to Chapter 3 (Affected Environment) and Tribal views and concerns were expressed here and incorporated into various resource areas throughout the chapter. Tribes were invited to contribute their own text to Chapter 3 and the Tribal Lands section (Section 1.5.2.3) of Chapter 1. For those Tribes who did not wish to write or did not have the resources to write the section themselves, Argonne National Laboratory (Argonne) provided text that was reviewed by a Tribal representative. To best incorporate Tribal views and concerns, Argonne reviewed meeting notes, ethnographic reports published for the 1995 LTEP EIS, and monitoring reports prepared for Tribal monitoring programs in the Canyon. Argonne requested additional relevant sources from Tribes that would be useful in the preparation of the chapter and information from these sources was incorporated into the EIS. Argonne communicated with Tribes via e-mail and phone during the preparation of Chapter 3 in order to ensure that Tribal views and concerns were being presented correctly.

TABLE N-4 Summary of Individual Tribal Consultation Meetings to Date

Tribe	Date	Attendees	Location
Fort Mojave Indian Tribe	May 4, 2012	Reclamation, NPS, Representatives of the Fort Mojave Indian Tribe	Needles, CA
Fort Yuma Quechan	June 22, 2012	Reclamation, NPS, Representatives of the Fort Yuma Quechan	Near Yuma, AZ
The Havasupai Tribe	November 8, 2013	Reclamation, NPS, DOI Tribal Liaison, Havasupai Tribal Council	Supai Village, AZ

On April 2, 2014, after a stakeholder workshop presenting modeling results and explaining SDA, Mike Runge (DOI), sent the LTEMP swing-weighting exercise and a summary consequence table to Stakeholders, including Tribes, to complete and be used as input to be considered in the EIS. A follow-up webinar where Stakeholders could ask questions regarding swing weighting was held on April 4, 2014, but no Tribal representatives were in attendance. Participation in the swing-weighting exercise was voluntary and some Tribes chose not to participate. Others returned their results and the results were incorporated into the EIS.

Chapters 1 and 2 of the preliminary LTEMP DEIS were sent to Tribes for review in December 2014. Chapter 3 of the LTEMP DEIS was sent to Tribes in for review in April 2015. A full copy of the LTEMP DEIS was sent to all Cooperating Agencies, including Tribes, in June 2015. Tribes were encouraged to provide comments during all three comment periods. Comments were received from the Havasupai Tribe, Hopi Tribe, Hualapai Tribe, Kaibab Band of Paiute Indians, Navajo Nation, and Pueblo of Zuni.

A listing of individual Tribal consultation meetings is provided in Table N-4, and an index of Tribal government consultation and coordination is provided in Table N-5. Table N-5 includes a page number reference to copies of correspondence that are located in Attachment 2.

N.2 CONSULTATION WITH THE STATE HISTORIC PRESERVATION OFFICE (SHPO)

This section presents the interactions that occurred as part of the NHPA Section 106 review for the LTEMP EIS. A brief overview of the consultation process with State Historic Preservation Officers (SHPOs) is provided below.

On June 12, 2014, the joint-leads sent a letter to the Arizona State SHPO notifying him of the intent to complete the LTEMP EIS. The letter provided a review of the LTEMP to date with a draft description of the proposed Area of Potential Effect. The letter also indicated the desire to consult with the SHPO pursuant to Section 106 of the NHPA. A copy of this letter was also sent to the Advisory Council on Historic Preservation and all Cooperating Agencies. The SHPO's office responded on July 18, 2014, indicating they look forward to working with the joint-leads on the Programmatic Agreement. A copy of these letters is provided in Attachment 3.

ATTACHMENT N.1

(a) Havasupai Tribe

Memorandum of Understanding
Between
the Bureau of Reclamation and the National Park Service
and
the Havasupai Tribe
for the Environmental Impact Statement for Adoption of a Long Term Experimental and Management Plan for the Operation of Glen Canyon Dam

I. Introduction and Purpose

Pursuant to the National Environmental Policy Act (NEPA), the Department of the Interior (Department), through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS), is preparing an environmental impact statement (EIS) for a Long Term Experimental and Management Plan (LTEMP) for the operation of Glen Canyon Dam. Reclamation and the NPS are the joint lead or "joint-lead agencies" for the completion of this EIS. The Havasupai Tribe hereafter "the cooperating agency", in addition to other parties, has agreed to serve as a cooperating agency for the completion of the LTEMP EIS. The purpose of this Memorandum of Understanding (MOU) is to outline the roles and responsibilities of the joint-lead and the cooperating agency (hereinafter collectively referred to alternatively as "agencies" or "parties") in accordance with 43 CFR § 46.225(d).

II. Background

The LTEMP process is intended to develop and implement a structured, long term experimental and management plan, to determine the need for potential future modifications to Glen Canyon Dam operations, and to determine whether to establish an Endangered Species Act (ESA) Recovery Implementation Program for endangered fish species below Glen Canyon Dam. Revised dam operations and other actions under the jurisdiction of the Secretary of the Interior will be considered within alternatives of the EIS, in keeping with the scope of the Grand Canyon Protection Act (GCPA). The NEPA process will document and evaluate impacts of the alternatives described in the EIS.

III. Purpose of this MOU

This MOU defines the relationship and duties of the joint-lead and the cooperating agency in completing NEPA compliance for the LTEMP, and how the parties will cooperate during the NEPA process.

By signing this MOU, the parties agree that this MOU provides the framework to fulfill compliance requirements for NEPA.

IV. Agency Designee

The cooperating agency will designate a primary point of contact (and alternate if desired) for the EIS by sending correspondence at the time of signing of this agreement to the joint-lead agencies with the contacts name and information. The cooperating agency may change its point

of contact at any time by providing written notice to the joint-lead agencies and the other cooperating agencies.

V. Authority

The authority of the joint-lead and the cooperating agency to participate in this agreement is provided by the National Environmental Policy Act, 42 U.S.C. §§ 4321 *et seq.* NEPA allows agencies to be designated as a cooperating agency when that agency has jurisdiction by law or special expertise (40 CFR § 1501.6 and 40 CFR§ 1508.5). Activities contemplated under this MOU are specifically authorized under:

A. Title I of NEPA;

B. "Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act," 40 CFR §§ 1500-1508, Council on Environmental Quality (in particular 40 CFR § 1501.6, Cooperating Agencies);

C. Department of the Interior NEPA Implementing Procedures in the Departmental Manual at 43 CFR § Part 46, Cooperating Agencies (40 CFR §1501.6).

VI. Joint-lead Agency Responsibilities

Reclamation and the NPS will be joint-leads for this effort because Reclamation has primary responsibility for operation of Glen Canyon Dam and the NPS has primary responsibility for managing Grand Canyon National Park, Glen Canyon National Recreation Area, and Lake Mead National Recreation Area.

The NPS and Reclamation, as joint-leads for the completion of the LTEMP EIS, shall:

A. Jointly be responsible for the preparation, quality, content and overall direction of the EIS and for ensuring the appropriate participation of cooperating agencies in developing the EIS.

B. Jointly be responsible for identifying the purpose and need for the project, scope of analysis, and decisions to be made. In coordination with the Department, the joint-lead agencies will make the final decision on the content of all EIS-related documents, including the preferred alternative and the Record of Decision to be signed by the Secretary of the Interior.

C. Jointly oversee the execution and administration of contracts or cooperative agreements with mutually agreed upon federal, state or local agencies, or tribal governments or mutually agreed upon private contractors to develop information for inclusion in the EIS.

D. Jointly conduct cooperating agency meetings, and provide advance information for discussions at these meetings, as necessary during the preparation of the EIS. Meeting dates and locations will be jointly agreed upon and may be chosen to coincide with the

dates of Adaptive Management Working Group meetings to minimize travel costs and maximize collaboration.

E. Ensure that cooperating agency proposals and substantive comments (including divergent views) within their jurisdiction or technical expertise are appropriately documented and considered in the EIS.

F. Provide advance copies (normally 30 days) of the preliminary draft and preliminary final EIS and related compliance documents for review by cooperating agencies.

VII. Cooperating Agency Responsibilities

Federal, state, and local agencies, and tribal governments with appropriate expertise or jurisdiction have been invited to participate as cooperating agencies. Reclamation and NPS may, at any time during the course of the EIS project, invite additional agencies to participate in the process.

The cooperating agency, subject to sufficient appropriations to carry out the following responsibilities, shall:

A. Participate in the NEPA process at the earliest possible time.

B. Participate in the scoping process.

C. Assume, on request of the lead agencies, responsibility for developing information and preparing environmental analyses including portions of the environmental impact statement concerning which the cooperating agency has special expertise.

D. Make available staff support at the lead agencies' request to enhance the latter's interdisciplinary capability.

E. Normally use their own funds.

F. The cooperating agency may in response to a lead agencies' request for assistance in preparing the environmental impact statement reply that other program commitments preclude any involvement or the degree of involvement requested in the action that is the subject of the environmental impact statement.

G. Provide comments in a timely manner (normally within 30 days of receipt) of draft documents when requested. One consolidated set of comments for the cooperating agency will be provided in the format specified by the joint-lead agencies.

H. As appropriate and practicable, attend cooperating agency meetings and public meetings and hearings on the EIS process.

I. Retain the right to comment on all issues related to the EIS through the normal EIS public review and comment process.

expand, or substitute for those provisions or regulations. This MOU does not impose legally-binding requirements on the Parties, nor does it create a legal right of action for the Parties or any third party.

J. **AGENCY AND PARTNERSHIP.** Unless expressly provided by law, personnel or volunteers of one party shall not be considered to be agents, partners or employees of the other party for any purpose, and no joint venture or principal-agent relationship shall be deemed to exist. The personnel and volunteers of one party are not entitled to any of the benefits that any other party provides for its employees or volunteers.

K. **LIABILITY.** To the extent authorized by law, on behalf of itself, its officers, directors, members, employees, agents, and representatives, each party agrees that it will be responsible for its own acts and omissions and the results thereof and that it shall not be responsible for the acts or omissions of other parties, nor the results thereof. To the extent authorized by law, each party therefore agrees that it will assume the risk and liability to itself, its agents, employees, and volunteers for any injury to or death of persons or loss or destruction of property resulting in any manner from the conduct of the party's own operations and/or the operations of its agents, employees, and/or volunteers under this MOU. To the extent authorized by law, each party further releases and waives all claims against the other party for compensation for any loss, cost, damage, expense, personal injury, death, claim, or other liability arising out of the performance of this MOU.

L. **NONDISCRIMINATION.** This MOU is subject to all Federal statutes relating to nondiscrimination. These include, but are not limited to: (a) Title VI of the Civil Rights Act of 1964 (P.L. 88-352); and (b) Title IX of the Education Amendments of 1972 (20 U.S.C. 1681-1683 and 1685-1686).

XI. Effective Dates, Amendment and Termination

A. This MOU will become effective on the date of the last signature and may be subsequently amended through written agreement of all signatories. The joint-lead agencies or the cooperating agency may terminate their cooperative status by providing 30 days written notice of termination to the other party. Otherwise, the cooperative status will terminate when a Record of Decision is issued or the EIS is terminated.

XII. Signatures

The parties hereto have executed this Memorandum of Understanding as of the dates shown below.

Memorandum of Understanding
Between
the Bureau of Reclamation and the National Park Service
and
the Hopi Tribe
for the Environmental Impact Statement for Adoption of a Long Term Experimental and Management Plan for the Operation of Glen Canyon Dam

I. Introduction and Purpose

Pursuant to the National Environmental Policy Act (NEPA), the Department of the Interior (Department), through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS), is preparing an environmental impact statement (EIS) for a Long Term Experimental and Management Plan (LTEMP) for the operation of Glen Canyon Dam. Reclamation and the NPS are the joint lead or "joint-lead agencies" for the completion of this EIS. The Hopi Tribe hereafter "the cooperating agency", in addition to other parties, has agreed to serve as a cooperating agency for the completion of the LTEMP EIS. The purpose of this Memorandum of Understanding (MOU) is to outline the roles and responsibilities of the joint-lead and the cooperating agency (hereinafter collectively referred to alternatively as "agencies" or "parties") in accordance with 43 CFR § 46.225(d).

II. Background

The LTEMP process is intended to develop and implement a structured, long term experimental and management plan, to determine the need for potential future modifications to Glen Canyon Dam operations, and to determine whether to establish an Endangered Species Act (ESA) Recovery Implementation Program for endangered fish species below Glen Canyon Dam. Revised dam operations and other actions under the jurisdiction of the Secretary of the Interior will be considered within alternatives of the EIS, in keeping with the scope of the Grand Canyon Protection Act (GCPA). The NEPA process will document and evaluate impacts of the alternatives described in the EIS.

III. Purpose of this MOU

This MOU defines the relationship and duties of the joint-lead and the cooperating agency in completing NEPA compliance for the LTEMP, and how the parties will cooperate during the NEPA process.

By signing this MOU, the parties agree that this MOU provides the framework to fulfill compliance requirements for NEPA.

IV. Agency Designee

The cooperating agency will designate a primary point of contact (and alternate if desired) for the EIS by sending correspondence at the time of signing of this agreement to the joint-lead agencies with the contacts name and information. The cooperating agency may change its point

of contact at any time by providing written notice to the joint-lead agencies and the other cooperating agencies.

V. Authority

The authority of the joint-lead and the cooperating agency to participate in this agreement is provided by the National Environmental Policy Act, 42 U.S.C. §§ 4321 *et seq.* NEPA allows agencies to be designated as a cooperating agency when that agency has jurisdiction by law or special expertise (40 CFR § 1501.6 and 40 CFR§ 1508.5). Activities contemplated under this MOU are specifically authorized under:

A. Title I of NEPA;

B. "Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act," 40 CFR §§ 1500-1508, Council on Environmental Quality (in particular 40 CFR § 1501.6, Cooperating Agencies);

C. Department of the Interior NEPA Implementing Procedures in the Departmental Manual at 43 CFR § Part 46, Cooperating Agencies (40 CFR §1501.6).

VI. Joint-lead Agency Responsibilities

Reclamation and the NPS will be joint-leads for this effort because Reclamation has primary responsibility for operation of Glen Canyon Dam and the NPS has primary responsibility for managing Grand Canyon National Park, Glen Canyon National Recreation Area, and Lake Mead National Recreation Area.

The NPS and Reclamation, as joint-leads for the completion of the LTEMP EIS, shall:

A. Jointly be responsible for the preparation, quality, content and overall direction of the EIS and for ensuring the appropriate participation of cooperating agencies in developing the EIS.

B. Jointly be responsible for identifying the purpose and need for the project, scope of analysis, and decisions to be made. In coordination with the Department, the joint-lead agencies will make the final decision on the content of all EIS-related documents, including the preferred alternative and the Record of Decision to be signed by the Secretary of the Interior.

C. Jointly oversee the execution and administration of contracts or cooperative agreements with mutually agreed upon federal, state or local agencies, or tribal governments or mutually agreed upon private contractors to develop information for inclusion in the EIS.

D. Jointly conduct cooperating agency meetings, and provide advance information for discussions at these meetings, as necessary during the preparation of the EIS. Meeting dates and locations will be jointly agreed upon and may be chosen to coincide with the

dates of Adaptive Management Working Group meetings to minimize travel costs and maximize collaboration.

E. Ensure that cooperating agency proposals and substantive comments (including divergent views) within their jurisdiction or technical expertise are appropriately documented and considered in the EIS.

F. Provide advance copies (normally 30 days) of the preliminary draft and preliminary final EIS and related compliance documents for review by cooperating agencies.

VII. Cooperating Agency Responsibilities

Federal, state, and local agencies, and tribal governments with appropriate expertise or jurisdiction have been invited to participate as cooperating agencies. Reclamation and NPS may, at any time during the course of the EIS project, invite additional agencies to participate in the process.

The cooperating agency, subject to sufficient appropriations to carry out the following responsibilities, shall:

A. Participate in the NEPA process at the earliest possible time.

B. Participate in the scoping process.

C. Assume, on request of the lead agencies, responsibility for developing information and preparing environmental analyses including portions of the environmental impact statement concerning which the cooperating agency has special expertise.

D. Make available staff support at the lead agencies' request to enhance the latter's interdisciplinary capability.

E. Normally use their own funds.

F. The cooperating agency may in response to a lead agencies' request for assistance in preparing the environmental impact statement reply that other program commitments preclude any involvement or the degree of involvement requested in the action that is the subject of the environmental impact statement.

G. Provide comments in a timely manner (normally within 30 days of receipt) of draft documents when requested. One consolidated set of comments for the cooperating agency will be provided in the format specified by the joint-lead agencies.

H. As appropriate and practicable, attend cooperating agency meetings and public meetings and hearings on the EIS process.

I. Retain the right to comment on all issues related to the EIS through the normal EIS public review and comment process.

J. Promptly advise the joint-lead agencies of concerns related to the EIS process.

VIII. Shared Responsibilities of all Parties

A. Reclamation and NPS may meet separately with any one or more cooperating agencies to discuss specific topics.

B. It is understood that the respective agencies are normally responsible for their own costs with regard to completion of tasks outlined herein, such as attendance at meetings, assembling data, analyzing effects, and providing input with regard to sections of the EIS subject to section VII.F. Funding requests from tribal governments with a demonstrated need will be considered on a case by case basis by the joint-lead agencies.

C. All parties agree that because of the need for timely completion of NEPA compliance, work will proceed as expeditiously as possible, including data gathering, analysis, and document review. However, all parties agree that sufficient time must be allowed to ensure thorough document review. It is anticipated that the parties will be given a minimum of 30 days to review the preliminary draft EIS and a minimum of 30 days to review the draft final EIS.

IX. Resolution of Disputes

Reclamation and NPS are responsible for all decisions involving the EIS and will make all final decisions on disputes arising during the NEPA process. The joint-lead agencies will document the nature of any dispute and the resolution of the dispute. Documentation of resolution will be made available to appropriate parties.

X. Standard Conditions:

A. AUTHORITIES. Nothing in this MOU shall be construed to extend the jurisdiction or decision-making authority of any party to this MOU beyond that which exists under current laws and regulations. Nothing in this MOU shall be construed as limiting or affecting the authority or legal responsibility of any party, or as binding any party to perform beyond the respective authority of each, or to require any party to assume or expend any specific sum of money. The provisions of this MOU are subject to the laws of the United States; and the regulations of the Department of the Interior, as they may be applicable. Nothing in this MOU shall be construed as affecting the decision-making requirements of any party or impairing the independent judgment of each party regarding policy decisions.

B. RELEASE OF INFORMATION. Except as required by court order or ruling, the joint - lead agencies and the cooperating agency will not release any pre-decisional material or working information or documents to the public other than through an approved Freedom of Information Act request or comparable tribal or state law-based process, or unless the agency or agencies have already disseminated the specific materials or documents to the public. The

agencies agree to inform each other if it is determined that there is a legal requirement to release any such information, and that information will include expected release date of the information.

C. **LEGAL RIGHTS AND REMEDIES.** Nothing in this MOU shall be construed to alter the legal rights and remedies that each party would otherwise have. No party waives any legal rights or defenses by entering into this MOU or participating in the process contemplated hereby. This MOU is not a Federal contract, rule, or regulation. This MOU shall not be construed as or interpreted to be final Federal agency action.

D. **SEVERABILITY.** Should any portion of this MOU be judicially determined to be illegal or unenforceable, the remainder of the MOU shall continue in full force and effect, and any party may renegotiate the terms affected by the severance.

E. **THIRD PARTY BENEFICIARY RIGHTS.** The parties do not intend to create in any other individual or entity the status of third party beneficiary, and this MOU shall not be construed so as to create such status. The rights, duties and obligations contained in this MOU shall operate only among the parties to this MOU, and shall inure solely to the benefit of the parties to this MOU. The provisions of this MOU are intended only to assist the parties in determining and performing their obligations under this MOU.

F. **NON-FUND OBLIGATION DOCUMENT.** This MOU is neither a fiscal nor a funds obligation document. Any endeavor or transfer of anything of value involving reimbursement or contribution of funds between the parties to this instrument will be handled in accordance with applicable laws, regulations, and procedures including those for Government procurement and printing. Such endeavors will be outlined in separate agreements that shall be made in writing by representatives of the parties and shall be independently authorized by appropriate rules, policies, and statutory authority. This MOU does not provide such authority. Specifically, this MOU does not establish authority for noncompetitive award to the cooperator of any contract or other agreement. Nothing herein constitutes a binding commitment to fund any of the proceedings encompassed by the MOU. Any specific cost sharing or funding shall be executed separately through other funding mechanisms, as deemed necessary and appropriate by each of the signatories.

G. **PARTICIPATION IN SIMILAR ACTIVITIES WITH OTHER ENTITIES.** This MOU in no way restricts any of the parties from participating in similar activities with other public or private agencies, organizations, and individuals.

H. **ENDORSEMENT.** Nothing in this MOU may be interpreted to imply that the United States, the Department of the Interior, the NPS, the Bureau of Reclamation, or the cooperating agency endorses any product, service or policy of the other parties. No party will take any action or make any statement that suggests or implies such an endorsement.

I. **STATUTES AND REGULATIONS.** The provisions of any statutes and/or regulations cited in this MOU contain legally binding requirements. The MOU itself does not alter, expand, or substitute for those provisions or regulations. This MOU does not impose legally-

binding requirements on the Parties, nor does it create a legal right of action for the Parties or any third party.

J. **AGENCY AND PARTNERSHIP.** Unless expressly provided by law, personnel or volunteers of one party shall not be considered to be agents, partners or employees of the other party for any purpose, and no joint venture or principal-agent relationship shall be deemed to exist. The personnel and volunteers of one party are not entitled to any of the benefits that any other party provides for its employees or volunteers.

K. **LIABILITY.** To the extent authorized by law, on behalf of itself, its officers, directors, members, employees, agents, and representatives, each party agrees that it will be responsible for its own acts and omissions and the results thereof and that it shall not be responsible for the acts or omissions of other parties, nor the results thereof. To the extent authorized by law, each party therefore agrees that it will assume the risk and liability to itself, its agents, employees, and volunteers for any injury to or death of persons or loss or destruction of property resulting in any manner from the conduct of the party's own operations and/or the operations of its agents, employees, and/or volunteers under this MOU. To the extent authorized by law, each party further releases and waives all claims against the other party for compensation for any loss, cost, damage, expense, personal injury, death, claim, or other liability arising out of the performance of this MOU.

L. **NONDISCRIMINATION.** This MOU is subject to all Federal statutes relating to nondiscrimination. These include, but are not limited to: (a) Title VI of the Civil Rights Act of 1964 (P.L. 88-352); and (b) Title IX of the Education Amendments of 1972 (20 U.S.C. 1681-1683 and 1685-1686).

XI. Effective Dates, Amendment and Termination

A. This MOU will become effective on the date of the last signature and may be subsequently amended through written agreement of all signatories. The joint-lead agencies or the cooperating agency may terminate their cooperative status by providing 30 days written notice of termination to the other party. Otherwise, the cooperative status will terminate when a Record of Decision is issued or the EIS is terminated.

XII. Signatures

Memorandum of Understanding
Between
the Bureau of Reclamation and the National Park Service
and
the Hualapai Tribe
for the Environmental Impact Statement for Adoption of a Long Term Experimental and Management Plan for the Operation of Glen Canyon Dam

I. Introduction and Purpose

Pursuant to the National Environmental Policy Act (NEPA), the Department of the Interior (Department), through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS), is preparing an environmental impact statement (EIS) for a Long Term Experimental and Management Plan (LTEMP) for the operation of Glen Canyon Dam. Reclamation and the NPS are the joint lead or "joint-lead agencies" for the completion of this EIS. The Hualapai Tribe hereafter "the cooperating agency", in addition to other parties, has agreed to serve as a cooperating agency for the completion of the LTEMP EIS. The purpose of this Memorandum of Understanding (MOU) is to outline the roles and responsibilities of the joint-lead and the cooperating agency (hereinafter collectively referred to alternatively as "agencies" or "parties") in accordance with 43 CFR § 46.225(d).

II. Background

The LTEMP process is intended to develop and implement a structured, long term experimental and management plan, to determine the need for potential future modifications to Glen Canyon Dam operations, and to determine whether to establish an Endangered Species Act (ESA) Recovery Implementation Program for endangered fish species below Glen Canyon Dam. Revised dam operations and other actions under the jurisdiction of the Secretary of the Interior will be considered within alternatives of the EIS, in keeping with the scope of the Grand Canyon Protection Act (GCPA). The NEPA process will document and evaluate impacts of the alternatives described in the EIS.

III. Purpose of this MOU

This MOU defines the relationship and duties of the joint-lead and the cooperating agency in completing NEPA compliance for the LTEMP, and how the parties will cooperate during the NEPA process.

By signing this MOU, the parties agree that this MOU provides the framework to fulfill compliance requirements for NEPA.

IV. Agency Designee

The cooperating agency will designate a primary point of contact (and alternate if desired) for the EIS by sending correspondence at the time of signing of this agreement to the joint-lead agencies with the contacts name and information. The cooperating agency may change its point

of contact at any time by providing written notice to the joint-lead agencies and the other cooperating agencies.

V. Authority

The authority of the joint-lead and the cooperating agency to participate in this agreement is provided by the National Environmental Policy Act, 42 U.S.C. §§ 4321 *et seq*. NEPA allows agencies to be designated as a cooperating agency when that agency has jurisdiction by law or special expertise (40 CFR § 1501.6 and 40 CFR§ 1508.5). Activities contemplated under this MOU are specifically authorized under:

A. Title I of NEPA;

B. "Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act," 40 CFR §§ 1500-1508, Council on Environmental Quality (in particular 40 CFR § 1501.6, Cooperating Agencies);

C. Department of the Interior NEPA Implementing Procedures in the Departmental Manual at 43 CFR § Part 46, Cooperating Agencies (40 CFR §1501.6).

VI. Joint-lead Agency Responsibilities

Reclamation and the NPS will be joint-leads for this effort because Reclamation has primary responsibility for operation of Glen Canyon Dam and the NPS has primary responsibility for managing Grand Canyon National Park, Glen Canyon National Recreation Area, and Lake Mead National Recreation Area.

The NPS and Reclamation, as joint-leads for the completion of the LTEMP EIS, shall:

A. Jointly be responsible for the preparation, quality, content and overall direction of the EIS and for ensuring the appropriate participation of cooperating agencies in developing the EIS.

B. Jointly be responsible for identifying the purpose and need for the project, scope of analysis, and decisions to be made. In coordination with the Department, the joint-lead agencies will make the final decision on the content of all EIS-related documents, including the preferred alternative and the Record of Decision to be signed by the Secretary of the Interior.

C. Jointly oversee the execution and administration of contracts or cooperative agreements with mutually agreed upon federal, state or local agencies, or tribal governments or mutually agreed upon private contractors to develop information for inclusion in the EIS.

D. Jointly conduct cooperating agency meetings, and provide advance information for discussions at these meetings, as necessary during the preparation of the EIS. Meeting

dates and locations will be jointly agreed upon and may be chosen to coincide with the dates of Adaptive Management Working Group meetings to minimize travel costs and maximize collaboration.

E. Ensure that cooperating agency proposals and substantive comments (including divergent views) within their jurisdiction or technical expertise are appropriately documented and considered in the EIS.

F. Provide advance copies (normally 30 days) of the preliminary draft and preliminary final EIS and related compliance documents for review by cooperating agencies.

VII. Cooperating Agency Responsibilities

Federal, state, and local agencies, and tribal governments with appropriate expertise or jurisdiction have been invited to participate as cooperating agencies. Reclamation and NPS may, at any time during the course of the EIS project, invite additional agencies to participate in the process.

The cooperating agency, subject to sufficient appropriations to carry out the following responsibilities, shall:

A. Participate in the NEPA process at the earliest possible time.

B. Participate in the scoping process.

C. Assume, on request of the lead agencies, responsibility for developing information and preparing environmental analyses including portions of the environmental impact statement concerning which the cooperating agency has special expertise.

D. Make available staff support at the lead agencies' request to enhance the latter's interdisciplinary capability.

E. Normally use their own funds.

F. The cooperating agency may in response to a lead agencies' request for assistance in preparing the environmental impact statement reply that other program commitments preclude any involvement or the degree of involvement requested in the action that is the subject of the environmental impact statement.

G. Provide comments in a timely manner (normally within 30 days of receipt) of draft documents when requested. One consolidated set of comments for the cooperating agency will be provided in the format specified by the joint-lead agencies.

H. As appropriate and practicable, attend cooperating agency meetings and public meetings and hearings on the EIS process.

I. Retain the right to comment on all issues related to the EIS through the normal EIS public review and comment process.

J. Promptly advise the joint-lead agencies of concerns related to the EIS process.

VIII. Shared Responsibilities of all Parties

A. Reclamation and NPS may meet separately with any one or more cooperating agencies to discuss specific topics.

B. It is understood that the respective agencies are normally responsible for their own costs with regard to completion of tasks outlined herein, such as attendance at meetings, assembling data, analyzing effects, and providing input with regard to sections of the EIS subject to section VII.F. Funding requests from tribal governments with a demonstrated need will be considered on a case by case basis by the joint-lead agencies.

C. All parties agree that because of the need for timely completion of NEPA compliance, work will proceed as expeditiously as possible, including data gathering, analysis, and document review. However, all parties agree that sufficient time must be allowed to ensure thorough document review. It is anticipated that the parties will be given a minimum of 30 days to review the preliminary draft EIS and a minimum of 30 days to review the draft final EIS.

IX. Resolution of Disputes

Reclamation and NPS are responsible for all decisions involving the EIS and will make all final decisions on disputes arising during the NEPA process. The joint-lead agencies will document the nature of any dispute and the resolution of the dispute. Documentation of resolution will be made available to appropriate parties.

X. Standard Conditions:

A. AUTHORITIES. Nothing in this MOU shall be construed to extend the jurisdiction or decision-making authority of any party to this MOU beyond that which exists under current laws and regulations. Nothing in this MOU shall be construed as limiting or affecting the authority or legal responsibility of any party, or as binding any party to perform beyond the respective authority of each, or to require any party to assume or expend any specific sum of money. The provisions of this MOU are subject to the laws of the United States; and the regulations of the Department of the Interior, as they may be applicable. Nothing in this MOU shall be construed as affecting the decision-making requirements of any party or impairing the independent judgment of each party regarding policy decisions.

B. RELEASE OF INFORMATION. Except as required by court order or ruling, the joint - lead agencies and the cooperating agency will not release any pre-decisional material or working information or documents to the public other than through an approved Freedom of

Information Act request or comparable tribal or state law-based process, or unless the agency or agencies have already disseminated the specific materials or documents to the public. The agencies agree to inform each other if it is determined that there is a legal requirement to release any such information, and that information will include expected release date of the information.

C. **SOVEREIGNTY.** Participation by a tribe in this National Environmental Policy Act process does not diminish the Tribe's rights to protect its sovereignty under their constitutional authorities and in consideration of applicable law.

D. **LEGAL RIGHTS AND REMEDIES.** Nothing in this MOU shall be construed to alter the legal rights and remedies that each party would otherwise have. No party waives any legal rights or defenses by entering into this MOU or participating in the process contemplated hereby. This MOU is not a Federal contract, rule, or regulation. This MOU shall not be construed as or interpreted to be final Federal agency action.

E. **SEVERABILITY.** Should any portion of this MOU be judicially determined to be illegal or unenforceable, the remainder of the MOU shall continue in full force and effect, and any party may renegotiate the terms affected by the severance.

F. **THIRD PARTY BENEFICIARY RIGHTS.** The parties do not intend to create in any other individual or entity the status of third party beneficiary, and this MOU shall not be construed so as to create such status. The rights, duties and obligations contained in this MOU shall operate only among the parties to this MOU, and shall inure solely to the benefit of the parties to this MOU. The provisions of this MOU are intended only to assist the parties in determining and performing their obligations under this MOU.

G. **NON-FUND OBLIGATION DOCUMENT.** This MOU is neither a fiscal nor a funds obligation document. Any endeavor or transfer of anything of value involving reimbursement or contribution of funds between the parties to this instrument will be handled in accordance with applicable laws, regulations, and procedures including those for Government procurement and printing. Such endeavors will be outlined in separate agreements that shall be made in writing by representatives of the parties and shall be independently authorized by appropriate rules, policies, and statutory authority. This MOU does not provide such authority. Specifically, this MOU does not establish authority for noncompetitive award to the cooperator of any contract or other agreement. Nothing herein constitutes a binding commitment to fund any of the proceedings encompassed by the MOU. Any specific cost sharing or funding shall be executed separately through other funding mechanisms, as deemed necessary and appropriate by each of the signatories.

H. **PARTICIPATION IN SIMILAR ACTIVITIES WITH OTHER ENTITIES.** This MOU in no way restricts any of the parties from participating in similar activities with other public or private agencies, organizations, and individuals.

I. **ENDORSEMENT.** Nothing in this MOU may be interpreted to imply that the United States, the Department of the Interior, the NPS, the Bureau of Reclamation, or the

cooperating agency endorses any product, service or policy of the other parties. No party will take any action or make any statement that suggests or implies such an endorsement.

J. **STATUTES AND REGULATIONS.** The provisions of any statutes and/or regulations cited in this MOU contain legally binding requirements. The MOU itself does not alter, expand, or substitute for those provisions or regulations. This MOU does not impose legally-binding requirements on the Parties, nor does it create a legal right of action for the Parties or any third party.

K. **AGENCY AND PARTNERSHIP.** Unless expressly provided by law, personnel or volunteers of one party shall not be considered to be agents, partners or employees of the other party for any purpose, and no joint venture or principal-agent relationship shall be deemed to exist. The personnel and volunteers of one party are not entitled to any of the benefits that any other party provides for its employees or volunteers.

L. **LIABILITY.** To the extent authorized by law, on behalf of itself, its officers, directors, members, employees, agents, and representatives, each party agrees that it will be responsible for its own acts and omissions and the results thereof and that it shall not be responsible for the acts or omissions of other parties, nor the results thereof. To the extent authorized by law, each party therefore agrees that it will assume the risk and liability to itself, its agents, employees, and volunteers for any injury to or death of persons or loss or destruction of property resulting in any manner from the conduct of the party's own operations and/or the operations of its agents, employees, and/or volunteers under this MOU. To the extent authorized by law, each party further releases and waives all claims against the other party for compensation for any loss, cost, damage, expense, personal injury, death, claim, or other liability arising out of the performance of this MOU.

M. **NONDISCRIMINATION.** This MOU is subject to all Federal statutes relating to nondiscrimination. These include, but are not limited to: (a) Title VI of the Civil Rights Act of 1964 (P.L. 88-352); and (b) Title IX of the Education Amendments of 1972 (20 U.S.C. 1681-1683 and 1685-1686).

XI. Effective Dates, Amendment and Termination

A. This MOU will become effective on the date of the last signature and may be subsequently amended through written agreement of all signatories. The joint-lead agencies or the cooperating agency may terminate their cooperative status by providing 30 days written notice of termination to the other party. Otherwise, the cooperative status will terminate when a Record of Decision is issued or the EIS is terminated.

Memorandum of Understanding
Between
the Bureau of Reclamation and the National Park Service
and
the Kaibab Band of Paiute Indians
for the Environmental Impact Statement for Adoption of a Long Term Experimental and Management Plan for the Operation of Glen Canyon Dam

I. Introduction and Purpose

Pursuant to the National Environmental Policy Act (NEPA), the Department of the Interior (Department), through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS), is preparing an environmental impact statement (EIS) for a Long Term Experimental and Management Plan (LTEMP) for the operation of Glen Canyon Dam. Reclamation and the NPS are the joint lead or "joint-lead agencies" for the completion of this EIS. The Kaibab Band of Paiute Indians hereafter "the cooperating agency", in addition to other parties, has agreed to serve as a cooperating agency for the completion of the LTEMP EIS. The purpose of this Memorandum of Understanding (MOU) is to outline the roles and responsibilities of the joint-lead and the cooperating agency (hereinafter collectively referred to alternatively as "agencies" or "parties") in accordance with 43 CFR § 46.225(d).

II. Background

The LTEMP process is intended to develop and implement a structured, long term experimental and management plan, to determine the need for potential future modifications to Glen Canyon Dam operations, and to determine whether to establish an Endangered Species Act (ESA) Recovery Implementation Program for endangered fish species below Glen Canyon Dam. Revised dam operations and other actions under the jurisdiction of the Secretary of the Interior will be considered within alternatives of the EIS, in keeping with the scope of the Grand Canyon Protection Act (GCPA). The NEPA process will document and evaluate impacts of the alternatives described in the EIS.

III. Purpose of this MOU

This MOU defines the relationship and duties of the joint-lead and the cooperating agency in completing NEPA compliance for the LTEMP, and how the parties will cooperate during the NEPA process.

By signing this MOU, the parties agree that this MOU provides the framework to fulfill compliance requirements for NEPA.

IV. Agency Designee

The cooperating agency will designate a primary point of contact (and alternate if desired) for the EIS by sending correspondence at the time of signing of this agreement to the joint-lead agencies with the contacts name and information. The cooperating agency may change its point

of contact at any time by providing written notice to the joint-lead agencies and the other cooperating agencies.

V. Authority

The authority of the joint-lead and the cooperating agency to participate in this agreement is provided by the National Environmental Policy Act, 42 U.S.C. §§ 4321 *et seq.* NEPA allows agencies to be designated as a cooperating agency when that agency has jurisdiction by law or special expertise (40 CFR § 1501.6 and 40 CFR§ 1508.5). Activities contemplated under this MOU are specifically authorized under:

A. Title I of NEPA;

B. "Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act," 40 CFR §§ 1500-1508, Council on Environmental Quality (in particular 40 CFR § 1501.6, Cooperating Agencies);

C. Department of the Interior NEPA Implementing Procedures in the Departmental Manual at 43 CFR § Part 46, Cooperating Agencies (40 CFR §1501.6).

VI. Joint-lead Agency Responsibilities

Reclamation and the NPS will be joint-leads for this effort because Reclamation has primary responsibility for operation of Glen Canyon Dam and the NPS has primary responsibility for managing Grand Canyon National Park, Glen Canyon National Recreation Area, and Lake Mead National Recreation Area.

The NPS and Reclamation, as joint-leads for the completion of the LTEMP EIS, shall:

A. Jointly be responsible for the preparation, quality, content and overall direction of the EIS and for ensuring the appropriate participation of cooperating agencies in developing the EIS.

B. Jointly be responsible for identifying the purpose and need for the project, scope of analysis, and decisions to be made. In coordination with the Department, the joint-lead agencies will make the final decision on the content of all EIS-related documents, including the preferred alternative and the Record of Decision to be signed by the Secretary of the Interior.

C. Jointly oversee the execution and administration of contracts or cooperative agreements with mutually agreed upon federal, state or local agencies, or tribal governments or mutually agreed upon private contractors to develop information for inclusion in the EIS.

D. Jointly conduct cooperating agency meetings, and provide advance information for discussions at these meetings, as necessary during the preparation of the EIS. Meeting dates and locations will be jointly agreed upon and may be chosen to coincide with the

dates of Adaptive Management Working Group meetings to minimize travel costs and maximize collaboration.

E. Ensure that cooperating agency proposals and substantive comments (including divergent views) within their jurisdiction or technical expertise are appropriately documented and considered in the EIS.

F. Provide advance copies (normally 30 days) of the preliminary draft and preliminary final EIS and related compliance documents for review by cooperating agencies.

VII. Cooperating Agency Responsibilities

Federal, state, and local agencies, and tribal governments with appropriate expertise or jurisdiction have been invited to participate as cooperating agencies. Reclamation and NPS may, at any time during the course of the EIS project, invite additional agencies to participate in the process.

The cooperating agency, subject to sufficient appropriations to carry out the following responsibilities, shall:

A. Participate in the NEPA process at the earliest possible time.

B. Participate in the scoping process.

C. Assume, on request of the lead agencies, responsibility for developing information and preparing environmental analyses including portions of the environmental impact statement concerning which the cooperating agency has special expertise.

D. Make available staff support at the lead agencies' request to enhance the latter's interdisciplinary capability.

E. Normally use their own funds.

F. The cooperating agency may in response to a lead agencies' request for assistance in preparing the environmental impact statement reply that other program commitments preclude any involvement or the degree of involvement requested in the action that is the subject of the environmental impact statement.

G. Provide comments in a timely manner (normally within 30 days of receipt) of draft documents when requested. One consolidated set of comments for the cooperating agency will be provided in the format specified by the joint-lead agencies.

H. As appropriate and practicable, attend cooperating agency meetings and public meetings and hearings on the EIS process.

I. Retain the right to comment on all issues related to the EIS through the normal EIS public review and comment process.

J. Promptly advise the joint-lead agencies of concerns related to the EIS process.

VIII. Shared Responsibilities of all Parties

A. Reclamation and NPS may meet separately with any one or more cooperating agencies to discuss specific topics.

B. It is understood that the respective agencies are normally responsible for their own costs with regard to completion of tasks outlined herein, such as attendance at meetings, assembling data, analyzing effects, and providing input with regard to sections of the EIS subject to section VII.F. Funding requests from tribal governments with a demonstrated need will be considered on a case by case basis by the joint-lead agencies.

C. All parties agree that because of the need for timely completion of NEPA compliance, work will proceed as expeditiously as possible, including data gathering, analysis, and document review. However, all parties agree that sufficient time must be allowed to ensure thorough document review. It is anticipated that the parties will be given a minimum of 30 days to review the preliminary draft EIS and a minimum of 30 days to review the draft final EIS.

IX. Resolution of Disputes

Reclamation and NPS are responsible for all decisions involving the EIS and will make all final decisions on disputes arising during the NEPA process. The joint-lead agencies will document the nature of any dispute and the resolution of the dispute. Documentation of resolution will be made available to appropriate parties.

X. Standard Conditions:

A. **AUTHORITIES.** Nothing in this MOU shall be construed to extend the jurisdiction or decision-making authority of any party to this MOU beyond that which exists under current laws and regulations. Nothing in this MOU shall be construed as limiting or affecting the authority or legal responsibility of any party, or as binding any party to perform beyond the respective authority of each, or to require any party to assume or expend any specific sum of money. The provisions of this MOU are subject to the laws of the United States; and the regulations of the Department of the Interior, as they may be applicable. Nothing in this MOU shall be construed as affecting the decision-making requirements of any party or impairing the independent judgment of each party regarding policy decisions.

B. **RELEASE OF INFORMATION.** Except as required by court order or ruling, the joint - lead agencies and the cooperating agency will not release any pre-decisional material or working information or documents to the public other than through an approved Freedom of Information Act request or comparable tribal or state law-based process, or unless the agency or agencies have already disseminated the specific materials or documents to the public. The

agencies agree to inform each other if it is determined that there is a legal requirement to release any such information, and that information will include expected release date of the information.

C. **LEGAL RIGHTS AND REMEDIES.** Nothing in this MOU shall be construed to alter the legal rights and remedies that each party would otherwise have. No party waives any legal rights or defenses by entering into this MOU or participating in the process contemplated hereby. This MOU is not a Federal contract, rule, or regulation. This MOU shall not be construed as or interpreted to be final Federal agency action.

D. **SEVERABILITY.** Should any portion of this MOU be judicially determined to be illegal or unenforceable, the remainder of the MOU shall continue in full force and effect, and any party may renegotiate the terms affected by the severance.

E. **THIRD PARTY BENEFICIARY RIGHTS.** The parties do not intend to create in any other individual or entity the status of third party beneficiary, and this MOU shall not be construed so as to create such status. The rights, duties and obligations contained in this MOU shall operate only among the parties to this MOU, and shall inure solely to the benefit of the parties to this MOU. The provisions of this MOU are intended only to assist the parties in determining and performing their obligations under this MOU.

F. **NON-FUND OBLIGATION DOCUMENT.** This MOU is neither a fiscal nor a funds obligation document. Any endeavor or transfer of anything of value involving reimbursement or contribution of funds between the parties to this instrument will be handled in accordance with applicable laws, regulations, and procedures including those for Government procurement and printing. Such endeavors will be outlined in separate agreements that shall be made in writing by representatives of the parties and shall be independently authorized by appropriate rules, policies, and statutory authority. This MOU does not provide such authority. Specifically, this MOU does not establish authority for noncompetitive award to the cooperator of any contract or other agreement. Nothing herein constitutes a binding commitment to fund any of the proceedings encompassed by the MOU. Any specific cost sharing or funding shall be executed separately through other funding mechanisms, as deemed necessary and appropriate by each of the signatories.

G. **PARTICIPATION IN SIMILAR ACTIVITIES WITH OTHER ENTITIES.** This MOU in no way restricts any of the parties from participating in similar activities with other public or private agencies, organizations, and individuals.

H. **ENDORSEMENT.** Nothing in this MOU may be interpreted to imply that the United States, the Department of the Interior, the NPS, the Bureau of Reclamation, or the cooperating agency endorses any product, service or policy of the other parties. No party will take any action or make any statement that suggests or implies such an endorsement.

I. **STATUTES AND REGULATIONS.** The provisions of any statutes and/or regulations cited in this MOU contain legally binding requirements. The MOU itself does not alter, expand, or substitute for those provisions or regulations. This MOU does not impose legally-

binding requirements on the Parties, nor does it create a legal right of action for the Parties or any third party.

J. **AGENCY AND PARTNERSHIP.** Unless expressly provided by law, personnel or volunteers of one party shall not be considered to be agents, partners or employees of the other party for any purpose, and no joint venture or principal-agent relationship shall be deemed to exist. The personnel and volunteers of one party are not entitled to any of the benefits that any other party provides for its employees or volunteers.

K. **LIABILITY.** To the extent authorized by law, on behalf of itself, its officers, directors, members, employees, agents, and representatives, each party agrees that it will be responsible for its own acts and omissions and the results thereof and that it shall not be responsible for the acts or omissions of other parties, nor the results thereof. To the extent authorized by law, each party therefore agrees that it will assume the risk and liability to itself, its agents, employees, and volunteers for any injury to or death of persons or loss or destruction of property resulting in any manner from the conduct of the party's own operations and/or the operations of its agents, employees, and/or volunteers under this MOU. To the extent authorized by law, each party further releases and waives all claims against the other party for compensation for any loss, cost, damage, expense, personal injury, death, claim, or other liability arising out of the performance of this MOU.

L. **NONDISCRIMINATION.** This MOU is subject to all Federal statutes relating to nondiscrimination. These include, but are not limited to: (a) Title VI of the Civil Rights Act of 1964 (P.L. 88-352); and (b) Title IX of the Education Amendments of 1972 (20 U.S.C. 1681-1683 and 1685-1686).

XI. Effective Dates, Amendment and Termination

A. This MOU will become effective on the date of the last signature and may be subsequently amended through written agreement of all signatories. The joint-lead agencies or the cooperating agency may terminate their cooperative status by providing 30 days written notice of termination to the other party. Otherwise, the cooperative status will terminate when a Record of Decision is issued or the EIS is terminated.

Memorandum of Understanding
Between
the Bureau of Reclamation and the National Park Service
and
the Navajo Nation
for the Environmental Impact Statement for Adoption of a Long Term Experimental and Management Plan for the Operation of Glen Canyon Dam

I. Introduction and Purpose

Pursuant to the National Environmental Policy Act (NEPA), the Department of the Interior (Department), through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS), is preparing an environmental impact statement (EIS) for a Long Term Experimental and Management Plan (LTEMP) for the operation of Glen Canyon Dam. Reclamation and the NPS are the joint lead or "joint-lead agencies" for the completion of this EIS. The Navajo Nation hereafter "the cooperating agency", in addition to other parties, has agreed to serve as a cooperating agency for the completion of the LTEMP EIS. The purpose of this Memorandum of Understanding (MOU) is to outline the roles and responsibilities of the joint-lead and the cooperating agency (hereinafter collectively referred to alternatively as "agencies" or "parties") in accordance with 43 CFR § 46.225(d).

II. Background

The LTEMP process is intended to develop and implement a structured, long term experimental and management plan, to determine the need for potential future modifications to Glen Canyon Dam operations, and to determine whether to establish an Endangered Species Act (ESA) Recovery Implementation Program for endangered fish species below Glen Canyon Dam. Revised dam operations and other actions under the jurisdiction of the Secretary of the Interior will be considered within alternatives of the EIS, in keeping with the scope of the Grand Canyon Protection Act (GCPA). The NEPA process will document and evaluate impacts of the alternatives described in the EIS.

III. Purpose of this MOU

This MOU defines the relationship and duties of the joint-lead and the cooperating agency in completing NEPA compliance for the LTEMP, and how the parties will cooperate during the NEPA process.

By signing this MOU, the parties agree that this MOU provides the framework to fulfill compliance requirements for NEPA.

IV. Agency Designee

The cooperating agency will designate a primary point of contact (and alternate if desired) for the EIS by sending correspondence at the time of signing of this agreement to the joint-lead agencies with the contacts name and information. The cooperating agency may change its point

of contact at any time by providing written notice to the joint-lead agencies and the other cooperating agencies.

V. Authority

The authority of the joint-lead and the cooperating agency to participate in this agreement is provided by the National Environmental Policy Act. 42 U.S.C. §§ 4321 *et seq.* NEPA allows agencies to be designated as a cooperating agency when that agency has jurisdiction by law or special expertise (40 CFR § 1501.6 and 40 CFR§ 1508.5). Activities contemplated under this MOU are specifically authorized under:

A. Title I of NEPA;

B. "Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act," 40 CFR §§ 1500-1508. Council on Environmental Quality (in particular 40 CFR § 1501.6, Cooperating Agencies);

C. Department of the Interior NEPA Implementing Procedures in the Departmental Manual at 43 CFR § Part 46. Cooperating Agencies (40 CFR §1501.6).

D. Section 106 of the National Historic Preservation Act, as amended. 16 U.S.C. §§ 470 *et seq.*

E. Applicable tribal consultation policies of the joint-lead agencies and the Department of the Interior, and Executive Order 13175 (Nov. 6, 2000).

F. Resolution No. NABIMY-33-14_ of the Naabik'kyati' Committee. Navajo Nation Council, pursuant to 2 N.N.C. § 301(B)(15).

VI. Joint-lead Agency Responsibilities

Reclamation and the NPS will be joint-leads for this effort because Reclamation has primary responsibility for operation of Glen Canyon Dam and the NPS has primary responsibility for managing Grand Canyon National Park, Glen Canyon National Recreation Area, and Lake Mead National Recreation Area.

The NPS and Reclamation, as joint-leads for the completion of the LTEMP EIS, shall:

A. Jointly be responsible for the preparation, quality, content and overall direction of the EIS and for ensuring the appropriate participation of cooperating agencies in developing the EIS.

B. Jointly be responsible for identifying the purpose and need for the project, scope of analysis, and decisions to be made. In coordination with the Department, the joint-lead agencies will make the final decision on the content of all EIS-related documents,

including the preferred alternative and the Record of Decision to be signed by the Secretary of the Interior.

C. Jointly oversee the execution and administration of contracts or cooperative agreements with mutually agreed upon federal, state or local agencies, or tribal governments or mutually agreed upon private contractors to develop information for inclusion in the EIS.

D. Jointly conduct cooperating agency meetings, and provide advance information for discussions at these meetings, as necessary during the preparation of the EIS. Meeting dates and locations will be jointly agreed upon and may be chosen to coincide with the dates of Adaptive Management Working Group meetings to minimize travel costs and maximize collaboration.

E. Ensure that cooperating agency proposals and substantive comments (including divergent views) within their jurisdiction or technical expertise are appropriately documented and considered in the EIS.

F. Provide advance copies (normally 30 days) of the preliminary draft and preliminary final EIS and related compliance documents for review by cooperating agencies.

VII. Cooperating Agency Responsibilities

Federal, state, and local agencies, and tribal governments with appropriate expertise or jurisdiction have been invited to participate as cooperating agencies. Reclamation and NPS may, at any time during the course of the EIS project, invite additional agencies to participate in the process.

The cooperating agency, subject to sufficient appropriations to carry out the following responsibilities, shall:

A. Participate in the NEPA process at the earliest possible time.

B. Participate in the scoping process.

C. Assume, on request of the lead agencies, responsibility for developing information and preparing environmental analyses including portions of the environmental impact statement concerning which the cooperating agency has special expertise.

D. Make available staff support at the lead agencies' request to enhance the latter's interdisciplinary capability.

E. Normally use their own funds.

F. The cooperating agency may in response to a lead agencies' request for assistance in preparing the environmental impact statement reply that other program commitments preclude any involvement or the degree of involvement requested in the action that is the subject of the environmental impact statement.

G. Provide comments in a timely manner (normally within 30 days of receipt) of draft documents when requested. One consolidated set of comments for the cooperating agency will be provided in the format specified by the joint-lead agencies.

H. As appropriate and practicable, attend cooperating agency meetings and public meetings and hearings on the EIS process.

I. Retain the right to comment on all issues related to the EIS through the normal EIS public review and comment process, as well as through the independently required tribal consultation process.

J. Promptly advise the joint-lead agencies of concerns related to the EIS process.

VIII. Shared Responsibilities of all Parties

A. Reclamation and NPS may meet separately with any one or more cooperating agencies to discuss specific topics.

B. It is understood that the respective agencies are normally responsible for their own costs with regard to completion of tasks outlined herein, such as attendance at meetings, assembling data, analyzing effects, and providing input with regard to sections of the EIS subject to section VII.F. Funding requests from tribal governments with a demonstrated need will be considered on a case by case basis by the joint-lead agencies.

C. All parties agree that because of the need for timely completion of NEPA compliance, work will proceed as expeditiously as possible, including data gathering, analysis, and document review. However, all parties agree that sufficient time must be allowed to ensure thorough document review. It is anticipated that the parties will be given a minimum of 30 days to review the preliminary draft EIS and a minimum of 30 days to review the draft final EIS.

IX. Resolution of Disputes

Reclamation and NPS are responsible for all decisions involving the EIS and will make all final decisions on disputes arising during the NEPA process. The joint-lead agencies will document the nature of any dispute and the resolution of the dispute. Documentation of resolution will be made available to appropriate parties.

X. Standard Conditions:

A. AUTHORITIES. Nothing in this MOU shall be construed to extend the jurisdiction or decision-making authority of any party to this MOU beyond that which exists under current laws and regulations. Nothing in this MOU shall be construed as limiting or affecting the authority or legal responsibility of any party, or as binding any party to perform beyond the

respective authority of each. , or to otherwise violate any applicable law, regulation or policy or to require any party to assume or expend any specific sum of money. The provisions of this MOU are subject to the laws of the United States; and the regulations of the Department of the Interior, as they may be applicable. Nothing in this MOU shall be construed as affecting the decision-making requirements of any party or impairing the independent judgment of each party regarding policy decisions.

B. **RELEASE OF INFORMATION.** Except as required by court order or ruling, the joint - lead agencies and the cooperating agency will not release any pre-decisional material or working information or documents to the public other than through an approved Freedom of Information Act request or an approved request made under the Navajo Nation Privacy Act, or unless the agency or agencies have already disseminated the specific materials or documents to the public. The agencies agree to inform each other if it is determined that there is a legal requirement to release any such information, and that information will include expected release date of the information.

C. **LEGAL RIGHTS AND REMEDIES.** Nothing in this MOU shall be construed to alter the legal rights and remedies that each party would otherwise have. No party waives any legal rights or defenses by entering into this MOU or participating in the process contemplated hereby, including that nothing herein shall be construed as a waiver, express or implied, of any party's sovereign immunity. This MOU is not a Federal contract, rule, or regulation. This MOU shall not be construed as or interpreted to be final Federal agency action.

D. **SEVERABILITY.** Should any portion of this MOU be judicially determined to be illegal or unenforceable, the remainder of the MOU shall continue in full force and effect, and any party may renegotiate the terms affected by the severance.

E. **THIRD PARTY BENEFICIARY RIGHTS.** The parties do not intend to create in any other individual or entity the status of third party beneficiary, and this MOU shall not be construed so as to create such status. The rights, duties and obligations contained in this MOU shall operate only among the parties to this MOU, and shall inure solely to the benefit of the parties to this MOU. The provisions of this MOU are intended only to assist the parties in determining and performing their obligations under this MOU.

F. **NON-FUND OBLIGATION DOCUMENT.** This MOU is neither a fiscal nor a funds obligation document. Any endeavor or transfer of anything of value involving reimbursement or contribution of funds between the parties to this instrument will be handled in accordance with applicable laws, regulations, and procedures including those for Government procurement and printing. Such endeavors will be outlined in separate agreements that shall be made in writing by representatives of the parties and shall be independently authorized by appropriate rules, policies, and statutory authority. This MOU does not provide such authority. Specifically, this MOU does not establish authority for noncompetitive award to the cooperator of any contract or other agreement. Nothing herein constitutes a binding commitment to fund any of the proceedings encompassed by the MOU. Any specific cost sharing or funding shall be executed separately through other funding mechanisms, as deemed necessary and appropriate by each of the signatories.

G. PARTICIPATION IN SIMILAR ACTIVITIES WITH OTHER ENTITIES. This MOU in no way restricts any of the parties from participating in similar activities with other public or private agencies, organizations, and individuals.

H. ENDORSEMENT. Nothing in this MOU may be interpreted to imply that the United States, the Department of the Interior, the NPS, the Bureau of Reclamation, or the cooperating agency endorses any product, service or policy of the other parties. No party will take any action or make any statement that suggests or implies such an endorsement.

I. STATUTES AND REGULATIONS. The provisions of any statutes and/or regulations cited in this MOU contain legally binding requirements. The MOU itself does not alter, expand, or substitute for those provisions or regulations. This MOU does not impose legally-binding requirements on the Parties, nor does it create a legal right of action for the Parties or any third party.

J. AGENCY AND PARTNERSHIP. Unless expressly provided by law, personnel or volunteers of one party shall not be considered to be agents, partners or employees of the other party for any purpose, and no joint venture or principal-agent relationship shall be deemed to exist. The personnel and volunteers of one party are not entitled to any of the benefits that any other party provides for its employees or volunteers.

K. LIABILITY. To the extent authorized by law, on behalf of itself, its officers, directors, members, employees, agents, and representatives, each party agrees that it will be responsible for its own acts and omissions and the results thereof and that it shall not be responsible for the acts or omissions of other parties, nor the results thereof. To the extent authorized by law, each party therefore agrees that it will assume the risk and liability to itself, its agents, employees, and volunteers for any injury to or death of persons or loss or destruction of property resulting in any manner from the conduct of the party's own operations and/or the operations of its agents, employees, and/or volunteers under this MOU, in accordance with applicable law, including the Navajo Sovereign Immunity Act, as amended. To the extent authorized by law, each party further releases and waives all claims against the other party for compensation for any loss, cost, damage, expense, personal injury, death, claim, or other liability arising out of the performance of this MOU.

L. NONDISCRIMINATION. This MOU is subject to all Federal statutes relating to nondiscrimination, as applicable to the parties. These include, but are not limited to: (a) Title VI of the Civil Rights Act of 1964 (P.L. 88-352); and (b) Title IX of the Education Amendments of 1972 (20 U.S.C. 1681-1683 and 1685-1686).

XI. Effective Dates, Amendment and Termination

A. This MOU will become effective on the date of the last signature and may be subsequently amended through written agreement of all signatories. The joint-lead agencies or the cooperating agency may terminate their cooperative status by providing 30 days written

notice of termination to the other party. Otherwise, the cooperative status will terminate when a Record of Decision is issued or the EIS is terminated.

B. This MOU may be executed in separate counterparts, and such counterparts when executed shall constitute an original.

XII. Signatures

The parties hereto have executed this Memorandum of Understanding as of the dates shown below.

(f) Pueblo of Zuni

Memorandum of Understanding
Between
The Bureau of Reclamation and the National Park Service
And
The Pueblo of Zuni
For the Environmental Impact Statement for Adoption of a Long Term Experimental and Management Plan for the Operation of Glen Canyon Dam

I. Introduction and Purpose

Pursuant to the National Environmental Policy Act (NEPA), the Department of the Interior (Department), through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS), is preparing an environmental impact statement (EIS) for a Long Term Experimental and Management Plan (LTEMP) for the operation of Glen Canyon Dam. Reclamation and the NPS are the joint lead or "joint-lead agencies" for the completion of this EIS. The Pueblo of Zuni hereafter "the cooperating agency", in addition to other parties, has agreed to serve as a cooperating agency for the completion of the LTEMP EIS. The purpose of this Memorandum of Understanding (MOU) is to outline the roles and responsibilities of the joint-lead and the cooperating agency (hereinafter collectively referred to alternatively as "agencies" or "parties") in accordance with 43 CFR § 46.225(d).

II. Background

The LTEMP process is intended to develop and implement a structured, long term experimental and management plan, to determine the need for potential future modifications to Glen Canyon Dam operations, and to determine whether to establish an Endangered Species Act (ESA) Recovery Implementation Program for endangered fish species below Glen Canyon Dam. Revised dam operations and other actions under the jurisdiction of the Secretary of the Interior will be considered within alternatives of the EIS, in keeping with the scope of the Grand Canyon Protection Act (GCPA). The NEPA process will document and evaluate impacts of the alternatives described in the EIS.

III. Purpose of this MOU

This MOU defines the relationship and duties of the joint-lead and the cooperating agency in completing NEPA compliance for the LTEMP, and how the parties will cooperate during the NEPA process.

By signing this MOU, the parties agree that this MOU provides the framework to fulfill compliance requirements for NEPA.

IV. Agency Designee

The cooperating agency will designate a primary point of contact (and alternate if desired) for the EIS by sending correspondence at the time of signing of this agreement to the joint-lead agencies with the contacts name and information. The cooperating agency may change its point

of contact at any time by providing written notice to the joint-lead agencies and the other cooperating agencies.

V. Authority

The authority of the joint-lead and the cooperating agency to participate in this agreement is provided by the National Environmental Policy Act, 42 U.S.C. §§ 4321 *et seq.* NEPA allows agencies to be designated as a cooperating agency when that agency has jurisdiction by law or special expertise (40 CFR § 1501.6 and 40 CFR§ 1508.5). Activities contemplated under this MOU are specifically authorized under:

A. Title I of NEPA;

B. "Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act," 40 CFR §§ 1500-1508, Council on Environmental Quality (in particular 40 CFR § 1501.6, Cooperating Agencies);

C. Department of the Interior NEPA Implementing Procedures in the Departmental Manual at 43 CFR § Part 46, Cooperating Agencies (40 CFR §1501.6).

VI. Joint-lead Agency Responsibilities

Reclamation and the NPS will be joint-leads for this effort because Reclamation has primary responsibility for operation of Glen Canyon Dam and the NPS has primary responsibility for managing Grand Canyon National Park, Glen Canyon National Recreation Area, and Lake Mead National Recreation Area.

The NPS and Reclamation, as joint-leads for the completion of the LTEMP EIS, shall:

A. Jointly be responsible for the preparation, quality, content and overall direction of the EIS and for ensuring the appropriate participation of cooperating agencies in developing the EIS.

B. Jointly be responsible for identifying the purpose and need for the project, scope of analysis, and decisions to be made. In coordination with the Department, the joint-lead agencies will make the final decision on the content of all EIS-related documents, including the preferred alternative and the Record of Decision to be signed by the Secretary of the Interior.

C. Jointly oversee the execution and administration of contracts or cooperative agreements with mutually agreed upon federal, state or local agencies, or tribal governments or mutually agreed upon private contractors to develop information for inclusion in the EIS.

D. Jointly conduct cooperating agency meetings, and provide advance information for discussions at these meetings, as necessary during the preparation of the EIS. Meeting dates and locations will be jointly agreed upon and may be chosen to coincide with the

dates of Adaptive Management Working Group meetings to minimize travel costs and maximize collaboration.

E. Ensure that cooperating agency proposals and substantive comments (including divergent views) within their jurisdiction or technical expertise are appropriately documented and considered in the EIS.

F. Provide advance copies (normally 30 days) of the preliminary draft and preliminary final EIS and related compliance documents for review by cooperating agencies.

VII. Cooperating Agency Responsibilities

Federal, state, and local agencies, and tribal governments with appropriate expertise or jurisdiction have been invited to participate as cooperating agencies. Reclamation and NPS may, at any time during the course of the EIS project, invite additional agencies to participate in the process.

The cooperating agency, subject to sufficient appropriations to carry out the following responsibilities, shall:

A. Participate in the NEPA process at the earliest possible time.

B. Participate in the scoping process.

C. Assume, on request of the lead agencies, responsibility for developing information and preparing environmental analyses including portions of the environmental impact statement concerning which the cooperating agency has special expertise.

D. Make available staff support at the lead agencies' request to enhance the latter's interdisciplinary capability.

E. Normally use their own funds.

F. The cooperating agency may in response to a lead agencies' request for assistance in preparing the environmental impact statement reply that other program commitments preclude any involvement or the degree of involvement requested in the action that is the subject of the environmental impact statement.

G. Provide comments in a timely manner (normally within 30 days of receipt) of draft documents when requested. One consolidated set of comments for the cooperating agency will be provided in the format specified by the joint-lead agencies.

H. As appropriate and practicable, attend cooperating agency meetings and public meetings and hearings on the EIS process.

I. Retain the right to comment on all issues related to the EIS through the normal EIS public review and comment process.

J. Promptly advise the joint-lead agencies of concerns related to the EIS process.

VIII. Shared Responsibilities of all Parties

A. Reclamation and NPS may meet separately with any one or more cooperating agencies to discuss specific topics.

B. It is understood that the respective agencies are normally responsible for their own costs with regard to completion of tasks outlined herein, such as attendance at meetings, assembling data, analyzing effects, and providing input with regard to sections of the EIS subject to section VII.F. Funding requests from tribal governments with a demonstrated need will be considered on a case by case basis by the joint-lead agencies.

C. All parties agree that because of the need for timely completion of NEPA compliance, work will proceed as expeditiously as possible, including data gathering, analysis, and document review. However, all parties agree that sufficient time must be allowed to ensure thorough document review. It is anticipated that the parties will be given a minimum of 30 days to review the preliminary draft EIS and a minimum of 30 days to review the draft final EIS.

IX. Resolution of Disputes

Reclamation and NPS are responsible for all decisions involving the EIS and will make all final decisions on disputes arising during the NEPA process. The joint-lead agencies will document the nature of any dispute and the resolution of the dispute. Documentation of resolution will be made available to appropriate parties.

X. Standard Conditions:

A. AUTHORITIES. Nothing in this MOU shall be construed to extend the jurisdiction or decision-making authority of any party to this MOU beyond that which exists under current laws and regulations. Nothing in this MOU shall be construed as limiting or affecting the authority or legal responsibility of any party, or as binding any party to perform beyond the respective authority of each, or to require any party to assume or expend any specific sum of money. The provisions of this MOU are subject to the laws of the United States; and the regulations of the Department of the Interior, as they may be applicable. Nothing in this MOU shall be construed as affecting the decision-making requirements of any party or impairing the independent judgment of each party regarding policy decisions.

B. RELEASE OF INFORMATION. Except as required by court order or ruling, the joint - lead agencies and the cooperating agency will not release any pre-decisional material or working information or documents to the public other than through an approved Freedom of Information Act request or comparable tribal or state law-based process, or unless the agency or agencies have already disseminated the specific materials or documents to the public. The

agencies agree to inform each other if it is determined that there is a legal requirement to release any such information, and that information will include expected release date of the information.

C. **LEGAL RIGHTS AND REMEDIES.** Nothing in this MOU shall be construed to alter the legal rights and remedies that each party would otherwise have. No party waives any legal rights or defenses by entering into this MOU or participating in the process contemplated hereby. This MOU is not a Federal contract, rule, or regulation. This MOU shall not be construed as or interpreted to be final Federal agency action.

D. **SEVERABILITY.** Should any portion of this MOU be judicially determined to be illegal or unenforceable, the remainder of the MOU shall continue in full force and effect, and any party may renegotiate the terms affected by the severance.

E. **THIRD PARTY BENEFICIARY RIGHTS.** The parties do not intend to create in any other individual or entity the status of third party beneficiary, and this MOU shall not be construed so as to create such status. The rights, duties and obligations contained in this MOU shall operate only among the parties to this MOU, and shall inure solely to the benefit of the parties to this MOU. The provisions of this MOU are intended only to assist the parties in determining and performing their obligations under this MOU.

F. **NON-FUND OBLIGATION DOCUMENT.** This MOU is neither a fiscal nor a funds obligation document. Any endeavor or transfer of anything of value involving reimbursement or contribution of funds between the parties to this instrument will be handled in accordance with applicable laws, regulations, and procedures including those for Government procurement and printing. Such endeavors will be outlined in separate agreements that shall be made in writing by representatives of the parties and shall be independently authorized by appropriate rules, policies, and statutory authority. This MOU does not provide such authority. Specifically, this MOU does not establish authority for noncompetitive award to the cooperator of any contract or other agreement. Nothing herein constitutes a binding commitment to fund any of the proceedings encompassed by the MOU. Any specific cost sharing or funding shall be executed separately through other funding mechanisms, as deemed necessary and appropriate by each of the signatories.

G. **PARTICIPATION IN SIMILAR ACTIVITIES WITH OTHER ENTITIES.** This MOU in no way restricts any of the parties from participating in similar activities with other public or private agencies, organizations, and individuals.

H. **ENDORSEMENT.** Nothing in this MOU may be interpreted to imply that the United States, the Department of the Interior, the NPS, the Bureau of Reclamation, or the cooperating agency endorses any product, service or policy of the other parties. No party will take any action or make any statement that suggests or implies such an endorsement.

I. **STATUTES AND REGULATIONS.** The provisions of any statutes and/or regulations cited in this MOU contain legally binding requirements. The MOU itself does not alter, expand, or substitute for those provisions or regulations. This MOU does not impose legally-

Bernadine Jones, Chairwoman
The Havasupai Tribe
PO BOX 10
Supai, AZ 86435

Dear Ms. Jones,

The Department of the Interior, through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS) as co-lead agencies, intend to prepare an Environmental Impact Statement (EIS) under the provisions of the National Environmental Policy Act (NEPA) for a Long-Term Experimental and Management Plan (LTEMP) for Glen Canyon Dam operations. A primary function of the LTEMP, which will be developed based on tribal and public input and the latest science, will be to review the results of experiments that have been successfully completed and use this information to guide development of future experimental and management actions. Through the LTEMP EIS, alternatives will be developed and evaluated that consider potential future modifications to Glen Canyon Dam operations and other resource management and protection actions.

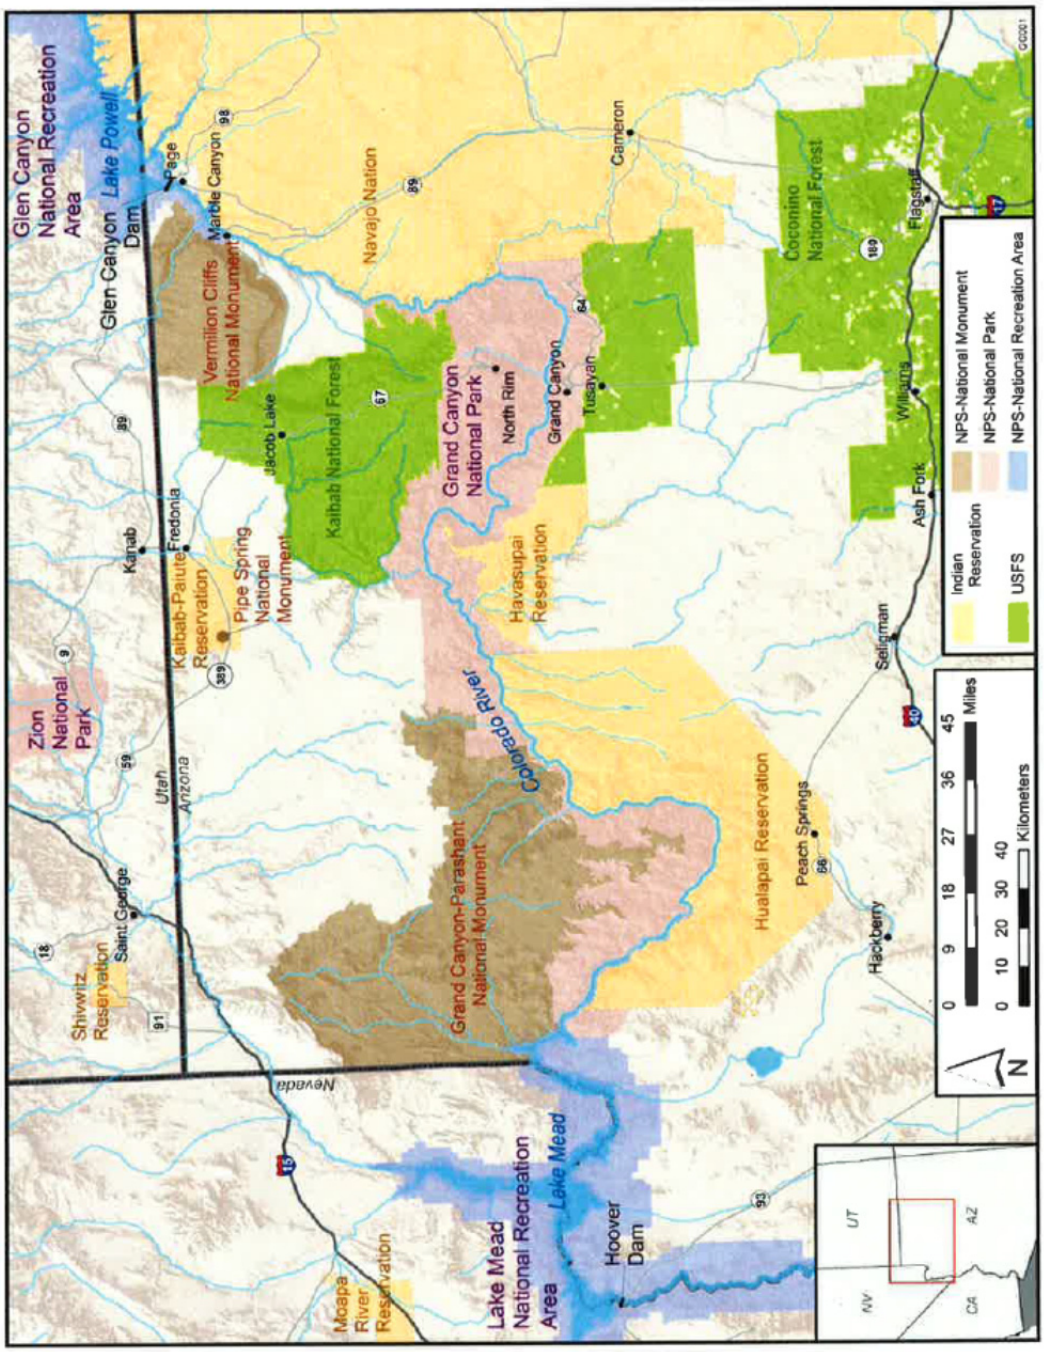
The Department's decision to develop the LTEMP is a component of its efforts to continue to comply with the ongoing requirements and obligations established by the Grand Canyon Protection Act of 1992 (Pub. L. 102-575) (GCPA) to protect, mitigate adverse impacts to, and improve the conditions for which Grand Canyon National Park and Glen Canyon National Recreation Area were established, while continuing to comply with the Law of the River. Although the GCPA does not apply to the Lake Mead National Recreation Area, effects to the resources at Lake Mead will be considered in the LTEMP EIS. Enclosed please find a map of the project area.

The purpose of this letter is to initiate government-to-government consultation on the LTEMP under Section 106 of the National Historic Preservation Act of 1966 (NHPA), as amended, and other relevant authorities. Through consultation, you will have opportunities to identify concerns related to historic properties, including traditional cultural properties and archaeological sites, natural resources, Indian trust assets as appropriate, and other issues of importance to your tribe. The NPS and Reclamation intend to follow 36 CFR 800.8(c), and use the process and documentation required for the preparation of all NEPA documents to comply with Section 106 in lieu of the procedures set forth in Sections 800.3 through 800.6.

The NPS and Reclamation began the NEPA Public Scoping process for this EIS with publication of the Notice of Intent in the Federal Register on July 6, 2011. We recently completed seven initial public scoping meetings; the deadline for receiving public comments on the scope of the EIS is January 31, 2012. More information can be found on the project website at http://ltempeis.anl.gov/.

Effects of the operations of Glen Canyon Dam have been evaluated for more than 20 years. The 1995 EIS for Glen Canyon Dam operations and the subsequent Glen Canyon Dam Adaptive Management Program have allowed us to better understand the relationship of water releases and downstream effects. The LTEMP EIS will draw on the research and knowledge we have acquired, and continue to acquire, to determine how the dam is operated for the next 20 years.

If you are interested in consulting on the LTEMP, please contact us at your earliest convenience and identify a point of contact for communication. If you would like to schedule meetings with us, please let us know as we plan to schedule these meetings by the end of January 2012, and conduct them as soon as is practicable. We will provide opportunities to meet and consult with you throughout the EIS process. Please contact Jan Balsom at (928) 638-7758 or Janet Cohen at (928) 638-7445, Grand Canyon National Park, or Keith Waldron, Bureau of Reclamation, at (801) 524-3816 at your earliest convenience.



Sincerely,

Larry Walkoviak

United States Department of the Interior

BUREAU OF RECLAMATION
Upper Colorado Regional Office
125 South State Street
Salt Lake City, UT 84138

NATIONAL PARK SERVICE
Intermountain Region Office
12795 Alameda Parkway
Denver, CO 80225

December 8, 2011

Bernadine Jones
Chairwoman
The Havasupai Tribe
PO BOX 10
Supai, AZ 86435

Dear Chairwoman Jones:

The Department of the Interior, through the Bureau of Reclamation (Reclamation) and the National Park Service (NPS) as co-lead agencies, intends to prepare an Environmental Impact Statement (EIS) under the provisions of the National Environmental Policy Act (NEPA) for a Long-Term Experimental and Management Plan (LTEMP) for Glen Canyon Dam operations. A primary function of the LTEMP, which will be developed based on cooperator, tribal, and public input and the latest science, will be to review the results of experiments that have been successfully completed and use this information to guide development of future experimental and management actions. The LTEMP is intended to develop and implement a structured, long-term experimental and management plan, to determine the need for potential future modifications to Glen Canyon Dam operations, and to determine whether to establish an Endangered Species Act Recovery Implementation Program for endangered fish species below Glen Canyon Dam.

The Department's decision to develop the LTEMP is a component of its efforts to continue to comply with the ongoing requirements and obligations established by the Grand Canyon Protection Act of 1992 (Pub. L. 102-575) (GCPA) to protect, mitigate adverse impacts to, and improve the conditions for which Grand Canyon National Park and Glen Canyon National Recreation Area were established, while continuing to comply with the Law of the River. Although the GCPA does not apply to the Lake Mead National Recreation Area, effects to the resources at Lake Mead will be considered in the LTEMP EIS. Enclosed, please find a map of the project area.

Effects of the operations of Glen Canyon Dam have been evaluated for more than 20 years. The 1995 EIS for Glen Canyon Dam operations and the subsequent Glen Canyon Dam Adaptive Management Program have allowed us to better understand the relationship of water releases and downstream effects. The LTEMP EIS will draw on this existing research and knowledge to determine how the dam will be operated in the future.

In accordance with 40 CFR 1501.6 of the Council on Environmental Quality's (CEQ) regulations for implementing the procedural provisions of NEPA, and 43 CFR 46.225 of the Department of

the Interior's regulations for implementation of NEPA, the NPS and Reclamation are inviting the Havasupai Tribe to be a cooperating agency in the LTEMP EIS process. Your participation in the LTEMP EIS process will assist us in making a more informed decision. Participation as a cooperating agency does not imply that your agency supports the proposed project.

The scope of your agency's involvement as a cooperating agency should include those areas, resources, or issues under its jurisdiction or within its area of expertise. Should your agency choose to assume cooperating status, your specific responsibilities as a cooperating agency will include:

- Participation in the NEPA scoping and environmental review process including draft document review.
- Providing comments on the project's purpose and need, goals and objectives, methodologies, and range of alternatives.
- Providing comment on project coordination and project schedule.
- Providing (upon request of the co-lead agencies) information and assistance with the preparation of environmental analyses (portions of the NEPA documents relevant to your agency's jurisdiction or area of special expertise).
- Providing staff support at the lead agencies' request to enhance the agencies' interdisciplinary capability.
- Using your agency's own funds for participation.

An email was sent from Anne Castle, Assistant Secretary of the Department of the Interior, on January 21, 2011, to determine preliminary interest from potential cooperating agencies. An initial meeting with potential cooperators was held on February 11, 2011, to address questions and concerns related to this process. To follow up on these initial contacts, we now ask that you formally let us know if you would like to participate as a cooperating agency in the development of the LTEMP EIS. Should the Havasupai Tribe choose to decline cooperating agency status in part or in whole, we ask that you confirm this in writing. We have enclosed a form to facilitate your response to this cooperating agency invitation and ask that you complete and return this form, or otherwise respond in writing, not later than Friday, January 6, 2012.

At this time we are tentatively planning cooperator meetings in Phoenix sometime in February 2012. We will arrange for phone-in capability for all cooperating agency meetings. If you have any questions, please contact the EIS project managers, Beverley Heffernan, Bureau of Reclamation, at (801) 524-3712, or Rob Billerbeck, National Park Service, at (303) 987-6789. We look forward to working with you in developing the LTEMP EIS.

Sincerely,

Larry Walkoviak
Regional Director
Upper Colorado Region
Bureau of Reclamation

John Wessels
Regional Director

Glen Canyon Dam
Long Term Experimental and Management Plan (LTEMP)
Cooperating Agency Interest

Please return this form by January 6, 2012, to indicate your interest in participating as a cooperating agency in the development of a Long-Term Experimental and Management Plan and Environmental Impact Statement for the Glen Canyon Dam.

A cooperating agency agreement will be developed to identify the specific roles and responsibilities of each agency. In general, cooperating agencies provide information in their areas of special expertise, which will assist the Bureau of Reclamation and the National Park Service in making a more informed decision.

_____ Yes, we are interested in participating as a cooperating agency.

_____ No, we are not interested in participating as a cooperating agency.

Re: Long-Term Experimental and Management Plan for Glen Canyon Dam operations

Dear Mr. Wessels:

The Ak-Chin Indian Community did receive your letter regarding your intentions to prepare an Environmental Impact Statement (EIS) under the provisions of the National Environmental Policy Act (NEPA) for a Long-Term Experimental and Management Plan (LTEMP) for Glen Canyon Dam operations.

Based on the location of this project, we would defer consultation to Native American Tribes that are located closer to the project area. The Ak-Chin Indian Community has no comments at this time.

Thank you for informing the Ak-Chin Indian Community about this project. If you should have any questions, please contact Mrs. Caroline Antone, Cultural Resources Manager at (520) 568-1372 or Mr. Gary Gilbert, Cultural Resources Technician II, at (520) 568-1369.

Sincerely,

RE: Department of the Interior, Bureau of Reclamation and National Park Service Co-Lead Agencies, Environmental Impact Statement (EIS) Preparation Long Term Experimental and Management Plan (LTEMP) Glen Canyon Dam Operations

Dear Mr. Wessels,

The Gila River Indian Community Tribal Historic Preservation Office (GRIC-THPO) has received your letter initiating government-to-government consultation regarding the preparation of an EIS for operations at the Glen Canyon Dam. The GRIC-THPO would be an interested consulting entity and we can be reached at the address listed on the letterhead. The proposed project area is within the ancestral lands of the Four Southern Tribes (Gila River Indian Community; Salt River Pima-Maricopa Indian Community; Ak-Chin Indian Community and the Tohono O'Odham Nation).

Thank you for consulting with the GRIC-THPO on this project. If you have any questions please do not hesitate to contact me or Archaeological Compliance Specialist Larry Benallie, Jr. at 520-562-7162.

Respectfully,

Barnaby V. Lewis
Tribal Historic Preservation Officer
Gila River Indian Community

Re: Comments on Preliminary Draft LTEMP Alternatives

Dr. LaGory,

We thank the NPS and BoR for the opportunity to work on the LTEMP EIS process as a cooperating agency. We have reviewed the Preliminary Draft Alternatives distributed for Cooperating Agency Review on June 7, 2012 and have the following comments.

The Havasupai Tribe supports operation of Glen Canyon Dam in a way that is closest to natural conditions prior to construction of the dam. The Havasupai have resided in the study area since time immemorial. Significant religious, cultural and historical sites are located in that part of the river corridor that is within their aboriginal territory.

As a matter of form and in recognition of the Secretary's trust responsibility to the Tribe, the Havasupai request that in the lists of considerations "Indian Tribal interests" be listed before ESA. (see page 2)

The Havasupai Tribe requests that the following actions be added to the Elements Potentially Common to All Alternatives:

1. Protection of burial sites and artifacts from erosion and exposure from high flows. In previous flood events burial sites and artifacts of the Havasupai located along the river have been exposed.

2. Timely notice to the Havasupai of changes in flow regimes. Numerous people access the river corridor through the Havasupai Reservation and their safety depends on adequate notice from the Tribe of potential hazards within the River Corridor.
3. River flow regimes should not disrupt the flow of springs close to the river.

Draft Alternative #1, Condition-Dependent Adaptive Strategy is not developed sufficiently to provide comments. The decision tree process cannot be evaluated without knowing the conditions and triggers that will prompt different decisions to be made.

Draft Alternative #3, No Action, includes modifications in the current Adaptive Management Plan as required by other decisions. In order to provide a baseline for comparison of Alternatives and comparison of the decisions under this EIS to the current Adaptive Management Plan, the No Action alternative should describe in detail current conditions. If the current conditions will change prior to implementation of the LTEMP this should be explained in detail so that comparisons may be made and cumulative impacts determined.

Thank you for the opportunity to participate in this process. We look forward to working with you.

Sincerely,

Don Watahomigie, Chairman

Response to Havasupai Tribal Council Comments Received on Preliminary Draft Alternatives

Thank you for your comments, your input is appreciated and helpful for the development of this EIS. Regarding your comment about the order of the tribal trust responsibilities in relation to ESA in the "Need" statement, we did not intend to imply any priority in the listing of items. Both responsibilities are important for this EIS.

Regarding the elements that you mentioned in your letter:

1. Impacts to burial sites and artifacts will be considered in the LTEMP EIS. As a part of compliance with both the NHPA and the GCPA, a goal of alternatives developed for the EIS will be to protect and where possible improve sites. In the context of your comment, we know that if additional sediment in certain areas would help reduce the likelihood of unwanted exposure of burials or other sites, this would be a desirable outcome.

2. The recently signed MOA for the High Flow Experiment Protocol EA provides that there will be at a minimum a 30-day notice for any high flow experiment. We expect to propose similar steps for any new actions under the LTEMP EIS.

3. The EIS team plans to examine impacts to all resources. We would like further explanation as to what the Havasupai mean by "disrupt the flow of springs close to the river." There has been research on these groundwater-fed springs, but we want to make sure that we understand your concerns before responding to this comment.

Draft Alternative #1. Thank you for your comment. We agree that the draft alternatives documented dated June 7, 2012, did not contain sufficient information for full evaluation, but we did want to circulate it for cooperating agency anyway in order to maximize cooperators' opportunities for input on the development of alternatives.

Draft Alternative #3. We agree that the EIS should fully describe current conditions and this will be appropriately captured in the 'affected environment' section of the EIS. The no action alternative is by definition how the Glen Canyon Dam will be operated in the future should none of the LTEMP EIS action alternatives be selected for implementation. This means that 'no action' would be continued operation under the 1996 ROD plus implementation of the HFEP and nonnative fish control in accordance with the two recently issued Findings of No Significant Impact.

Subject: Havasupai Comments on Tribal Perspectives and Process

Dr. LaGory,

Please find attached two documents: the comments and revised text from the Havasupai Tribe for the section titled Tribal Perspectives and my comments as attorney for the Havasupai Tribe on the EIS process for incorporating tribal input.

The Havasupai Tribal Council discussed the draft section on Tribal Perspectives at several different tribal council meetings. They want to point out to the consultants drafting these documents that the Havasupai do not share a common origin story with other Pai tribes. It should also be noted that the exclusive aboriginal territory of the Havasupai as determined by the Indian Claims Commission was from the Colorado River on the north to the Little Colorado River on the east to the San Francisco Peaks, south to Bill Williams Mountain and on the west to the Aubry Cliffs. Other tribes now claim areas within the Havasupai aboriginal territory but the Havasupai do not support this and the ICC found otherwise.

The attached statement of the Havasupai relationship to the affected area is the only statement that has been approved for inclusion.

Thank you for your cooperation.

Best regards,

Margaret Vick

Re: Tribal consultation and incorporation of information in the LTEMP EIS

Dear Dr. LaGory,

I represent the Havasupai Tribe and provide these comments on the process for inclusion of data and information from Tribes in the LTEMP EIS. This letter incorporates my comments made at the LTEMP Tribal Consultation meeting in Tempe on August 10, 2012.

1. Draft "American Indian Perspectives and Values Related to the Glen Canyon Dam Long-Term Experimental and Management Plan Environmental Impact Statement," prepared by Jennifer Abplanalp and Burce Verhaaren, Argonne National Laboratory.

The EIS for operations of Glen Canyon Dam is not the appropriate document to discuss tribal religious practices, religious origins for Native Americans, regional religious connections or other matters not related to the federal action at issue, the operations of Glen Canyon Dam. Information written by a consultant based on third party publications is suspect to many tribal members and should not be re-published in this document.

The Grand Canyon National Park and the Bureau of Reclamation, the co-lead agencies are both within the Department of Interior and have long standing relationships with the Tribes and Native Americans within the affected region. Those Tribes for whom the operations of Glen Canyon Dam may be of concern have been identified as potential cooperating agencies and the process includes them in tribal consultations. Each Tribe's religious, cultural and historical connection to the Grand Canyon and surrounding area does not need to be, and cannot be, written into a Tribal Perspectives section of this EIS and remain consistent with those beliefs.

Tribal governments have limited resources to participate in federal EIS processes. Those resources are better used for the substantive issues of concern to the EIS, not refuting third party information published in books and reports.

The descriptions of individual Tribal histories in the Tribal Perspectives section as circulated for comment, do not include tribal perspectives on the operations of Glen Canyon Dam and should be deleted from the EIS.

2. Use of Tribal Comments.

The authorized representatives of Tribes will present data, information and comments on many different aspects of the EIS. The Tribal input must be given the same consideration, weight and prominence as other input on the substantive topics. An EIS that reproduces Tribal input in its own section or attaches it as an appendix relegates this input to a class of information separate from "scientific" information. The Decision Maker and the public providing comments on the EIS should have all information on a topic presented in a manner that permits a comprehensive and comparative review.

For example, at the consultation meetings representatives of the Zuni Tribe expressed concerns over the treatment of fish within the Colorado River in particular efforts to control the rainbow trout population. This information should be included in the section on fish, not in a separate Tribal or Zuni section.

The Havasupai Tribe requested notification of high-flow releases in sufficient time to warn hikers within Havasu Canyon. This is a safety concern for recreational users and should be included in the appropriate section.

Appropriate references and attribution to Tribal input may be included in the text similar to other citations. For example, references might look like this: Havasupai, 2012a, Letter from Chairman, Havasupai Tribe, August 10, 2012, on file.

3. Cultural Resources.

The Grand Canyon Protection Act requires that the Secretary operate Glen Canyon Dam "in such a manner as to protect, mitigate adverse impacts to, and improve the values for which Grand Canyon National Park and Glen Canyon National Recreation Area were established, including, but not limited to natural and cultural resources…." Tribal governments and Native Americans have worked with the NPS for decades to identify and protect religious and cultural resources within GCNP and Glen Canyon. The natural environment of the Grand Canyon is significant to Native Americans. The resources are well known to the NPS.

This EIS process should not require a new listing or cultural resources through separate identification of sites, a separate listing or Tribal specific descriptions of locations, their uses or the importance of cultural resources. Consultations with Tribal government

representatives and with Native Americans may be used for clarification and to avoid omissions and is important to the process. However, the requirements of federal law, the Grand Canyon Protection Act and the trust obligation of the Secretary require an analysis of impacts to all cultural resources already known to the Department of Interior. Tribes are not required to submit separate listings for this EIS.

If you have any questions or would like to discuss these comments, please contact me.

Best regards,

Margaret J. Vick, JSD

Comments of the Havasupai Tribe on:

AMERICAN INDIAN PERSPECTIVES AND VALUES
RELATED TO THE GLEN CANYON DAM
LONG-TERM EXPERIMENTAL AND MANAGEMENT PLAN
ENVIRONMENTAL IMPACT STATEMENT

Prepared by
Jennifer Abplanalp and Bruce Verhaaren
Environmental Science Division
Argonne National Laboratory

The Havasupai Tribe requests that if the section titled American Indian Perspectives is included in a Draft EIS for LTEMP that the sections related to the Pai be revised to delete all references to the Havasupai making clear that the discussion of origins currently in the draft does not apply to Havasupai. The section on the Havasupai Tribe should be limited to the statements set forth below.

Havasupai

The Havasupai Reservation consists of 188,077 acres of canyon and plateau along the western portion of the Grand Canyon's south rim. In 1975, the Grand Canyon National Park Enlargement Act (PL 93-620) restored 185,000 acres to the Havasupai reservation and identified 95,300 acres of traditional use lands within Grand Canyon National Park that were made available for traditional Havasupai practices. The Havasupai Traditional Use Lands are north of the reservation from the plateau to the Colorado River and extend from approximately river mile 116 to river mile 165. (P.L. 93-620)

The Havasupai Tribe and tribal members have a history interwoven with that of Grand Canyon National Park since creation of the Park from within the Havasupai aboriginal territory. Members of the Havasupai Tribe have access to locations of importance within Grand Canyon National Park guaranteed by the 1919 Act to Establish Grand Canyon National Park, (40 Stat. 1175, 1919) and the 1975 Grand Canyon Enlargement Act, (88 Stat. 2089, 1975).

The Havasupai view everything in and around the Grand Canyon as sacred in all aspects of their cultural, spiritual, and traditional life (Reclamation 1995). The Havasupai were signatories to the 1994 PA, yet, chose not to participate in the GCDAMP. The Tribe works closely with the NPS for protection of cultural sites, historic locations and water resources. They are also members of the Native Voices on the Colorado River, a group that works with Grand Canyon Colorado River Outfitters to increase understanding of tribal relationships with Grand Canyon from their own perspective (NVCR 2012).

Attached are some comments on the LTEMP performance metrics from the Hopi Tribe-

Mike Yeatts
HCPO

Hopi comments on Draft LTEMP
Performance Metrics (01, August, 2013)

General Comment:
An aspect that is still lacking an adequate integration of tribal values overall in the performance measures. Nine goals were developed by the tribes for consideration as additional goals to those that were developed by the agencies. Of these, five were discarded (not by the tribes) as not being useful for discriminating among the alternatives. Of the four remaining ones, only two were addressed within the final performance metrics, and only partially at that. Looking again at the overall suite of tribal goals and expanding on the performance metrics should be a first start at revising the performance metrics. The following comments will provide some specific thoughts on better addressing the tribal values.

1) Archaeological and Cultural Resources
The performance metric currently only addresses an (unknown) subset of the archaeological sites. This measure is probably unlikely to measure the overall impacts/benefits to the full suite of archeological sites and certainly does not get at non-archeological historic properties (eg. TCPs).

For the archeological sites, going back to the Park's monitoring data should provide some other measures with regard to site impacts, flow patterns, visitor effects, etc. Prioritization of sites for treatment was based on this information in the past – hopefully this data can also be used going forward into the future.

For the TCP's the only mechanism I can see to adequately address them is to have specific culturally focused performance metrics under <u>each</u> of the resource categories for which there is a tribal value. In addition, the "ecosystem health" goal needs to be added as something separate from the "natural processes" goal. This is in effect getting at the overall integrity of the Grand Canyon as a TCP. It may be some type of a summation of the individual resource goal (from a tribal perspective). This could be in effect a summation that is calculated from the other data rather than being directly entered.

Finally, from the description of the GLCA penalized flow index, this really doesn't get at historic properties in a systematic manner – it seems to primarily capture recreational issues. Instead, there needs to be a performance measure that gets at site stability throughout the system and not just in Glen Canyon. I do agree that using the aeolian deposition completely ignores the Glen Canyon stretch (and likely most of the sites in Grand Canyon.

2) Sanctity of Life
Measurement of trout removal actions get at one portion of this concept, but do not get at the positive aspects of enhancing opportunities for life. For instance, increasing

habitat for culturally valued birds or animals. As with TCPs, it may be appropriate to add a measure that is the sum of tribal value measures in each of the other specific resource categories.

3) Natural Processes
As currently measured, this is a limited, arbitrary measure of "natural processes" and definitely does not measure system health. In order to be somewhat more rigorous, at a minimum, what is being taken as the "natural pattern" needs to be better defined. Why is only flow and water temperate being used? Why not sediment load, number of species in the riparian zone, percent of the CRE covered by vegetation, number of people present in the canyon, fish species composition, etc? All of these are part of the natural processes. As currently used, this measure is misleading and should either be expanded on or dropped. With what is currently being measured, the desired direction is wrong from the standpoint of Hopi values for the current ecosystem (with a dam in place).

4) Riparian Vegetation
To get at the Hopi values, a metric that looks at marsh habitats might be appropriate as a proxy for on aspect of the canyon as a TCP. In addition, a measure of the "value" of the vegetation as habitat for birds and other animal life would be helpful in addressing the both TCP aspects and sanctity of life. Both the type and coverage may have substantially different carrying capacities and species compositions.

5) Non-native Aquatic Species
Aquatic (or other) parasites that only effect non-native species might be considered a positive development.

6) Recreation
Use of crowding at the head of rapids because of "low" flows is really not an effective measure of wilderness, particularly at the flows that are being considered (if flows below 5,000cfs were in alternatives then there would be more of an issue, particularly with motor boats – though wilderness and motor boat has its own issue).

Also, for the Hopi, anything that increases the amount of recreation, distributes it more broadly throughout the year, or puts more people at greater numbers of places throughout the canyon would be viewed as negative, not positive.

7) Trout Fishery
Increasing the angler catch rate would seem to imply more trout, which might be viewed as not positive some tribes. Similarly with the trout abundance index.

Glen Canyon Dam
Long Term Experimental and Management Plan (LTEMP)
Cooperating Agency Interest

Please return this form by January 6, 2012, to indicate your interest in participating as a cooperating agency in the development of a Long-Term Experimental and Management Plan and Environmental Impact Statement for the Glen Canyon Dam.

A cooperating agency agreement will be developed to identify the specific roles and responsibilities of each agency. In general, cooperating agencies provide information in their areas of special expertise, which will assist the Bureau of Reclamation and the National Park Service in making a more informed decision.

XX Yes, we are interested in participating as a cooperating agency.

_____ No, we are not interested in participating as a cooperating agency.

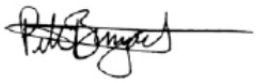
June 27, 2012

In reading the preliminary draft alternatives, it was striking that the various kinds of input resulting from the breakout sessions at the April 2012 LTEMP meeting in Flagstaff were apparently not integrated into this document in any tangible way. It appears the preparers narrowed the focus of the alternatives simply toward managing flows using various protocols that will affect sediment movement and native and non-native fish survival.

We understand that this document outlines preliminary draft alternatives for the LTEMP EIS, but aside from the quote in the *Purpose* section, there is absolutely no acknowledgement of the importance of tribal perspectives or values. This is disheartening, especially considering the past several years of working together, more or less successfully, on the GCDAMP. If the expectation is that tribal concerns will be brought to light later through NEPA consultation, then this approach will surely devolve into an unsatisfactory process. Consider that federal agencies have managed the area undergoing study for a few generations, yet the tribes have called the place home for countless centuries. We urge the preparers to engage the tribes more proactively and more inclusively as soon as possible.

Likewise, there is little reference to the GCPA, or explanations of how each of the preliminary draft alternatives meet its requirements or, conversely, have the potential to adversely affect river corridor resources. It would be helpful if predicted or expected



outcomes vis a vis the GCPA were provided in the discussion of alternatives, especially since it is a key component of the EIS.

The various alternatives all seem conceptually very linear, and perhaps overly simplistic in the suggested implementations of proposed actions. There seems to be three main ingredients: flows, fish, and sand. Each alternative seems to be simply variations on a theme, without regard to how their outcome may affect the values of different stakeholders. In addition, although the Colorado River ecosystem and ecological concerns are mentioned in passing, there is little to inform the reader how the various alternatives may actually affect the broader ecosystem, or even most of its components (aside from fish). This seems to be a document mainly concerned with complying with the Endangered Species Act rather than the Grand Canyon Protection Act.

Other comments and suggested language are included in the attached Track Changes version of the Preliminary Draft Alternatives.

If you have any questions, comments, or suggestions please feel free to call Loretta Jackson-Kelly or Peter Bungart at (928) 769-2223. Thank you for your consideration.

Sincerely,

Peter Bungart, Senior Archaeologist
Hualapai Department of Cultural Resources

Response to Hualapai Tribe Comments Received on Preliminary Draft Alternatives –

Thank you for your letter dated June 27, 2012 with comments on the LTEMP preliminary alternatives and the process. Your feedback helps us adjust our process and produce a better EIS. Below are our responses to the concerns raised in your letter.

Comment regarding alternatives structured around flows:

As the co-lead agencies worked on developing more detailed alternatives out of the concepts which came out of the April workshop, we did incorporate input received in the breakout sessions and continue to take the results of that workshop into account as we develop the alternatives.

Comment regarding incorporation of tribal perspectives and values in document:

The co-lead agencies place great importance on the input from tribes and we appreciate your feedback. If there are specific ideas on how to be better involved tribes, then we would welcome those specific suggestions. To date we have offered to meet with tribes through the tribal consultation process, and have met with the Hualapai and a number of other tribes. We have also offered additional consultation meetings with the intent of seeking input and feedback from tribes on the draft alternatives, above and beyond the opportunity provided through the cooperating agency relationship. We have also scheduled a meeting with just tribal representatives on August 10th in Phoenix, prior to the cooperating agencies meeting, as another opportunity for face to face dialogue about the LTEMP EIS process and the alternatives. We have also provided draft text for a tribal perspectives section of the EIS, and are continuing to coordinate with tribes on development of that draft, or alternate information from each tribe. As stated in that draft document, our intent is to provide to each interested tribe the opportunity to communicate their values and perspectives in the EIS.

If the Hualapai feel that there are additional steps we can take to enhance your participation in development of the EIS, we urge you to communicate that information to the joint lead project managers.

Concern about Grand Canyon Protection Act (GCPA) and potential effects of the alternatives:

We appreciate the comments regarding Hualapai concerns about the potential effects of the alternatives. At this time we are in the alternatives development phase and it would be premature at this early point in the process to attempt a description of effects or outcomes of the alternatives. The analysis of effects of alternatives to all resources will be undertaken during the process of preparing the draft EIS. At a public forum to be scheduled after the alternatives are developed, there will be presentations to articulate the scientific basis for each flow regime (and non-flow actions) included in the alternatives. As noted above, we would welcome more

discussion with tribes on what input they would like to provide for this public meeting and we hope to discuss that further at the meeting with interested tribes on August 10th.

Concern about the focus on flow, fish, sediment vs. the Grand Canyon Protection Act (GCPA).

Compliance with the GCPA is one of the main reasons that the LTEMP EIS is being prepared. The Secretary of the Interior has noted that revisiting resource conditions, and applying the knowledge we have gained since the ROD was signed in 1996, will help us to better achieve the requirements and goals of the GCPA. Accordingly, the GCPA is referenced within the purpose and need of this process which will inform the range of alternatives and the evaluation of impacts. We have also developed resource goals (based on the DFCs and other relevant documents) to inform this evaluation that consider specific resources as well as tribal values.

Response numbers here correspond to comment numbers in the June 7, 2012 draft alternatives document submitted with the June 27 letter.

1. Tribal Involvement in Alternative Development. Please see the response to the second comment in your letter, above. We have received input on the alternatives from tribes, cooperating agencies and the public at the April 4-5, 2012 meeting and via other communications. In addition to our ongoing Government to Government consultation with interested tribes, the Hualapai and other tribes who are serving as cooperating agencies have many additional opportunities to inform the EIS development process, including our monthly cooperating agency calls and the upcoming cooperating agency meeting on August 10. Prior to the meeting with all cooperators on August 10, we have scheduled a meeting with interested tribes on August 10, 2012 in Phoenix as an additional opportunity for face-to-face participation specifically to focus on tribal values and concerns.

2. Sediment Augmentation - We appreciate your concern about the engineering solution proposed to increase sediment with the goal of trying to improve downstream resources. Infrastructure additions and other alternative elements are still being considered. It is understood that sediment augmentation and other infrastructure proposals would require in-depth analysis and may require separate and additional NEPA.

3. Other Types of Knowledge - The EIS team has also recently offered additional meetings with tribes, and is planning a meeting on August 10 to discuss alternatives and seek feedback from tribes on alternatives. Recognizing the ongoing GCDAMP effort to improve consideration of tribal ecological knowledge, we would like to discuss additional approaches to incorporating tribal knowledge into the EIS process. We have also shared with Hualapai and other interested tribes the first draft of tribal perspectives write-ups for eventual inclusion in the EIS, and we do need feedback on that draft from the tribes as soon as possible.

Salt Lake City, UT 84138

To Whom It May Concern:

The Historic Preservation Department – Traditional Culture Program (HPD-TCP) is submitting the following comments on behalf of the Navajo Nation. HPD-TCP has provided the following comments for the Glen Canyon Dam Long Term Experimental and Management Plan Preliminary Draft Outline.

The Glen Canyon Dam Adaptive Management Program (AMP) was implemented as a result of the Record of Decision on the Operation of Glen Canyon Dan Final Environmental Impact Statement to comply with consultation requirements of the Grand Canyon Protection Act (Pub. L.102-575) of 1992. The Amp includes a Federal advisory committee, the Adaptive Management Work Group (AMWG), a technical work group (TWG), a Grand Canyon Monitoring and Research Center, and independent review panels. The AMWG makes recommendations to the Secretary of the Interior concerning Glen Canyon Dam operations and other management actions to protect resources downstream of Glen Canyon Dam consistent with the Grand Canyon Protection Act. The TWG is a subcommittee of the AMWG and provides technical advice and recommendations to the AMWG.

Recommendations:

1. The Navajo Nation is in support of the removal of Non-Native fish from the Grand Canyon. The Nation recommends the removal of Non-Native fish be done about a half mile from the confluence of the Little Colorado River and the Colorado River up and down stream.
.
2. The Navajo Nation supports the lethal removal of Non-Native Fish outside the half a mile buffer from the confluence. The disposal of the Non-Native fish is something the Nation supports. The lethal extermination of the Non-Native fish outside the areas of concern and has no objections with the lethal eradication of the Non-Native fish as long as it is away from the confluence.

Concerns:

1. Operations conducted by the Bureau of Reclamation and National Park Service

negatively effect the sacredness of the Grand Canyon. Local Navajo families refuse to conduct ceremonies near the river due to the Non-Natives consideration of the river as a place of recreation.

2. Navajo communities have no access to the river because of the constant flow of river trips and scientific research. Navajo tribal members hesitate to conduct offerings and ceremonies because of fear their prayers will not be answered.

If the Bureau of Reclamation (BOR) and the National Park Service (NPS) want to consult with the Nation on any of the raised concerns, we would be more than happy to accommodate.

The Navajo Nation appreciates the opportunity to comment on such a complicated issue. If you have any questions or comments, do not hesitate to call Tony Joe at (928) 871-7750.

Sincerely,

Tony H. Joe, Jr.
Historic Preservation Department

Response to Comments by Navajo on Purpose, Need, and Objectives

We thank you for your comments on the purpose, need, and objectives of the Glen Canyon Dam LTEMP. The joint lead EIS team carefully reviewed these comments and concerns. Some changes were incorporated if they substantially helped to clarify purpose, need, and objectives. However, NEPA provides that the purpose and need statements should "briefly specify the underlying purpose and need," and the level of detail suggested in many comments would contravene the direction that the purpose and need statements be concise.

Purpose

- Resources of importance to Indian Tribes are not specifically listed in the GCPA; but the EIS team feels it is important to include them based on public comments, AMWG desired future conditions, and agency goals for this project. Consistent with input received, we reworded this sentence to be clearer about the intent of this statement by adding "including those" before "of importance to Indian Tribes."

Need

- No comments were received.

Objectives

- We did not make the suggested change of "Protect the interests and perspectives of the Indian Tribes" from the original "Respect the interests and perspectives of the Indian Tribes" in the fifth objective. The EIS will contain a section on tribal perspectives, which will be developed in consultation with the tribes to ensure interests and perspectives are accurately portrayed. Achieving the objective of respecting tribal interests and perspectives will depend on government-to-government consultation, which will be an important part of the LTEMP EIS process.

Argonne, Illinois 60439

Dear Mr. LaGory,

The Navajo Historic Preservation Department is in response to the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP EIS) Performance Metrix.

The tribes were invited to Flagstaff, AZ on March 14-15, 2013 for their input. At this meeting federal officials labeled the meeting as "Tribal Values". The tribes along with representatives from the National Park Service were in attendance. It was more of a brainstorming about tribal concerns. The tribes gave suggestions and all of the tribe's issues and concerns were written on a flip chart. On March 15, 2013, the tribes developed nine goals we thought would be included in the Performance Metrix, in addition to the agencies goals. I am concerned eight of the tribal values were not considered. The following comments are in reference to concerns we have.

1. **Archaeological and Cultural Resources**
   The anticipation for windblown deposits seems to be dependent upon hope. We support the idea of wind deposits covering up cultural resources but I think more evidence needs to be shared with the interested parties. Only a few archaeological sites might benefit and overall there is no specific sites mentioned that will yield positive benefits. The Grand Canyon river corridor exhibits archaeological sites that are not mentioned or considered.

2. **Natural Processes**
   The Nation supports native habitat improvement. Native fish and plant species need some attention to recreate the natural beauty of the Grand and Glen Canyon. I suggest more studies and more emphasis on re-establishing native fish and plant species. The eradication of non-Native plants species should be a goal.

3. **Humpback Chub**

HISTORIC PRESERVATION DEPARTMENT P.O. BOX 4950 WINDOW ROCK, ARIZONA 86515 928.871.7198 (v) 928.871.7886 (fax)

Humpback Chub research is supported by the Nation. I would like to see more studies on other native fish population.

4. **Other Native Fish**
   More research needs to be conducted on other native fish. The Nation would like to be consulted on studies past and present on these species. A map showing projects that are occurring on other native fish be of recommendation so we can have a better understanding of locations for the 2014 boat trip initiated by Navajo.

5. **Recreation**
   The cultural resources will be impacted by the heavy flow of the visitor experience each year. This is an issue for the Nation.

If you have any questions, do not hesitate to contact me at 928-871-7750. Thank you for honoring our request.

Tony Joe
Historic Preservation Department
P.O. Box 4950
Window Rock, AZ 86515

Dear Mr.John and and Mr. Joe,

We are writing regarding the pending Memorandum of Understanding (MOU) between the Bureau of Reclamation (Reclamation) and the National Park Service (NPS) and the Navajo Nation for the Environmental Impact Statement (EIS) for Adoption of a Long Term Experimental and Management Plan (LTEMP) for the Operation of Glen Canyon Dam.

Reclamation and NPS first extended an invitation to the Navajo Nation to become a cooperating agency for the LTEMP EIS in a letter dated December 8, 2011. In January 2012, John Leeper of the Navajo Department of Water Resources returned the invitation form indicating an interest in the Navajo Nation becoming a cooperating agency. A draft MOU outlining the roles and responsibilities of Reclamation, NPS, and the cooperating agencies was emailed to representatives of the Navajo Nation on March 6, 2012. Suggested revisions were provided by Alan Downer of the Navajo Nation Historic Preservation Department on March 22, 2012. A revised MOU was sent to Dr. Downer and to Jason John of the Department of Water Resources on April 11, 2012 with a request that it be signed and returned.

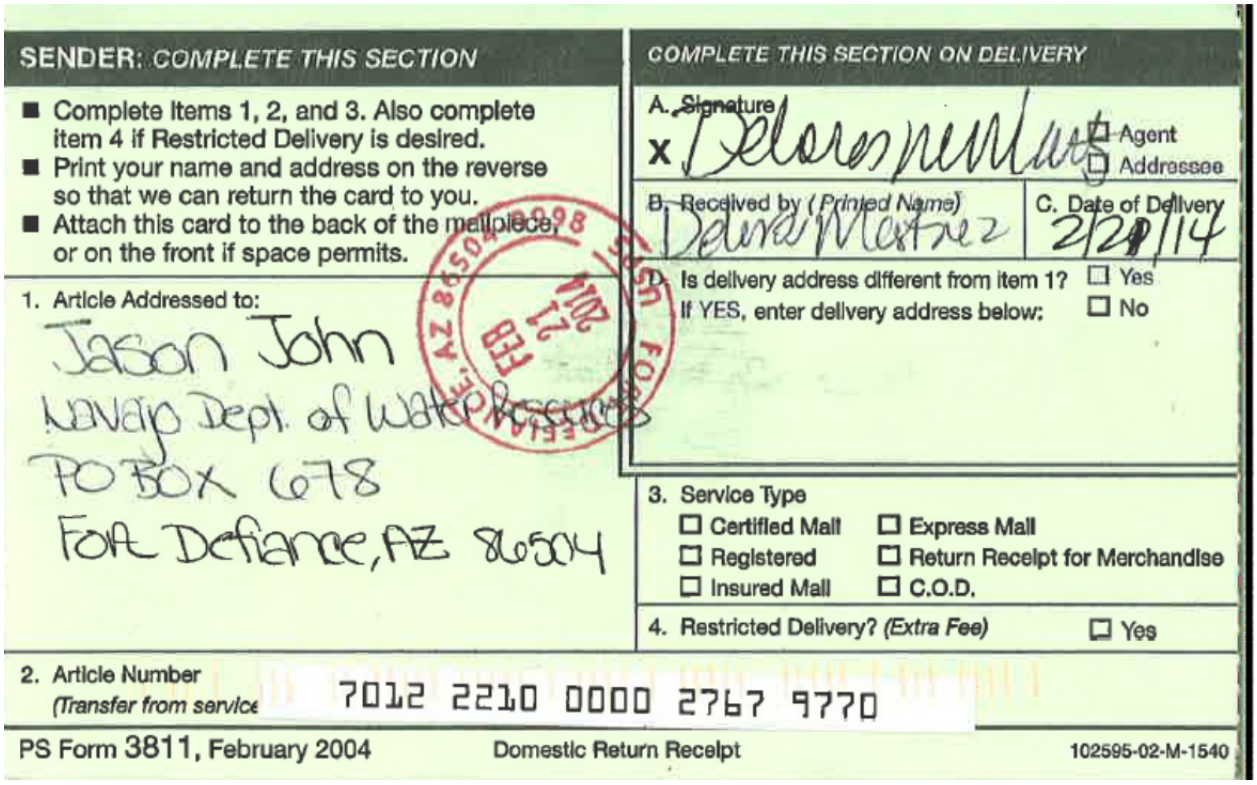
We are aware that Navajo procedures require an MOU to be reviewed and approved by legislative committees and ultimately by the legislature as a whole before it can be signed and returned. It is our understanding that the committees involved have requested an additional work session to determine whether being a cooperating agency would impact current negotiations regarding Navajo water rights.

Sections of the EIS are currently being drafted. Signing and returning the MOU will facilitate the Navajo Nation's role as a cooperating agency in reviewing drafted sections. We request that the MOU be signed by February 21, 2012. If the Navajo Nation chooses not to act as a cooperating agency please notify the LTEMP EIS team in writing. If Navajo Nation chooses not to act as a cooperating agency, we will still conduct government to government consultation with the Navajo Nation.

To return the signed MOU you may scan it in and return via email, send by fax, or send via postal mail. The fax number is 630-252-6090, and the mailing address is as follows:

Kirk LaGory
Argonne National Laboratory
9700 S. Cass Avenue, EVS-240
Argonne, IL 60439

Please feel free to contact us if you need any additional information regarding the LTEMP EIS and MOU. We look forward to hearing from you.



Sincerely,

Glen, Rob and Bruce,

I was at the meeting this morning with some of the Council Delegates. I can assist in the communication.

They would like a government to government meeting with NPS and BOR in Flagstaff on either March 28 at 1pm or March 4 (after 10am) or March 6 (after 10am). Their preference is in that order. The President of Navajo Nation should be signing that letter today requesting the meeting. When signed it will be emailed. I hope one of those dates work.

The Nation is in receipt of your letter dated February 6, 2014, requesting that the Nation choose whether or not to be a cooperating agency in the development of the Environmental Impact Statement for Adoption of a Long Term Experimental and Management Plan (LTEMP) for the Operation of Glen Canyon Dam.

As you are aware, in order to be a cooperating agency, the Nation requires approval by the Naabik'iyati Committee of the Navajo Nation Council of the proposed Memorandum of Understanding with the Bureau of Reclamation and the National Park Service. When the Naabik'iyati Committee considered approving the legislation for the MOU, the legislation was tabled by Delegate Walter Phelps in order to better understand the purpose of the LTEMP for the Operation of Glen Canyon Dam and its impact to interests of the Navajo Nation.

Accordingly, we are requesting a government to government consultation meeting with the Bureau of Reclamation and the National Park Service to discuss the purpose of the LTEMP for Operation of Glen Canyon Dam and whether or not the Nation could serve in a joint lead agency role.

The Nation therefore requests a government-to-government consultation. The following are suggested dates in order of preference: February 28 at 1:00 pm, March 4, or March 6, 2014 in Flagstaff at the National Park Service agency office or other available facility.

Sincerely,

Ben Shelly, President
THE NAVAJO NATION

Subject: Re: Request for Government to Government LTEMP Consultation

I talked to Jason John on the phone today. Mostly it sounds like a misunderstanding between levels. Jason just tried to convey the need to sign the MOU to be a cooperating agency. He mentioned that we would do govt to govt down the road, but it sounds like some others were unclear on the scope of the projects and the roles. They are not requesting that Larry W and Dave U or others come to this meeting, they are just looking to have Glen and I come out and explain the process again and Jason believes that if roles and scope are explained that they will likely want to sign the cooperating agency MOU and will likely want to wait until the summer for the formal govt to govt.

I told Jason that meeting next week looked pretty difficult and he recommended an email back with dates further out. I think before we send an email back I'll try to connect with Tony Joe on the phone as well.
If we do need a meeting, we could see if that same week of the 17 works I guess.

Subject: Re: Request for Government to Government LTEMP Consultation

This email is in reply to the email sent on Feb 21, 2014 and attached letter from the Navajo Nation requesting to meet with the project managers of the Glen Canyon Dam Long Term Experimental and Management Plan (LTEMP) Environmental Impact Statement (EIS). We are sorry we could not meet the dates proposed for a meeting due to prior scheduling conflict, and we are happy to come out in the next few weeks to meet with representatives of the Navajo Nation and council. Based upon travel schedules and availability, we offer the following potential dates for a meeting in Window Rock:

April 2,3,10, or 14

We would have the project managers from the two lead agencies, NPS and BOR, come to discuss the LTEMP scope, issue, stakeholder roles and timelines, and answer questions regarding the LTEMP or participation from the Navajo Nation. Please let us know if any of these dates are convenient and if we are correctly understanding what you would like us to cover in the meeting. We are also available for a phone call in advance if that would help answer any specific questions.

Based on discussions with staff, here is some additional information about the LTEMP project in advance of a meeting that might be helpful:

LTEMP Scope and Issues

Federal laws and regulations require the federal government to evaluate the effects of its actions on the environment and to consider alternative courses of action. National Environmental Policy Act (NEPA) regulations require, among other things, federal agencies to include discussion of proposed actions and a range of reasonable alternatives in an EIS.

Generally, the scope of the LTEMP EIS project involves consideration of actions that could change flows from Glen Canyon Dam as well as a set of non-flow actions to address resource concerns. All alternatives will still comply with the 2007 Interim Guidelines for the annual delivery volumes. All of the action alternatives include High Flow Experiments with maximum flows of 45,000 cfs, but with some variation among how frequent or when these high flows would be employed. There is variation among the alternatives with approaches to fish management as some alternatives will have mechanical removal, some will have trout management flows and mechanical removal and one alternative utilizes neither fish management tool.

With this general scope in mind , we have heard the following might be of interest to the Navajo Nation:

- Potential impacts (positive or negative) to cultural sites
- Potential impacts (positive or negative) to natural resources such as sandbars/beaches, vegetation, wildlife habitat, fish and other aquatic resources
- Potential impacts (positive or negative) to hydropower production/effect on ratepayers
- Potential impacts (positive or negative) to the Glen Canyon fishery
- Potential impacts (positive or negative) to river recreation

There are also several issues that we have heard that are interest to the Navajo Nation that are outside the scope of this project:

- Boundary demarcation
- Water rights
- Operational concerns at Antelope Point

LTEMP Roles

- Lead Agencies - the two lead agencies for this project are the Bureau of Reclamation and the National Park Service. The responsibility for this project was delegated to these two agencies because Reclamation is responsible for the operation of Glen Canyon Dam and NPS has land management responsibility at Glen Canyon National Recreation Area and Grand Canyon National Park.. Joint lead responsibilities generally include consulting with the affected Tribes, identifying the purpose and need for the project, defining the scope of analysis, and managing the contracts for preparation of the EIS and responding to comments from cooperating agencies and the public, etc.

- Cooperating Agencies - Generally, cooperating agencies participate in the EIS by attending cooperating agency meetings, commenting on EIS materials and internal cooperating agency drafts, and assisting with the development of parts of the EIS if needed. This is a role with more interaction and opportunity to comment than a member of the public or a non-governmental entity.

- The following are the entities are cooperating agencies because they are state, local or tribal governments with appropriate expertise or jurisdiction for this project and that have signed an MOU confirming their role as a cooperating agency:

  - Arizona Game and Fish Department
  - Bureau of Indian Affairs
  - Colorado River Commission of Nevada
  - The Havasupai Tribe
  - The Hopi Tribe
  - The Hualapai Tribe
  - Kaibab Band of Paiute Indians
  - The Pueblo of Zuni
  - Salt River Project
  - U.S. Fish and Wildlife Service
  - Upper Colorado River Commission
  - Utah Associated Municipal Power Systems
  - Western Area Power Administration

- Thus far we have understood that the Navajo Nation wanted to be considered a cooperating agency so we have been inviting the Navajo Nation to meetings of cooperating agencies and providing information that is distributed to cooperating agencies.

Project Timeline

Past activities:

- July 2011 -Project started with a notice of intent in the Federal Register
- November 2012 - Public scoping meetings
- April 2012 - Public meeting presented preliminary draft alternative concepts
- June 2012 - Tribes provided comments on Tribal Consultation Plan and Tribes/cooperating agencies provided comments on preliminary alternatives

- August 2012 - in person meeting with Tribes/cooperating agencies to discuss and solicit comments on draft alternatives and goals and objectives
- February 2013 - development of models and metrics with experts, and meetings with Tribes and stakeholders regarding involvement in the process and modeling metrics
- March 2013 - meeting with Tribes regarding written contribution process to the EIS and modeling metrics.
- April-July 2013 - additional meetings with Tribes regarding modeling metrics
- August 2013 - Held meetings with Tribes and AMWG stakeholders, presented preliminary modeling and solicited structured decision making input
- November 2013 - Meeting with Tribal representatives to further develop modeling metrics useful for Tribes and discussed text that some Tribes wanted to contribute to the EIS.
- February 2014 - Revised alternatives and modeling metrics presented to Tribes and stakeholders at the AMWG meeting

---

Planned activities:

- March 2014 - Meetings with stakeholders and Tribes. On March 18 there will be a web session to explain structure decision input methods and a meeting March 31-April 1 in Phoenix to present modeling results
- April 2014 - We are seeking structured decision information back from stakeholders and Tribes
- May-June 2014 - We will prepare preliminary EIS draft
- June 2014 - We plan to distribute preliminary draft EIS to cooperating agencies for comment
- July-Sept 2014- planning Government to Government meetings with most Tribes because at that point we can discuss a draft and a potentially preferred alternative
- Sept/Oct 2014 - We plan to publish a draft EIS for public comment
- 2015 - We plan to publish a final EIS

We hope this information helps with understanding the LTEMP EIS project, where we are in the process and helps the Navajo Nation understand potential participation in this project.

Council Delegate Phelps,
We wanted to send you a follow-up note to our meeting in Flagstaff in April regarding the Long Term Experimental and Management Plan (LTEMP) EIS for the Glen Canyon Dam. We thank you again for meeting with us and hope our information on the project was helpful. We wanted to see if there was any follow-up that you foresee in terms of the cooperating agency status of the Navajo Nation on this project. We can make ourselves available if you would like us to come out and meet with the council.

In terms of schedule, we plan to distribute a first preliminary draft EIS to cooperating agencies in July, a second cooperating agency draft in late Aug-Sept, and a public draft EIS in October.

Thank you,

Rob Billerbeck, NPS and Glen Knowles, Reclamation

RE: Cooperating Agency Status for Pueblo of Zuni for the Development of an Environmental Impact Statement for a Long-Term Experimental and Management Plan (LTEMP) for Glen Canyon Dam operations. OR100

Dear Mr. Walkoviak and Mr. Wessels,

The Pueblo of Zuni has received your letter, dated 08 December 2011, inviting the Pueblo of Zuni to be a cooperating agency in the Long-Term Experimental and Management Plan (LTEMP) Environmental Impact Statement process. As you are aware the Grand Canyon, Colorado River, Little Colorado River, and all the physical, biological, and cultural resources located there are of extreme historical, cultural, and religious significance to the Zuni people. The appropriate care and management of this very sacred place and all the resources that comprise this important Zuni traditional cultural property is an on-going issue for the Zuni people; therefore, the Pueblo of Zuni accepts your invitation to become a cooperating agency in the development of this Environmental Impact Statement (EIS) for the LTEMP.

As Governor of Zuni, I designate Kurt Dongoske, RPA, Tribal Historic Preservation Officer of the Zuni Heritage and Historic Preservation Office as the primary Zuni representative as a cooperating agency in this process. Mr. Dongoske's contact information is provided in the attached form. Should you have any questions or require additional information please contact my office at 505.782.7000 or the Zuni Heritage and Historic Preservation Office at 505.782.2393. Thank you for consulting with the Pueblo of Zuni.

Sincerely,

Governor Arlen Quetawki, Sr.

Hello Mary,

I had talked to our advisors about the EIS for the Glen Canyon Dam flows. From a water resources/water rights position, we do not feel that the Glen Canyon EIS alternatives will have any impact on White Mountain Apache Tribe. Mark Altaha had stated that there are impact on cultural resources. Thus, I have will recommend to Chairman Lupe that we do not need to be cooperators on this EIS. Would you need a letter from the Chairman stating such?

Thank you,

ATTACHMENT N.3

United States Department of the Interior

BUREAU OF RECLAMATION
Upper Colorado Regional Office
125 South State Street, Room 6107
Salt Lake City, UT 84138-1102

IN REPLY REFER TO:
UC-725
ENV-3.00

JUN 12 2014

Mr. James Garrison
Arizona State Historic Preservation Office
Arizona State Parks
1300 West Washington Street
Phoenix, AZ 85007

Subject: Initiation of the National Historic Preservation Act of 1966 (NHPA) Section 106 Compliance for Operation of Glen Canyon Dam (GCD)

Dear Mr. Garrison:

The Bureau of Reclamation, Upper Colorado Region, and National Park Service (NPS), Intermountain Region are proposing to complete an Environmental Impact Statement (EIS) for GCD operations. This EIS will address a change in dam operation for approximately the next 20 years and is called the Long Term Experimental and Management Plan (LTEMP).

We recently completed developing six alternatives for this EIS, and as a result, have a better understanding of any potential to affect historic properties. Of the six alternatives, the highest flow proposed is 45,000 cubic feet per second, the same as was identified in the Memorandum of Agreement for the GCD High Flow Experimental Protocol.

Since the LTEMP effort has started, we have briefed stakeholders and the signatories for the Operation of GCD 1994 Programmatic Agreement (PA) on our intent to complete a new PA. We also had a meeting on January 9, 2013, with both our Federal Preservation Officers (FPOs), the Advisory Council on Historic Preservation (ACHP), and Reclamation and the NPS management to discuss a potential Section 106 process. We sent a joint letter from the NPS and Reclamation to the ACHP on February 27, 2013, that discussed the results of that meeting and your office was copied, along with the PA signatories.

Currently, we have a draft Area of Potential Effects (APE) identified for the LTEMP undertaking as follows:

> Longitudinally, the Area of Potential Effect (APE) for the LTEMP undertaking associated with GCD operations includes the active channel of the Colorado River in Glen, Marble, and Grand Canyons from Glen Canyon Dam to the western boundary of Grand Canyon National Park near Pearce Ferry. Laterally, the APE extends from the Colorado River both horizontally and vertically to varying extent based on the specific

operational, topographic, and natural processes at each location. The variable upslope extent of the APE is primarily dependent on the distribution of sandbars and the potential for fine sediment redistribution by canyon winds under the prevailing flow regimes of the Colorado River as described in the LTEMP EIS. The APE includes areas affected by the flow of the Colorado River and active aeolian processes.

Pursuant to Section 106 of the NHPA, as the Federal lead agency for this undertaking, Reclamation would like to consult with you on developing the PA for this new undertaking. Please note that we are currently in the process of identifying our consulting parties per 36 CFR 800.3, and coordinating with the NPS on the first draft PA for review by consulting parties. We will be convening a meeting of these consulting parties, including your office, in the near future.

If you have any questions, please contact Mary Barger at 602-615-0809.

Sincerely,

for Larry Walkoviak

Laterally, the APE extends from the Colorado River both horizontally and vertically to varying extent based on the specific

operational, topographic, and natural processes at each location. The variable upslope extent of the APE is primarily dependent on the distribution of sandbars and the potential for fine sediment redistribution by canyon winds under the prevailing flow regimes of the Colorado River as described in the LTEMP EIS. The APE includes areas affected by the flow of the Colorado River and active aeolian processes.

Pursuant to Section 106 of the NHPA, as the Federal lead agency for this undertaking, Reclamation would like to consult with you on developing the PA for this new undertaking. Please note that we are currently in the process of identifying our consulting parties per 36 CFR 800.3, and coordinating with the NPS on the first draft PA for review by consulting parties. We will be convening a meeting of these consulting parties, including your office, in the near future.

If you have any questions, please contact Mary Barger at 602-615-0809.

7/18/14
Thank you for this information
We look forward to working with you
on the PA.

ABSTRACT

The U.S. Department of the Interior (DOI), through the Bureau of Reclamation and National Park Service (NPS), proposes to develop and implement a Long-Term Experimental and Management Plan (LTEMP) for operations of Glen Canyon Dam. The LTEMP would provide a framework for adaptively managing Glen Canyon Dam operations over the next 20 years, consistent with the Grand Canyon Protection Act of 1992 (GCPA) and other provisions of applicable federal law. The LTEMP would determine specific options for dam operations, non-flow actions, and appropriate experimental and management actions that will meet the GCPA's requirements and minimize impacts on resources within the area impacted by dam operations, including those of importance to American Indian Tribes.

The Final Environmental Impact Statement (FEIS) was developed in accordance with the National Environmental Policy Act of 1969, as amended (NEPA), and followed the implementing regulations developed by the President's Council on Environmental Quality in Title 40 *Code of Federal Regulations* (CFR) Parts 1500 to 1508 and DOI regulations implementing NEPA in 43 CFR Part 46. The FEIS analysis draws on the scientific information that has been collected under the Glen Canyon Dam Adaptive Management Program over the last 20 years to identify the potential environmental effects associated with taking no action, as well as a reasonable range of alternatives to no action for implementing the proposed federal action. Seven alternatives were considered and analyzed for the LTEMP EIS—a no action alternative (Alternative A), a hydropower-focused alternative (Alternative B), three condition-dependent alternatives (Alternatives C, D, and E), and two steady flow alternatives (Alternatives F and G). These alternatives incorporated a broad range of operations and experimental actions that together allowed for a full evaluation of possible impacts of the

proposed action. Based on the impact analyses conducted, DOI has chosen Alternative D as both the preferred and the environmentally preferred alternative. Alternative D is expected to result in an improvement in conditions for humpback chub, trout, and the aquatic food base; have the least impact on vegetation, wetlands, and terrestrial wildlife; improve sandbar building potential and conserve sediment; sustain or improve conditions for reservoir and river recreation; improve preservation of cultural resources; respect and enhance Tribal resources and values; and have limited impacts on hydropower resources.

1 INTRODUCTION 1-1

1.1 Description of the Proposed Action 1-4
1.2 Purpose of and Need for Action 1-5
1.3 Lead and Cooperating Agencies and Consulting Tribes 1-9
1.3.1 Lead Agencies 1-9
1.3.2 Cooperating Agencies and Consulting Tribes 1-9
1.4 Objectives and Resource Goals of the LTEMP 1-10
1.5 Scope of the EIS 1-13
1.5.1 Affected Region and Resources 1-13
1.5.2 Impact Topics Selected for Detailed Analysis 1-14
1.5.3 Impact Topics Dismissed from Detailed Analysis 1-15
1.6 Role of Adaptive Management 1-16
1.6.1 History of the Existing Adaptive Management Program 1-16
1.6.2 Relationship of Adaptive Management to NEPA and Changes to Operations 1-17
1.7 Role of Decision Analysis in the EIS Process 1-17
1.8 History, Location, and Setting 1-18
1.8.1 History and Purpose of Glen Canyon Dam 1-18
1.8.2 Location of Glen Canyon Dam and LTEMP Affected Area 1-19
1.8.3 Operation of the Glen Canyon Dam 1-20
1.8.4 History, Purpose, and Significance of the National Park System Units 1-22
1.8.4.1 Grand Canyon National Park 1-22
1.8.4.2 Glen Canyon National Recreation Area 1-24
1.8.4.3 Lake Mead National Recreation Area 1-24
1.8.5 Tribal Lands 1-25
1.8.5.1 Fort Mojave Tribe 1-26

APPENDIX A: Adaptive Management Working Group Desired Future Conditions A-1

A.1 Desired Future Conditions: Colorado River Ecosystem A-5
A.1.1 DFC Description A-5
A.1.2 DFC Background and Legislation A-6
A.1.3 Why the Colorado River Ecosystem DFCs Are Important A-6
A.1.4 Colorado River Ecosystem DFCs A-6
A.1.4.1 Sediment-Related Resources DFCs A-6
A.1.4.2 Water Quality DFCs A-7
A.1.4.3 Colorado River Ecosystem Aquatic Resource DFCs A-7
A.1.4.4 Colorado River Ecosystem Riparian Resource DFCs A-9
A.1.5 Colorado River Ecosystem DFCs Additional Information A-9
A.1.5.1 Colorado River Ecosystem Linkages A-9
A.1.5.2 Colorado River Ecosystem Metrics A-10
A.2 Power Desired Future Conditions A-10
A.2.1 Power DFC Description A-10
A.2.2 Power DFC Background and Legislation A-10
A.2.3 Why the Power DFC Is Important A-11
A.2.4 Power DFCs A-11
A.2.5 Power DFC Additional Information A-12
A.2.5.1 Power Linkages A-12
A.2.5.2 Power Metrics A-12
A.3 Cultural Resources Desired Future Conditions A-13
A.3.1 Cultural Resources DFC Description A-13
A.3.2 DFC Background and Legislation A-13
A.3.3 Why the Cultural Resources DFCs Are Important A-13
A.3.4 NRHP Eligible Historic Properties DFCs A-14
A.3.4.1 Prehistoric Archaeological Sites and Historic Sites A-14
A.3.4.2 Traditional Cultural Properties A-14
A.3.5 NRHP Eligible Historic Properties DFC Additional Information A-15
A.3.5.1 NRHP Eligible Historic Properties Linkages A-15

CONTENTS (Cont.)

A.3.5.2 NRHP Eligible Historic Properties Metrics A-16
A.3.6 Resources of Traditional Cultural Significance but Not NRHP Eligible A-16
A.3.7 Resources of Traditional Cultural Significance DFCs A-16
A.3.8 Resources of Traditional Cultural Significance Linkages A-17
A.3.9 Resources of Traditional Cultural Significance Metrics A-17
A.4 Recreation Desired Future Conditions A-17
A.4.1 Recreation DFC Description A-17
A.4.2 DFC Background and Legislation A-17
A.4.3 Why the Recreation DFC Is Important A-18
A.4.3.1 Grand Canyon National Park A-18
A.4.3.2 Glen Canyon National Recreation Area A-18
A.4.4 Recreation DFCs A-18
A.4.4.1 River Recreation in Grand Canyon National Park A-18
A.4.4.2 River Recreation in Glen Canyon National Recreation Area A-19
A.4.4.3 Blue Ribbon Trout Fishery in Glen Canyon National Recreation Area A-19
A.4.4.4 River Corridor Stewardship A-19
A.4.5 Recreation DFC Additional Information A-20
A.4.6 Recreation Linkages A-20
A.4.7 Recreation Metrics A-20
A.5 Reference A-21

APPENDIX B: Performance Metrics Used to Evaluate Alternatives B-1

B.1 Aquatic Ecology B-3
B.1.1 Humpback Chub B-3
B.1.2 Other Native Fish B-5
B.1.3 Trout Fishery B-5
B.1.4 Nonnative Aquatic Species B-6
B.2 Archaeological and Cultural Resources B-7
B.3 Hydropower and Energy B-9
B.4 Natural Processes B-10
B.5 Recreational Experience B-11
B.5.1 Grand Canyon Metrics B-11
B.5.2 Glen Canyon Metrics B-15
B.6 Riparian Vegetation B-16
B.7 Sediment B-18
B.8 Tribal Resources B-18
B.9 Water Delivery B-24
B.10 References B-25

APPENDIX C: Decision Analysis to Support Development of the Glen Canyon Dam Long-Term Experimental and Management Plan C-1

APPENDIX D: Hydrology Technical Information and Analysis D-1

D.1 Analysis Methods D-3
D.1.1 Background D-3
D.1.2 Initial Conditions D-4
D.1.3 Reservoir Operations D-4
D.1.3.1 Upper Basin Reservoirs above Lake Powell D-4
D.1.3.2 Lake Powell and Lake Mead D-5
D.1.3.3 Lake Mohave and Lake Havasu D-9
D.1.4 Representation of the Different Alternatives in CRSS D-9
D.1.4.1 Experimental Components Modeled in CRSS D-22
D.1.5 Input Hydrology D-23
D.1.6 Input Demands D-26
D.1.7 Other Key Assumptions D-26
D.2 Supplemental Information on Impact Modeling D-27
D.2.1 Low Summer Flows D-27
D.2.2 Modeled Annual Releases Extending beyond the End of the Water Year D-28
D.2.3 Lake Elevation D-29
D.3 References D-36

APPENDIX E: Sediment Resources Technical Information and Analysis E-1

E.1 Introduction E-3
E.1.1 Analysis Period E-3
E.1.2 General Scope E-3
E.2 Methods E-4
E.2.1 Sand Budget Model E-4
E.2.1.1 Model Description E-4
E.2.1.2 Sand Budget Model Modifications E-5
E.2.1.3 Modified Sand Budget Model Inputs E-6
E.2.2 Sediment Metrics E-8
E.2.2.1 Sand Load Index E-9
E.2.2.2 Standard Deviation of High Flows E-9
E.2.2.3 Sand Mass Balance Index E-10
E.3 Results E-10
E.3.1 HFEs Determined by Alternative E-10
E.3.2 Metrics E-11
E.3.2.1 Sand Load Index E-12
E.3.2.2 Standard Deviation of High Flows E-12

CONTENTS (Cont.)

E.3.3 Sand Mass Balance Index E-12
E.3.4 Alternative Performance under Climate Change Scenarios E-13
E.3.5 Relative Impacts of Dam Operations and Hydrology on Performance E-13
E.4 Lake Deltas E-15
E.5 Limitations and Known Issues E-17
E.5.1 Geographic Scope E-17
E.5.2 Modeling Improvements E-17
E.6 References E-18

APPENDIX F: Aquatic Resources Technical Information and Analysis F-1

F.1 Introduction F-3
F.2 Aquatic Food Base Assessment F-4
F.2.1 Description of the Aquatic Food Base Downstream from Glen Canyon Dam F-4
F.2.1.1 The Aquatic Food Base Prior to Construction of Glen Canyon Dam F-5
F.2.1.2 The Aquatic Food Base of the Colorado River Downstream from Glen Canyon Dam F-5
F.2.1.3 Influence of New Zealand Mudsnail on the Aquatic Food Base F-13
F.2.2 Impacts of LTEMP Alternatives on the Aquatic Food Base F-14
F.2.2.1 Flow Effects on the Aquatic Food Base F-15
F.2.2.2 Temperature Effects on the Aquatic Food Base F-23
F.2.3 Conclusion F-26
F.3 Modeling Effects of LTEMP Alternatives on Rainbow Trout and Humpback Chub F-28
F.3.1 Model Overview F-28
F.3.1.1 Glen Canyon Trout Submodel F-29
F.3.1.2 Trout Movement Submodel F-36
F.3.1.3 Humpback Chub Population Submodel F-40
F.3.2 Results for LTEMP Alternatives F-52
F.3.2.1 Rainbow Trout Performance Measures F-52
F.3.2.2 Humpback Chub Performance Measures F-60
F.4 Modeling the Effects of LTEMP Alternatives on Temperature Suitability F-62
F.4.1 Model Overview F-64
F.4.2 Humpback Chub Aggregations F-67
F.4.2.1 Historic Temperature Suitability for Humpback Chub F-69
F.4.2.2 Results for LTEMP Alternatives F-70
F.4.3 Other Native Fish F-71
F.4.3.1 Historic Temperature Suitability for Native Fish F-73
F.4.3.2 Results for LTEMP Alternatives F-73

CONTENTS (Cont.)

F.4.4 Nonnative Fish F-78
F.4.4.1 Historic Temperature Suitability for Nonnative Fish F-79
F.4.4.2 Results for LTEMP Alternatives F-79
F.4.5 Aquatic Parasites F-81
F.4.5.1 Historic Temperature Suitability for Aquatic Parasites F-84
F.4.5.2 Results for LTEMP Alternatives F-86
F.5 References F-90

APPENDIX G: Vegetation Technical Information and Analysis G-1

G.1 Analysis Methods G-3
G.1.1 Old High-Water Zone Analysis G-4
G.1.2 New High-Water Zone G-5
G.1.2.1 Native Cover Metric G-6
G.1.2.2 Native Diversity Metric G-7
G.1.2.3 Native/Nonnative Ratio Metric G-7
G.1.2.4 Arrowweed Metric G-8
G.1.2.5 Overall Score G-8
G.1.3 Wetlands G-9
G.2 Alternative-Specific Impacts G-10
G.2.1 Alternative A (No Action Alternative) G-10
G.2.2 Alternative B G-10
G.2.3 Alternative C G-10
G.2.4 Alternative D (Preferred Alternative) G-11
G.2.5 Alternative E G-11
G.2.6 Alternative F G-12
G.2.7 Alternative G G-12
G.3 Summary G-12
G.4 References G-13

APPENDIX H: Cultural Resources Technical Information and Analysis H-1

H.1 Wind Transport of Sediment H-3
H.1.1 Wind Transport of Sediment—Methods H-4
H.1.2 Wind Transport of Sediment—Results H-5
H.2 Flow Effects on Cultural Resources in Glen Canyon H-8
H.2.1 Flow Effects on Cultural Resources in Glen Canyon—Methods H-9
H.2.2 Flow Effects on Cultural Resources in Glen Canyon—Results H-10
H.3 Time Off River H-13
H.3.1 Time Off River—Methods H-13
H.3.2 Time Off River—Results H-14

APPENDIX K: Hydropower Systems Technical Information and Analysis K-1

K.1 Economic Value of Glen Canyon Dam Powerplant Capacity and Energy Production K-3
K.1.1 Power Systems Background K-3
K.1.2 Glen Canyon Dam, Reservoir, and Powerplant Background K-5
K.1.3 Power Systems Geographic Scope K-8
K.1.3.1 Top Tier: General Western Interconnection Perspective Modeling K-9
K.1.3.2 Middle Tier: LTF Customer Utility Systems K-11
K.1.3.3 Bottom Tier: WAPA SLCA/IP Hydropower Resources K-15
K.1.4 Overview of Power Systems Methods K-16
K.1.5 Description of Individual Power System Models K-20
K.1.5.1 Colorado River Simulation System Model K-20
K.1.5.2 Representative Trace Tool K-21
K.1.5.3 Hydropower Outage Model K-21
K.1.5.4 Generation and Transmission Maximization-Lite K-21
K.1.5.5 Sand Budget Model K-29
K.1.5.6 Large SLCA/IP Powerplant Spreadsheets K-29
K.1.5.7 Small SLCA/IP Powerplant Spreadsheet K-30
K.1.5.8 Loads Shaping Algorithm K-30
K.1.5.9 AURORA K-31
K.1.5.10 LMP Calibration Spreadsheet K-34
K.1.5.11 Firm Capacity Spreadsheet K-35
K.1.6 SLCA/IP Market System, Data Sources, and Model K-38
K.1.6.1 Historical Data Sources K-38
K.1.6.2 AURORA Model Dispatch Results for 2013 ..... K-42
K.1.6.3 SLCA/IP Market System Projections K-43
K.1.7 Glen Canyon Dam Powerplant Capacity Cost and Benefit Methodology K-59
K.1.7.1 Treatment of Glen Canyon Dam Capital and Fixed O&M Costs K-61
K.1.7.2 WAPA's SLCA/IP LTF Obligations and Glen Canyon Dam Replacement Capacity K-61
K.1.7.3 WAPA SLCA/IP Firm Hydropower Capacity K-62
K.1.7.4 Firm Capacity Curves for LTEMP Power Systems Analyses for the Peak Month of August K-79
K.1.7.5 AURORA Capacity Expansion Reserve Margin Targets and Capacity Additions K-82
K.1.7.6 Dispatch Performed by AURORA Model Capacity Expansion Runs K-86
K.1.7.7 Rationale for the Selection of Hydrology Conditions Used for Capacity Expansion Runs K-90

CONTENTS (Cont.)

K.1.8 Glen Canyon Dam Energy Economic Benefits Methodology K-90
K.1.9 Net Present Value Calculations and Study Period Adjustments K-94
K.1.10 Power Systems Results K-96
K.1.10.1 Main Drivers of Differences among Alternatives K-97
K.1.10.2 Capacity Expansion Modeling K-101
K.1.10.3 Economic Impacts K-108
K.1.10.4 Sensitivity of Results to Exceedance Level K-116
K.1.10.5 Sensitivity of Results to Discount Rate K-121
K.1.10.6 Sensitivity of Results to the Base Capacity Expansion Path K-121
K.1.10.7 Sensitivity of Results to the Assumed Future Hydrological Conditions K-123
K.1.10.8 Sensitivity of Results to Changes in Ancillary Services K-125
K.1.10.9 Sensitivity of Results to Customer Capacity Expansion Assumptions K-129
K.1.10.10 Summary of Economic Ranking K-131
K.2 WAPA's SLCA/IP Firm Electric Service Rate Impacts K-131
K.2.1 Relationship between the Economic Impacts of LTEMP Alternatives and Impacts on SLCA/IP FES Rates K-133
K.2.2 Temporal Scope of the Analysis and Input Data K-133
K.2.3 SLCA/IP Rate Setting K-134
K.2.4 Calculation of Net Electrical Energy Expense K-135
K.2.4.1 SLCA/IP Electrical Production K-135
K.2.4.2 Sustainable Hydropower and Available Hydropower Capacity and Energy K-135
K.2.5 Calculation of Capacity Expenses and Total Net Costs K-139
K.2.6 WAPA Replacement Resources K-143
K.2.7 Post-2024 Marketing Period K-144
K.2.8 Power Repayment Studies to Determine Rate Impacts K-146
K.2.8.1 PRS Expenses K-146
K.2.8.2 PRS Revenue Distribution K-149
K.2.8.3 The SLCA/IP PRS K-149
K.2.8.4 Standard PRS Rate-Setting Method Versus the Method Used in This Analysis K-150
K.2.9 Results K-150
K.2.9.1 Pinch-Point Year K-152
K.2.10 Definitions Used in Section K.2 ..... K-153
K.3 Impacts on Retail Electricity Rates K-154
K.3.1 Analysis Approach K-154
K.3.1.1 Database of Sales, Rates, and SLCA/IP Allocation for Retail Utility Systems K-156
K.3.1.2 Incorporation of Power Systems Analysis and Capital Recovery Factors K-158

CONTENTS (Cont.)

K.3.1.3 Inflation Rates, Sales Growth, and Interest Rates from EIA K-161
K.3.1.4 Calculation Process for Computing Rate and Bill Impacts K-162
K.3.2 Results K-167
K.3.2.1 Grid Cost Changes Relative to WAPA Wholesale Revenues K-168
K.3.2.2 Retail Rate Changes for Individual Systems and SLCA/IP Power Relative to Total Resources K-169
K.3.2.3 Using Regression Equations to Approximate Retail Rate Changes for Systems Not Included in the Database K-171
K.3.3 Summary of Impacts K-172
K.3.3.1 Average Rate Impacts under LTEMP Alternatives over the 20-Year LTEMP Period K-172
K.3.3.2 Average Year-by-Year Rate Impacts K-174
K.3.3.3 Individual System Impacts and Summary Descriptions of LTEMP Alternatives K-179
K.3.4 Impacts on Small Systems K-185
K.3.5 Alternative-Specific Impacts K-187
K.3.5.1 Alternative A K-187
K.3.5.2 Alternative B K-187
K.3.5.3 Alternative C K-188
K.3.5.4 Alternative D K-189
K.3.5.5 Alternative E K-189
K.3.5.6 Alternative F K-190
K.3.5.7 Alternative G K-190
K.4 Financial Impacts of LTEMP Alternatives on American Indian Tribes K-190
K.4.1 Contractual Requirements for Calculating and Delivering Benefits to Tribes K-192
K.4.2 Calculation of Tribal Benefit Baseline under Alternative A (No Action Alternative) K-193
K.4.3 Calculation of Change in Tribal Benefit as a Result of LTEMP EIS Alternatives K-193
K.4.4 Impacts on Tribes through a Change in the Retail Rate of the Electrical Supplier to Tribal Lands K-194
K.4.5 Calculation of Tribal Impacts for Tribes That Are Direct SLCA/IP Recipients K-195
K.4.6 Total Impact of LTEMP EIS Alternatives: Benefit Change and Rate Effect K-196
K.4.7 Total Impact on Tribes and Tribal Members Versus Retail Rate Changes to Households K-202
K.4.8 Conclusions K-202
K.5 Impacts of LTEMP Alternatives on Lake Mead and the Hoover Dam Powerplant K-206

CONTENTS (Cont.)

K.5.1 Hoover Analysis Methods, Model, and Supporting Data K-209

APPENDIX Q: Responses to Public Comments on the Glen Canyon Dam Long-Term Experimental and Management Plan Draft Environmental Impact Statement Q-1

FIGURES

1-1 Generalized Locations of Glen Canyon Dam, Lake Powell, the Colorado River between Lake Powell and Lake Mead, and Adjacent Lands 1-5

1-2 Glen Canyon Dam..... 1-6

1-3 Map of the Colorado River between Lake Powell and Lake Mead 1-20

1-4 Indian Reservations within or Adjacent to the LTEMP EIS Project Area..... 1-25

2-1 Mean, Minimum, and Maximum Daily Flows under Alternative A in an 8.23-maf Year Based on Values Presented in Table 2-3 2-18

2-2 Simulated Hourly Flows under Alternative A in an 8.23-maf Year 2-18

2-3 Simulated Hourly Flows under Alternative A for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-19

2-4 Mean, Minimum, and Maximum Daily Flows under Alternative B in an 8.23-maf Year Based on Values Presented in Table 2-4 2-21

2-5 Simulated Hourly Flows under Alternative B in an 8.23-maf Year 2-22

2-6 Simulated Hourly Flows under Alternative B for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-22

2-7 Example Mean, Minimum, and Maximum Daily Flows for a Hydropower Improvement Experiment under Alternative B in an 8.23-maf Year 2-24

2-8 Simulated Hourly Flows for a Hydropower Improvement Experiment under Alternative B in an 8.23-maf Year..... 2-24

2-9 Simulated Hourly Flows for a Hydropower Improvement Experiment under Alternative B for a Week in July in an 8.23-maf Year 2-25

2-10 Mean, Minimum, and Maximum Daily Flows under Base Operations of Alternative C in an 8.23-maf Year Based on the Values Presented in Table 2-5.... 2-26

2-11 Simulated Hourly Flows under Alternative C in an 8.23-maf Year 2-28

2-12 Simulated Hourly Flows under Alternative C for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-28

2-13 Decision Tree for Sediment-Related Actions under Alternative C..... 2-29

FIGURES (Cont.)

2-14 Decision Tree for Humpback Chub-Related Actions under Alternative C 2-30

2-15 Example Implementation of a Two-Cycle TMF in June and July with Resumption of Normal Fluctuations between Cycles and Afterward 2-40

2-16 Mean, Minimum, and Maximum Daily Flows under Triggered Low Summer Flows of Alternative C in an 8.23-maf Year Based on the Values Presented in Table 2-6 2-42

2-17 Mean, Minimum, and Maximum Daily Flows under Alternative D in an 8.23-maf Year Based on Values Presented in Table 2-8 2-45

2-18 Simulated Hourly Flows under Alternative D in an 8.23-maf Year 2-47

2-19 Simulated Hourly Flows under Alternative D for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-47

2-20 Decision Tree for Implementation of Sediment-Related Experimental Treatments under Alternative D..... 2-55

2-21 Decision Tree for Implementation of Aquatic Resource-Related Experimental Treatments under Alternative D..... 2-56

2-22 Mean, Minimum, and Maximum Daily Flows under Triggered Low Summer Flows of Alternative D in an 8.23-maf Year Based on the Values Presented in Table 2-10 2-69

2-23 Mean, Minimum, and Maximum Daily Flows under Alternative E in an 8.23-maf Year Based on the Values Presented in Table 2-11 2-74

2-24 Simulated Hourly Flows under Alternative E in an 8.23-maf Year..... 2-74

2-25 Simulated Hourly Flows under Alternative E for a Week in July in an 8.23-maf Year Showing Typically Lower Weekend Flows 2-75

2-26 Decision Tree for Sediment-Related Actions under Alternative E 2-76

2-27 Decision Tree for Trout-Related Actions under Alternative E..... 2-77

2-28 Mean, Minimum, and Maximum Daily Flows under Base Operations of Alternative F in an 8.23-maf Year Based on the Values Presented in Table 2-12 2-82

FIGURES (Cont.)

2-29 Mean, Minimum, and Maximum Daily Flows under Alternative G in an 8.23-maf Year Based on Values Presented in Table 2-13 2-83

3.1-1 LTEMP Project Area and Surrounding Lands 3-2

3.2-1 Map of Lake Powell and Associated Major Tributaries 3-8

3.2-2 Pattern of Annual Historic Flows at Lees Ferry 3-12

3.2-3 Map of Lake Mead and Associated Major Tributaries 3-13

3.2-4 Profile of Lake Powell from Glen Canyon Dam to the Inflow of the Colorado River 3-16

3.2-5 Water Temperature at Lees Ferry 3-18

3.2-6 Water Temperatures at Four Stations along the Colorado River from Lees Ferry to Diamond Creek, 1995–2014 3-21

3.2-7 Mid-June Warming above Release Temperatures Measured at Diamond Creek, 1994–2004, as a Function of Mean Weekly Discharge 3-22

3.3-1 Geomorphic Features of the Colorado River 3-36

3.3-2 Schematic Diagram of the Fan-Eddy Complex on the Colorado River 3-38

3.3-3 River Cross Section Depicting Sediment Entrapment and Sandbar Building 3-38

3.3-4 Aeolian and Fluvial Sand Deposits along the Colorado River 3-40

3.3-5 Debris Fans and Variation in Water-Surface Elevation and Channel Width for Colorado River Flows below Glen Canyon Dam 3-42

3.3-6 Comparison of Sandbars Used as Campsites, based on Inventories Conducted in 1973, 1983, and 1991 3-42

3.3-7 Repeated Photography Illustrating Sediment Losses and Sandbar Changes along the Colorado River 3-44

3.3-8 Annual Sediment Contributions from the Paria and Little Colorado Rivers 3-49

3.3-9 Matched Photographs of RM 172 Illustrating Positive Depositional Response to the 2008 HFE 3-52

FIGURES (Cont.)

3.3-10 Conceptual Diagram of the Dependency between Net Sandbar Size, Duration and Frequency of HFEs, and Post-HFE Erosion Rates 3-54

3.3-11 Average Campsite Area above the References Stage: before, after, and 6 Months following the 2008 HFE 3-55

3.3-12 Longitudinal Profiles of the Mainstem Colorado Riverbed Upstream of the Hoover Dam in 1935, 1948, 1963, and 2001 3-57

3.5-1 Temperature Ranges for Spawning, Egg Incubation, and Growth by Native and Nonnative Fishes of the Colorado River System below Glen Canyon Dam 3-71

3.5-2 Humpback Chub Aggregation Areas along the Colorado River between Glen Canyon Dam and Lake Mead 3-74

3.5-3 Estimated Adult Humpback Chub Abundance from Age-Structured Mark-Recapture Model Incorporating Uncertainty in Assignment of Age 3-75

3.5-4 Estimated Total Adult Abundance of Humpback Chub in the Lower 8 mi of the Little Colorado River and a 2-mi Portion of the Colorado River Just Downriver of the Confluence of the Little Colorado and Colorado Rivers, for September, 2009 through 2012 3-76

3.5-5 Water Temperatures at Lees Ferry and the Little Colorado River Confluence, 1995 to Present 3-81

3.5-6 Mean Electrofishing Catch Rates of Rainbow Trout in the Glen Canyon Reach, 1991–2013 3-96

3.5-7 Mean Electrofishing Catch Rates of Brown Trout in the Colorado River between Lees Ferry and Lake Mead, 2000–2009 3-99

3.6-1 Riparian Vegetation Zones along the Colorado River below Glen Canyon Dam ... 3-114

3.7-1 Riparian Zones Used by Nesting Birds 3-124

3.7-2 Threatened, Endangered, and Sensitive Species Observed along the Colorado River Corridor 3-135

3.8-1 Spencer Steamboat 3-148

3.8-2 A Roasting Pit Feature in a Grand Canyon Dune 3-148

3.8-3 An Archaic Period Site on the Colorado River in GCNP 3-151

3.8-4 Glen Canyon Linear Style Petroglyph in GCNRA 3-151

3.8-5 Puebloan Era Architecture along the Colorado River in GCNP 3-152

3.8-6 Lees Ferry and Lonely Dell Ranch Historic District Located in GCNRA 3-155

3.10-1 Glen Canyon Reach Rainbow Trout 3-170

3.10-2 Mean Rainbow Trout Catch Per Unit Effort of Both Boat Anglers and Shore-Line Anglers from Creel Surveys at Lees Ferry 3-171

3.10-3 Fishing User Days by Month in the Glen Canyon Reach for 2006 and 2009..... 3-172

3.10-4 Angler Days in the Glen Canyon Reach from 1965 through 2011 3-173

3.10-5 Designated Campsite Areas in the Glen Canyon Reach 3-175

3.10-6 Shoreline Environment with Steep Erosion Banks at Glen Canyon Reach Ferry Swale Campsite 3-176

3.10-7 Pontoon Raft Operated by Colorado River Discovery..... 3-176

3.10-8 Boating in Grand Canyon, Anticipated Annual Use by Month 3-179

3.10-9 Change in Camp Size over Time in the Lees Ferry to Diamond Creek Reach of GCNP..... 3-181

3.10-10 Total High-Elevation Campsite Area for Each Survey between 1998 and 2006 3-182

3.10-11 High-Elevation Campsite Area in Critical and Noncritical Reaches between 1998 and 2006..... 3-182

3.12-1 Glen Canyon Viewed from the Colorado River 3-194

3.12-2 Horseshoe Bend 3-194

3.12-3 Typical View of the Colorado River and Grand Canyon Afforded Recreationists on a River Trip 3-196

3.12-4 Colorado River and Granaries at Nankoweap..... 3-196

FIGURES (Cont.)

3.12-5 Entrance to Havasu Canyon 3-197

3.12-6 Vasey's Paradise 3-197

3.14-1 Minority Population Groups in the 11-County Area 3-219

3.14-2 Low-Income Population Groups in the 11-County Area 3-220

3.15-1 Nonattainment Areas for SO_2, 8-Hour O_3, $PM_{2.5}$, PM_{10}, and Pb in the 11-State Area 3-233

3.15-2 PSD Class I Areas in the 11-State Affected Area 3-235

3.16-1 Historical Supply and Use and Projected Future Colorado River Basin Water Supply and Demand 3-238

4-1 Integrated Multiple-Resource Modeling Framework Showing Inputs, Intermediate Calculations, and Output 4-3

4-2 Example Box-and-Whisker Plot for Alternatives and Their Resource Metric Values 4-6

4.2-1 Monthly Releases under Each Alternative in Years with Different Annual Release Volumes 4-22

4.2-2 Mean Monthly Volume under the LTEMP Alternatives Showing the Mean, Median, 75th Percentile, 25th Percentile, Minimum, and Maximum Values for 21 Hydrology Scenarios and Three Sediment Scenarios 4-24

4.2-3 Mean Daily Flows by Month under the LTEMP Alternatives Showing the Mean, Median, 75th Percentile, 25th Percentile, Minimum, and Maximum Values for 21 Hydrology Scenarios and Three Sediment Scenarios 4-27

4.2-4 Mean Daily Change in Flows by Month under the LTEMP Alternatives Showing the Mean, Median, 75th Percentile, 25th Percentile, Minimum, and Maximum Values for 21 Hydrology Scenarios and Three Sediment Scenarios..... 4-29

4.2-5 Lake Powell and Lake Mead End of Calendar Year Pool Elevation for 21 Hydrology Traces and Seven Alternatives 4-32

4.2-6 Percentage of Traces below Lake Powell's Minimum Power Pool and Percentage of Traces with a Lower Basin Shortage for 21 Hydrology Traces and Seven Alternatives 4-33

FIGURES (Cont.)

4.2-7 Percentage of Time in Different Operating Tier than Alternative 4-34

4.2-8 Frequency of Lake Powell Operating Tiers from 2014 to 2026 under Each of the Alternatives for 21 Hydrologic Traces..... 4-35

4.2-9 Frequency of Lake Powell Operating Tiers from 2027 to 2033 under Each of the Alternatives for 21 Hydrologic Traces..... 4-36

4.2-10 Frequency of Occurrence of Modeled Annual Releases Extending Beyond the Water Year per 20-Year Trace for Each of the Alternatives 4-37

4.2-11 Comparison of Mean Water Temperatures for Representative Wetter, Moderate, and Drier Hydrology Traces for Glen Canyon Dam Releases 4-39

4.2-12 Seasonal Glen Canyon Dam Release Temperatures for LTEMP Alternatives..... 4-40

4.2-13 Seasonal Temperature Trends under the Seven LTEMP Alternatives 4-42

4.2-14 Projected Mean Salinity Concentrations under the LTEMP Alternatives at Lees Ferry 4-46

4.3-1 Conceptual Depiction of the Sand Load Index 4-67

4.3-2 Conceptual Depiction of the Sand Mass Balance Model..... 4-68

4.3-3 Variation in Lake Powell Pool Elevation Relative to Full for 21 Hydrology Traces and Seven Alternatives..... 4-75

4.3-4 Variation in Lake Mead Pool Elevation Relative to Full for 21 Hydrology Traces and Seven Alternatives..... 4-76

4.3-5 Number and Type of HFEs Expected to Occur during the 20-Year LTEMP Period under the Seven Alternatives..... 4-77

4.3-6 Sand Load Index Values for the 20-Year LTEMP Period under the Seven Alternatives 4-78

4.3-7 Sand Mass Balance Index Values for the 20-Year LTEMP Period under the Seven Alternatives 4-79

4.4-1 Anticipated Relationships among Dam Releases, Physical Conditions, Habitats, and Ecological Resources in the Colorado River Ecosystem..... 4-89

FIGURES (Cont.)

4.5-1 Modeled Average Population Size of Age-1 and Older Rainbow Trout in the Glen Canyon Reach during the 20-Year LTEMP Period under the LTEMP Alternatives Showing the Mean, Median, 75th Percentile, 25th Percentile, Minimum, and Maximum Values for 21 Hydrology Scenarios 4-121

4.5-2 Modeled Annual Average Number of Rainbow Trout Emigrating into the Marble Canyon Reach from the Glen Canyon Reach during the 20-Year LTEMP Period under the LTEMP Alternatives 4-123

4.5-3 Modeled Mean Annual Number of Rainbow Trout in the Glen Canyon Reach Exceeding 16 in. Total Length during 20-Year Simulation Periods under the LTEMP Alternatives 4-124

4.5-4 Modeled Mean Annual Temperature Suitability for Rainbow and Brown Trout under LTEMP Alternatives at Four Locations Downstream of Glen Canyon Dam 4-125

4.5-5 Modeled Mean Annual Temperature Suitability for Warmwater Nonnative Fish under LTEMP Alternatives at Four Locations Downstream of Glen Canyon Dam 4-127

4.5-6 Mean Annual Mainstem Temperature Suitability for Humpback Chub under LTEMP Alternatives at Reported Aggregation Locations and Combined Temperature Suitability for RM 157 and RM 213 Locations 4-129

4.5-7 Mean Modeled Total Length Attained by December 31 for YOY Humpback Chub Based on Predicted Mainstem Water Temperatures at the Little Colorado River Confluence and at Pumpkin Spring under Each Alternative..... 4-130

4.5-8 Modeled Minimum Population Size for Humpback Chub during the 20-Year LTEMP Period under LTEMP Alternatives 4-131

4.5-9 Modeled Mean Annual Temperature Suitability for Native Fish under LTEMP Alternatives at Four Locations Downstream of Glen Canyon Dam 4-135

4.5-10 Overall Modeled Mean Annual Temperature Suitability under LTEMP Alternatives for Aquatic Fish Parasites at Four Locations Downstream of Glen Canyon Dam..... 4-136

4.6-1 Dominant Factors Affecting Riparian Plant Communities below Glen Canyon Dam..... 4-177

FIGURES (Cont.)

4.6-2 Comparison among Alternatives for Four Riparian Vegetation Metrics as Predicted by a Vegetation Model 4-178

4.6-3 Comparison among Alternatives for Combined Riparian Vegetation Metrics as Predicted by a Vegetation Model 4-179

4.6-4 Comparison among Alternatives for Wetland Cover as Predicted by a Vegetation Model 4-187

4.8-1 Number of Days per Year Flows Would Be >23,200 cfs under LTEMP Alternatives 4-243

4.8-2 Wind Transport of Sediment Index Values for LTEMP Alternatives 4-245

4.10-1 Recreation, Visitor Use, and Experience Metric Results for LTEMP Alternatives 4-288

4.13-1 Flow Diagram of the Power Systems Methodology Used in the LTEMP EIS 4-326

4.13-2 Average Daily Glen Canyon Dam Generation under Representative Hydrological Conditions under LTEMP Alternatives 4-341

4.13-3 Total NPV of Hoover Powerplant Energy over a 20-Year Period under LTEMP Alternatives 4-352

4.15-1 Annual Power Generation by Alternative over the 20-Year LTEMP Period 4-407

4.16-1 Weights Used To Reflect the Expected Frequency of Hydrologic Conditions under Climate Change 4-415

4.16-2 Mean Annual Inflow Showing the Mean, Median, 75th Percentile, 25th Percentile, Minimum, and Maximum Values for 112 Climate-Change Inflow Traces and 21 Historic Inflow Traces 4-416

4.16-3 Differences between Historic and Climate-Change-Weighted Values of Mean Daily Flow and Mean Daily Change in Flow by Month for LTEMP Alternatives 4-420

D-1 Operating Tiers as Specified by the 2007 Interim Guidelines for the Operations of Lake Powell and Lake Mead D-7

D-2 Monthly Releases for Each Alternative in an 8.23-maf Release Year D-21

FIGURES (Cont.)

D-3 Locations of CRSS 29 Natural Flow Nodes D-24

F-18 Relationship between Modeled Mean Numbers of Rainbow Trout Out-migrants from the Glen Canyon Reach and the Modeled Mean Minimum Abundance of Adult Humpback Chub during the 20-year LTEMP Period under the LTEMP Alternatives and Long-Term Strategies F-63

F-19 Suitability for Spawning, Egg Incubation, and Growth of Humpback Chub as a Function of Water Temperature F-68

F-20 Months for Which Annual Temperature Suitability for Specific Life History Aspects of Humpback Chub Were Calculated..... F-68

F-21 Modeled Historic Water Temperatures in the Colorado River at Humpback Chub Aggregation Locations, Water Years 1990–2012 ..... F-70

FIGURES (Cont.)

F-22 Output from the Temperature Suitability Model for Humpback Chub Aggregation Locations Based on Modeled Water Temperatures for Water Years 1990–2012 ..... F-71

F-23 Mainstem Temperature Suitability for Humpback Chub Aggregation Locations under LTEMP Alternatives and Long-Term Strategies F-72

F-24 Suitability of Water Temperatures for Spawning, Egg Incubation, and Growth of Native Fish Species F-74

F-25 Months for Which Temperature Suitability for Specific Life History Aspects Were Considered for Native Fish Species F-74

F-26 Modeled Historic Water Temperatures in the Colorado River Downstream of Glen Canyon Dam, Water Years 1990–2012 ..... F-75

F-27 Annual Temperature Suitability Scores for Growth, Spawning, and Egg Incubation of Native Fish Species at RM 225 Based on Modeled Water Temperatures for Water Years 1990–2012 ..... F-76

F-28 Annual Temperature Suitability Scores for Native Fish by Assessment Location Based on Modeled Water Temperatures for Water Years 1990–2012 ..... F-77

F-29 Mean Annual Overall Temperature Suitability for Native Fish by Assessment Location Based on Modeled Water Temperatures for Water Years 1990–2012 ..... F-77

F-30 Mean Annual Mainstem Temperature Suitability for Native Fish under LTEMP Alternatives and Long-Term Strategies at RM 61, RM 157, and RM 225, and Overall Mean for RM 61–225 ..... F-78

F-31 Suitability of Water Temperatures for Spawning, Egg Incubation, and Growth of Nonnative Fish Species F-80

F-32 Months during Which Temperature Suitability for Specific Life History Aspects Were Calculated for Nonnative Fish Species F-81

F-33 Annual Temperature Suitability Scores for Spawning, Incubation, and Growth of Nonnative Fish Species at RM 225 Based on Modeled Temperatures for Water Years 1990 to 2012 ..... F-82

F-34 Mean Annual Temperature Suitability Scores for Nonnative Fish Species and for Temperature Groups by River Location Based on Modeled Water Temperatures for Water Years 1990–2012 ..... F-83

FIGURES (Cont.)

F-35 Mean Annual Overall Temperature Suitability Scores for Coldwater and Warmwater Nonnative Fish Species Groups Based on Modeled Historic Temperatures for Water Years 1990–2012 ..... F-83

F-36 Mean Annual Mainstem Temperature Suitability for Coldwater Nonnative Fish under LTEMP Alternatives and Long-Term Strategies at RM 15, RM 61, RS 157, and RM 225 ..... F-84

F-37 Mean Annual Mainstem Temperature Suitability for Warmwater Nonnative Fish under LTEMP Alternatives and Long-Term Strategies at RM 0, RM 61, RM 157, and RM 225 ..... F-85

F-38 Suitability of Various Water Temperatures for Host Activity and Infestation Rates of Parasite Species F-86

F-39 Annual Temperature Suitability Scores for Parasite Species at RM 225 Based on Modeled Water Temperatures for Water Years 1990–2012 ..... F-87

F-40 Mean Annual Temperature Suitability Scores for Parasite Species by River Location Based on Modeled Water Temperatures for Water Years 1990–2012 ..... F-87

F-41 Overall Means of Annual Suitability Scores for Parasite Species across All River Locations during the 1990–2012 Water Years F-88

F-42 Overall Modeled Mean Annual Temperature Suitability under LTEMP Alternatives and Long-Term Strategies for Aquatic Fish Parasites at Four Locations Downstream of Glen Canyon Dam F-89

G-1 Native Cover Metric for the LTEMP Alternatives and Associated Long-Term Strategies G-46

G-2 Native Cover Metric under Climate Change for the LTEMP Alternatives and Associated Long-Term Strategies G-46

G-3 Native Diversity Metric for the LTEMP Alternatives and Associated Long-Term Strategies G-47

G-4 Native Diversity Metric under Climate Change for the LTEMP Alternatives and Associated Long-Term Strategies G-47

G-5 Native/Nonnative Ratio Metric for the LTEMP Alternatives and Associated Long-Term Strategies G-48

FIGURES (Cont.)

G-6 Native/Nonnative Ratio Metric under Climate Change for the LTEMP Alternatives and Associated Long-Term G-48

G-7 Arrowweed Metric for the LTEMP Alternatives and Associated Long-Term Strategies; Higher Values Indicate Less G-49

G-8 Arrowweed Metric under Climate Change for the LTEMP Alternatives and Associated Long-Term Strategies; Higher Values Indicate Less Arrowweed G-49

G-9 Overall Combined Score for the LTEMP Alternatives and Associated Long-Term Strategies G-50

G-10 Overall Combined Score under Climate Change for the LTEMP Alternatives and Associated Long-Term Strategies G-50

G-11 Relative Change in Wetland Cover for the LTEMP Alternatives and Associated Long-Term Strategies G-51

G-12 Relative Change in Wetland Cover under Climate Change for the LTEMP Alternatives and Associated Long-Term Strategies G-51

H-1 Wind Transport of Sediment Index Values for the LTEMP Alternatives and Associated Long-Term Strategies H-6

H-2 Average Number of HFEs in the 20-Year LTEMP Period H-7

H-3 Daily Maximum Discharge in a Typical 8.23-maf Water Volume Release Year from the Glen Canyon Dam during the Windy Season of March–June H-8

H-4 Number of Days per Year Flows Would Be >23,200 cfs under LTEMP Alternatives and Long-Term Strategies H-10

H-5 Average Number of Days of an HFE Event per Year H-11

H-6 Modeled Glen Canyon Dam Discharge for the Same Year H-12

H-7 Time Off River Index Values for All LTEMP Alternatives and Associated Long-Term Strategies H-14

H-8 Daily Average Discharge for Representative Long-Term LTEMP Strategies H-15

1 INTRODUCTION AND BACKGROUND

The Bureau of Reclamation (Reclamation) has prepared this biological assessment (BA) to analyze the potential effects of the proposed Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP) as described in the associated Environmental Impact Statement (EIS) on federally listed species. The BA analyzes the effects of implementation of flow and non-flow actions over a 20-year period at Glen Canyon Dam and in the Colorado River downstream of Glen Canyon Dam within Glen Canyon National Recreation Area (GCNRA) and Grand Canyon National Park (GCNP), Coconino County, Arizona, to Lake Mead National Recreation Area (LMNRA) (Figure 1). This BA was prepared by Reclamation as part of its compliance with the Endangered Species Act of 1973, as amended (ESA; 87 Stat. 884; 16 U.S.C. §1531 et seq.). A BA evaluates the potential effects of the action on listed and proposed species and designated and proposed critical habitat and determines whether any such species or habitat are likely to be adversely affected by the action (50 CFR 402.12).

A total of nine species currently listed under the ESA occur within the project area (Table 1). Five species are addressed in this BA due to potential effects from the proposed action: humpback chub (*Gila cypha*), razorback sucker (*Xyrauchen texanus*), southwestern willow flycatcher (*Empidonax traillii extimus*), Ridgway's Rail (formerly Yuma Clapper Rail) (*Rallus obsoletus*), and the Kanab ambersnail (*Oxyloma kanabensis*). Reclamation made "No effect" determinations for the Mexican spotted owl (*Strix occidentalis lucida*), the western yellow-billed cuckoo (*Coccyzus americanus*), and sentry milk-vetch (*Astragalus cremnophylax cremnophyla*). None of these species, or their habitat, occur in the area where activities would be implemented, and thus they are not considered further in this analysis. Reclamation has previously consulted on the bald eagle (*Haliaeetus leucocephalus*), American peregrine falcon (*Falco peregrinus anatum*), and California condor (*Gymnogyps californianus*). The California condor is an endangered species that would not be affected by this action, and the condors released in Arizona are designated as a non-essential, experimental population under the 10(j) rule of the ESA. The peregrine falcon and bald eagle have been removed from the list of threatened and endangered species and are not addressed in this BA.

TABLE 1 Federally Listed Species Occurring within the Project Area

Name	Species	Status
Mexican Spotted Owl	*Strix occidentalis lucida*	Threatened
Southwestern Willow Flycatcher	*Empidonax traillii extimus*	Endangered
California Condor	*Gymnogyps californianus*	Considered Threatened in National Parks; Experimental Non-Essential population in Northern Arizona
Western Yellow-billed Cuckoo	*Coccyzus americanus*	Threatened
Yuma Ridgway's (formerly Yuma Clapper) Rail	*Rallus obsoletus yumanensis*	Endangered
Kanab Ambersnail	*Oxyloma haydeni kanabensis*	Endangered
Humpback Chub	*Gila cypha*	Endangered
Razorback Sucker	*Xyrauchen texanus*	Endangered
Sentry Milk-vetch	*Astragalus cremnophylax cremnophylax*	Endangered

The BA provides the information and analysis to support Reclamation's conclusions concerning possible effects on the species and habitats listed in Table 1. Based upon the information contained in this BA, Reclamation has determined that the proposed action may affect, but is not likely to adversely affect, the southwestern willow flycatcher and Ridgway's Rail, and requests concurrence from the U.S. Fish and Wildlife Service (FWS). Reclamation has also determined that the proposed action may affect and is likely to adversely affect the humpback chub and its critical habitat, the razorback sucker and its critical habitat, and the Kanab ambersnail, and provides this information to the FWS to initiate formal consultation.

Reclamation is the lead agency within the U.S. Department of the Interior (DOI) that operates Glen Canyon Dam of the Colorado River Storage Project as a multipurpose storage facility in northern Arizona. Construction and operation of the dam were authorized by the 1956 Colorado River Storage Project Act. Operation of the dam is governed by a complex set of compacts, federal statutes and regulations, court decrees, and an international treaty collectively and commonly referred to as the Law of the River.

Development of the proposed action included the evaluation of specific alternatives that could be implemented to meet the Grand Canyon Protection Act's (GCPA's; 1992) requirements and to minimize, consistent with law, adverse impacts on the downstream natural, recreational, and cultural resources in the two park units, including resources of importance to American Indian Tribes. The need for the proposed action stems from the need to use scientific information developed since the 1996 Record of Decision (ROD) and the Operation of Glen Canyon Dam Final Environmental Impact Statement (1995 EIS) to better inform DOI decisions on dam operations and other management and experimental actions so that the Secretary of the Interior (Secretary) may continue to meet statutory responsibilities for protecting downstream resources for future generations, conserving federally listed species, avoiding or mitigating impacts on National Register-eligible properties, and protecting Native American interests, while meeting obligations for water delivery and the generation of hydroelectric power. The action will provide a framework for adaptively managing Glen Canyon Dam over the next 20 years consistent with the GCPA and other provisions of applicable federal law. Several key issues related to natural resources downstream of Glen Canyon Dam and new scientific information related to them are summarized below.

The Colorado River downstream from Glen Canyon Dam is depleted of its natural sediment load due to the presence of the dam, and many types of ongoing dam releases further deplete sediment delivered to the main channel by causing erosion. However, high-flow releases, between approximately 30,000 and 45,000 cfs that are triggered when there is sufficient sediment from the Paria River, mobilize sand stored in the river channel and redeposit it as sandbars and beaches and associated backwater and riparian habitats (Melis et al. 2011). Because sandbars are one of the natural resources addressed by the GCPA that are to be protected, mitigated, and, where possible, improved, the LTEMP EIS uses current comprehensive scientific data and modeling to consider possible improvements related to the use of high-flow experiments (HFEs), as well as possible intervening flow operations, that may help better achieve the goal of retaining sandbars.

Since the 1995 EIS, the status of the endangered humpback chub has continued to be an issue of concern since the population in Grand Canyon, the largest in existence, declined during the late 1990s coincident with cooler water temperatures and high nonnative trout abundance and other factors. The cause of the decline was probably the result of a combination of factors, and based on Age-Structured Mark Recapture (ASMR) and multi-state models (see Figure 8), the species has since rebounded over the last decade, when water temperatures were warmer and trout abundance lower (Yackulic et al. 2014; Yard et al. 2011). Until recently, Rainbow trout have been the nonnative species of concern, but brown trout and warmwater nonnatives are becoming or are likely to become an additional concern. Uncertainty remains as to future humpback chub population response to changes in flows, nonnative species, and water temperatures that are largely driven by reservoir elevation.

There is concern among managers and scientists that nonnative fish compete with or prey upon the native or endangered fish to varying degrees (Yard et al. 2011; Whiting et al. 2014; Gloss and Coggins 2005). The effects of dam operations were examined in the 1995 EIS, and much additional information has been accumulated about the effects of dam operations on native and nonnative fish since that time. The LTEMP EIS applies the best available science and modeling methods to further consider the impacts of a variety of dam operations on native and nonnative fish and to determine what future experimentation is needed regarding these flow regimes to reduce the negative interactions of nonnative fish with native fish.

In addition to humpback chub, other important fish fauna found in the Colorado River below Glen Canyon Dam include razorback sucker (also listed as endangered), and three other native fish, flannelmouth sucker (*Catostomus latippinis*), bluehead sucker (*Catostomus discobolus*), and speckled dace (*Rhinichthys osculus*). Razorback sucker were thought to be extirpated from the Grand Canyon, but adults (Arizona Game and Fish Department [AZGFD], 2012 Data) and larval razorback sucker (Albrecht et al. 2014) have recently been found in the western Grand Canyon. Populations of bluehead and flannelmouth suckers have fluctuated in the Colorado River in the Grand Canyon since the 1995 EIS (Rogowski et al. 2015).

1.1 SYNOPSIS OF THE PROPOSED ACTION

The LTEMP EIS proposed action (Alternative D) affects monthly, daily, and hourly releases from Glen Canyon Dam but does not affect annual water release determinations. Under the proposed action (Alternative D of the EIS), the total monthly release volume of October, November, and December would be equal to that under Modified Low Fluctuating Flows (MLFF), the current operations, to avoid the possibility of the operational tier differing from that of MLFF, as established in the Interim Guidelines (Reclamation 2007a). The August volume was set to a moderate volume level (800 kaf in an 8.23-maf release year) to balance sediment conservation prior to a potential fall HFE, and power production and capacity concerns. January through July monthly volumes were set at levels that roughly track Western Area Power Administration's (WAPA's) contract rate of power delivery. This produced a redistribution of monthly release volumes under the proposed action and results in a relatively even distribution of flows. Under the proposed action, the allowable within-day fluctuation range from Glen Canyon Dam would be proportional to the volume of water scheduled to be released during the month

(10 × monthly volume in kaf in the high-demand months of June, July, and August and 9 × monthly volume in kaf in other months), with a maximum daily fluctuation of 8,000 cfs. The down-ramp rate would be increased to 2,500 cfs/hr, but the up-ramp rate would remain unchanged at 4,000 cfs/hr.

Experimentation under the proposed action includes testing the effects of the following actions:

1. Sediment-triggered spring and fall HFEs through the entire 20-year LTEMP period;

2. 24-hr proactive spring HFEs in high volume years (≥10 maf release volume);

3. Extension of the duration of up to 45,000 cfs fall HFEs for as many as 250 hr depending on sediment availability;

4. Proactive conservation actions for humpback chub if triggered by declines in humpback chub abundance and mechanical removal of nonnative fish near the Little Colorado River confluence, if proactive conservation actions fail to arrest humpback chub population decline;

5. Trout management flows;

6. A test of low summer flows in the second 10 years of the LTEMP period to allow greater warming; and

7. Sustained low flows to improve the aquatic food base.

A wide range of possible hydrologic conditions will occur over the LTEMP implementation time frame in response to intra-annual and inter-annual variability in basin-wide precipitation cycles. Within a year, monthly operations are typically adjusted (increased or decreased) based on changing annual runoff forecasts, and, since 2007, application of the Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (Reclamation 2007a).

1.2 DESCRIPTION OF THE FEDERAL ACTION

1.2.1 Regulatory Context

Past consultations have evaluated the impact of proposed actions on the threatened and endangered species that live in the Colorado River and its floodplain between Glen Canyon Dam and at the time, Separation Canyon, near the inflow area of Lake Mead, Coconino and Mohave Counties, northern Arizona. This BA focuses on the area of the Colorado River from Glen Canyon Dam to Lake Mead below Pierce Ferry Rapid (river mile [RM] 280, [451 km]), although

the impacts of some elements of the proposed action could extend downstream and upstream of this area, and into tributary streams. The anticipated area of effect lies within the State of Arizona and in LMNRA, GCNRA, and GCNP. The area is bordered by, or is in proximity to, the Navajo Nation, Havasupai, and Hualapai tribal lands.

1.2.2 Action Area

The action area for this proposed federal action is the Colorado River corridor from Glen Canyon Dam in Coconino County, Arizona, downstream to the Colorado River Inflow in Lake Mead. The action area includes the area potentially affected by implementation of the LTEMP (normal and experimental operations of Glen Canyon Dam and non-flow actions). This area includes Lake Powell, Glen Canyon Dam, and the river downstream to Lake Mead (see Figure 1 for the locations of Lakes Powell and Mead, Glen Canyon Dam, the Colorado River, and adjacent lands). More specifically, the scope primarily encompasses the Colorado River Ecosystem, which includes the Colorado River mainstream corridor and interacting resources in associated riparian and terrace zones, located primarily from the forebay of Glen Canyon Dam to the western boundary of GCNP. It includes the area where dam operations impact physical,

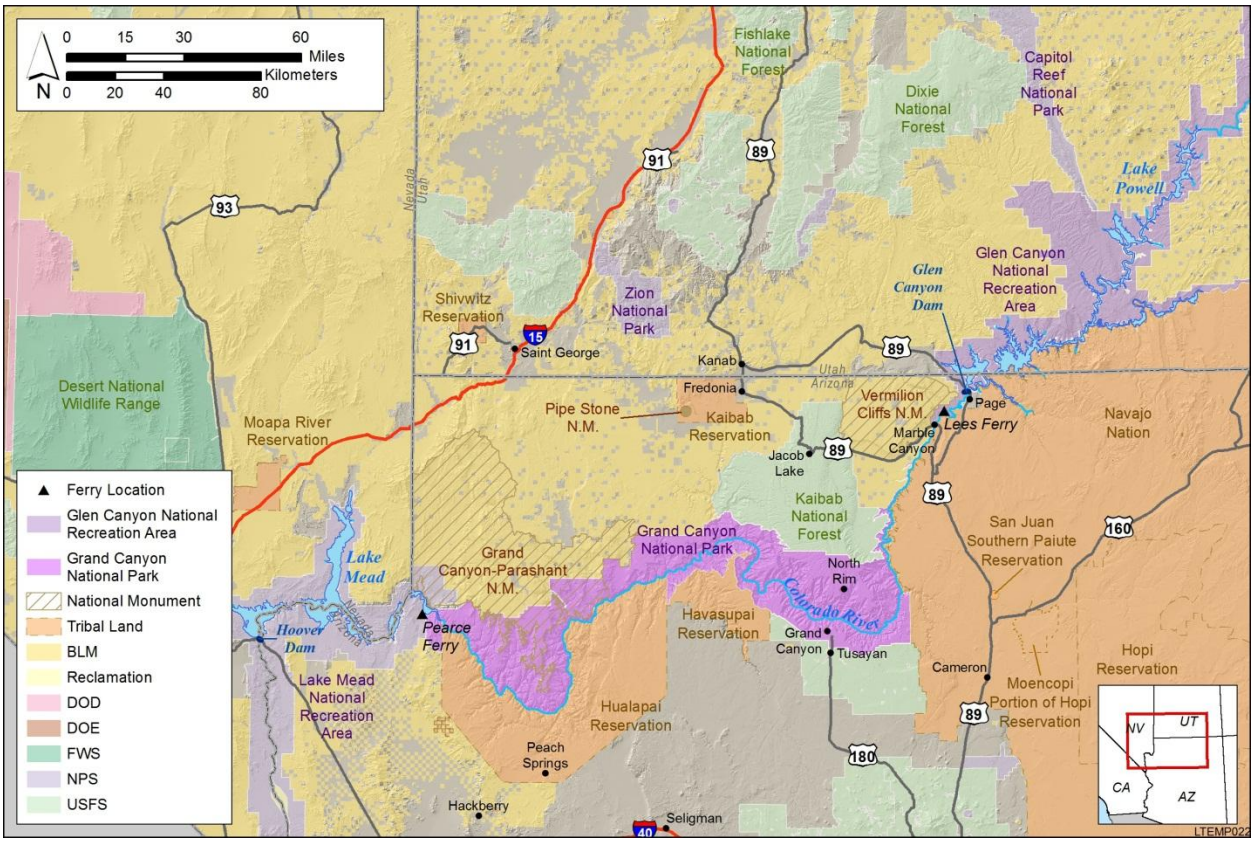

FIGURE 1 Locations of Glen Canyon Dam, Lake Powell, and the Colorado River between Lake Powell and Lake Mead, and Adjacent Lands

biological, recreational, cultural, and other resources. Portions of GCNRA, GCNP, and LMNRA are included within this area.

1.2.3 Project Description

The DOI has identified several primary objectives of operating Glen Canyon Dam under the LTEMP, as well as more specific goals to improve resources within the Colorado River ecosystem (primarily from Glen Canyon Dam downstream to the headwaters of Lake Mead) through experimental and management actions. These objectives and resource goals were considered in the formulation and development of alternatives in this EIS.

The following is a list of the objectives of the LTEMP:

- Develop an operating plan for Glen Canyon Dam in accordance with the GCPA to protect, mitigate adverse impacts on, and improve the values for which GCNP and GCNRA were established, including, but not limited to, natural and cultural resources and visitor use, and to do so in such a manner as is fully consistent with and subject to the Colorado River Compact, the Upper Colorado River Basin Compact, the Water Treaty of 1944 with Mexico, the decree of the U.S. Supreme Court in Arizona v. California, and the provisions of the Colorado River Storage Project Act (CRSPA) of 1956 and the Colorado River Basin Project Act of 1968 that govern the allocation, appropriation, development, and exportation of the waters of the Colorado River Basin and in conformance with the Criteria for Coordinated Long-Range Operations of Colorado River Reservoirs as currently implemented by the 2007 Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead.

- Ensure water delivery to the communities and agriculture that depend on Colorado River water consistent with applicable determinations of annual water release volumes from Glen Canyon Dam made pursuant to the Long-Range Operating Criteria for Colorado River Basin Reservoirs, which are currently implemented through the 2007 Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead.

- Consider potential future modifications to Glen Canyon Dam operations and other flow and non-flow actions to protect and improve downstream resources.

- Maintain or increase Glen Canyon Dam electric energy generation, load following capability, and ramp rate capability, and minimize emissions and costs to the greatest extent practicable, consistent with improvement and long-term sustainability of downstream resources.

- Respect the interests and perspectives of American Indian Tribes.

- Make use of the latest relevant scientific studies, especially those conducted since 1996.

- Determine the appropriate experimental framework that allows for a range of programs and actions, including ongoing and necessary research, monitoring, studies, and management actions in keeping with the adaptive management process.

- Identify the need for a Recovery Implementation Program for endangered fish species below Glen Canyon Dam.

- Ensure Glen Canyon Dam operations are consistent with the GCPA, ESA, National Historic Preservation Act (NHPA), CRSPA, and other applicable federal laws.

Reclamation and the National Park Service (NPS) developed resource goals considering public input and desired future conditions (DFCs) previously adopted by the Glen Canyon Dam Adaptive Management Work Group (AMWG). The following resource goals were identified:

1. *Archaeological and Cultural Resources.* Maintain the integrity of potentially affected *National Register of Historic Places* (NRHP)-eligible or listed historic properties in place, where possible, with preservation methods employed on a site-specific basis.

2. *Natural Processes.* Restore, to the extent practicable, ecological patterns and processes within their range of natural variability, including the natural abundance, diversity, and genetic and ecological integrity of the plant and animal species native to those ecosystems.

3. *Humpback Chub.* Meet humpback chub recovery goals, including maintaining a self-sustaining population, spawning habitat, and aggregations in the humpback chub's natural range in the Colorado River and its tributaries below the Glen Canyon Dam.

4. *Hydropower and Energy.* Maintain or increase Glen Canyon Dam electric energy generation, load following capability, and ramp rate capability, and minimize emissions and costs to the greatest extent practicable, consistent with improvement and long-term sustainability of downstream resources.

5. *Other Native Fish.* Maintain self-sustaining native fish species populations and their habitats in their natural ranges on the Colorado River and its tributaries.

6. *Recreational Experience.* Maintain and improve the quality of recreational experiences for the users of the Colorado River ecosystem. Recreation includes, but is not limited to, flatwater and whitewater boating, river corridor camping, and angling in Glen Canyon.

7. *Sediment.* Increase and retain fine sediment volume, area, and distribution in the Glen, Marble, and Grand Canyon reaches above the elevation of the average base flow for ecological, cultural, and recreational purposes.

8. *Tribal Resources.* Maintain the diverse values and resources of traditionally associated Tribes along the Colorado River corridor through Glen, Marble, and Grand Canyons.

9. *Rainbow Trout Fishery.* Achieve a healthy high-quality recreational rainbow trout fishery in GCNRA and reduce or eliminate downstream trout migration consistent with NPS fish management and ESA compliance.

10. *Nonnative Invasive Species.* Minimize or reduce the presence and expansion of aquatic nonnative invasive species.

11. *Riparian Vegetation.* Maintain native vegetation and wildlife habitat, in various stages of maturity, such that they are diverse, healthy, productive, self-sustaining, and ecologically appropriate.

The preferred alternative in the LTEMP EIS is Alternative D, which was developed by the DOI after a full analysis of the other six LTEMP alternatives had been completed. Alternative D adopted operational and experimental characteristics from other alternatives, after the effects of operations under other alternatives were modeled, and the results of that modeling suggested ways in which characteristics of each could be combined and modified to improve performance and reduce impacts, while meeting the purpose, need, and objectives of the LTEMP EIS. Alternative D features condition-dependent flow actions (operations at Glen Canyon Dam) and non-flow actions that would be triggered by resource conditions. Operations under the preferred alternative would use only existing dam infrastructure. There are a number of experimental and management actions that are a part of the preferred alternative; these are described briefly in the list below.

- Spring and fall HFEs would be implemented when triggered to rebuild sandbars. These HFEs include sediment-triggered HFEs in spring or fall, proactive spring HFEs as triggered by high annual release volume (> 10 maf), and extended duration (>96 hr) fall HFEs (Section 1.2.9).

- Nonnative fish control actions would be implemented if the Little Colorado River humpback chub population declined, and proactive conservation actions had failed to reverse declining populations. Two different tiers of population metrics would be used to trigger responses such as actions to increase growth and survival of humpback chub (Tier 1), or mechanical nonnative fish control

(Tier 2), which would only be implemented when Tier 1 actions fail to slow or reverse the decline in the humpback chub population (Section 1.2.10; Appendix D).

- Experimental trout management flows (TMFs) could be used to control annual trout production in the Glen Canyon reach for the purposes of managing the trout fishery and for limiting emigration to Marble Canyon and the Little Colorado River reach. Trout management flows will be tested early in the experimental period, preferably in the first 5 years (Section 1.2.10).

- Low summer flows may be tested in the second 10 years of the LTEMP period, for the purpose of achieving warmer river temperatures (> 14°C) to benefit humpback chub and other native species. Under low summer flows, daily fluctuations would be less than under base operations (e.g., approximately 2,000 cfs) (Section 1.2.10).

- Low steady weekend flows for macroinvertebrate production, "bug flows." The primary objective of bug flows is to test whether these flows will increase insect abundance. On an experimental basis, for example, flows would be held low and steady for 2 days per week (weekends) from May through August to attempt to improve the productivity of the aquatic food base, and increase the diversity and abundance of mayflies (Ephemeroptera), stoneflies (Plecoptera), and caddisflies (Trichoptera), referred to as EPT. While seeing EPT in the canyon is a worthwhile goal, it is a very long-term goal and unlikely to occur during initial experimentation (Section 1.2.11).

- Preservation of historic properties through a program of research, monitoring, and mitigation to address erosion and preservation of archeological and ethnographic sites and minimize loss of integrity at National Register historic properties.

- Continued adaptive management under the Glen Canyon Dam Adaptive Management Program (GCDAMP), including a research and monitoring component. Research projects have been developed on a 3-year funding cycle under the direction of the GCDAMP, which would continue under the proposed action. The level of fisheries monitoring will be expected to remain the same, or increase slightly, in order to address uncertainties and monitor responses to experiments and changed operations.

In addition, the joint-lead agencies have established "sideboards" that constrain the breadth and nature of the implementation of flow and non-flow actions of the proposed action.

1.2.4 Conservation Measures

Conservation measures identified in the 2011 Biological Opinion (BO) on operations of Glen Canyon Dam (FWS 2011a) included the establishment of a humpback chub refuge, evaluation of the suitability of habitat in the lower Grand Canyon for the razorback sucker, and establishment of an augmentation program for the razorback sucker, if appropriate. Other measures include humpback chub translocation; Bright Angel Creek brown trout control; Kanab ambersnail monitoring; determination of the feasibility of flow options to control trout, including increasing daily down-ramp rates to strand or displace age-0 trout, and high flow followed by low flow to strand or displace age-0 trout; assessments of the effects of actions on humpback chub populations; sediment research to determine effects of equalization flows; and Asian tapeworm (*Bothriocephalus acheilognathi*) monitoring. Most of these conservation measures are ongoing and are elements of existing management practices (e.g., brown trout control, humpback chub translocation, and sediment research to determine the effects of equalization flows), while new conservation measures or adjustments to the existing ones have been developed for the proposed action. These include experimental and management actions at specific sites such as nonnative plant removal, revegetation with native species, and mitigation at specific and appropriate cultural sites.

Five species listed under the ESA are addressed in the BA: humpback chub (*Gila cypha*), razorback sucker (*Xyrauchen texanus*), Kanab ambersnail (*Oxyloma kanabensis*), southwestern willow flycatcher (*Empidonax traillii extimus*), and Yuma Ridgway's rail (*Rallus longirostris yumanensis*). Conservation measures to minimize or reduce the effects of the proposed action or benefit or improve the status of listed species as part of the LTEMP are organized by species below.

1.2.4.1 Humpback Chub

Ongoing actions for the humpback chub include the following:

- Reclamation will continue to support the NPS, FWS, Grand Canyon Monitoring and Research Center (GCMRC), and the GCDAMP in funding and implementing translocations of humpback chub into tributaries of the Colorado River in Marble and Grand Canyons, and in monitoring the results of these translocations, consistent with agencies' plans and guidance (e.g., NPS Comprehensive Fisheries Management Plan [CFMP], FWS Humpback Chub Genetics Management Plan, and Translocation Framework, and GCMRC Triennial Work Plan). Specifically, the following will occur:
  - Humpback chub will be translocated from the lower reaches of the Little Colorado River to areas above Chute Falls in an effort to increase growth rates and survivorship.
  - Monitoring will be conducted annually, or as needed, depending on the data required, to determine survivability, population status, or genetic integrity of the Havasu humpback chub population. Intermittent translocations of additional humpback chub in Havasu Creek will be

conducted if the FWS and NPS determine it is necessary to maintain genetic integrity of the population.

- Reclamation will continue to fund a spring and fall population estimate annually, using a mark recapture based model for the Little Colorado River or the most appropriate model developed for the current collecting techniques and data.

- Reclamation will continue to fund control or removal of nonnative fish in tributaries prior to chub translocations depending on the existing fish community in each tributary. Reclamation, NPS, and FWS will lead any investigation into the possibility of using a chemical piscicide, or other tools, as appropriate. Tributaries and the appropriate control methods will be identified by the FWS, NPS, Reclamation, and GCMRC, in consultation with the AZGFD. Depending on the removal methods identified, additional planning and compliance (e.g., National Environmental Policy Act [NEPA], NHPA) may be necessary.

- Reclamation will continue to fund the FWS in maintenance of a humpback chub refuge population at a federal hatchery (Reclamation has assisted the FWS in creating a humpback chub refuge at the Southwestern Native Aquatic Resources and Recovery Center [SNARRC]) or other appropriate facility by providing funding to assist in annual maintenance (including the collection of additional humpback chub from the Little Colorado River for this purpose). In the unlikely event of a catastrophic loss of the Grand Canyon population of humpback chub, a humpback chub refuge will provide a permanent source of sufficient numbers of genetically representative stock for repatriating the species.

- Reclamation will continue to assist the FWS, NPS and the GCDAMP to ensure that a stable or upward trend of humpback chub mainstem aggregations can be achieved by:
  - Continuing to conduct annual monitoring of the Little Colorado River humpback chub aggregation (e.g., juvenile chub monitoring [JCM] parameters). Periodically, an open or multistate model should be run to estimate abundance of the entire Little Colorado River aggregation inclusive of mainstem fish.
  - Supporting annual monitoring in the mainstem Colorado River to determine status and trends of humpback chub and continuing to investigate sampling and analytical methods to estimate abundance of chub in the mainstem.
  - Conducting periodic surveys to identify additional aggregations and individual humpback chub.
  - Evaluating existing aggregations and determining drivers of these aggregations, for example, recruitment, natal origins, spawning locations,

and spawning habitat (e.g., consider new and innovative methods such as telemetry or the Judas-fish approach) (Keggeries et al. 2015).
  - Exploring means of expanding humpback chub populations outside of the Little Colorado River Inflow aggregation. Evaluate the feasibility of mainstem augmentation of humpback chub that would include larval collection, rearing, and release into the mainstem at suitable areas outside of or within existing aggregations.

An ongoing action for the humpback chub that needs enhancement is the following:

- Reclamation will, through the GCDAMP, conduct disease and parasite monitoring in humpback chub and other fishes in the mainstem Colorado. The U.S. Geological Survey (USGS) and GCMRC are currently conducting parasite monitoring in the Little Colorado River. However, in order to better understand how/if disease and parasites (primarily Asian tapeworm) are affecting chub and how temperature differences may affect parasite occurrence, this work will be expanded to include investigations of parasites in humpback chub (and surrogate fish if necessary) in the mainstem.

New actions for the humpback chub include the following:

- Reclamation will collaborate with the FWS, GCMRC, NPS, and the Havasupai Tribe to conduct preliminary surveys and a feasibility study for translocation of humpback chub into Upper Havasu Creek (above Beaver Falls). The implementation of surveys and translocations, following the feasibility study, will be dependent on interagency discussions, planning and compliance, and resulting outcomes of Tribal consultation under Section 106 of the NHPA.

- Reclamation will, in cooperation with the FWS, NPS, GCMRC, and AZGFD, explore and evaluate other tributaries for potential translocations.

1.2.4.2 Razorback Sucker

Ongoing actions for the razorback sucker include the following:

- Reclamation will continue to assist the NPS, FWS, and the GCDAMP in funding larval and small-bodied fish monitoring in order to:
  - Determine the extent of hybridization in flannelmouth and razorback sucker larvae collected in the western Grand Canyon through genetic analysis.

- Determine habitat use and distribution of different life stages of razorback sucker to assist in future management of flows that may help conserve the species. Sensitive habitats to flow fluctuations could be identified and prioritized for monitoring.
- Assess the effects of TMFs and other dam operations on razorback sucker.

1.2.4.3 Nonnative Species – Removal and Control Actions (for all native aquatic species)

Nonnative fish are important stressors contributing to the decline of native and endangered fish species in the Colorado River. While many of these species are ubiquitous and likely impossible to remove or control, actions targeted on particular species and locations can decrease nonnative effects on endangered species. Reclamation maintains, through the GCDAMP, the experimental fund that retains funding for emergency needs such as removal of nonnative fish.

Reclamation will continue, in cooperation with, the NPS, FWS, AZGFD, GCMRC, and GCDAMP, funding and implementation of the following ongoing actions:

- Reclamation, in collaboration with the NPS and FWS, and in consultation with the AZGFD, will investigate the possibility of renovating Bright Angel and Shinumo Creeks with a chemical piscicide, or other tools, as appropriate. Additional planning and compliance, and Tribal consultation under Section 106 of the NHPA, would be required. This feasibility study is outlined in the CFMP (see "Feasibility Study for Use of Chemical Fish Control Methods").

- Reclamation will continue to fund efforts of the GCMRC and NPS to remove brown trout (and other nonnative species) from Bright Angel Creek and the Bright Angel Creek Inflow reach of the Colorado River, and from other areas where new or expanded spawning populations develop, consistent with the NPS CFMP. After 5 years of removal efforts are completed (in 2017), an analysis of success will be conducted. Piscicides may be considered for removal of nonnative species if determined to be appropriate and following completion of the necessary planning and compliance actions.

Reclamation will continue, in cooperation with, the NPS, FWS, AZGFD, GCMRC, and the GCDAMP, funding and implementation of the following new actions:

- Reclamation will explore the efficacy of a temperature control device at the dam to respond to potential extremes in hydrological conditions due to climate change and could result in nonnative fish establishment. Evaluations would be ongoing for all current and evolving technological advances that could provide for warming and cooling the river in both high- and low-flow discharge scenarios, high and low reservoir levels. These studies should

include evaluating and pursuing new technologies, an analysis of the feasibility, and a risk assessment and cost analysis for any potential solutions.

- Reclamation will pursue means of preventing the passage of deleterious invasive nonnative fish through Glen Canyon Dam. Because Glen Canyon Dam release temperatures are expected to be warmer under low reservoir elevations that may occur through the LTEMP period, options to hinder expansion of warmwater nonnative fishes into Glen and Grand Canyons will be evaluated. Potential options to minimize or eliminate passage through the turbine or bypass intakes, or minimize survival of nonnative fish that pass through the dam will be assessed (flows, provide cold water, other). While feasible options may not currently exist, technology may be developed in the LTEMP period that could help achieve this goal.

- Reclamation will, in consultation with the FWS and AZGFD, fund the NPS and GCMRC on the completion of planning and compliance to alter the backwater slough at RM-12, making it unsuitable or inaccessible to warmwater nonnative species. Depending on the outcome of NPS planning and compliance, Reclamation will implement the plan in coordination with the FWS, AZGFD, NPS and GCMRC. Additional coordination will be conducted to determine and access any habitats that may support warmwater nonnatives.

- Reclamation will support the GCMRC and NPS in consultation with the FWS and AZGFD on the completion of planning and compliance of a plan for implementing rapid response control efforts for newly establishing or existing deleterious invasive nonnative species within and contiguous to the action area. Control efforts may include chemical, mechanical, or physical methods. While feasible options may not currently exist, new technology or innovative methods may be developed in the LTEMP period that could help achieve this goal. Rapid response to new warmwater fish invasions may become a more frequent need in the future with lower reservoir elevations and warmer dam releases.

- Reclamation, in cooperation with the GCDAMP, will explore the use of flow (e.g., TMFs) to inhibit brown trout spawning and recruitment in Glen Canyon, or other mainstem locations.

1.2.4.4 Southwestern Willow Flycatcher and Yuma Ridgway's Rail

Reclamation will fund the NPS to conduct southwestern willow flycatcher and Yuma Ridgway's rail presence/absence, nest surveys, and on-the-ground monitoring of habitat throughout the action area throughout the life of the LTEMP. Specifically, the following will occur:

- Reclamation will partially assist in funding NPS to conduct Yuma Ridgway's rail surveys once every 3 years for the life of the LTEMP.

- Reclamation will partially assist in funding NPS to conduct southwestern willow-flycatcher surveys once every 2 years for the life of the LTEMP.

1.2.5 Base Operations

Under the proposed action, monthly water release volumes correspond closely to the monthly hydropower demand as shown in Table 2. The total monthly release volume of October, November, and December is equal to that under current operations (MLFF) to minimize the possibility of the operational tier differing from that of current operations, as established in the Interim Guidelines (Reclamation 2007a). The distribution of monthly release volumes under the proposed action results in a more even distribution of flows over the course of a water year relative to existing, or baseline, MLFF.

Under base operations of the proposed action, the allowable daily fluctuation range from Glen Canyon Dam (i.e., the difference between the minimum and maximum flows within a day) is proportional to the volume of water scheduled to be released during the month (10 × monthly volume in thousand acre-feet (kaf) in the high-demand months of June, July, and August and 9 × monthly volume in kaf in other months; Table 2; Figure 2). For example, the daily fluctuation range in July with a scheduled release volume of 800 kaf would be 8,000 cfs, and the daily fluctuation range in December with the same scheduled release volume would be 7,200 cfs. The maximum allowable daily fluctuation range in flows in any month would be 8,000 cfs, which is the same as under current operations. However, the down-ramp rate limit under the proposed action would be increased by 1,000 cfs/hr, to 2,500 cfs/hr. The up-ramp rate would remain the same at 4,000 cfs/hr. Figure 2 shows minimum, mean, and maximum daily flows in an 8.23-milion acre-foot (maf) year, assuming all days in a month adhere to the same mean daily flow within a month. Figure 3 shows the hourly flows in a simulated 8.23-maf year within the constraints of the proposed action.

1.2.6 Operational Flexibility

Reclamation retains the authority to utilize operational flexibility at Glen Canyon Dam because hydrologic conditions of the Colorado River Basin (or the operational conditions of Colorado River reservoirs) cannot be completely known in advance. Consistent with current operations, Reclamation, in consultation with WAPA, will make specific adjustments to daily and monthly release volumes during the water year. Monthly release volumes may be rounded for practical implementation or for maintenance needs. In addition, when releases are actually implemented, minor variations may occur regularly for a number of operational reasons that cannot be projected in advance.

TABLE 2 Flow Parameters under the Proposed Action in an 8.23-maf Year[a]

Month	Monthly Release Volume (kaf)	Proportion of Total Annual Volume	Mean Daily Flow (cfs)	Daily Fluctuation Range (cfs)
October	643	0.0781	10,451	5,783
November	642	0.0780	10,781	5,774
December	716	0.0870	11,643	6,443
January	763	0.0928	12,415	6,871
February	675	0.0820	12,157	6,076
March	713	0.0866	11,596	6,417
April	635	0.0772	10,672	5,715
May	632	0.0768	10,278	5,688
June	663	0.0806	11,142	6,630
July	749	0.0910	12,181	7,490
August	800	0.0972	13,011	8,000
September	600	0.0729	10,083	5,400

[a] Within a year, monthly operations may be increased or decreased based on changing annual runoff forecasts and other factors, such as application of the Long-Range Operating Criteria for Colorado River Basin Reservoirs, which are currently implemented through the 2007 Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (Reclamation 2007a).

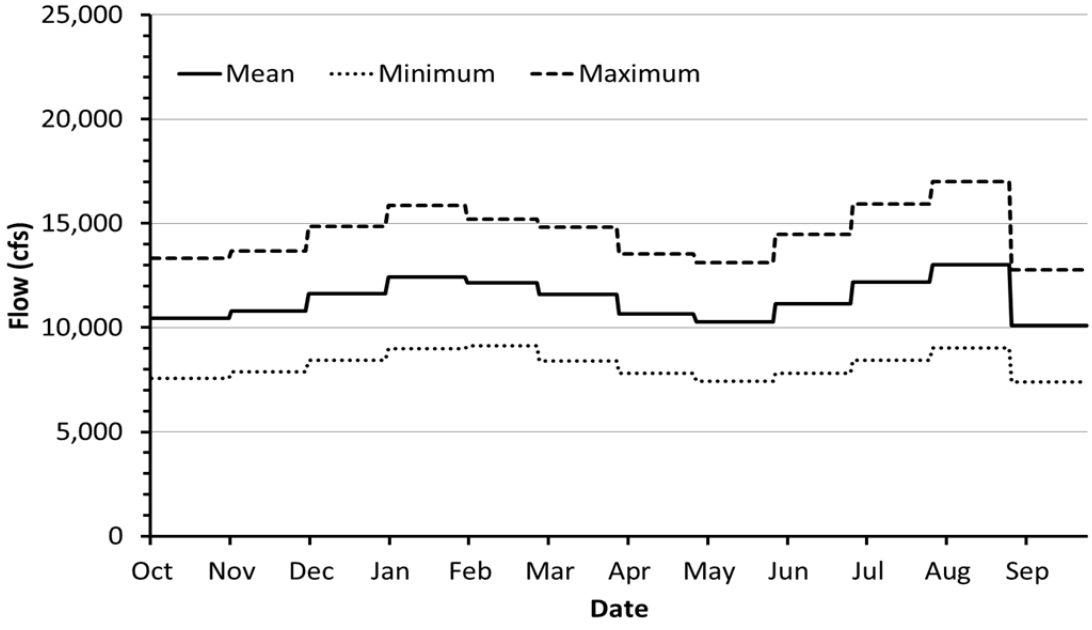

FIGURE 2 Mean, Minimum, and Maximum Daily Flows under the Proposed Action in an 8.23-maf Year

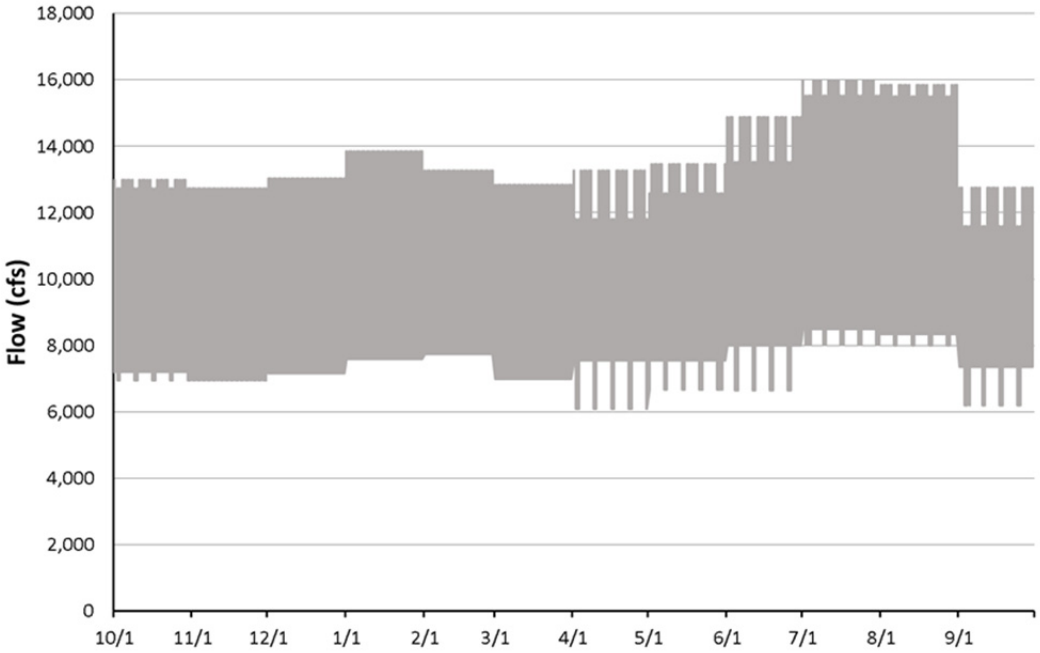

FIGURE 3 Simulated Hourly Flows under the Proposed Action in an 8.23-maf Year (Note that there are differences in the mean, maximum, and minimum flows shown here and in Figure 2. These differences reflect flexibility in operational patterns allowed within the constraints of the proposed action.)

Reclamation also will make specific adjustments to daily and monthly release volumes, in consultation with other entities as appropriate, for a number of reasons, including operational, resource-related, and hydropower-related issues. Examples of these adjustments may include, but are not limited to, the following:

- For water distribution purposes, volumes may be adjusted to allocate water between the Upper and Lower Basins, consistent with the Law of the River as a result of changing hydrology;

- For resource-related issues that may occur uniquely in a given year, release adjustments may be made to accommodate nonnative species removal, to assist with aerial photography, or to accommodate other resource considerations separate from experimental treatments under the LTEMP; and

- For hydropower-related issues, adjustments may occur to address issues such as electrical grid reliability, actual or forecasted prices for purchased power, transmission outages, and experimental releases from other Colorado River Storage Project dams.

In addition, Reclamation may make modifications under circumstances that may include operations that are prudent or necessary for the safety of dams, public health and safety, other

emergency situations, or other unanticipated or unforeseen activities arising from actual operating experience (including, in coordination with the Basin States, actions to respond to low reservoir conditions as a result of drought in the Colorado River Basin). Also, the Emergency Exception Criteria established for Glen Canyon Dam will continue under the proposed action. (See, e.g., Section 3 of the Glen Canyon Operating Criteria at 62 FR 9448, March 3, 1997.)

1.2.7 Implementation of Experimental Elements

The proposed action identifies condition-dependent flow and non-flow treatments intended to safeguard against unforeseen adverse changes in resource impacts, and to prevent irreversible changes to those resources. These condition-dependent treatments will be implemented experimentally during the LTEMP period unless they prove ineffective or result in unacceptable adverse impacts on other resources. Experimental treatments include sediment treatments, triggered humpback chub conservation actions, TMFs, mechanical removal of nonnative fish, low summer flows, macroinvertebrate production flows, and non-flow-related vegetation treatments.

1.2.8 Overall Implementation Process for Experiments

Prior to implementation of any experiment, the relative effects of the experiment on the following resource areas will be evaluated and considered: (1) water quality and water delivery, (2) humpback chub, (3) sediment, (4) riparian ecosystems, (5) historic properties and traditional cultural properties, (6) Tribal concerns, (7) hydropower production and WAPA's assessment of the status of the Basin Fund, (8) the rainbow trout fishery, (9) recreation, and (10) other resources. Although these key resources are listed for consideration on a regular basis, the DOI intends to retain sufficient flexibility in implementation of experiments to allow for response to unforeseen circumstances or events that involve any other resources not listed here. The recent discovery of nonnative green sunfish in the Glen Canyon reach illustrates the need to be responsive to unforeseen conditions.

The proposed approach differs fundamentally from a more formal experimental design (e.g., before-after control-impact design, factorial design) that attempts to resolve uncertainties by controlling for or treating potentially influential or confounding factors. There are several reasons to avoid such a formal design and instead focus on the condition-dependent approach described here. Among these are (1) the difficulties in controlling for specific conditions in a system as complex as the Colorado River; (2) wide variability in temperature and flow conditions that are important drivers in ecological processes; (3) inherent risk of some experimentation to protected sensitive resources, in particular, endangered humpback chub; (4) conflicting multiple-use values and objectives; and (5) low expected value-of-information for the uncertainties that could be articulated, and around which a formal experimental design would be established. For these reasons, the proposed action includes a condition-dependent adaptive approach.

Table 3 provides the implementation criteria for condition-dependent experimental treatments of the proposed action, and triggers for treatments are discussed under the description below. Triggers for experimental changes in operations, implementation considerations for determining if an experimental treatment should proceed, conditions that would cause the treatment to be terminated prior to completion (i.e., off-ramps), and the number of replicates that are initially considered needed are discussed below. In many cases, two to three replicates of an experimental treatment are considered necessary. The results of these tests will be used to determine if these condition-dependent treatments should be retained as part of the suite of long-term actions implemented under LTEMP. In other cases, implementation of experimental treatments would continue throughout the LTEMP period if triggered (e.g., spring and fall HFEs), except in years when it was determined that the proposed experiment could result in unacceptable adverse impacts on resource conditions. For these experiments, effectiveness would be monitored and the experiments would be terminated or modified only if sufficient evidence suggested the treatment was ineffective or had unacceptable adverse impacts on other resources. All experimental treatments will be closely monitored for adverse side effects on important resources. At a minimum, an unacceptable adverse impact would include significant negative impacts on resources as a result of experimental treatments that have not been analyzed for the proposed action in the LTEMP EIS.

In implementing the processes described here and the associated decision process shown in Table 3, the DOI will exercise a formal process of stakeholder engagement to ensure decisions are made with sufficient information regarding the condition and potential effects on important resources. As an initial platform to discuss potential future experimental actions, the DOI will hold GCDAMP annual reporting meetings for all interested stakeholders; these meetings will present the best available scientific information and learning from previously implemented experiments and ongoing monitoring of resources. As a follow-up to this process, the DOI will meet with the Technical Working Group (TWG) to discuss the experimental actions being contemplated for the year.

The DOI also will conduct monthly Glen Canyon Dam operational coordination meetings or calls with the DOI bureaus (USGS, NPS, FWS, Bureau of Indian Affairs [BIA], and Reclamation), WAPA, AZGFD, and representatives from the Basin States and the Upper Colorado River Commission (UCRC). Each DOI bureau will provide updates on the status of resources and dam operations. In addition, WAPA will provide updates on the status of the Basin Fund, projected purchase power prices, and its financial and operational considerations. These meetings or calls are intended to provide an opportunity for participants to share and obtain the most up-to-date information on dam operational considerations and the status of resources (including ecological, cultural, Tribal, recreation, and the Basin Fund). One liaison from each Basin State and from the UCRC will be allowed to participate in the monthly operational coordination meetings or calls.

TABLE 3 Implementation Criteria for Experimental Treatments under the Proposed Action

Experimental Treatment	Trigger and Primary Objective	Replicates	Duration	Annual Implementation Considerations[a]	Long-Term Off-Ramp Conditions	Action, If Successful
Sediment Treatments						
Spring HFE up to 45,000 ft^3/s (cfs) (in Mar. or Apr.)	Trigger: Sufficient Paria River sediment input in spring accounting period (Dec.–Jun.) to achieve a positive sand mass balance in Marble Canyon with implementation of an HFE Objective: Rebuild sandbars	Not conducted during first 2 years of LTEMP, otherwise, implement in each year triggered, dependent on resource condition and response	≤96 hr	Potential short-term unacceptable impacts on the resources listed in footnote (a); unacceptable cumulative effects of sequential HFEs; sediment-triggered spring HFEs will not occur in the same water year as an extended-duration (>96 hr) fall HFE	Sediment-triggered spring HFEs are not effective in building sandbars, or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment when triggered and resource conditions allow
Proactive spring HFE up to 45,000 cfs (Apr., May, or Jun.)	Trigger: High-volume year with planned equalization releases (≥10 maf) Objective: Protect sand supply from equalization releases	Not conducted during first 2 years of LTEMP, otherwise, implement in each year triggered, dependent on resource condition and response	First test 24 hr; subsequent tests could be shorter, but not longer, depending on results of first tests	Potential short-term unacceptable impacts on the resources listed in footnote (a); unacceptable cumulative effects of sequential HFEs; would not be implemented in same water year as a sediment-triggered spring HFE or extended duration fall HFE	Proactive spring HFEs are not effective in building sandbars; or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment when triggered and existing resource conditions allow
Fall HFEs ≤ 96 up to 45,000 cfs in Oct. or Nov.	Trigger: Sufficient Paria River sediment input in fall accounting period (Jul.–Nov.) to achieve a positive sand mass balance in Marble Canyon with implementation of an HFE Objective: Rebuild sandbars	Implement in each year triggered dependent on resource condition and response	≤96 hr	Potential unacceptable impacts on resources listed in footnote (a)	This type of HFE was not effective in building sandbars; or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment when triggered and existing resource conditions allow

TABLE 3 (Cont.)

Experimental Treatment	Trigger and Primary Objective	Replicates	Duration	Annual Implementation Considerations[a]	Long-Term Off-Ramp Conditions	Action, If Successful
Sediment Treatments (Cont.)						
Fall HFEs longer than 96-hr duration up to 45,000 cfs in Oct. or Nov.	Trigger: Sufficient Paria River sediment input in fall accounting period (Jul.–Nov.) to achieve a positive sand mass balance in Marble Canyon with implementation of an HFE longer than a 96-hr, up to 45,000-cfs flow Objective: Rebuild sandbars	Implement in each year triggered; limited to total of four tests in LTEMP period	Up to 250 hr depending on availability of sand; duration of first test not to exceed 192 hr	Potential short-term unacceptable impacts on the resources listed in footnote (a); unacceptable cumulative effects of sequential HFEs.	Extended duration fall HFEs are not effective in building sandbars; resulting sandbars are no bigger than those created by shorter-duration HFEs; or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment when triggered and existing resource conditions allow
Aquatic Resource Treatments						
Trout management flows	Trigger: Predicted high trout recruitment in the Glen Canyon reach Objective: Test efficacy of flow regime on trout numbers and survival of chub	Implement as needed when triggered; after consultation with Tribes; test may be conducted early in the 20-year period even if not triggered by high trout recruitment[b]	Implemented in as many as 4 months (May–Aug.)	Potential unacceptable impacts on resources listed in footnote (a)	Trout management flows have little or no effect on trout recruitment after at least three tests, or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment triggered by predicted high trout recruitment in Glen Canyon, taking into consideration Tribal concerns
Tier 1: Expanded translocation of humpback chub in the Little Colorado River	Trigger: Number of adult or subadult humpback chub in the Little Colorado River reach below tier 1 triggers Objective: Increase number of adult and subadult humpback chub	Implement in each year triggered unless determined ineffective.	As needed	Potential short-term unacceptable impacts on resources listed in footnote (a)	Expanded translocation has little or no effect on increasing the number of adult or subadult humpback chub; or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment when triggered

TABLE 3 (Cont.)

Experimental Treatment	Trigger and Primary Objective	Replicates	Duration	Annual Implementation Considerations[a]	Long-Term Off-Ramp Conditions	Action, If Successful
Aquatic Resource Treatments (Cont.)						
Tier 1: Implement headstart program for larval humpback chub	Trigger: Number of adult or subadult humpback chub in Little Colorado River reach below Tier 1 triggers Objective: Increase number of adult and subadult humpback chub	Implement in each year triggered unless determined ineffective	As needed	Potential short-term unacceptable impacts on resources listed in footnote (a)	Head-start program has little or no effect on increasing the number of adult or subadult humpback chub; or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment when triggered
Tier 2: Mechanical removal of nonnative fish in Little Colorado River reach	Trigger: Tier 1 actions ineffective; humpback chub number in Little Colorado River below Tier 2 triggers Objective: Increase number of adult and sub-adult humpback chub	Implement in each year triggered unless determined ineffective, after consultation with Tribes	Monthly removal trips (Feb.–Jul.) until "predator index" or adult humpback chub reach acceptable levels (Appendix D)	Potential short-term unacceptable impacts on resources listed in footnote (a)	Mechanical removal has little or no reduction in predator index in the Little Colorado River reach; no population-level benefit on humpback chub or unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment when triggered, taking into consideration Tribal concerns
Low summer flows (minimum daily mean 5,000 to 8,000 cfs) to target ≥ 14°C at Little Colorado River confluence	Trigger: Initial experiment in the second 10 years of the LTEMP period, when target temperature of ≥14°C can only be achieved with low summer flow Objective: Increase humpback chub growth	Subsequent experimental use if (1) initial test was successful, (2) humpback chub population concerns warrant their use, (3) water temperature appears to be limiting recruitment and (4) target temperature of ≥14°C could be achieved only with low summer flow	3 months (Jul.–Sep.)	Potential unacceptable impacts on resources listed in listed in footnote (a)	Low summer flows do not increase growth and recruitment of humpback chub; increase in warmwater nonnative species or trout at the Little Colorado River; or long-term unacceptable impacts on resources listed in footnote (a) are observed, or sufficient warming does not occur as predicted	Implement as adaptive treatment when conditions allow

TABLE 3 (Cont.)

Experimental Treatment	Trigger and Primary Objective	Replicates	Duration	Annual Implementation Considerations[a]	Long-Term Off-Ramp Conditions	Action, If Successful
Aquatic Resource Treatments (Cont.)						
Low steady weekend flows for macroinvertebrate production	Trigger: None Objective: Improve food base productivity and abundance or diversity of mayflies, stoneflies, and caddisflies	Target two to three replicates	Up to 4 months (May–Aug.)	Potential short-term unacceptable impacts on resources listed in footnote (a); coordinate planning with other experiments to avoid confounding conditions or results	Steady weekend flows have little or no benefit on food base, trout fishery, or native fish; increase in warmwater nonnative species or trout in the Little Colorado River reach; or long-term unacceptable adverse impacts on the impacts on resources listed in footnote (a) are observed	Implement as adaptive treatment in target months when conditions allow
Riparian Vegetation Treatments						
Non-flow vegetation treatments	Trigger: None Objective: Improve vegetation conditions at key sites	Not applicable	20 years if successful pilot phase	Potential short-term unacceptable impacts on resources listed in footnote (a)	Control and replanting techniques are not effective or practical; or long-term unacceptable adverse impacts on the resources listed in footnote (a) are observed	Implement as adaptive treatment if invasive species can be reduced and native species increased

[a] Prior to implementation of any experiment, the relative effects of the experiment on the following resource areas will be evaluated and considered: (1) water quality and water delivery, (2) humpback chub, (3) sediment, (4) riparian ecosystems, (5) historic properties and traditional cultural properties, (6) Tribal concerns, (7) hydropower production and WAPA's assessment of the status of the Basin Fund, (8) the rainbow trout fishery, (9) recreation, and (10) other resources.

[b] The decision to conduct TMFs in a given year would consider the resource conditions listed in footnote (a) and would also involve considerations regarding the efficacy of the test based on those resource conditions.

To determine whether conditions are suitable for implementing or discontinuing experimental treatments or management actions, the DOI will schedule implementation/planning meetings or calls with the DOI bureaus (USGS, NPS, FWS, BIA and Reclamation), WAPA, AZGFD, and one liaison from each Basin State and from the UCRC, as needed or requested by the participants. The implementation/planning group will strive to develop a consensus recommendation to bring forth to the DOI regarding resource issues as detailed at the beginning of this section, as well as including WAPA's assessment of the status of the Basin Fund. The Secretary of the Interior will consider the consensus recommendations of the implementation/planning group; however, it retains sole discretion to decide how best to accomplish operations and experiments in any given year pursuant to the LTEMP ROD and other binding obligations.

The DOI will also continue separate consultation meetings with the Tribes, AZGFD, the Basin States, and UCRC upon request, or as required under existing RODs.

Sections 1.2.9 and 1.2.10 describe specific processes for development and implementation of experiments related to sediment, aquatic resources, and riparian vegetation. The overall approach attempts to strike a balance between identifying specific experiments and providing flexibility to implement those experiments when resource conditions are appropriate. As discussed above, rather than proposing a prescriptive approach to experimentation, an adaptive management-based approach that is responsive and flexible would be used to adapt to changing environmental and resource conditions and new information. The potential for confounding interactions among individual experimental treatments is discussed when relevant for each of the proposed treatments. Given the size of the project area, and the variability inherent in the system, this pragmatic approach to experimentation is warranted. Although confounding treatments are possible given the complexity of the experimental plan, they are not expected to limit learning over the life of the LTEMP.

1.2.9 Sediment-Related Experimental Treatments

Figure 4 shows the decision tree for implementation of sediment experiments during the LTEMP period. Under the proposed action, the existing HFE protocol was updated and incorporated into the LTEMP process as specified in Appendix P of the LTEMP EIS. Changes to the existing protocol were related to implementation of the new HFEs that are included under the proposed action and an extension of the protocol to the end of the LTEMP period. This new protocol would replace the existing protocol when the LTEMP ROD is issued. Spring and fall HFEs would be implemented when triggered during the 20-year LTEMP period based on the estimated sand mass balance resulting from Paria River sediment inputs during the spring and fall accounting periods, and the dam release pattern during the accounting period. HFE releases would be 1 to 250 hr long and between 31,500 and 45,000 cfs. Depending on the cumulative amount of sediment input from the Paria River during the spring (December 1 through June 30) or fall (July 1 through November 30) accounting periods, and the expected accumulation of sand, the maximum possible magnitude and duration of HFEs that would achieve a positive sand mass balance in Marble Canyon, as determined by modeling, would be implemented.

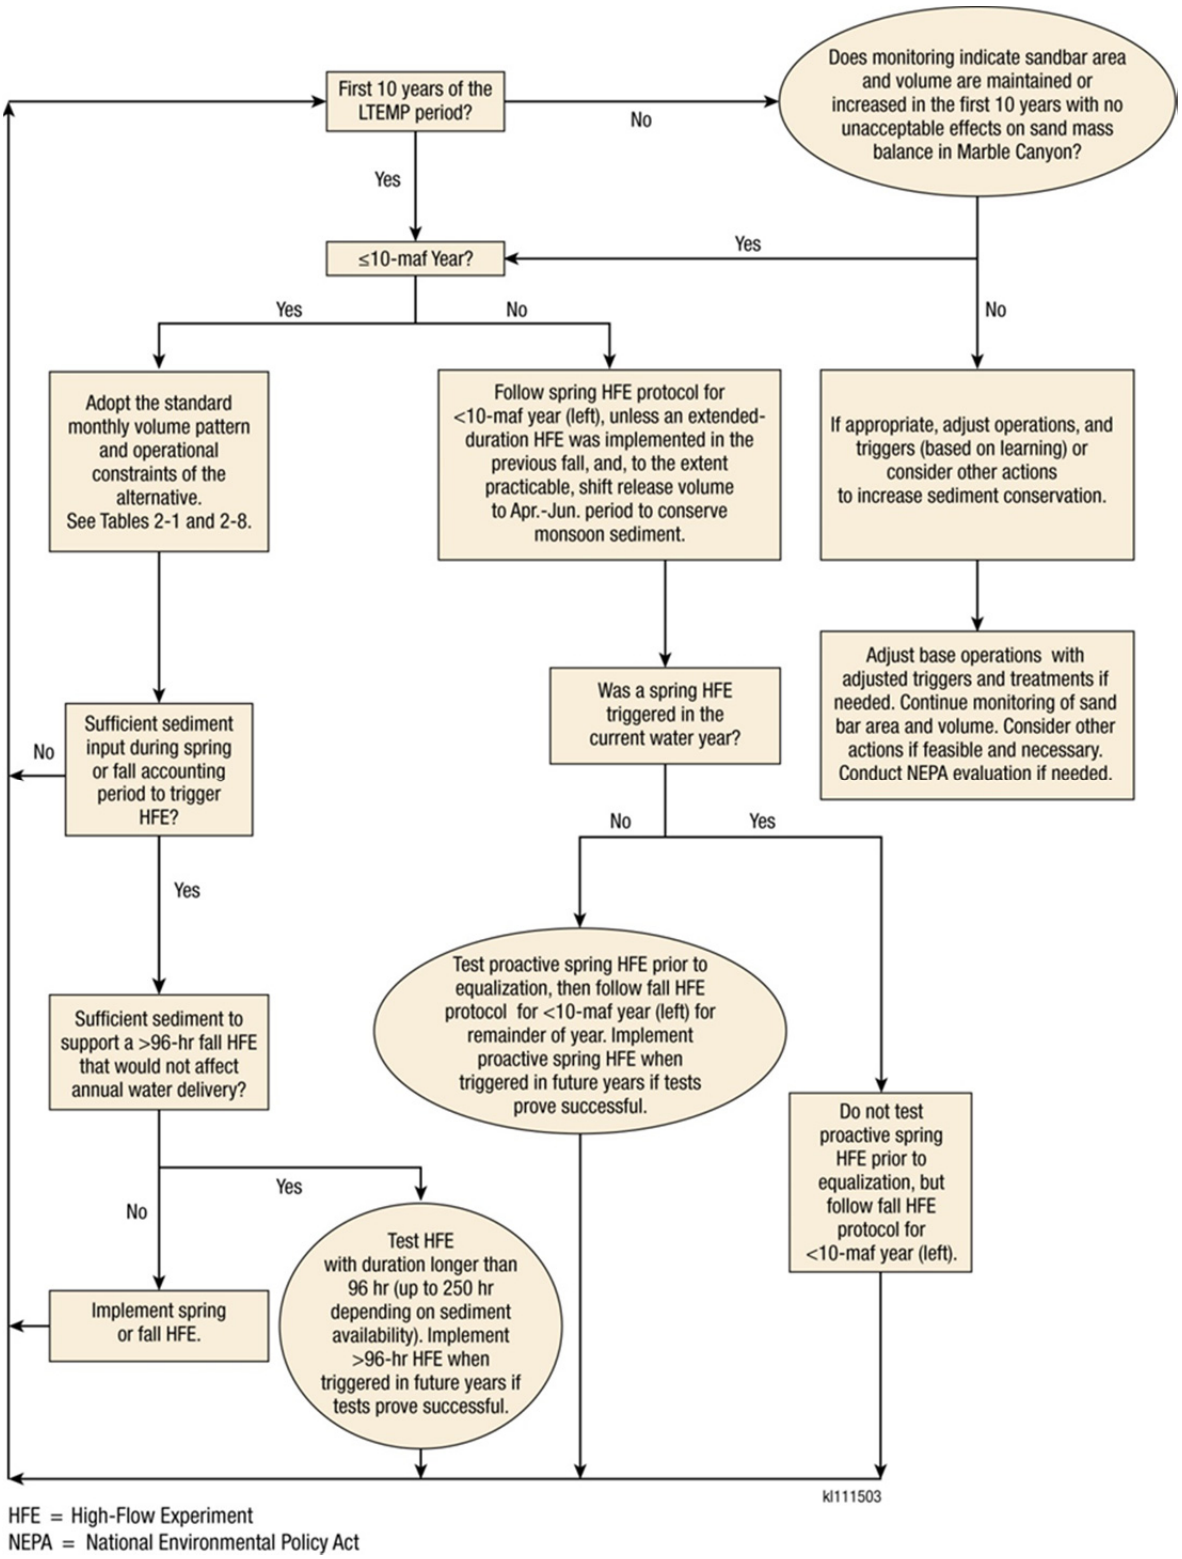

FIGURE 4 Decision Tree for Implementation of Sediment-Related Experimental Treatments under the Proposed Action

Sand mass balance modeling would be used to ensure that the duration and magnitude of an HFE are best matched with the mass of sand present in the system during a particular release window. The magnitude and duration of HFEs will not affect the total annual release from Glen Canyon Dam. Reclamation will consider the total water to be released in the water year when determining the magnitude and duration of an HFE.

Sediment-related experiments under the proposed action include (1) sediment-triggered spring and fall HFEs up to 96-hr duration; (2) short-duration (24-hr) proactive spring HFEs in high-volume equalization years prior to equalization releases; and (3) implementation of up to four extended-duration (>96 hr) HFEs, up to 250 hr long, depending on sediment conditions. The pattern of transferring water volumes from other months to make up the HFE volume would be discussed in the monthly Glen Canyon Dam operational coordination meetings described in Section 1.2.8.

If sediment resources are stable or improving, the combination of base operations, HFE protocols, and other treatments will continue as prescribed. If sediment resource conditions decrease to unacceptable levels during the LTEMP period, operations may be modified to the extent allowable under the LTEMP ROD or would be evaluated and considered under a separate NEPA process, potentially including additional studies of sediment augmentation or other actions.

For all sediment experiments, testing will be modified or temporarily or permanently suspended if (1) experimental treatments are ineffective at accomplishing their objectives, or (2) there were unacceptable adverse impacts on resources (Table 3). Monitoring results will be evaluated to determine whether additional tests, modification of experimental treatments, or discontinuation of experimental treatments are warranted.

Implementation of HFEs would consider resource condition assessments and resource concerns using the annual processes described in Section 1.2.8. HFEs may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section 1.2.8. In addition, there is uncertainty associated with cumulative impacts from sequential HFEs. These cumulative impacts would be considered before implementing an HFE.

1.2.9.1 Sediment-Triggered Spring HFEs

Under the proposed action, sediment-triggered spring HFEs will be implemented after an initial 2-year delay in order to enable testing of the effectiveness of TMFs, if warranted, and address concerns raised by the apparent positive response of trout to the 2008 spring HFE (Korman et al. 2011; Melis et al. 2011). Modeling the trout response to spring HFEs for the EIS was based on relationships developed from the observed response to the 2008 spring HFE. That modeling also evaluated uncertainty related to the effectiveness of TMFs to control excess trout produced by HFEs. Modeling indicated that even at a relatively low level of effectiveness (10% reduction in trout recruitment), TMFs could effectively reduce the number of trout out-migrants from Glen Canyon to the Little Colorado River reach (RM 61) where humpback chub occur.

After the first 2 years of the LTEMP period, spring HFEs will be implemented when triggered in accordance with the HFE protocol unless an extended-duration fall HFE occurred in the same water year. Modeling indicates spring HFEs will be triggered in about 26% of the years in the LTEMP period. Sediment-triggered spring HFEs would be implemented when triggered during the entire LTEMP period unless new information indicated they were not effective in building sandbars, or there were unacceptable adverse effects on resources (Section 1.2.8).

Implementation of a spring HFE may provide important replication of the 2008 spring HFE and aid in understanding the effect of spring HFEs on the trout population. It is possible that the strong 2008 response was a result of the specific conditions present in 2008 (e.g., condition of the food base, trout population size). It is unclear whether implementation under current conditions would produce the same result, and there is a good deal of learning that could result from implementation early in the LTEMP period. Implementing a spring HFE early in the LTEMP period when chub numbers are relatively high may also be a relatively low-risk option. To provide a means of controlling trout recruitment following tests of spring HFEs, TMFs will be experimentally implemented and tested for efficacy early in the LTEMP period (see discussion of TMFs below).

Implementation of sediment-triggered spring HFEs would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. Spring HFEs may not be tested when there appears to be the potential for unacceptable adverse impacts on the resources listed in Section 1.2.8. In addition, there is uncertainty associated with the cumulative impacts of sequential HFEs on sediment, aquatic, and potentially other resources. These cumulative impacts would be considered before implementing a spring HFE particularly if a fall HFE had been implemented in the same water year.

1.2.9.2 Proactive Spring HFEs

GCMRC scientists identified proactive spring HFEs as a potential experimental treatment to transport and deposit in-channel sand at elevations above those of equalization flows. These HFEs will be tested only in years with high annual water volume (i.e., ≥10 maf), and modeling suggests that this would be a relatively rare treatment. A first test would be a 24-hr 45,000-cfs release conducted in April, May, or June. Duration in subsequent tests could be shortened depending on the observed response during the first tests. It would be preferable to test proactive spring HFEs at least two to three times in the 20-year LTEMP period, but being able to do so will be dependent upon annual hydrology. Modeling indicates that proactive spring HFEs would be triggered in about 10% of the years in the LTEMP period.

Proactive spring HFEs would not be tested in the first 2 years of the LTEMP period. In addition, proactive spring HFEs will not be tested in years when there had been a spring HFE or extended-duration fall HFE earlier in the same water year. Proactive spring HFEs could be performed in the same water year as a 96-hr or shorter sediment-triggered fall HFE, although prior to implementation, the potential effects of these HFEs would be carefully evaluated using the processes described in Section 1.2.8. The first test would be carefully evaluated to determine whether additional tests were warranted based on the efficacy of building and maintaining

sandbars. If initial tests show positive results without unacceptable adverse effects on the resources listed in Section 2.2.4.3, proactive spring HFEs would be implemented when triggered during the entire LTEMP period..

Implementation of proactive spring HFEs would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. Proactive spring HFEs may not be tested when there appears to be the potential for unacceptable impacts on the resources identified in Section 1.2.8. The cumulative impacts of sequential HFEs would be considered before implementing a proactive spring HFE.

1.2.9.3 Sediment-Triggered Fall HFEs

The effects of sediment-triggered fall HFEs on trout recruitment are uncertain, but fall HFEs are expected to have less effect on trout production than spring HFEs. HFEs in November 2012, 2013, and 2014 resulted in little or no increase in the number of young-of-the-year (YOY) trout (VanderKooi 2015; Winters et al. 2016), and this observation may be based on the observed resilience of the food base to disturbance in the fall (Kennedy et al. 2015). However, factors affecting trout response to fall HFEs are not well understood. Modeling for the EIS considered the effect of fall HFEs on trout and modeled fall HFEs in two ways: in one, the effect of fall HFEs was half as long as that of a spring HFE (i.e., it affected trout production only in the water year in which it occurred); in the other, fall HFEs had no effect on trout production. Modeling the effect of fall HFEs in these two ways had an effect on the overall predicted number of trout produced, the number of out-migrants, and ultimately their effect on humpback chub. The number of trout produced and out-migrants were higher, and the number of humpback chub was lower if fall HFEs were assumed to have an effect on trout production.

Modeling indicates fall HFEs would be triggered in about 77% of the years in the LTEMP period. Testing fall HFEs is considered to be a relatively low-risk treatment due to the lack of observed or documented trout response from previous fall HFEs, and testing would be implemented when triggered during the entire LTEMP period unless new information indicated fall HFEs were not effective in building sandbars, or there were unacceptable adverse effects.

Implementation of sediment-triggered fall HFEs would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. Fall HFEs may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section 1.2.8. The cumulative impacts of sequential HFEs would be considered before implementing a sediment-triggered fall HFE.

1.2.9.4 Extended-Duration Fall HFEs

Sediment-triggered fall HFEs with durations longer than 96 hr (up to 250 hr) would be tested under the proposed action. The duration of these extended-duration fall HFEs would be based on the amount of sediment delivered from the Paria River during the fall accounting period and would be no more than the maximum magnitude and duration of an HFE that would achieve

a positive sand mass balance in Marble Canyon, as determined by modeling. Based on examination of the observed historical sediment input from the Paria River, it was determined that HFEs up to 10.4 days in length (250 hr) could be supported before exhausting seasonal sediment inputs and affecting water delivery requirements. GCMRC scientists have suggested that increasing the duration of HFEs when sediment supply can support a longer duration may lead to more sand being deposited at higher elevations, resulting in bigger sandbars. Modeling indicates that this treatment will be triggered in 25% of the years in the LTEMP period. There will be no more than four extended-duration fall HFEs over the 20-year LTEMP period.

The duration of the first implementation of an extended-duration HFE will be limited to no more than 192 hr (twice as long as the current limit of 96 hr). This duration is considered long enough to produce a measurable result if the treatment represents an effective approach to building sandbars under enriched sediment conditions. The duration of all tests will be based on available sediment, current hydrology, reviews of available information, the expert opinion of GCMRC and other Grand Canyon scientists, and consideration of potential effects on the resources listed in Section 1.2.8. If feasible, monitoring will include real-time observations of sediment concentrations to determine if sediment deposition continues throughout the duration of the extended HFEs.

Implementation of extended-duration fall HFEs would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. Extended-duration fall HFEs may not be tested when there appears to be potential unacceptable impacts on the resources listed in Section 1.2.8. Because the effects of extended-duration HFEs on Lake Mead water quality are a concern, DOI will coordinate with relevant water quality monitoring programs or affected agencies prior to implementing any test of extended-duration HFEs. The cumulative impacts of sequential HFEs would be considered before implementing an extended-duration fall HFE.

Another important concern that results from the large volume of water bypassed is water delivery. Water delivery issues would be considered before deciding to implement an extended-duration fall HFE. An extended-duration HFE would not be implemented if annual release volume would be affected. It is possible that in lower volume years there would not be sufficient water available to support an extended-duration HFE. A 250-hr extended-duration HFE would result in a monthly total release of approximately 1.2 maf. In lower volume release years (e.g., 7.0 maf or 7.48 maf), the maximum duration may be less than 250 hr. In addition, a sediment-triggered spring HFE or proactive spring HFE would not be conducted in the same water year as an extended-duration fall HFE. If an extended-duration fall HFE was triggered but not implemented for any of the reasons described above, a fall HFE 96 hr or less in duration could be implemented instead. Implementation would necessitate reducing water volume in other months of the same water year.

In order to fully test the efficacy of these longer HFEs, several replicates would be desirable in the 20 year LTEMP period. Extended-duration HFEs would be considered successful and would be continued up to a total of four times in the 20-year LTEMP period as part of an adaptive experimental treatment if there was a widespread increase in bar size relative to ≤96-hr HFEs, and if sand mass balance was not significantly compromised relative to the

ability to maintain a long-term equilibrium. Extended-duration HFEs would not continue to be tested if they were not effective in building sandbars, if resulting total sandbar volumes were no bigger than those created by shorter-duration HFEs, or if unacceptable adverse impacts on the resources listed in Section 1.2.8 were observed.

1.2.10 Aquatic Resource-Related Experimental Treatments

Under the proposed action, most experimental flow and non-flow actions will be triggered or adjusted by considering the estimated number of humpback chub, number of rainbow trout, number of other nonnative fish, water release temperature, or a combination of these variables, depending on the action under consideration. Humpback chub triggers and trout triggers were developed in consultation with the FWS, NPS, and AZGFD. These triggers may be modified based on experimentation conducted early in the LTEMP period.

Aquatic resource experiments that will be tested include (1) TMFs, (2) Tier 1 conservation actions for humpback chub; (3) Tier 2 mechanical removal of nonnative fish, (3) low summer flows in the second 10 years of the LTEMP, and (4) macroinvertebrate production flows. Aquatic resource experiments would seek to refine our understanding of the impacts of water releases, HFEs, and TMFs on these resources. The primary uncertainty surrounding HFEs revolves around the extent to which the seasonality of HFEs or the number of adult rainbow trout determines the strength of rainbow trout recruitment.

Experimental nonnative fish control actions would be implemented if the humpback chub population declined, and proactive conservation actions had failed to reverse declining populations. Two different tiers of population metrics would be used to trigger responses including actions to increase growth and survival of humpback chub (Tier 1) and mechanical removal of nonnative fish (Tier 2); these would only be implemented when Tier 1 actions fail to slow or reverse the decline in the humpback chub population. This tiered approach and the triggers that would be used to implement it are described below.

For all aquatic resource experiments, testing will be modified or temporarily or permanently suspended if (1) experimental treatments are ineffective at accomplishing their objectives, or (2) there are potential unacceptable adverse impacts on the resources listed in Section 1.2.8. Monitoring results will be evaluated to determine whether additional tests, modification of experimental treatments, or discontinuation of experimental treatments are warranted.

Implementation of aquatic resource experiments would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. Aquatic resource experiments may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section 1.2.8.

1.2.10.1 Trout Management Flows

Mechanical removal of nonnative fish is a controversial issue in the Colorado River through Glen and Grand Canyons. A spring 2015 meeting of Grand Canyon biologists (NPS, FWS, AZGFD, and GCMRC) to assess current removal triggers resulted in a concept of early conservation measure intervention to maximize conservation benefit to humpback chub and minimize the likelihood of mechanical predator removal. Trout management flows are a potential tool that could be used to control annual trout production in the Glen Canyon reach for the purposes of managing the trout fishery and for limiting emigration from the Glen Canyon reach to Marble Canyon and the Little Colorado River reach.

Trout management flows are a special type of fluctuating flow designed to reduce the recruitment of trout by disadvantaging YOY trout (Figure 5). Trout management flows have been proposed and developed on the basis of research described in Korman et al. (2005). The underlying premise of TMFs is based on observations that YOY trout tend to occupy nearshore shallow-water habitats to avoid predation by larger fish. A potential scenario for TMFs features repeated fluctuation cycles that consist of relatively high flows (e.g., 20,000 cfs) sustained for a period of time (potentially ranging from 2 days to 1 week) followed by a rapid drop to a low flow (e.g., 5,000 to 8,000 cfs). This low flow will be maintained for a period of less than a day (e.g., 12 hr) to prevent adverse effects on the food base. Low flows would be timed to start in the morning, after sunrise, to expose stranded fish to direct sunlight and heat. Up-ramp rates to the

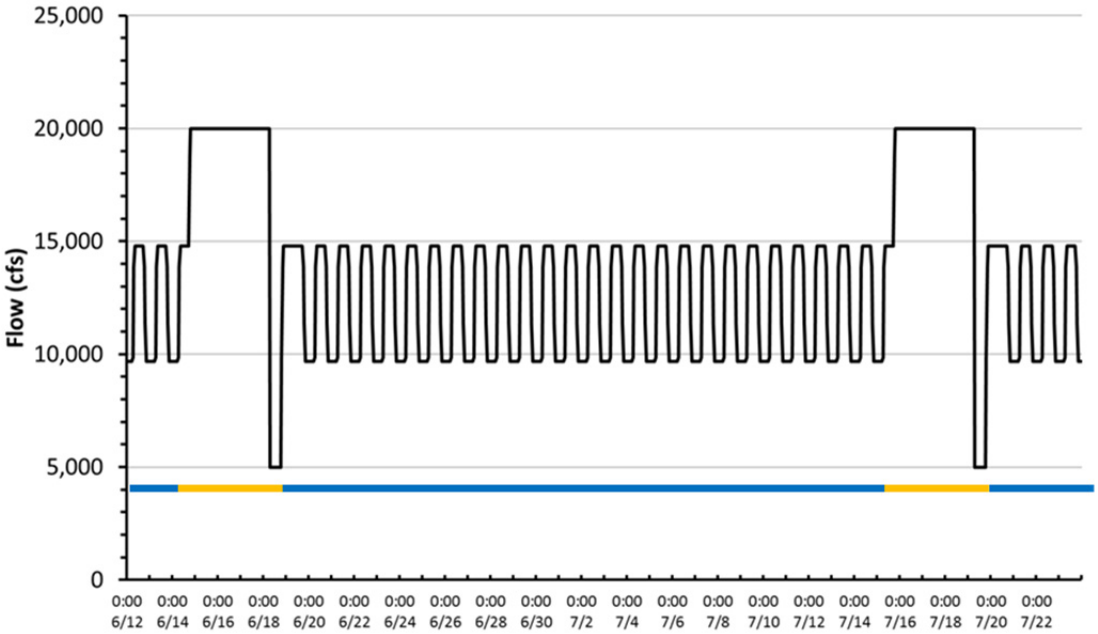

FIGURE 5 Example Implementation of a Two-Cycle Trout Management Flow in June and July with Resumption of Normal Fluctuations between Cycles and Afterward (Monitoring for effectiveness would occur before and after each cycle. The horizontal line below the graph shows periods of normal fluctuation [blue] and TMFs [orange].)

peak TMF will be the same as the limit for the proposed action overall (i.e., 4,000 cfs/hr). The down-ramp from peak to base would be over a single hour (e.g., 15,000 cfs/hr for a drop from 20,000 cfs to 5,000 cfs). These flow levels and rates are not fixed in order to allow flexibility in their design. In a TMF cycle, YOY trout are expected to occupy nearshore habitat when flows are highest, and would be subsequently stranded by the sudden drop to low flow. Because older age classes of trout tend to occupy deeper habitats toward the middle of the river channel, they are less susceptible to stranding and are less likely to be directly affected by TMFs. Trout management flows will be used to control trout recruitment in the Glen Canyon reach to manage the rainbow trout fishery, and to limit emigration of juvenile trout to downstream reaches, particularly to habitat occupied by humpback chub near the confluence with the Little Colorado River. Triggers for implementation of TMFs will be determined in consultation with the AZGFD, GCMRC, NPS, and Reclamation.

If resource conditions are appropriate, TMFs may be tested early in the experimental period, preferably in the first 5 years. These first tests could be triggered by modeled trout recruitment levels or otherwise implemented to test the effectiveness of TMFs. The intent of early tests is to determine the effectiveness of TMFs and a best approach to trout management. If TMFs are determined to be effective for controlling trout numbers while minimizing impacts on other resources, they may be deployed as an adaptive experimental treatment triggered by estimated trout recruitment.

It should be noted that several Tribes have expressed concerns about TMFs as a taking of life within the canyon without a beneficial use. The Pueblo of Zuni has expressed concern that the taking of life by trout stranding has an adverse effect on the Zuni value system. The joint-lead agencies will continue to work with the Tribes regarding options for trout management and to determine the most appropriate means of mitigating impacts on Tribal values when TMFs are implemented.

As many as three TMF cycles per month in a period of up to 4 months during May through August could be tested, depending on the results of early tests. Aspects of TMF design that would be investigated include:

- Duration of high flows needed to lure YOY rainbow trout into nearshore habitats,
- Magnitude of the high flow that would be more effective in luring YOY trout to nearshore habitats,
- Whether or not moving to high flows first is needed to reduce YOY trout numbers (as opposed to simply dropping rapidly from normal flows to minimum flows),
- Timing of TMF cycles during the May–August period of trout emergence, and
- Number of cycles necessary to effectively limit trout recruitment.

If TMFs prove to be effective in controlling trout production and emigration to the Little Colorado River reach and they become an integral part of the LTEMP, regular implementation of TMFs may need to include variable timing to prevent adaptation of the population to specific timing (e.g., increase in recruitment by fall-spawning rainbow trout).

Certain aspects of TMF effectiveness can be addressed through observational studies (e.g., the number of YOY rainbow trout observed in the nearshore environment in daily increments after the high flow is initiated)[1]; others may be addressed through consideration of the physical environment in Glen Canyon (i.e., what areas are inundated or exposed at different flows). Ultimately, however, effectiveness will be judged based on comparison of fall trout recruitment estimates to expectations based on prior years. It may take several years to make this determination, depending on the strength of the response and the type of TMFs tested. Ultimately, however, effectiveness will be based on the ability of TMFs to reduce recruitment in and emigration from the Glen Canyon reach. The driving forces behind emigration are not fully understood, but they are expected to be related to population size and food base in the Glen Canyon reach.

For the EIS modeling, a trigger of 200,000 YOY trout was used to determine when TMFs would be implemented. A regression equation based on annual volume, the variability in flows from May through August, and the occurrence of a spring HFE was used to predict the number of YOY. The actual trigger used could be higher or lower depending on the results of experiments that will be conducted on the effectiveness of TMFs. In addition, the predictive regression equation could be modified based on new information. The trigger and predictive equation used would be modified as needed in an adaptive management context utilizing the process described in Section 1.2.8. Triggers for implementation of TMFs would also be developed in consultation with the AZGFD and other entities as appropriate.

Monitoring of other resources, particularly the food base and the physiologic condition of adult rainbow trout, will also be considered. In addition, the number of YOY trout at the end of the summer would be estimated to determine if it equals or exceeds the estimated number of recruits needed to sustain the desired number of adult trout. If the estimated number of recruits is less than the recruitment target, TMFs will be re-evaluated for modification before implementation in subsequent years. It is anticipated that the trout population could rebound from a 1-year drop below this target level.

As discussed in relation to sediment experiments above, there is concern among scientists and stakeholders with regard to the risk associated with the implementation of spring HFEs as related to trout response and subsequent effects on the humpback chub population. For this reason, TMFs will be implemented and tested for effectiveness early in the LTEMP period if possible; preferably before the first spring HFEs are triggered, even if not triggered by high trout recruitment. Trout management flows could be implemented in years that featured a spring HFE and in the water year that follows an equalization flow because of the expected positive effects of

[1] Because older age classes of trout tend to occupy deeper habitats toward the middle of the river channel, they are less susceptible to stranding and are less likely to be directly affected by TMFs.

equalization on rainbow trout recruitment. Modeling indicates TMFs will be triggered by trout recruitment numbers in 32% of the years in the LTEMP period.

There is potential for confounding effects when coupling TMFs with HFEs. If trout recruitment is still high after implementation of TMFs that follow HFEs, this would suggest that TMFs were not as effective as designed for that trial. If recruitment is lower than expected after TMF implementation, however, uncertainty will remain about whether an HFE failed to stimulate trout recruitment or whether TMFs were effective in suppressing otherwise strong recruitment. It may not be necessary to determine the underlying effect on trout numbers unless TMFs have undesirable side effects on other resources or the trout population.

If TMFs are found to be highly effective in controlling trout recruitment and emigration of trout, and emigration only occurs or primarily occurs immediately following high recruitment years, it may be possible to limit TMF implementation and achieve multiple resource goals, particularly if unintended impacts of TMFs on other resources such as native fish become evident. If adverse impacts of TMFs become evident, this may also suggest revisiting whether or not TMFs are necessary in response to spring HFEs. Lastly, if there is an observed increase in trout recruitment due to fall HFEs, then application of TMFs in the spring following a fall HFE would be considered.

Implementation of TMFs would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. TMFs may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section 1.2.8.

1.2.10.2 Tier 1 Conservation Actions for Humpback Chub

Tier 1 conservation actions designed to improve rearing and recruitment of juvenile humpback chub would be implemented if the combined point estimate for adult (≥200 mm) humpback chub in the Colorado River mainstem Little Colorado River aggregation (RM 57–RM 65.9) and in the Little Colorado River falls below 9,000 (2,000 in the mainstem and 7,000 in the Little Colorado River) as estimated by the currently accepted humpback chub population model, or if recruitment of subadult (150–199 mm) humpback chub does not meet or exceed estimated adult mortality. Tier 1 actions would include expanded translocations of YOY humpback chub within the Little Colorado River to areas within the river that have relatively few predators (i.e., above Chute Falls, Big Canyon), or larval fish would be taken to a rearing facility and released in the Little Colorado River inflow area once they reach 150 to 200 mm. In addition to these translocation activities, 300 to 750 larval or YOY humpback chub would be collected from the Little Colorado River and reared in a fish hatchery to less vulnerable sizes before releasing them. Once these fish reach 150 to 200 mm, they would be translocated to the Little Colorado River in the following year.

1.2.10.3 Tier 2 Mechanical Removal of Nonnative Fish

Experimental implementation of mechanical removal of nonnative fish will incorporate aspects of the protocol outlined in Reclamation's Non-Native Fish Control Environmental Assessment (NNFC EA) (Reclamation 2011b). However, modifications to the trigger criteria (Appendix D) were made to address Tribal concerns related to "taking of life" in the canyon, which prioritize proactive humpback chub conservation actions over mechanical removal of nonnative fish at the Little Colorado River when humpback chub abundance begins to decline. These modifications attempt to minimize the likelihood of mechanical removal, and mechanical removal of nonnative fish at the Little Colorado River would only occur if proactive conservation actions failed to reverse declines in adult humpback chub, and the adult abundance falls below 7,000. Modeling conducted for the EIS indicated that mechanical removal at this level was effective unless immigration rates into the Little Colorado River reach were high.

Two tiers of sequential actions were identified; the first would emphasize conservation actions that would take place early during an adult or subadult humpback chub population decline (Section 1.2.10.2). The second tier would serve as a backstop prescribing predator removal (Threat Reduction) if conservation measures did not mitigate a decline in humpback chub abundance.

Many factors affect humpback chub population dynamics such as water temperature and turbidity in the Colorado River, and potentially the hydrology of the Little Colorado River. These factors may constrain the effectiveness of available conservation actions that can be implemented in the event of a declining population of humpback chub. Juveniles and YOY can be translocated to other areas within and outside the Little Colorado River system; YOY or juvenile humpback chub can be head-started (temporarily held until sufficient growth is achieved) at a hatchery, and predator control can be implemented. Under current constraints, these are the only conservation tools available for humpback chub within the Colorado River reach and associated tributaries between Glen Canyon Dam and Lake Mead.

While healthy wildlife populations are rarely static, trigger objectives include prescribing actions to reverse/ameliorate impacts in order to maintain the Little Colorado River humpback chub population within an acceptable range, and, secondarily to reduce reliance on mechanical removal of nonnative fish. For the purposes of these triggers, it is assumed that the primary drivers of humpback chub population dynamics are interspecific interactions with nonnative species, especially rainbow trout (or brown trout), and low water temperature in the mainstem of the Colorado River (Kaeding and Zimmerman 1983; Douglas and Marsh 1996; FWS 2002a; Coggins et al. 2011; Yard et al. 2011). It is suspected that coldwater temperatures suppress growth and thus subject young humpback chub to predation for extended periods of time. The triggers focus on management of predator impacts only, if management actions are found to be ineffective or other factors are found to negatively control the humpback chub population, adaptation of triggers and conservation responses will be necessary.

The DOI recognizes that lethal mechanical removal is a concern for Tribes, particularly the Hopi Tribe and Pueblo of Zuni, who view it as a taking of life in the canyon without a beneficial use. Reclamation had committed in agreements with Tribes in 2012 to consider live removal when feasible (Reclamation 2012a); however, the presence of whirling disease prohibits live removal of trout due to the risk of spreading the disease to other waters. Reclamation and NPS have worked with the Tribes to determine a beneficial use of the removed fish on other projects and understand that what is considered beneficial use may not be the same for all Tribes. Reclamation and NPS are committed to consult further with the Tribes to determine acceptable mitigation for nonnative fish control.

1.2.10.4 Low Summer Flows

Low summer flows could be considered a potential tool for improving the growth and recruitment of young humpback chub if temperature had been limiting these processes for a period of years. Low summer flows may lead to warmer water temperatures in the Little Colorado River reach and farther downstream, as well as contributing to enhanced growth rates of young humpback chub. There are also potential negative effects from low summer flows to several resources such as hydropower, sediment, water quality, vegetation, and recreation. Low summer flows may also negatively affect humpback chub due to an increase in warmwater nonnative fish or a decrease in the aquatic food base. One test of low steady summer flows was conducted below Glen Canyon Dam in 2000; the results, however, relative to humpback chub were not conclusive (Ralston et al 2012).

Because of the uncertainty related to the effects of low summer flows on humpback chub, other native fish, warmwater nonnative fish, water quality, and potentially other resources, DOI will ensure that the appropriate baseline data are collected throughout the implementation of LTEMP. In addition, DOI will convene a scientific panel that includes independent experts prior to the first potential use of low summer flows to synthesize the best available scientific information related to low summer flows. The panel may meet periodically to update the information, as needed. This information will be shared as part of the AMWG annual reporting process.

It is thought that the potential benefit of an increase in temperature will be greatest if a water temperature of at least 14°C could be achieved at the Little Colorado River, because these warmer temperatures could favor higher growth rates of humpback chub (nearly 60% higher). For comparison, the July through September growth increments of YOY humpback chub are estimated to be 4, 7, 11, 14, and 17 mm at temperatures of 12, 13, 14, 15, and 16°C, respectively, based on a growth-temperature regression in Robinson and Childs (2001). Note that reduction in summer flows would necessitate increasing flows in other months relative to base operations (Table 4; Figure 6).

TABLE 4 Flow Parameters for a Year with Low Summer Flows under the Proposed Action in an 8.23-maf Year[a]

Month	Monthly Release Volume (kaf)	Proportion of Total Annual Volume	Mean Daily Flow (cfs)	Daily Fluctuation Range (cfs)
October	643	0.0781	10,451	5,783
November	642	0.0780	10,781	5,774
December	716	0.0870	11,643	6,443
January	764	0.0928	12,423	6,874
February	675	0.0820	12,153	6,074
March	691	0.0840	11,245	6,223
April	859	0.1044	14,433	7,730
May	851	0.1034	13,841	7,659
June	930	0.1130	15,631	8,000
July	492	0.0598	8,000	2,000
August	492	0.0598	8,000	2,000
September	476	0.0578	8,000	2,000

[a] Within a year, monthly operations may be increased or decreased based on changing annual runoff forecasts and other factors, such as application of the Long-Range Operating Criteria for Colorado River Basin Reservoirs, which are currently implemented through the 2007 Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (Reclamation 2007a).

If tested, low summer flows would occur for 3 months (July, August, and September), and only in the second 10 years of the LTEMP period. The duration of low summer flows could be shortened to less than 3 months in successive experiments if supported by the scientific panel described above or based on the scientific data and observed effects. The probability of triggering a low summer flow experiment is considered low (about 7% of years) because the water temperature conditions that would allow such a test occur infrequently.

Low summer flows would only be implemented in years when the projected annual release was less than 10 maf, and if the temperature at the Little Colorado River confluence would be below 14°C without low summer flows, and release temperature was sufficiently high that 14°C could be achieved at the Little Colorado River with the use of low summer flows.

The ability to achieve target temperatures at the Little Colorado River confluence by providing lower flows is dependent on release temperatures, which are in turn dependent on reservoir elevation. For example, using the temperature model of Wright et al. (2008), in a 8.23-maf year, release temperatures of 10.8°C, 11.0°C, and 11.7°C would be needed in July, August, and September, respectively, to achieve a target temperature of 14°C at the Little Colorado River confluence at flows of 8,000 cfs.

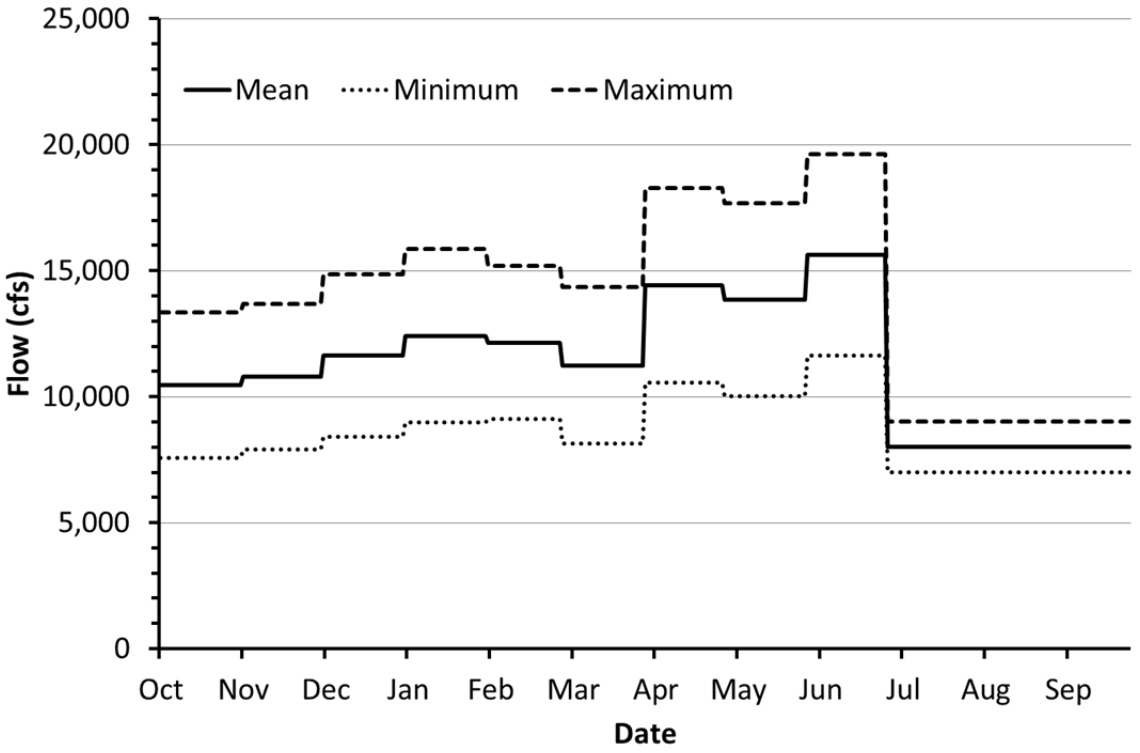

FIGURE 6 Mean, Minimum, and Maximum Daily Flows under Triggered Low Summer Flows of the Proposed Action in an 8.23-maf Year Based on the Values Presented in Table 4

Release temperatures fall into three categories for any temperature target: (1) too low to achieve the target temperature at the Little Colorado River even at low flow, (2) high enough to achieve the target temperature at the Little Colorado River only if low flows (5,000 to 8,000 cfs) are provided, and (3) high enough to achieve target temperature at the Little Colorado River regardless of the flow level. Low summer flows would only be triggered in years that fell into the second category.

Implementation of a low-flow experiment is complicated by two factors: the earliest date at which it could be determined that a target temperature of at least 14°C could be achieved in all 3 months, and the ability to release the remaining annual volume once that determination is made. The earliest time a determination could be made would be in early April of each year, and it would be based on the April 1 forecast of reservoir elevation. Because low summer flows could be implemented in the 3 months at the end of the water year, it is possible that by the time a determination was made to conduct a low summer flow experiment, it may not be possible to release enough water in the remainder of the spring to compensate for the low-flow period. A low-flow experiment would only be tested in years when performing the experiment would not result in a deviation from the annual Glen Canyon Dam release volumes made pursuant to the Long-Range Operating Criteria for Colorado River Basin Reservoirs, which are currently implemented through the 2007 Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (Reclamation 2007a).

It is possible that a low summer flow could negatively impact humpback chub through impacts on the food base. In moderate or higher water years, the April–June monthly volumes would have to be quite high and would likely be at or near 25,000 cfs. Following these high flows, there would be an abrupt drop to 8,000 cfs or lower (e.g., 5,000 cfs), which would likely leave much or all of the food base in Glen Canyon and downriver up above the new lower water line (Kennedy and Ralston 2011). These values represent declines in midges and gammarus in the portions of the channel that have been dewatered, and only a small portion of the channel is actually dewatered. Low summer flows will also provide ideal egg laying conditions for aquatic insects, which should facilitate a rapid recovery of the invertebrate prey base to the reduced habitat area associated with this type of experiment. Nonetheless, the potential for low summer flow experiments to negatively impact the food base exist, and measures that seek to minimize any negative impacts will be considered if a low summer flow is implemented.

Finch et al. (2015) found that humpback chub grew more slowly during steady flows than they did during fluctuating flows in the same year, but that turbidity was potentially confounding in this analysis. Recent evidence suggests that not only is the system food limited in most years (Cross et. al. 2013), but that in 2014 and 2015, a system-wide reduction in fish numbers and condition resulting from food limitation was observed. This was a strong enough response that spring Little Colorado River adult estimates were extremely low, and the leading hypothesis was that the adults were skipping spawning and remaining in the mainstem due to lack of sufficient conditions to spawn, yet temperatures were quite warm in 2014 and 2015 (reaching 16°C and 15°C, respectively). Thus, it would seem that under the right conditions, low summer flow could benefit chub, but under conditions that already show high numbers of fish and relatively low food availability, the impacts could be adverse, the rate of skip spawning could increase, and the net impact on chub could be low reproduction and recruitment for that year. However, in 3 years of monitoring the Little Colorado River in June and July, YOY numbers were highest despite the lowest number of spawners (Van Haverbeke 2015). Also key to this experiment being successful is the number of YOY humpback chub being produced in the Little Colorado River, which was pointed out as a confounding factor in the 2000 low summer flow experiment. Production in the Little Colorado River was low (poor habitat conditions), and thus few fish were in the mainstem to be exposed to the treatment. If similar conditions occur, low summer flow would be expected to not have a beneficial impact on the population.

A first test of a low summer flow would feature low flow of 8,000 cfs and relatively little fluctuation (±1,000 cfs per day). Depending on the results of the first test with regard to warming and humpback chub response, the magnitude of the low flow could be adjusted up or down (as low as 5,000 cfs), and the level of fluctuation also modified up to the full range allowed under the proposed action (i.e., 10 × monthly volume [in kaf] in July and August, and 9 × monthly volume [in kaf] in September).

The first test of low summer flows will be determined to be successful or unsuccessful for humpback chub based on input from an independent scientific panel review. If the first test was determined to be unsuccessful (and it was determined to have been implemented properly without major confounding factors), then additional tests would not be performed. Low summer flows would be considered successful if it can be determined that they produced sufficient growth of YOY humpback chub and that growth resulted in an increase in recruitment, but

avoided unacceptable increases in warmwater nonnative fishes, trout, or aquatic parasites, or resulted in unacceptable adverse impacts on other aquatic resources. If it was determined to be successful, then additional low summer flows would occur only when humpback chub population concerns warranted them and water temperature has been colder for a period of years and the desired warming could be achieved only with low summer flows. The temperature target could be adjusted 1°C higher based on the results of the first test or the limitations between predicted and measured temperatures.

Implementation of low summer flows would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. Low summer flows may not be conducted in years when there appears to be the potential for unacceptable impacts on the resources listed in Section 1.2.8.

The effects of low summer flows on Lake Mead water quality are an identified concern. DOI will coordinate with relevant water quality monitoring programs or affected agencies prior to implementing any test of low summer flows. There are concerns related to the risk of warmwater nonnative fish expansion or invasion (e.g., the elevation of Lake Mead was high or the number of warmwater nonnative fish was high). These issues are potential off-ramps as described in Section 1.2.8.

1.2.10.5 Low Steady Weekend Flows for Macroinvertebrate Production

A more diverse and productive aquatic food base could benefit a variety of priority resources including native fish (including the endangered humpback chub), the rainbow trout fishery, and other riparian species that occur in Glen, Marble, and Grand Canyons. Mayflies (Ephemeroptera), stoneflies (Plecoptera), and caddisflies (Trichoptera), collectively referred to as EPT, are notably absent from the Glen and Marble Canyon reaches and very low in abundance and diversity in the Colorado River in the Grand Canyon. Furthermore, it has been demonstrated that EPT taxa are recruitment limited, because daily flow fluctuations to meet hydropower demand cause high egg mortality and which is the limiting factor. The rationale behind this hypothesis is that fluctuations from Glen Canyon Dam create a varial (intermittently wetted) zone along shorelines that is large enough to dewater eggs. The varial zone is primarily determined by the shape of the canyon, and in narrow stretches of the canyon the varial zone can be high, while in wider stretches of the river the varial zone is much smaller. Because the Colorado River in Glen, Marble, and Grand Canyons is canyon-bound and the tributaries that join the river all have comparatively low flow, the size of the varial zone does not appreciably decrease with distance downstream. Thus, although water temperature regimes become more naturalized with distance downstream, the effect that daily flow fluctuations to meet hydropower demand have on the stability of shoreline habitat does not attenuate with distance from the dam.

This hypothesis attributes the absence of EPT and the poor health of the invertebrate assemblage to the width of the varial zone, similar to earlier investigations (Blinn et al. 1995), but focuses on the effects unstable shorelines have on the eggs of these species. This hypothesis assumes that egg-laying by EPT occurs principally along shorelines. According to the hypothesis, EPT taxa downstream of Glen Canyon Dam are recruitment limited, because daily

flow fluctuations to meet hydropower demand negatively affect habitat quality along the shorelines where egg-laying is assumed to occur. This could have been tested during the 2000 Low Steady Summer Flow experiment or in the fall steady-flow experiment from 2008 to 2012, but food base field research was not adequate at the time to detect any changes in EPT related to the steady flows. However, even though substantial steady flow periods were implemented, especially in 2000, increases in EPT species and production were not observed (Kennedy and Ralston 2011).

To test this hypothesis, steady flows would be provided every weekend from May through August (34 days total).[2] The flow on weekends would be held to the minimum flow for that month, which would ensure that the insect eggs laid during weekends would remain submerged throughout larval development. If the hypothesis is true, there would be an increase in insect production, and possibly diversity, due to the reproductive success of insects that laid eggs during weekends. No changes in monthly volumes, ramping rates, or the maximum daily range in flow during weekdays would be required for this experiment. To offset the smaller water releases that would occur during weekends within a given month, larger releases would need to occur during the weekdays within a given month.

Implementation of macroinvertebrate production flows would consider resource condition assessments and resource concerns using the processes described in Section 1.2.8. These flows may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section 1.2.8.

Effects of the tests would be evaluated using observations to determine the locations where insect eggs are deposited and the emergence rates of species. Depending on the outcome of the tests, the experiment could be discontinued if there were unacceptable effects on other resources. There is also the possibility that implementation would result in confounding interactions with TMF experiments, and this would be discussed during the process described in Section 1.2.8.

1.2.11 Native and Nonnative Plant Management and Experimental Actions

Experimental riparian vegetation treatment activities would be implemented by NPS under the proposed action and would modify the cover and distribution of riparian plant communities along the Colorado River. All activities would be consistent with NPS Management Policies (NPS 2006) and would occur only within the Colorado River Ecosystem in areas that are influenced by dam operations. NPS will work with Tribal partners and GCMRC to experimentally implement and evaluate a number of vegetation control and native replanting activities on the riparian vegetation within the Colorado River Ecosystem in GCNP and GCNRA. These activities would include ongoing monitoring and removal of selected nonnative plants, species in the corridor, systematic removal of nonnative vegetation at targeted sites, and native replanting at targeted sites and subreaches, which may include complete removal of

[2] The duration and other characteristics of experimental macroinvertebrate production flows could be adjusted within the range of the analysis based on the results of initial experiments.

tamarisk (both live and dead) and revegetation with native vegetation. Treatments would fall into two broad categories, including the control of nonnative plant species and revegetation with native plant species. Principal elements of this experimental riparian vegetation proposal include:

- Control nonnative plant species affected by dam operations, including tamarisk and other highly invasive species;
- Develop native plant materials for replanting through partnerships and use of regional greenhouses;
- Replant native plant species to priority sites along the river corridor, including native species of interest to Tribes;
- Remove vegetation encroaching on campsites; and
- Manage vegetation to assist with cultural site protection.

2 ENVIRONMENTAL BASELINE

2.1 DESCRIPTION OF SPECIES IDENTIFIED FOR ANALYSIS

2.1.1 Kanab Ambersnail

2.1.1.1 Legal Status

The Kanab ambersnail, *Oxyloma haydeniensis*, was listed as endangered in 1992 (FWS 1995). The Kanab ambersnail is the only threatened, endangered, or sensitive invertebrate species that may occur along the Colorado River in the Grand Canyon. However, recent evidence from anatomical and molecular genetics studies indicates that this is a geographically widespread taxon whose listing under the ESA may have been incorrect (Littlefield 2007). In a study of *Oxyloma* specimens collected from 12 locations throughout the western United States, including Kanab ambersnail from the Grand Canyon, morphometric and genetic results indicated that the Kanab ambersnail can be regarded as a member of the same species as the other *Oxyloma* populations analyzed (Culver et al. 2013). However, until this taxonomic change occurs, the Kanab ambersnail remains a listed species (FWS 2011b). No critical habitat is designated for this species.

2.1.1.2 Recovery Goals and Status

The recovery plan for Kanab ambersnail was completed in 1995 (FWS 1995). The Kanab ambersnail may be considered for downlisting to threatened when the following criteria have been attained:

1. The location and/or establishment of additional populations. Maintain 10 separate populations which have been demonstrated to have population numbers large enough to allow for the long-term viability of the population. This criterion is provisional. It is probable that this criterion will be modified as additional information is acquired concerning the species distribution, abundance, and stability of its separate populations.

2. The establishment of formal land management designations and/or implementation of land management plans which provide long-term, undisturbed habitat for the Kanab ambersnail for the above 10 populations.

The 5-year status review for the Kanab ambersnail was completed in 2011 (FWS 2011d). The FWS found that no change in the status of the species was warranted due to the ongoing, existing threats due to private land development, controlled flooding in the Colorado River, climate change, and inadequate existing regulatory mechanisms. However, Arizona and Utah ambersnail populations identified as “Kanab ambersnail” and “Niobrara ambersnail” are based

primarily on morphological distinctions. Recent genetic analysis and morphological evaluation by Culver et al. (2013) on ambersnail specimens suggests that the Arizona and Utah populations, including Vaseys Paradise, are genetically and morphologically similar to other *Oxyloma* populations in the study, and their taxonomic identity may be revised in the future. The consensus appears to be that this snail is part of a much larger population that has higher numbers and distribution. The FWS did recognize that genetic, anatomical, and morphological information resulted in conflicting views on the taxonomy of the species.

2.1.1.3 Historic and Current Range

Globally, the Kanab ambersnail is only found in three locations. Two of these are within the Grand Canyon: the riparian vegetation at Vasey's Paradise and Elves Chasm. Vasey's Paradise is at RM 31.5, and Upper Elves Chasm is at RM 116.6. The latter population was created from snails translocated from Vasey's Paradise (FWS 2008). The third location for the Kanab ambersnail is Three Lakes, Utah (Reclamation 2007b).

2.1.1.4 Habitat

The Kanab ambersnail lives in association with watercress (*Nasturtium officinale*), cardinal monkeyflower (*Mimulus cardinalis*), cattails (*Typha*), sedges (*Carex*), and rushes (*Juncus*). Populations within the Grand Canyon occur in areas with water sources originating from limestone or sandstone geologic strata (Meretsky and Wegner 2000; Sorensen 2009). The increase in cover, reduction in beach-scouring flows, and introduction of the nonnative watercress led to a >40% increase in suitable Kanab ambersnail habitat area at Vasey's Paradise compared to pre-dam conditions (Stevens et al. 1997a).

Climate change has the potential to affect the Kanab ambersnail habitat. The water source at Vasey's Paradise consists of waterfalls emanating from groundwater and emerging from the cliff face. In 2014 and 2015, the flow was noticeably reduced, likely as a result of basinwide drought. Consequently, the usually dense vegetation at Vasey's Paradise is notably diminished.

2.1.1.5 Life History

Kanab ambersnails live 12 to 15 months and are capable of self-fertilization. Mating and reproduction occur from May to August. Subadults dominate the overwinter population. Snails enter dormancy in October–November and become active in March–April. Overwinter mortality ranges between 25 and 80% (Stevens et al. 1997a; IKAMT 1998). During mild winters, they can continue their life cycle without dormancy or may go in and out of dormancy several times throughout the winter (Sorensen and Nelson 2002).

Based on annual survey data, live counts of Kanab ambersnails at Vasey's Paradise declined in 2011 from previous years, although the ambersnail habitat at Vasey's Paradise was in overall good condition in 2011. At Elves Chasm, live counts of Kanab ambersnails remained

higher in 2011 than previous years, and habitat at this location was in good condition in 2011 (Sorensen 2012). The population at Vasey's Paradise generally occurs at elevations above 33,000-cfs flows. However, as much as 7.3% of the Vasey's Paradise population occurs below the elevation of 33,000-cfs flow, and as much as 16.4% of the population occurs below the elevation of 45,000-cfs flow. The Elves Chasm population is located above the elevation of 45,000-cfs flow (Reclamation 2011b).

2.1.2 Humpback Chub

2.1.2.1 Legal Status

The humpback chub (*Gila cypha*) is currently listed as "endangered" under the ESA. It was first included in the List of Endangered Species issued by the Office of Endangered Species on March 11, 1967 (32 FR 4001) and was considered endangered under provisions of the Endangered Species Conservation Act of 1969 (16 U.S.C. 668aa). The humpback chub was included in the United States List of Endangered Native Fish and Wildlife issued on June 4, 1973 (38 FR 33085), and received protection as endangered under Section 4(c)(3) of the original ESA of 1973. Critical habitat includes 280 km of the Colorado River through Marble and Grand Canyons from Nautiloid Canyon (RM 34) to Granite Park (RM 208), and the lower 13 km of the Little Colorado River. Primary threats to the species include streamflow regulation and habitat modification (including coldwater dam releases and habitat loss), competition with and predation by nonnative fish species, parasitism, hybridization with other native Gila, and pesticides and pollutants (FWS 1990, 2002a).

2.1.2.2 Recovery Goals and Status

Recovery for the humpback chub was defined by the FWS Humpback Chub Recovery Goals (Recovery Goals) (67 FR 55270) (FWS 2002a). In 2006, a U.S. District Court ruling set aside the Recovery Goals, because they lacked time and cost estimates for recovery. Nevertheless, the recovery programs and the GCDAMP continue to utilize the underlying science in the Recovery Goals. The FWS's 2011 Humpback Chub 5-Year Review relies on the information provided in the recovery goals and provides supplemental information on the species' distribution and status.

The court did not fault the Recovery Goals as deficient in any other respect, thus the FWS, the GCDAMP, and the Upper Colorado River Endangered Fish Recovery Program (UCRRP), the program that addresses conservation of all of the upper Colorado River basin populations of humpback chub, continue to utilize the underlying science in the Recovery Goals. In the 2009 Supplemental Opinion, the FWS referenced the draft 2009 revisions to the Recovery Goals document because that document provided updates on species biology and distribution and represented the best available scientific information at that time. The draft 2009 revisions to the Recovery Goals included the same demographic criteria found in the 2002 Recovery Goals. Thus, we are using the demographic criteria found in both the 2002 Recovery Goals and

2009 draft Recovery Goals. The FWS's 2011 Humpback Chub 5-Year Review relies on the information provided in the Recovery Goals and provides supplemental information on the species' distribution and status.

That supplemental information, as well as the demographic criteria found in the Recovery Goals, has been considered in this BA and is summarized here.

The Recovery Goals consist of actions to improve habitat and minimize threats.

The Recovery Goal demographic criteria for downlisting (endangered to threatened) are as follows:

Upper Basin Recovery Unit

1. Each of the five self-sustaining populations is maintained over a 5-year period, starting with the first point estimate acceptable to the FWS, such that:

    a. The trend in adult (age 4+; ≥ 200 mm [7.9 in.] total length [TL]) point estimates does not decline significantly, and

    b. Mean estimated recruitment of age-3 (150–199 mm [5.9–7.8 in.] TL) naturally produced fish equals or exceeds mean annual adult mortality, and

2. One of the five populations (e.g., Black Rocks/Westwater Canyon or Desolation/Grey Canyons) is maintained as a core population such that each point estimate exceeds 2,100 adults (Note: 2,100 is the estimated Minimum Viable Population (MVP) number; see Section 3.3.2 of the Recovery Goals).

Lower Basin Recovery Unit

1. The Grand Canyon population is maintained as a core over a 5-year period, starting with the first point estimate acceptable to the FWS, such that:

    a. The trend in adult (age 4+; ≥ 200 mm [7.9 in.] TL) point estimates does not decline significantly,

    b. Mean estimated recruitment of age-3 (150–199 mm [5.9–7.8 in.] TL) naturally produced fish equals or exceeds mean annual adult mortality, and

    c. Each core population point estimate exceeds 2,100 adults (MVP).

The Recovery Goal demographic criteria for delisting are as follows:

Upper Basin Recovery Unit

1. Each of the five self-sustaining populations is maintained over a 3-year period beyond downlisting, starting with the first point estimate acceptable to the FWS, such that:

    a. The trend in adult (age 4+; ≥ 200 mm [7.9 in.] TL) point estimates does not decline significantly, and

    b. Mean estimated recruitment of age-3 (150–199 mm [5.9–7.8 in.] TL) naturally produced fish equals or exceeds mean annual adult mortality, and

2. Two of the five populations (e.g., Black Rocks/Westwater Canyon and Desolation/Grey Canyons) are maintained as core populations such that each point estimate exceeds 2,100 adults (MVP).

Lower Basin Recovery Unit

a. The Grand Canyon population is maintained as a core over a 3-year period beyond downlisting, starting with the first point estimate acceptable to the FWS, such that:

b. The trend in adult (age 4+; ≥ 200 mm [7.9 in.] TL) point estimates does not decline significantly,

c. Mean estimated recruitment of age-3 (150–199 mm [5.9–7.8 in.] TL) naturally produced fish equals or exceeds mean annual adult mortality, and

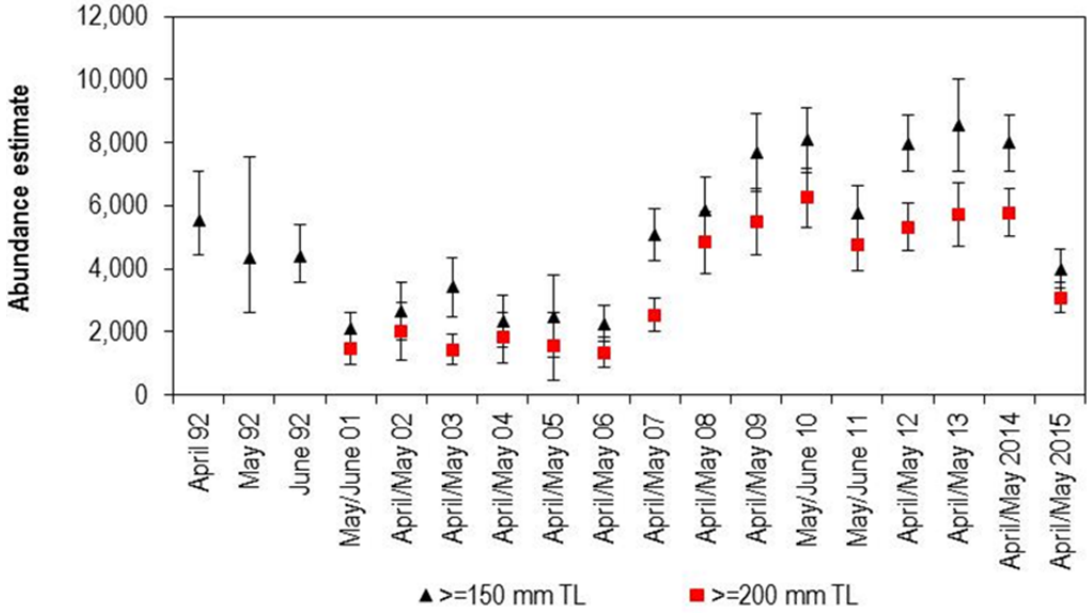
d. Each core population point estimate exceeds 2,100 adults (MVP).

The 5-year status review for the humpback chub was completed in 2011 (FWS 2011c). A change in the status of the humpback chub was not recommended because 5 of 6 demographic recovery criteria and 4 of 22 downlisting criteria had not been met. Factors continuing to threaten the Grand Canyon humpback chub population are described below.

2.1.2.3 Historic and Current Range

The humpback chub is a large, long-lived species endemic to the Colorado River system. This member of the minnow family may attain a length of 20 in., weigh 2 lb or more, and live as long as 40 years (Andersen 2009). Historically, this species occurred throughout much of the Colorado River and its larger tributaries from below Hoover Dam upstream into Arizona, Utah, Colorado, and Wyoming (FWS 2002b and refs. therein). Although historic abundance levels are

unknown, the humpback chub is currently thought to occupy 24% of its historic range, restricted to six population centers, five in the upper Colorado River basin and one in the lower basin (FWS 2002b). The upper basin populations occur in (1) the Colorado River in Cataract Canyon, Utah; (2) the Colorado River in Black Rocks, Colorado; (3) the Colorado River in Westwater Canyon, Utah; (4) the Green River in Desolation and Gray Canyons, Utah; and (5) the Yampa River in Yampa Canyon, Colorado. The only population in the lower basin occurs in the Colorado River in Marble Canyon, the Grand Canyon, and Little Colorado River (FWS 2011a).



The Colorado River/Little Colorado River population is the largest of the six population centers of the humpback chub (FWS 2011c). Within the Grand Canyon, this species is most abundant in the vicinity of the confluence of the Colorado River and Little Colorado River (Kaeding and Zimmerman 1983; Douglas and Marsh 1996; Valdez and Ryel 1995). This population is specifically referred to as the Little Colorado River aggregation of humpback chub and includes those fish residing in the Little Colorado River and in the mainstem within proximity of a few miles to the Little Colorado River mouth. In addition, there are eight other areas (aggregation areas) where humpback chub are, or have been, regularly collected; these aggregation areas are located in the mainstem at 30 Mile, Lava Chuar-Hance, Bright Angel Creek inflow, Shinumo Creek inflow, Stephen Aisle, Middle Granite Gorge, Havasu Creek inflow, and Pumpkin Spring (Figure 7; Valdez and Ryel 1995; Ackerman 2008; Persons et al. 2016). In addition, since 2009, translocations of humpback chub have been made by the FWS to introduce juvenile fish upstream of Chute Falls in the Little Colorado River, and by the NPS, with assistance provided by Reclamation, to introduce juvenile fish into Shinumo and Havasu Creeks, with the goal of establishing additional spawning populations within the Grand Canyon (NPS 2013). Survey data collected in 2013, 2014, and 2015 suggest that translocated humpback chub have successfully spawned in Havasu Creek (NPS 2013). Humpback chub occupy approximately 3.5 mi (5.6 km) of lower Havasu Creek, from the mouth to Beaver Falls, which is a barrier to upstream movement of fish.

Sampling conducted between October 2013 and September 2014 in western Grand Canyon between Lava Falls (RM 180) and Pearce Ferry (RM 280) captured 144 juvenile humpback chub during sampling of the small-bodied fish community. In addition, 209 humpback chub larvae were collected during sampling of the larval fish community in randomly selected sites (Albrecht et al. 2014). Results were similar in larval and small-bodied fish sampling in 2015 (Kegerries et al. 2015): 285 juvenile and 67 age-0 humpback chub were captured during small-bodied and larval fish sampling, respectively, from throughout the study area. These results suggest that young humpback chub are using widespread nursery and rearing habitats between RM 180 and RM 280 in the western Grand Canyon.

2.1.2.4 Population within the Action Area

The Little Colorado River population (aggregation) of humpback chub is measured with closed and open population models. Closed models estimate the annual spring and the annual fall abundance of various size classes of chub within the Little Colorado River (Van Haverbeke et al. 2013, 2016). As such, the closed models do not account for chub that are not residing in the

A.

B.

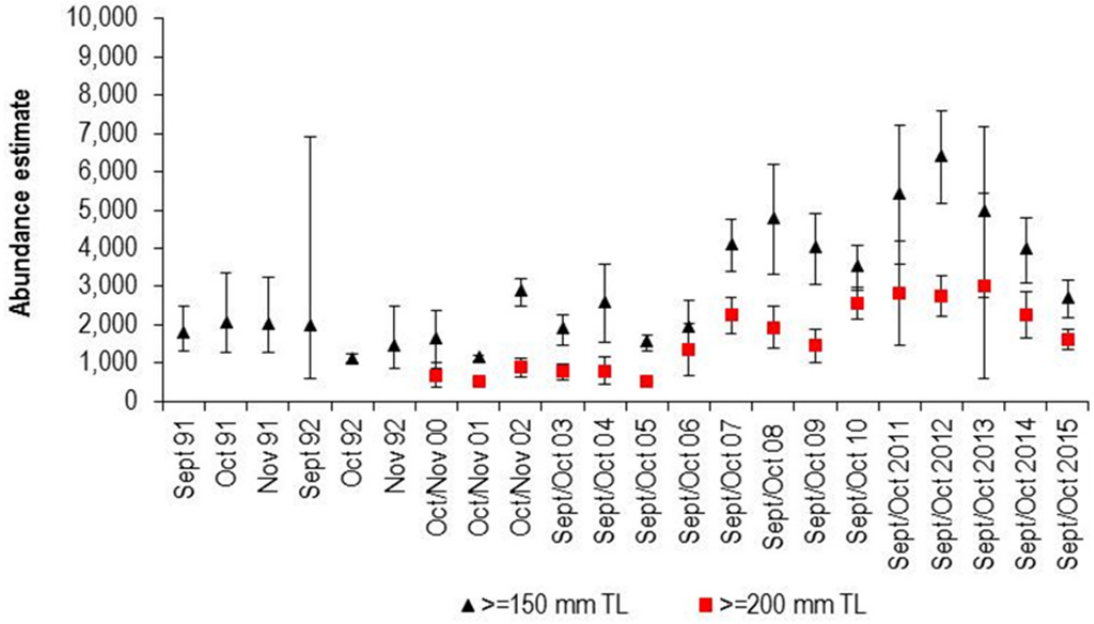


FIGURE 7 Closed Chapman Petersen Abundance Estimates (±95% CI) of Humpback Chub ≥150 mm and ≥200 mm in the Little Colorado River during (A) Spring (2001–2015) and (B) Fall Seasons (2000–2015) (Closed spring and fall abundance estimates of humpback chub >150 mm in the Little Colorado River during 1991 and 1992 are from Douglas and Marsh [1996].)

Little Colorado River during any particular year (i.e., there is always a portion of the Little Colorado River aggregation that is residing in the nearby mainstem each year). Initial closed mark-recapture population efforts in the Little Colorado River were conducted in the early 1990s (Douglas and Marsh 1996), after which there was a hiatus until they were resumed again in 2000 (Van Haverbeke et al. 2013, 2016). Results from both of these studies indicate that sometime in the mid- to late-1990s, humpback chub underwent a significant decline in the Little Colorado River (Figures 7 and 8). This was followed by a period of relatively low, but stable abundance between 2000 and 2006, and by a period (2007–2014) of significantly increased abundance levels (Van Haverbeke et al. 2013). The post-2006 increase in humpback chub ≥150 mm and ≥200 mm was visible during both spring and fall seasons, but it was more apparent during spring months (Figure 7). Spring 2015 saw a significant lowering of abundance of humpback chub ≥150 mm and ≥200 mm compared to the previous several years. The cause of this decline is unknown, but there is evidence from sampling in the mainstem during 2015 that many chub may have simply remained or emigrated into the mainstem during 2015 (i.e., the portion of the Little Colorado River aggregation of chub residing in the nearby mainstem was higher than usual).

In addition, open population models are conducted to estimate the abundance of the Little Colorado River aggregation of humpback chub (Coggins and Walters 2009; Yackulic et al. 2014), both those fish residing in the Little Colorado River and those residing in the nearby mainstem. Because the open models use capture histories of humpback chub that span across years and because most humpback chub will eventually be captured either in the Little Colorado River or in the mainstem (and thus accounted for in the open models), the open models estimate the abundance of humpback chub in the Little Colorado River as well as those residing in the nearby mainstem. As such, the open models provide annual abundance estimates that are higher than the closed model estimates described above. Open models show that from 1989 through 2001, there was a decline of adult humpback chub within the Grand Canyon, with estimated numbers of the Little Colorado River aggregation declining from approximately 11,000 adults (age 4+) in 1989 to about 5,000 adults in 2001 (Coggins and Walters 2009) (Figure 8). However, since about 2001, the downward population trend reversed, with the estimated number of adult fish increasing to approximately 8,000 fish by 2008 (Figure 8) (Coggins and Walters 2009). More recently, abundance estimates for 2009 to 2012 suggest the population has continued to increase to approximately 11,000 adults (Figure 9) (Yackulic et al. 2014). Unlike the closed models, Coggins and Walters (2009) open models suggested that the increasing trend in adult humpback chub abundance began earlier than 2007. They explain that this may be an effect of aging error, with the least biased estimates for recruitment and adult abundance trends being those most proximal to the end of the dataset being analyzed. As such, one might expect to see the adult increases in abundances beginning earlier in their open models (Figure 8). Importantly, both the closed and open population estimators provide the same trend, and that is that the humpback chub experienced a period of significant decline followed by a period of significant increase.

Aside from the Little Colorado River aggregation, based on sampling within and outside the other known aggregations of humpback chub by Persons et al. (2016), catch rates of humpback chub generally increased as well. Factors suggested as being responsible for this estimated increase are discussed later in this section. In addition, recent preliminary population estimates for humpback chub aggregations suggest that humpback chub in several aggregations

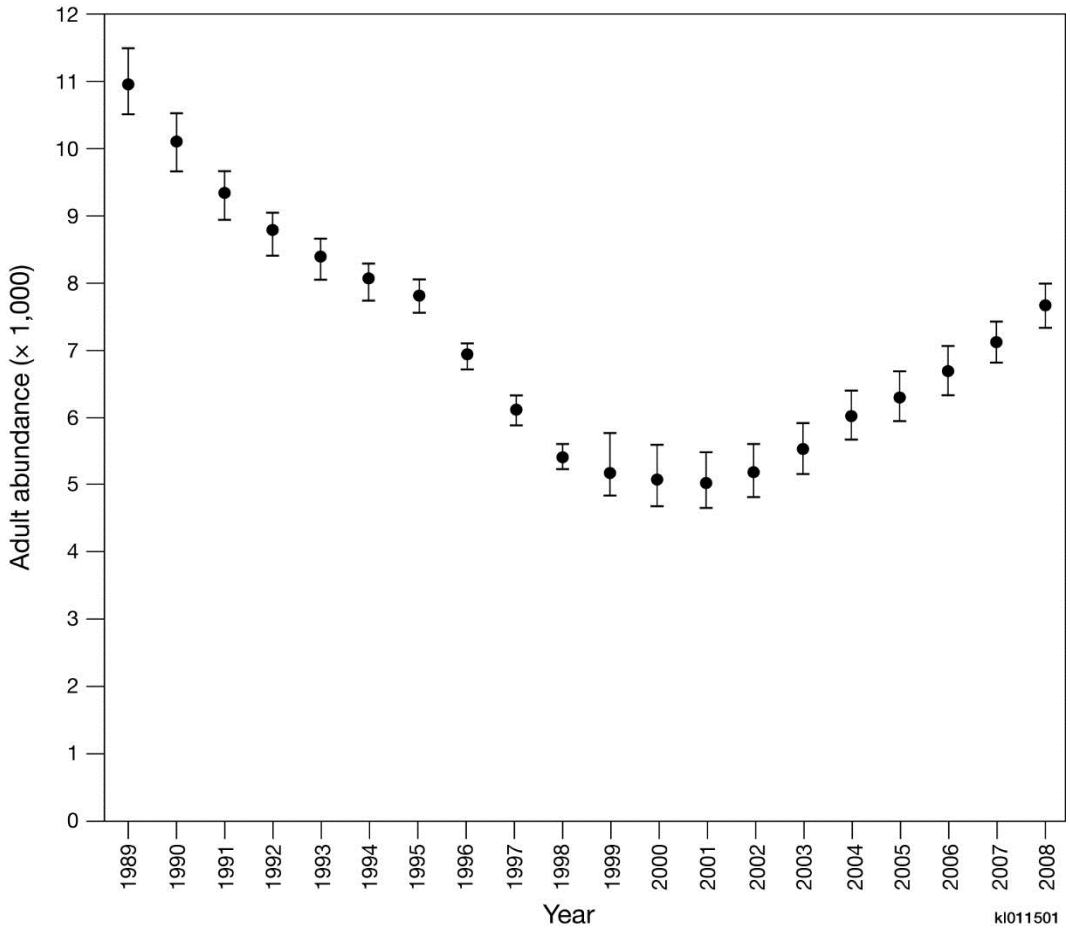

FIGURE 8 Estimated Adult Humpback Chub Abundance (Age 4+) from Age-Structured Mark-Recapture Model Incorporating Uncertainty in Assignment of Age (Error bars represent minimum 95% confidence intervals and do not consider uncertainty in growth or mortality.) (Source: Coggins and Walters 2009)

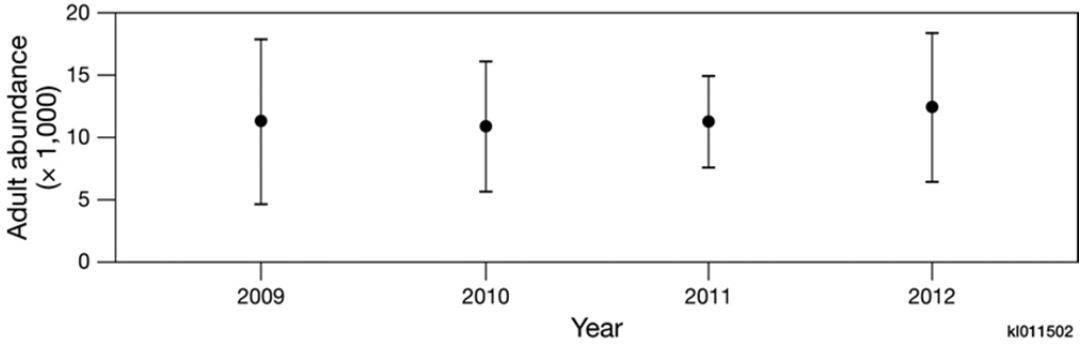

FIGURE 9 Estimated Total Adult Abundance of Humpback Chub in the Lower 8 mi of the Little Colorado River and a 2-mi Portion of the Colorado River Just Downriver of the Confluence of the Little Colorado and Colorado Rivers, for September 2009 through 2012 (Error bars represent the 95% confidence intervals.) (Source: Yackulic et al. 2014)

may have increased as a result of (1) translocations to Shinumo and Havasu Creeks; (2) good production in the Little Colorado River; (3) water temperatures that were about 1°C warmer since the early 2000s; (4) significantly warmer than normal water temperatures in 2004, 2005, and 2011; and (5) trout control implemented at the Little Colorado River inflow (NPS 2013; Yackulic et al. 2014).

The most recent humpback chub population estimate in Havasu Creek was approximately 280 individuals as of May, 2015 (Figure 10). While reproduction has been documented, the population has increased primarily as a result of continued translocations, and less attributed to recruitment.

2.1.2.5 Habitat

Adult humpback chub occupy swift, deep, canyon reaches of the river (Valdez and Clemmer 1982; Valdez and Ryel 1995), with microhabitat use varying among age-groups (Valdez 1990; Stone and Gorman 2006; Gerig et al 2014; Dodrill et al 2015). Within the Grand Canyon, the largest number of humpback chub and their primary spawning are in the vicinity of the Little Colorado River and its inflow reach (RM 57–RM 77; Persons et al. 2016; (Figure 11), with adults being associated with large eddy complexes. Mark-recapture studies in the Grand Canyon reported that most captures of humpback chub occurred in and around the Little Colorado River, with more than 80% of recaptured fish being collected in the same mainstem river reach or tributary where they were originally tagged (Paukert et al. 2006; Persons et al. 2016). However, some of the marked fish were determined to have moved as much as 154.5 km (96 mi) throughout the Grand Canyon (Paukert et al. 2006).

Valdez and Ryel (1995, 1997) reported on adult humpback chub habitat use in the Colorado River in GCNP. They found adults used primarily large recirculating eddies, occupying areas of low velocity adjacent to high-velocity currents that deliver food items. Within GCNP, adults demonstrate high microsite fidelity and occupy main channel eddies, while subadults use nearshore habitats (Valdez and Ryel 1995; Robinson et al. 1998, Stone and Gorman 2006). Adults also congregated at tributary mouths and flooded side canyons during high flows.

Recently, a study conducted in 2010 examined the habitat use and movement of 30 radio-tagged adult humpback chub in the Colorado River during 2 months of fluctuating flow followed by 2 months of steady flow (Gerig et al. 2014). The radio-tagged fish were found to use eddies extensively while avoiding runs. During both flow treatments, the tagged fish exhibited only small daily movements of about 33 ft/day, and no effect of flow was observed on either habitat selection or movement.

The main spawning area for the humpback chub within the Grand Canyon is the Little Colorado River, which provides warm temperatures suitable for spawning and shallow low-velocity pools for larvae (Gorman 1994). The species spawns primarily in the lower 13.6 km of the Little Colorado River, but occasional spawning is suspected in other areas of the Colorado River as well (Valdez and Masslich 1999; Anderson et al. 2010). Gorman and Stone (1999) found ripe adults aggregated in areas of complex habitat structure associated with clean gravel

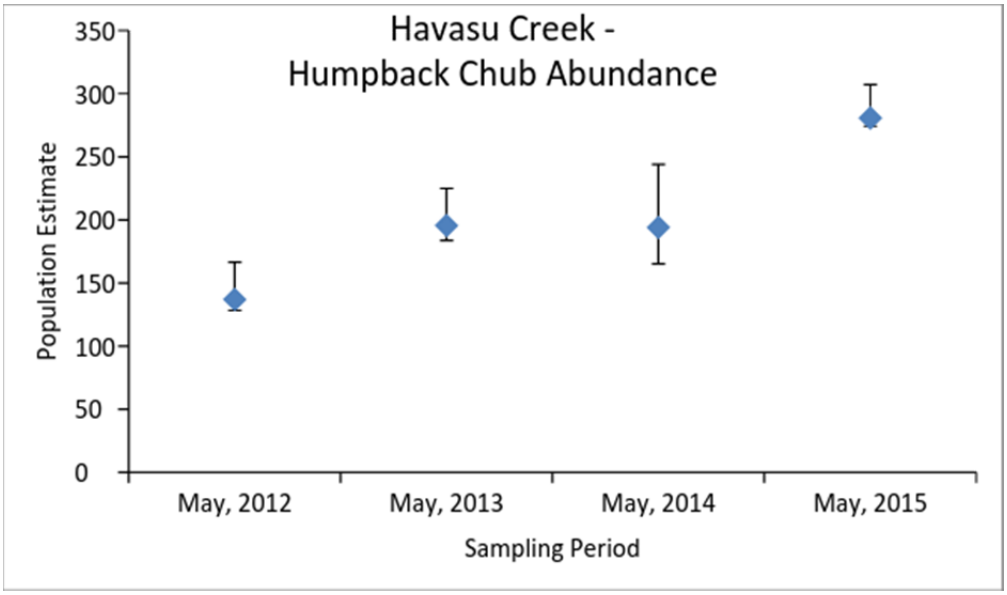

FIGURE 10 Total Abundance of Humpback Chub in Havasu Creek, Based on Annual Population Estimates between 2012 and 2015 (Error bars represent 95% confidence intervals.)

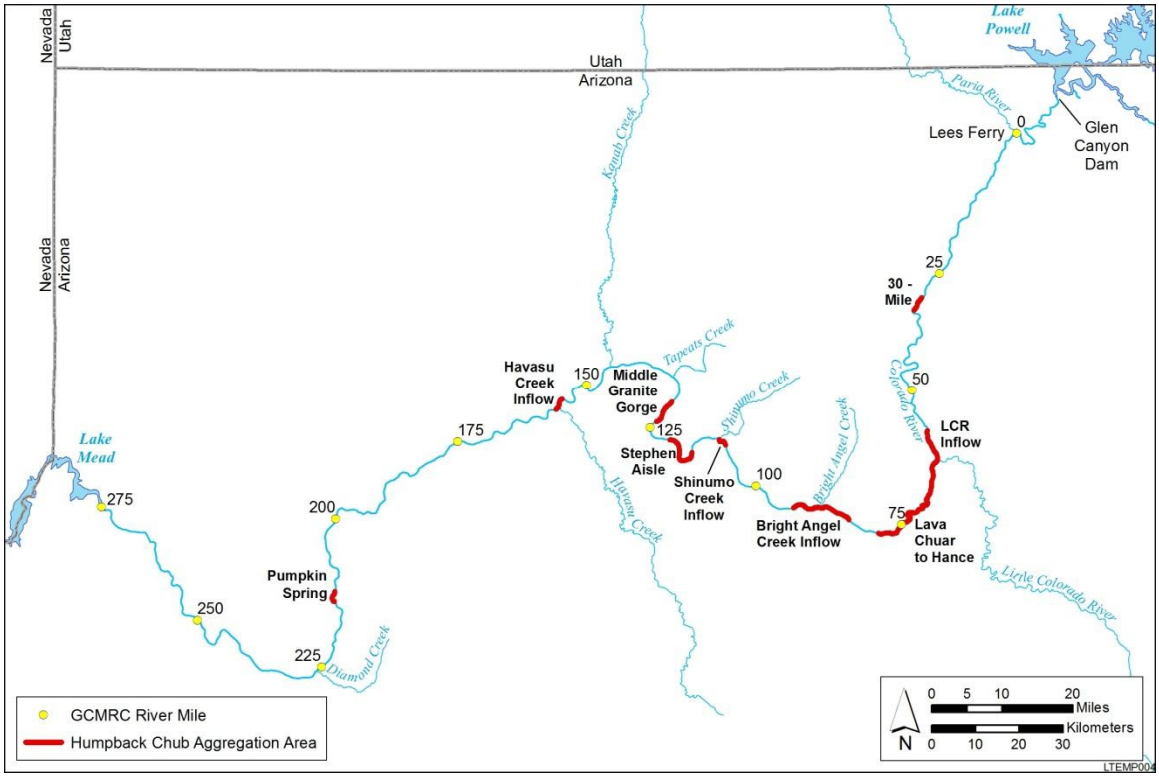

FIGURE 11 Humpback Chub Aggregation Areas along the Colorado River between Glen Canyon Dam and Lake Mead (Sources: NPS 2013)

deposits among large boulders mixed with travertine masses in or near runs and eddies. While mainstem spawning is suspected near 30-Mile Spring, or in other areas in the western Grand Canyon following the detection of larval humpback chub in recent years (Albrecht et al. 2014; Kegerries et al. 2015), studies have not been completed to identify spawning areas or habitat in the Colorado River in the Grand Canyon.

Young humpback chub seek areas that provide physical cover and contain some velocity refuges, including shoreline talus, vegetation, and backwaters typically formed by eddy return current channels (AZGFD 1996; Converse et al. 1998; Dodrill et al. 2015). Backwaters can have warmer water temperatures than other habitats, and native fish, including the humpback chub, are frequently observed in backwaters, leading to a common perception that this habitat is critical for juvenile native fish conservation. However, backwaters are rare and ephemeral habitats, so they contain only a small portion of the overall population. For example, Dodrill et al. (2015)) showed the total abundance of juvenile humpback chub was much higher in talus than in backwater habitats. Moreover, when extrapolated to relative densities based on estimates of backwater prevalence directly after a controlled flood, the majority of juvenile humpback chub were still found outside of backwaters. This suggests that the role of controlled floods in influencing native fish population trends may be limited. As young humpback chub grow, they exhibit an ontogenic shift toward deeper and swifter offshore habitats. Valdez and Ryel (1995, 1997) found that young humpback chub (21–74 mm [0.83–2.9 in.] TL) remain along shallow shoreline habitats throughout their first summer, at low water velocities and depths less than 1 m (3.3 ft). They shift as they grow larger (75–259 mm [2.95–10.20 in] TL), and by fall and winter move into deeper habitat with higher water velocities and depths up to 1.5 m (4.9 ft). Stone and Gorman (2006) found similar results in the Little Colorado River, discovering that humpback chub undergo an ontogenesis from diurnally active, vulnerable, nearshore-reliant YOY (30–90 mm [1.81–3.54 in.] TL) to nocturnally active, large-bodied adults (180 mm [7.09 in.] TL), which primarily reside in deep mid-channel pools during the day and move inshore at night. This ontogenetic habitat shift may be important for smaller streams to which humpback chub have been translocated. Spurgeon (2012) found that larger humpback chub translocated to Shinumo Creek were more likely to emigrate, and in addition, most movements were nocturnal.

Young humpback chub prefer shallow, low-velocity nearshore pools and backwaters, vegetated undercut banks often harbor high densities of juvenile chub in the Little Colorado River; they move to deeper and faster areas with increasing size and age, within the Little Colorado River (AZGFD 2001). In the mainstem of the Colorado River, juvenile fish may be found in backwater and other nearshore, slow-velocity areas that may serve as nursery habitats (Valdez and Ryel 1995; Robinson et al. 1998; AZGFD 2001; Stone and Gorman 2006); however, detection probability is also higher in these areas. Juvenile humpback chub (<3 years old) have been collected in all types of nearshore habitats by the Nearshore Ecology Study, with the highest density found in backwaters in both years of the study. However, the greatest number of humpback chub were collected from talus slopes (Dodrill et al. 2015). Backwater habitats are perceived to be important to juvenile native fish in the Grand Canyon; however, they are relatively rare habitats in the Little Colorado River inflow reach, and thus support only a small proportion of the native fish there (Dodrill et al. 2015). Thus the significance of these backwater habitats to the overall population is unclear.

The low summer flow experiment conducted in 2000 studied four nearshore geomorphic unit types between the confluence of the Colorado and Little Colorado Rivers and Lava Canyon in the summer and fall of 2010, for study periods of 10 to 27 days. Five to seven sites were studied during each interval. Persistent thermal gradients greater than the 0.2°C accuracy of the instruments were not observed in any of the sampled shoreline environments. Temperature gradients between the shoreline and mainstem on the order of 4°C, believed to be important to the habitat-seeking behavior of native or nonnative fishes, were not detected (Ross and Grams 2013). Temperature differences between main channel and nearshore habitats that are isolated from the main channel can be pronounced in backwaters and other low-velocity areas. The extent of warming is variable and depends on the timing of the daily minimum and maximum flows, the difference between air and water temperatures, and the topography and orientation of the backwater relative to solar insolation (Korman et al. 2006). For example, summertime water temperatures in backwaters have been reported to be as high as 25°C (77°F), while main channel temperatures are near 10°C (50°F) (Maddux et al. 1987). The amount of warming that occurs in backwaters is affected by daily fluctuations that drain and fill backwater habitats with cold main channel waters (Valdez 1991; Angradi et al. 1992; AZGFD 1996; Behn et al. 2010). During the low summer flow experiment, temperatures in one backwater were as much as 13°C (23°F) warmer than in the adjacent main channel during some portions of the day; temperature differences were much less at night (Vernieu and Anderson 2013). Backwater temperatures in summer have been reported to be as much as 2 to 4°C (3.6 to 7.2°F) warmer under steady flows than under fluctuating flows (Hoffnagle 1996; Trammell et al. 2002; Korman et al. 2006; Anderson and Wright 2007).

Although the use of thermal refugia such as backwaters has been documented in a variety of systems (e.g., Tyus and Haines 1991; Bodensteiner and Lewis 1992; Torgersen et al. 1999; Ebersole et al. 2001; Westhoff et al. 2014), the overall importance of backwater habitats in the Colorado River relative to humpback chub survival and recruitment is uncertain (Reclamation 2011b). While juvenile humpback chub have been reported to show positive selection for backwater habitats, the spatial extent of such habitats in the Colorado River in the Little Colorado River inflow reach is small compared to other nearshore habitats such as talus slopes (Dodrill et al. 2015). Nevertheless, the presence of backwaters and other types of nearshore habitats that may be important to native fish varies by reach in the Grand Canyon and is related to sediment deposition that is dependent on the reach geomorphology (i.e., reach width and depth, etc.; reviewed in Stevens et al. 1997b).

2.1.2.6 Life History

The humpback chub is primarily an insectivore, with larvae, juveniles, and adults all feeding on a variety of aquatic insect larvae and adults, including dipterans (primarily chironomids and simuliids), Thysanoptera (thrips), Hymenoptera (ants, wasps, bees), and amphipods (such as *Gammarus lacustris*) (AZGFD 2001). Donner (2011) found that 65% of humpback chub production in the Grand Canyon was attributed to chironomids and simuliids, and that the potential for competition between humpback chub and nonnative fish was high when nonnative fish abundance was high. Feeding by all life stages may occur throughout the water column as well as at the water surface and on the river bottom. Spurgeon et al. (2015) also found

that humpback chub consumed and assimilated native fish, and that they occupied a high trophic position in the food web in a Grand Canyon tributary, similar to rainbow trout.

Adult humpback chub move into the Little Colorado River from the Colorado River to spawn from March to May (Gorman and Stone 1999). Relatively little spawning and juvenile rearing occur in the mainstem of the Colorado River, primarily because of the cold mainstem water temperatures (Kaeding and Zimmerman 1983; Minckley et al. 1991); however, in recent years, some evidence of rearing has been observed in the western Grand Canyon (Albrecht et al. 2014; Kegerries et al. 2015). Optimal spawning temperature for the species is 16°C, but mainstem water temperatures typically have ranged from 7 to 12°C (45 to 54°F) near the Little Colorado, due to coldwater releases from Glen Canyon Dam (Wright et al. 2008). Drought-induced warming has resulted in mainstem water temperatures since 2003 consistently exceeding 12°C (54°F) in the summer and fall months, which may have played a role in the estimated increase in the humpback chub population in the system since that time (Andersen 2009; Coggins and Walters 2009; Yackulic et al. 2014). Water temperatures in Havasu Creek typically exceed 16 degrees by April (GCMRC 2016), and humpback chub in spawning condition have been captured in mid-May during monitoring trips (Healy and Nelson 2013; Nelson et al. 2015).

Following spawning, larvae have been reported to drift in the Little Colorado River from April through June, and many drift out into nearshore habitats of the Colorado River (FWS 2008). Robinson et al. (1998) estimated about 38,000 larval humpback chub drifted from the Little Colorado River into the mainstem in May and June 1993. In addition, larval and juvenile humpback chub have been relatively common in the first 2 years of a study that includes sampling of nearshore habitats from Lava Falls (RM 180) to Pearce Ferry (RM 208; Albrecht et al. 2014; Kegerries et al. 2015). The natal source of these fish is unknown; however, data on the timing, age, and location of these larval humpback chub captures may suggest spawning in the mainstem or tributaries (Albrecht et al. 2015; Kegerries et al. 2015). Juveniles generally have lower monthly rates of movement than adults, with the exception of a high probability of juveniles being transported from the Little Colorado River to the Colorado River during high flows of the monsoon season, when numbers of juvenile humpback chub in the mainstem have been documented to increase by as much as 4,000 fish (Yackulic et al. 2014).

Although survival of larval and juvenile fish in the mainstem was once thought to be very rare because of seasonally constant, low water temperatures (Clarkson and Childs 2000), more recent information suggests that juveniles can successfully rear to adulthood in the Colorado River mainstem, at least under recent environmental conditions that include warmer water (Yackulic et al. 2014; Albrecht et al. 2014; Kegerries et al. 2015). Increasing water temperatures have been shown in the laboratory to increase hatching success and larval survival (Hamman 1982), larval and juvenile growth (Clarkson and Childs 2000), and improve swimming ability and reduce predation vulnerability (Ward 2011). Yackulic et al. (2014) postulated that, with warmer water, growth and survival of juveniles in the mainstem will be greater and result in increased mainstem recruitment, and thus contribute to the overall adult population.

2.1.2.7 Factors Affecting Distribution and Abundance in the Grand Canyon

Primary threats to humpback chub include habitat alterations associated with dams and reservoirs and the introduction of nonnative fishes (FWS 2011c), which act as competitors and/or predators of the humpback chub (Andersen 2009; Yard et al. 2011; Kennedy et al. 2013). In addition, the Colorado River now includes nonnative fish parasites, such as the Asian tapeworm and anchor worm, which may infect some humpback chub and affect survival (Clarkson et al. 1997; Andersen 2009). While coldwater releases from Glen Canyon Dam have been implicated in affecting reproduction and recruitment of humpback chub (and other native fishes) in the mainstem Colorado River, warmer water temperatures in the mainstem over the last decade may be providing some temporary benefit and contributing to the improving status of the humpback chub (Reclamation 2011a). Recent studies also indicated that toxic mercury (Hg) and selenium (Se) concentrations in native fish were elevated in the Grand Canyon (Walters et al. 2015). While humpback chub were not tested in the study, elevated levels of Hg in the food web, and in particular, primary prey items, including blackfly larvae (*Simuliidae*), may result in impacts on the species (Walters et al. 2015).

Population estimates indicate that the number of adult humpback chub in the Grand Canyon has been increasing since 2000 or 2001 and has been stable for about the last 5 years (Figure 8). A number of factors have been suggested as being responsible for the observed increases, including experimental water releases, trout removal, and drought-induced warming (Andersen 2009; Coggins and Walters 2009). In addition, translocations of juvenile humpback chub to Shinumo and Havasu Creeks have resulted in increased numbers of adult humpback chub captured in the mainstem aggregations (Persons et al. 2016). Translocations to tributaries have been shown to provide an adequate mechanism for rearing juvenile humpback chub that may later disperse to the Colorado River and augment aggregations (Spurgeon et al. 2015).

Dam discharge and river flow regimes have mixed results. They both may impact the shoreline rearing habitat, and thus survival of juvenile humpback chub (Converse et al. 1998). Releases such as HFEs can create shallow backwater habitats associated with sandbars and are thought to provide rearing habitat for native fish, because they can be warmer than the mainstem river during the summer months due to solar radiation (Behn et al. 2010, reviewed in Dodrill et al. 2015). Flow regimes include, for example, fluctuating flows, which destabilize backwater habitats and may impact warming and primary production (Behn et al. 2010). Backwater habitat is relatively rare in the Little Colorado River inflow area, and thus may be less important to maintaining the Little Colorado River aggregation of humpback chub than previously thought (Dodrill et al. 2015). Even though HFE water releases from Glen Canyon Dam between 2000 and 2008 may have improved some habitat characteristics (e.g., backwaters for humpback chub and other native fish), the limited availability of suitably warmwater temperatures in the mainstem may have constrained the potential for positive population responses (Kennedy and Ralston 2011). Some experimental releases, such as the November HFE in 2004, may have affected nonnative fish (possible humpback chub predators or competitors) and improved humpback chub habitat along the main channel (Korman et al. 2010). However, the March 2008 HFE may have improved the quality of spawning habitat for rainbow trout in the Lees Ferry reach, and the abundance of rainbow trout (using catch-per-unit-effort as a surrogate for abundance) in this reach was reported to be about 300% larger in 2009 than in 2007 (about

3.9 fish per minute versus 1.3 fish per minute, respectively) (Makinster et al. 2011). A similar increase in rainbow trout abundance between 2007 and 2009 was observed at the Little Colorado River confluence (RM 56–RM 69) (Kennedy and Ralston 2010). The effects of HFEs on trout abundance are discussed in more detail in Section 1.2.9. Complete evaluations of more recent fall HFEs, conducted in 2013 and 2014, are incomplete.

Predation by rainbow and brown trout at the Little Colorado River confluence has been identified as an additional mortality source affecting humpback chub survival, reproduction, and recruitment (Valdez and Ryel 1995; Marsh and Douglas 1997; Yard et al. 2011). The incidence of piscivory by brown trout has been found to be much higher than for rainbow trout in the Grand Canyon (Yard et al. 2011; Whiting et al. 2014), but rainbow trout have been much more abundant in the Colorado River, and thus may impact native fish at a similar magnitude (Yard et al. 2011). Predation by channel catfish and black bullhead are also thought to impact humpback chub in the Grand Canyon, particularly if warmer water conditions occur (NPS 2013). Because of their size, adult humpback chub are less likely to be preyed on by trout; however, emergent fry, YOY, and juvenile humpback chub are susceptible to predation in the Little Colorado River and mainstem Colorado River (Yard et al. 2011).

Experimental removal of nonnative brown and rainbow trout was conducted in the Colorado River in the Grand Canyon between 2003 and 2006. Twenty-three trips to remove trout from the vicinity of the confluence of the Little Colorado River (RM 56–RM 66) resulted in the removal of more than 23,000 fish (mostly rainbow trout). During this time, the rainbow trout population in the Colorado River in the vicinity of the Little Colorado River was reduced by more than 80% (Andersen 2009), while estimated humpback chub abundance increased during this time (Figure 9). However, this increase may be attributable to a variety of other factors, including warmer water temperatures that occurred during this time and the HFE experimental flows (Andersen 2009; Coggins et al. 2011).

As previously discussed, the coldwater temperatures in most places of the main channel are below the temperature needed for spawning, egg incubation, and growth of the humpback chub. Survival of humpback chub young in the mainstem near the Little Colorado River is thought to be low because of cold mainstem water temperatures (Clarkson and Childs 2000; Robinson and Childs 2001), which may limit hatching success, reduce larval survival and larval and juvenile growth, reduce swimming ability, and increase predation vulnerability (Ward and Bonar 2003; Ward 2011). Water temperatures in the mainstem Colorado River have generally been warmer over the last decade, and warming over the summer increases downstream, due to solar radiation. For example, maximum daily temperatures exceeded 20°C (68°F) in the lower river (RM 180–RM 280), and daily average temperature was 18.3°C (65°F) in early July (Kegerries et al. 2015). There is some evidence of recruitment at the 30-mi aggregation possibly due to the presence of warm springs. Adult chub captured near RM 35 suggests the possibility of a new aggregation or expansion of the 30-mi aggregation, and during 2013 and 2014, three female humpback chub were captured near the 30-mi aggregation that expressed eggs. Ultrasonic images of several hundred adult humpback chub from many locations in the mainstem, as well as in the Little Colorado River and Havasu and Shinumo Creeks, indicated that adult female humpback chub are able to produce eggs in the mainstem Colorado River. In 2013, approximately 33% of humpback chub examined from the mainstem Colorado River, 52% of

chub examined from the Little Colorado River, and 23% of chub examined from Havasu Creek were females with eggs (GCMRC 2015).

Temperatures, particularly in the upper reaches of the Colorado River, even in warmer years, are not optimal for humpback chub spawning and growth. However, juveniles can now successfully rear to adulthood in the Colorado River mainstem, and mainstem recruitment is likely contributing to the overall adult population that increased from about 5,000 adults in 2000 to about 11,000 adults in 2012 (Yackulic et al. 2014; Figures 8 and 9). Water temperatures below Glen Canyon Dam began increasing in 2003 as a result of drought conditions that lowered the level of Lake Powell and resulted in the release of warmer water from the dam (Andersen 2009; Andersen et al. 2010); temperatures have remained elevated relative to operations during the 1980s and 1990s due to continued drought-induced lower Lake Powell reservoir levels and somewhat due to relatively high inflow in 2008, 2009, and 2011. In 2005, maximum mainstem water temperature exceeded 15°C (59°F) at Lees Ferry and approached 18°C (64°F) in the vicinity of the Little Colorado River (RM 61), the warmest temperature at those locations since the reservoir was filled in 1980. Maximum water temperature in the mainstem at Lees Ferry reached about 14°C (57°F) in 2008 (USGS 2014), similar to temperatures in 2003 when drought effects from low Lake Powell levels began to raise Glen Canyon Dam release temperatures. In 2011, maximum mainstem water temperatures at the Little Colorado River confluence (RM 61) reached about 15°C (59°F) and 16°C (61°F), respectively (Figure 12). This warmer water appears to have benefitted the humpback chub and other native fish, but they may have benefitted nonnative warmwater species as well (Andersen 2009; Coggins and Walters 2009; Kennedy and Ralston 2011). Low reservoir levels can be attributed to drought, as well as consumptive water use in the Colorado River basin.

Increased water temperatures may also affect predation of YOY humpback chub by rainbow and brown trout (Ward 2011; Yard et al. 2011; Ward and Morton-Starner 2015). Ward (2011) reported that in the laboratory, the level of attempted predation by brown trout was positively correlated with increasing water temperature, but predation success of rainbow trout on YOY humpback chub decreased as water temperature increased from 10°C to 20°C (50°F to 68°F); predation success by brown trout did not change significantly over the same temperature range (Ward 2011; Ward and Morton-Starner 2015). Yard et al. (2011) examined the effects of temperature on trout piscivory in the Colorado River and reported no relationship between water temperature and the incidence of piscivory by rainbow trout, but a significant positive correlation was found between water temperature and the incidence of piscivory for the brown trout.

Climate change and drought have direct influences on hydrologic patterns and water temperature, thus impacting humpback chub. In the Colorado River Basin, hydrologic impacts include lower precipitation and decreased inflow to the reservoir system, resulting in more frequent lower reservoir release volumes, potentially impacting shoreline habitats and riparian areas. More frequent droughts and warmer atmospheric temperatures have the potential to result in warmer temperature of water being released from the dam. Although this may improve thermal suitability for humpback chub, any subsequent benefits may be offset by increased abundance and expansion of warmwater nonnative fish and aquatic fish parasites.

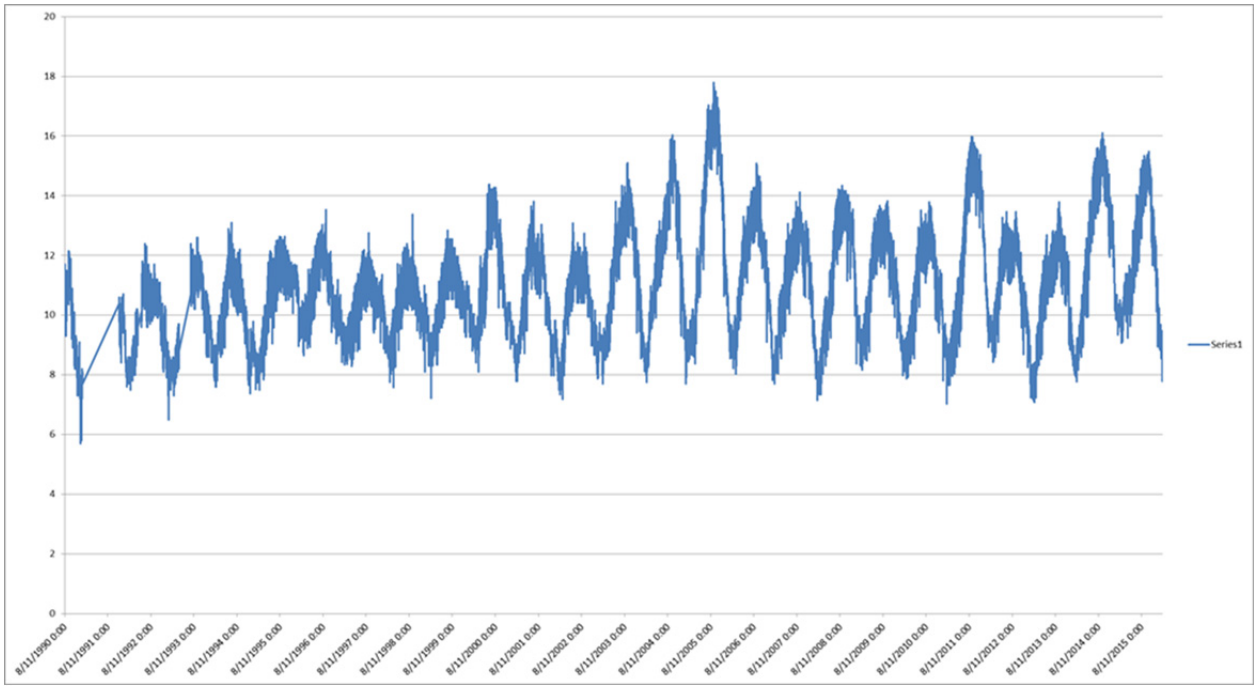

FIGURE 12 Water Temperatures at the Little Colorado River Confluence (RM 61), 1995 to Present (Source: USGS 2014)

Although the Little Colorado River stretches almost 340 m (550 km), only the headwaters and the lowermost reaches flow year-round. The lower 13 mi (21 km) of the Little Colorado River is fed by groundwater springs. This reach is occupied by the largest self-sustaining population for the species, and the lower 8 mi (13 km) is designated critical habitat. These water sources may also be vulnerable to basinwide drought and climate change impacting overall habitat availability and the population.

The development of a second population of reproducing humpback chub in the Grand Canyon was identified as an important conservation action in the 1995 EIS on the operations of Glen Canyon Dam, in case of catastrophic loss of the Little Colorado River population (Valdez et al. 2000). While some reproduction of humpback chub has been documented in Havasu Creek (Healy and Nelson 2013) near 30-mile spring (RM 30; Valdez and Masslich 1999) and may occur in the western Grand Canyon (Albrecht et al. 2015; Kegerries et al. 2015), it is likely limited in the Colorado River by water temperature, rearing habitat, or other factors.

2.1.3 Razorback Sucker

2.1.3.1 Legal Status

The razorback sucker (*Xyrauchen texanus*) was listed as endangered under the ESA on October 23, 1991 (56 FR 54957). The final rule for determination of critical habitat was

published on March 21, 1994 (59 FR 13374), and the final designation became effective on April 20, 1994. Designated critical habitat within the project area includes the Colorado River and its 100-year floodplain from the Paria River downstream through Marble and Grand Canyons to Hoover Dam, including the full pool elevation of Lake Mead.

2.1.3.2 Recovery Goals and Status

Recovery goals for razorback sucker were established in 2002 (FWS 2002b). Demographic criteria that describe numbers of populations and individuals (adults and juveniles) for downlisting and delisting are presented for upper and lower basin recovery units in the FWS's razorback sucker Recovery Goals document:

> These criteria require four genetically and demographically viable, self-sustaining populations (two in each recovery unit), based on requirements of no significant decline in numbers of adults for each population and recruitment equal to or exceeding adult mortality. In addition, a genetic refuge needs to be maintained in Lake Mohave of the lower basin recovery unit (based on the majority opinion of lower basin biologists, the number of adults for maintaining this refuge is 50,000).

Monitoring is also necessary to determine if the recovery criteria are met. Adequate habitat and sufficient range are required to support recovered populations, in addition to demographic criteria.

The 5-year status review for the razorback sucker was completed by the FWS in 2012 (FWS 2012). The recovery of the species is based on whether the reduction or removal of threats has occurred, and on whether improvement in the demographic criteria has been achieved. Based on the review, only 1 of the 10 demographic criteria had been met, 2 had been partially met, and 7 were unmet. In addition, the majority of the most meaningful threats to the species were not mitigated, as only 9 of the 29 recovery factor criteria were met. As a result, the FWS decided that a change in the species' endangered status was not warranted (FWS 2012).

2.1.3.3 Historic and Current Range

The razorback sucker is a large river sucker (Catostomidae) endemic to the Colorado River system. It is a large fish, with adults reaching lengths up to 3 ft and weighing as much as 13 lb, and it may live 40 years or more (FWS 2002b). The species is endemic to large rivers of the Colorado River Basin from Wyoming to Mexico; however, the specie's range has been substantially reduced (Figure 13; Marsh et al. 2015). Currently, it occurs in the Green River, upper Colorado River, and San Juan River subbasins; the lower Colorado River between Lake Havasu and Davis Dam; Lake Mead and Lake Mohave; and tributaries of the Gila River subbasin (FWS 2002b) and Lake Powell (Francis et al. 2015).

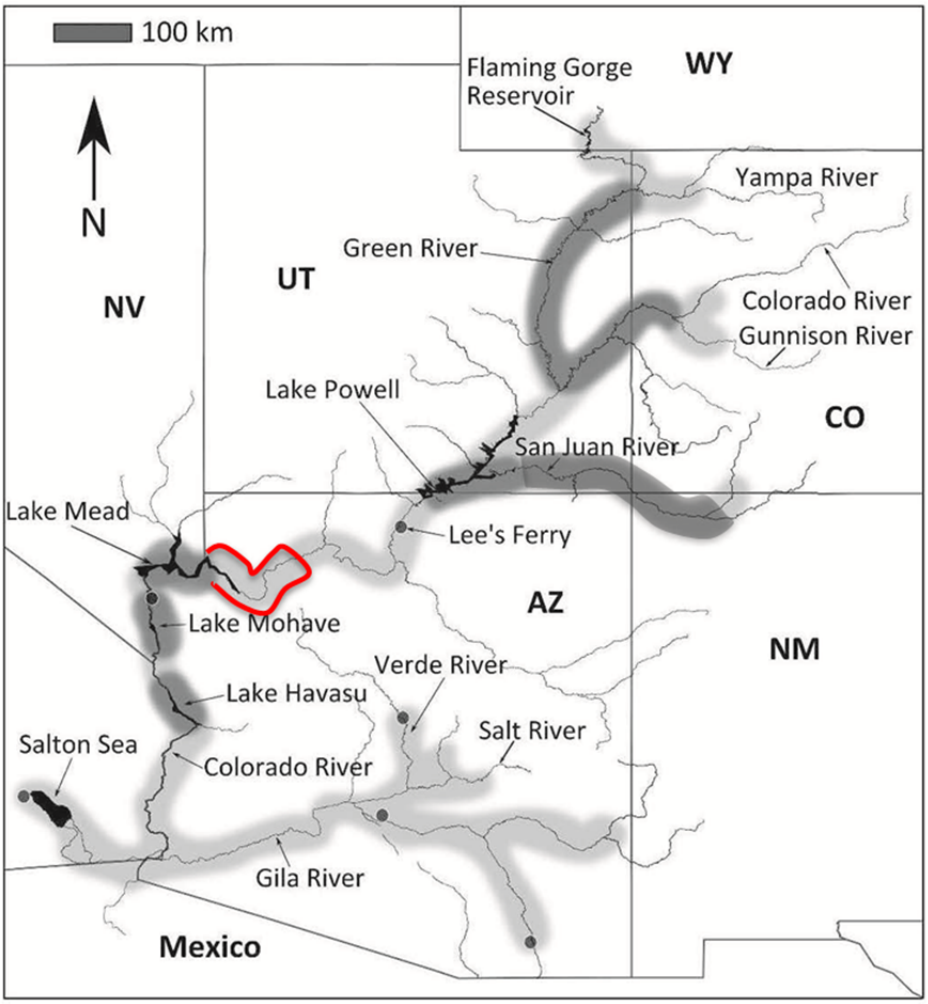

FIGURE 13 Historic (light gray) and Present Range (dark) of Razorback Sucker in the Colorado River Basin (The lower Grand Canyon/Colorado River inflow area of Lake Mead, where razorback sucker larvae have been detected is shown in red [Albrecht et al. 2014; Kegerries et al. 2015].) Source: Marsh et al. (2015)

Recent estimates of razorback sucker populations were summarized by Marsh et al. (2015), but the authors noted that the precision of many estimates was questionable given low recapture rates of marked individuals. Despite this, collectively, the number of remaining individuals is likely only a fraction of historic populations. Many populations in the upper Colorado River Basin are maintained by stocking, and in the lower basin, with the exception of Lake Mead, razorback sucker are maintained through stocking, including populations in Lakes Mohave and Havasu (Marsh et al. 2015). Recruitment has been occurring since the 1970s, sustaining the small population remaining in Lake Mead (Albrecht et al. 2010; FWS 2012; Mohn et al. 2015), which was estimated to consist of approximately 596 individuals through 2012 (95% Confidence Interval: 468–786; Albrecht et al. 2013). Low numbers of recaptures likely precluded a population estimate for the sampling period between 2013 and 2015 in

Lake Mead (Mohn et al. 2015). Lake Mead contains one of the smaller populations; rangewide, however, recruitment is rare or nonexistent in other populations (Marsh et al. 2015).

2.1.3.4 Population within the Action Area

Inventories of fish populations in the pre-dam Grand Canyon were extremely rare, and thus describing historic fish distribution and abundance is difficult (Webb et al. 2002). Within the Grand Canyon, it is likely that razorback sucker historically occurred throughout the Colorado River to Lake Mead (after Hoover Dam construction), with several documented captures in the mainstem (near Bright Angel and Shinumo Creeks), at the Little Colorado River inflow in 1989 and 1990, and from the Paria River mouth (in 1963 and 1978, as reported in NPS 2013). Until recently, the last razorback sucker collected from the Grand Canyon (RM 39.3) was caught in 1993, and the species was considered extirpated from the Grand Canyon.

Adult razorback suckers have recently been captured from the western Grand Canyon (summarized in NPS 2013). Four fish that were sonic-tagged in Lake Mead in 2010 and 2011 were detected in the spring and summer of 2012 in GCNP up to Quartermaster Canyon (RM 260) (Kegerries and Albrecht 2012, as cited in NPS 2013). An additional untagged adult razorback sucker was captured in GCNP near Spencer Creek (RM 246) in October 2012 (as reported in NPS 2013), and another adult was captured in late 2013 (GCMRC 2014). Sampling of channel margin habitats has also documented 462 and 81 razorback sucker larvae as far upstream as RM 179 (just upstream of Lava Falls) in 2014 (Albrecht et al. 2014) and 2015 (Kegerries et al. 2015), respectively, indicating that spawning is occurring in the mainstem river in the western Grand Canyon (Albrecht et al. 2014; Kegerries et al. 2015). However, small-bodied fish sampling designed to detect juvenile razorback sucker in western Grand Canyon has failed to detect any older larval fish or those that have transformed to juveniles.

Tagged adult razorback suckers have also been located as far upstream as RM 184.4 near Lava Falls, and along with the collection of larvae, indicates that the species utilizes the Colorado River above the Lake Mead inflow area more than previously thought (Albrecht et al. 2014). In 2015, Submersible ultrasonic receivers (SURs), which are devices that detect sonic-tagged razorback suckers, were installed upstream of Lava Falls, to an area below Bright Angel Creek. No detections of razorback sucker were recorded above Lava Falls through September 2015; however, the continued collection of larval fish upstream of Lava Falls (Kegerries et al. 2015) indicates spawning is occurring in an unknown location in the mainstem or tributaries.

Occurrences since 2013 of adult and larval razorback sucker in Lake Mead and the lower Grand Canyon downstream of RM 180 indicate that the connectivity of the lake to the riverine reaches may be important to maintenance of razorback sucker in the project area.

2.1.3.5 Habitat

Razorback sucker use a wide variety of habitats, including rivers and streams and their associated floodplains, as well as reservoirs (Valdez et al. 2012a). Habitat use varies by life stage and by habitat type (i.e., lentic vs. lotic habitats). Valdez et al. (2012a) completed a comprehensive review of razorback sucker habitat use studies conducted throughout the species' range. In rivers, habitat requirements of adults in spring include low-velocity runs, eddies, backwaters, and areas of inundated vegetation (e.g., flooded off-channel areas); in summer, runs and mid-channel bars; and in winter, low-velocity runs, pools, and eddies (reviewed in Valdez et al. 2012a). Razorback suckers spawn on cobble and gravel bars in rivers, and on gravel and cobble shorelines in reservoirs. In reservoirs, adults prefer areas with water depths of 3 ft or more over sand, mud, or gravel substrates. Young require nursery areas with quiet, warm, shallow water such as tributary mouths, backwaters, and inundated floodplains along rivers and coves or shorelines in reservoirs (FWS 2002a). Recent captures of larval razorback sucker in the western Grand Canyon found the highest density of larvae in isolated pools, which comprised less than 2% of all habitat sampled (Albrecht et al. 2014). Similar results were found in 2015, when the highest catch of larval razorback sucker was found in isolated pools, followed by backwaters, which composed 2.1% and 9.1% of habitats sampled, respectively (Kegerries et al. 2015). Larval razorback sucker may drift along the shoreline adjacent to the main channel until settling into warmer, shallow backwaters, or floodplain wetlands (Valdez et al. 2012a).

Critical habitat was designated for this species in 1994, and within the project area, including the Colorado River and its 100-year floodplain from the confluence of the Paria River downstream to Hoover Dam (a distance of about 500 mi), including Lake Mead to full pool elevation (59 FR 13374).

2.1.3.6 Life History

Razorback suckers are long-lived (40+ years) and exhibit relatively fast growth the first 5 to 7 years of life in warm, food-rich environments, until adulthood, and after which growth slows and possibly stops (FWS 2002b). Both sexes are sexually mature by age 4 and can reach a maximum size of about 1 meter. As described above, spawning in rivers occurs over bars of cobble, gravel, and sand substrates during spring runoff at widely ranging flows and at water temperatures as low as 6°C (reviewed in Marsh 1985), but typically greater than 14°C (57°F) (FWS 2002b). High flow and temperature cues during spring were thought to be important to the initiation and success of spawning (reviewed in FWS 2002b). For example, vegetated floodplain wetlands and other off-channel habitats inundated by spring high flows provide warmer, food-rich rearing habitats for drifting larval razorback sucker (reviewed in Modde et al. 2001). High flows may also have flushed fine sediment from cobble bars, maintaining interstitial space for egg deposition and incubation. In reservoirs, spawning occurs over wave-swept rocky shoals and shorelines.

Historically, this species exhibited upstream migrations in spring for spawning, although current populations include groups that are sedentary and others that move extensively (Minckley et al. 1991). Adults in the Green River subbasin have been reported to move as much as 62 mi to specific areas to spawn (Tyus and Karp 1990). In Lake Mohave, individuals have been reported to move 12 to 19 mi between spring spawning and summer use areas (Mueller et al. 2000). Sonic-tagged razorback sucker, either stayed near spawning areas, or have moved great distances, up to 361 km (224 mi) within the western Grand Canyon, the Colorado River inflow to Lake Mead, and throughout the lake (Kegerries et al. 2015).

Razorback sucker have high fecundity, with the average number of eggs per female ranging from 27,614 to 103,000 in various studies (reviewed in FWS 2002b). Eggs incubate for 6 to 7 days before hatching, prior to emerging from cobbles and being transported downstream to floodplains or backwaters. Hatching success is temperature dependent, with the potential for complete mortality occurring at temperatures less than 10°C (50°F; Marsh 1985; Bozek et al. 1990). Marsh (1985) found the highest survival of embryos and percentage hatched was at 20°C in laboratory studies, while Bozek et al. (1990) showed that hatching success was between 32 and 65% in 15°C water.

In the Grand Canyon, the estimated onset of spawning was in mid-February, based on back-calculation from the dates of larval collection, when average daily water temperatures were between 10 and 12°C (50 and 53.6°F; Kegerries et al. (2015). Spawning appeared to peak toward the end of March when water temperatures ranged from 12 to 14°C, but the duration of spawning was protracted—occurring between mid-February and July (Kegerries et al. 2015). A faster larval razorback sucker growth rate is thought to benefit survival by minimizing the time larvae are susceptible to predation by small-bodied fish. Growth was 50% greater at 19.5°C compared to growth in 16.5°C water, with the highest growth rates at 25.5°C (Bestgen 2008). As described above, following hatching, larval razorback sucker may drift into low-velocity, warm, backwaters or floodplain wetlands to rear. Maturity is reached in 2 to 5 years.

Both adults and immature fish are omnivorous, feeding on algae, zooplankton, and aquatic insect larvae; however, diet varies by life stage. In Lake Mohave, their diet has been reported to be dominated by zooplankton, diatoms, filamentous algae, and detritus (Marsh 1987). Larval razorback sucker feed on planktonic organisms, switching to benthic organisms as their sub-terminal mouth develops, with chironomid larvae being a primary food item (FWS 2002b).

2.1.3.7 Factors Affecting Distribution and Abundance in the Grand Canyon

The decline of the razorback sucker in the Grand Canyon and throughout its range has been attributed primarily to habitat modification due to dam construction (including coldwater dam releases, habitat loss, and migration impediments), streamflow regulation, and predation by nonnative fish species, which have resulted in a lack of recruitment (FWS 2002b; Gloss and Coggins 2005). For example, the estimated 80% rangewide reduction in distribution of this species has been attributed to the construction of Hoover, Parker, Davis, and Glen Canyon Dams on the Colorado River and Flaming Gorge Dam on the Green River (Valdez et al. 2012a). Similar to the humpback chub, as described above, cold hypolimnetic releases from dams,

including Glen Canyon Dam, have also contributed to reproductive failure in razorback sucker (Gloss and Coggins 2005). Flow regulation and water diversions have decreased the magnitude of spring peak runoff, which is closely linked to reproduction of the razorback sucker. The loss or drastic reduction in peak flows, along with channelization or disconnection of floodplain nursery habitats with the main channel (as a result of loss of peak flows), have resulted in the elimination of reproduction and recruitment (FWS 2002b). In 2012, the FWS (2012) determined that flow regimes necessary to establish and maintain razorback sucker populations in the lower basin, including flows that provided adequate spawning cues and spawning and nursery habitat, had not been established. Similar to impacts on humpback chub, elevated Hg and Se described by Walters et al. (2015) may be another factor that may impact razorback sucker. While not tested, other native suckers with similar diets were found to have high levels of Hg and Se in the Grand Canyon (Walters et al. 2015).

The large reservoirs formed by dams also provide habitat for nonnative sport fishes, which were stocked with nonnative sport fish predators. Competition with and predation by nonnative fishes have also been identified as important factors in the decline of this razorback sucker (Minckley et al. 1991; FWS 2002a). The reduced sediment supply and resulting clear water due to dam operations also is thought to favor sight-feeding nonnative predators, over razorback sucker and other native fish that evolved in highly turbid conditions (reviewed in Gloss and Coggins 2005). Large-scale nonnative fish control and management programs have been implemented to meet recovery goals for razorback sucker in the upper basin, including control of small- and large-bodied predators in the San Juan and Upper Colorado River Basins, and revising nonnative fish stocking procedures (FWS 2012). Marsh et al. (2015) professed that only complete elimination of nonnative fish from razorback sucker spawning and nursery areas, such as off-channel ponds, would lead to successful conservation of the species in Lake Mohave. The success of stocking programs has been limited by the presence of nonnative predators. For example, Schooley and Marsh (2007) found that few individuals survived out of millions of small razorback suckers that had been stocked in the lower basin, likely because of predation by nonnative fish, and larger stocked fish had a much higher likelihood of survival.

In the Grand Canyon, the decline of native fish, including razorback sucker, has been attributed in large part to an increased diversity and abundance of nonnative fishes, along with the effects of Glen Canyon Dam on water temperatures, flow, and sediment (Gloss and Coggins 2005). As described above, recent efforts to better understand the use of the western Grand Canyon by razorback sucker has revealed that the species is more widespread there than previously thought. Spawning has occurred in unknown locations in the river or tributaries from Lake Mead to at least to areas upstream of Lava Falls in the Grand Canyon, or in the inflow areas of tributaries to Lake Mead, which has led to the maintenance of a small, but recruiting population in the project area (Albrecht et al. 2014). It is unclear whether razorback sucker spawning had been occurring previous to larval fish studies initiated in the western Grand Canyon in 2014.

Through the first 2 years of the first phase of a study to determine the habitat suitability and status of razorback sucker in the Grand Canyon (see NPS 2013), it was found that adult razorback sucker moved throughout the study area, and spawned, but no habitat preference could be inferred. Larval razorback sucker catches were higher in isolated pools and backwaters than

other nearshore habitats that were sampled (Kegerries et al. 2015). Despite the presence of adults and larval fish, no juvenile razorback sucker had been captured (Kegerries et al. 2015). Plausible explanations for this, assuming appropriate habitats are sampled for juvenile suckers, could be that all larval suckers are consumed by nonnative fish prior to their transformation to juveniles, or suitable low-velocity nursery habitats with sufficient food and water temperatures may not be available in the western Grand Canyon. However, relatively few nonnative fish have been sampled in the past 2 years in nearshore habitats from Lava Falls to Pearce Ferry, compared to native fish (Albrecht et al. 2014; Kegerries et al. 2015), and Valdez et al. (2012a) observed that there were backwaters similar to those on the San Juan River that are used by razorback sucker larvae, downstream of Lava Falls. Since the flow and temperature regime of the Colorado River in the Grand Canyon has been altered (i.e., reduced sediment supply, lack of high annual peaks, daily fluctuating flows, and cold dam releases), leading to less backwater stability and more frequent flushing (Behn et al. 2010), these backwaters may be less suitable for rearing than under stable summer flows (see Trammell et al. 2002; Vernieu and Anderson 2013). Alternatively, larval razorback sucker may drift out of the Grand Canyon and rear in the Colorado River Inflow of Lake Mead, which may provide suitable cover (turbidity) and temperatures (Valdez et al. 2012b; Kegerries et al. 2015). Captures of an age-2 and an age-3 immature razorback sucker, and an age-0 juvenile in or near the Colorado River Inflow of Lake Mead, suggests that some recruitment is occurring associated with the Colorado River in the Grand Canyon (summarized in Kegerries et al. 2015), despite altered habitats.

The presence of razorback suckers and their use of habitats in the Grand Canyon have only recently been investigated, and it is unclear how long spawning has been occurring, since larval fish studies were not conducted prior to 2014. Recent warming river temperatures due to lower Lake Powell elevations, attributed to drought and consumptive water use, may have resulted in more suitable habitats in the western Grand Canyon. For example, in 2015, river temperatures were within the acceptable range needed for razorback sucker spawning and successful hatching, particularly farther downstream (Kegerries et al. 2015). In addition, fish community composition in the lower river below Diamond Creek has changed dramatically from one dominated by nonnative species, to native species (reviewed in Kegerries et al. 2015). However, the cause of the change in fish community composition is unknown. The drop in nonnative predator abundance, combined with periodically warmer water temperatures, may have allowed for the expansion of razorback sucker into the western Grand Canyon. Additional research and monitoring are needed to better understand the management implications for recovery of razorback sucker in this reach of its range (Albrecht et al. 2014).

More frequent droughts and warmer atmospheric temperatures as a result of climate change and warmer temperature of water being released from the dam are likely to impact razorback suckers in the Grand Canyon. Razorback suckers are currently located in the lower reaches of the canyon where backwater habitat is more available. Warmer water temperatures may create more suitable habitat for larvae and juveniles. However, these effects may be offset by increased abundance and expansion of nonnative fish and aquatic fish parasites. Also, lower reservoir releases may result in fewer backwater habitats available for spawning and rearing of razorback sucker.

2.1.4 Southwestern Willow Flycatcher

2.1.4.1 Legal Status

The southwestern willow flycatcher (*Empidonax traillii extimus*) is one of four currently recognized willow flycatcher subspecies (Phillips 1948; Unitt 1987; Browning 1993). On March 29, 1995, the southwestern willow flycatcher was listed as endangered (60 FR 10694) in its entire range, which is known to include Arizona, California, Colorado, New Mexico, Texas, Utah, and Mexico. In August 2002, the FWS released the "Final Recovery Plan for the Southwestern Willow Flycatcher." The Recovery Plan establishes six recovery units that are further subdivided into management units. These Recovery and Management Units are based on watershed and hydrologic units within the breeding range of the flycatcher (FWS 2002c).The Grand Canyon is within the Lower Colorado Recovery Unit. This Recovery Unit encompasses the Colorado River and its tributaries from Glen Canyon Dam downstream to the Mexican border. Despite the large size of this Recovery Unit, the unit contains only 146 known territories (15% of the rangewide total) (FWS 2002c).

2.1.4.2 Recovery Goals and Status

The Recovery Plan and goals for the southwestern willow flycatcher were completed in 2002 (FWS 2002c). The recovery objective for the species is to attain a population size and distribution of habitat sufficient to maintain metapopulations over the long term. Threats to the species must be addressed to achieve this goal. In general, the minimum number of territories needed and maintained over a 5-year period is 1,950 (approximately 3,900 individuals), distributed geographically to allow for functioning metapopulations. In addition, the total known population would need to be increased to 1,500 territories (3,000 individuals) distributed geographically among the Management Units and Recovery Units, so that the species is no longer in danger of extinction.

The 5-year status review for the southwestern willow flycatcher was completed by the FWS in 2014 (FWS 2014). It was determined that the status of the species had improved due to an increase in the number of known territories since it was listed in 1995. However, ongoing threats related to the spread of tamarisk leaf beetle and land management remained concerns. Due to these ongoing threats, a decline in the rangewide distribution of the species, and anticipated future adverse effects of the tamarisk leaf beetle to its habitat, the FWS determined that no change in status was warranted.

2.1.4.3 Historic and Current Range

The southwestern willow flycatcher is a neotropical migrant that breeds in the southwestern United States and migrates to Mexico, Central America, and possibly northern South America during the non-breeding season (Phillips 1948; Stiles and Skutch 1989; Peterson 1990; Ridgely and Tudor 1994; Howell and Webb 1995). The Pacific lowlands of

Costa Rica appear to be a key winter location for the southwestern willow flycatcher, although other countries in Central America may also be important (Paxton et al. 2011). Historically, the range of the flycatcher in Arizona included portions of all major watersheds (FWS 2002c); however, these watersheds have changed in many cases. As a result, most of the areas where flycatchers were locally abundant now support few or no individuals (FWS 2002c). Habitat and population numbers of southwestern willow flycatchers have declined in recent decades due to several factors, including loss, degradation, and fragmentation of riparian habitat; invasion by nonnative plants; brood parasitism by brown-headed cowbirds; and loss of wintering habitat (Stroud-Settles et al. 2013).

2.1.4.4 Population within the Action Area

Seventeen flycatcher sites were identified in the 2002 Recovery Plan (FWS 2002c) within the Grand Canyon. Flycatcher territories in the Grand Canyon are generally located in the tamarisk-dominated riparian vegetation along the river corridor but not in the mesquite-acacia and hackberry-dominated habitats higher on the slopes (Sogge et al. 1997a). The flycatcher's nesting habitat is dynamic in that it varies in occupancy, suitability, and location over time. In GCNRA, southwestern willow flycatchers are uncommon restricted migrants in riparian areas, rare summer residents, and probable breeders (Spence et al. 2011). Historic and recent nesting site locations in the Grand Canyon have been documented below Lees Ferry in Marble Canyon and in lower Grand Canyon below Diamond Creek (RM 225.5–RM 277) (Appendix B). No southwestern willow flycatcher nests or nesting behavior have been identified in the inner gorge (RM 77.9–RM 116.5); however, migrant birds have been documented. Because river channels, river flows, and floodplains are varied and can change over time, the location and quality of nesting habitat may also change over time. This is especially noticeable in the lower Grand Canyon where dropping lake levels in Lake Mead have resulted in high walls (approximately 10 to 20 ft high in many areas) of sediment topped with tamarisk bordering the Colorado River. The backwaters and saturated soils preferred by southwestern willow flycatchers have become rare.

Numbers of southwestern willow flycatcher detections in the Grand Canyon have declined since the 1980s, which is based on studies referenced below. There is little information on the number of willow flycatchers along the river before the construction of the Glen Canyon Dam. However, what data are available suggest that southwestern willow flycatchers were not common breeders along the Colorado River in the Grand Canyon (Brown 1988a,b; Brown 1991; Sogge et al. 1997b). Studies conducted along the river from 1982 to 1991 between Lees Ferry and Phantom Ranch found a total of 47 adult southwestern willow flycatchers—14 pairs, and 15 nests (Brown 1988a; Sogge et al. 1997a). From 1992 to 2001, the breeding population fluctuated between 1 and 4 breeding pairs per year with a total over the 10 years of 66 adult southwestern willow flycatchers, 14 pairs, and 20 nests (Brown 1988a,b; Brown 1991; Sogge et al. 1997a; Sogge and Tibbitts 1992; Sogge et al. 1993; Sogge and Tibbitts 1994; Sogge et al. 1995; Petterson and Sogge 1996; Sogge 1998; Yard 2001, 2002, 2003). Appendix B summarizes southwestern willow flycatcher observation data, territories, and nesting sites located in the Grand Canyon from 1909 to 2011. Although surveys were conducted in 2012, southwestern willow flycatchers were not detected. Survey methods followed the most recent

USGS survey protocol, at the time of survey, and involved the use of broadcast calling to elicit southwestern willow flycatcher responses (Sogge et al. 2010). Nest searches were not conducted during the 2010–2012 surveys at the Grand Canyon; however, due to behavior and timing of southwestern willow flycatcher detections at RM 275 in 2010, two breeding pairs were suspected to be present. Appendix A and Appendix B provide information on the locations of birds and nests from 1982 to 2011. Data are based on the following monitoring reports: Sogge et al.1997a; McKernan and Braden 1997, 1998, 1999, 2000, 2001, 2002, 2004; Paradzick et al. 2001; Smith et al. 2002, 2003, 2004; Koronkiewicz 2004, 2005, 2006, 2007, 2008; Yard et al. 2004; Albert 2005; Laczek-Johnson and Ward 2006; Ward and Haynes 2007; Northrip et al. 2008; Slayton et al. 2009; Palarino et al. 2010; Stroud-Settles and Lawrence 2011.

After the 2004 survey season, the USGS and GCMRC elected to discontinue their monitoring of known southwestern willow flycatcher nesting habitat in the Grand Canyon. Beginning in 2005, the Grand Canyon conducted annual surveys from Lees Ferry to Phantom Ranch, but funding prevented surveying the isolated habitat patches between Phantom Ranch and Diamond Creek. From 2004 to 2008, only two southwestern willow flycatchers were detected between Lees Ferry and Phantom Ranch.

2.1.4.5 Lees Ferry to Diamond Creek

Suitable habitat is located disjunctly through the river corridor from approximately RM 28.3 to RM 275. Surveys conducted between 1992 and 2004 indicated a small resident breeding population between Lees Ferry and Cardenas Marsh (RM 71), but no territories from RM 71 through RM 246 have been located. Recent (2007–2009) surveys have only detected non-resident/migratory flycatchers between Lees Ferry and Phantom Ranch (Palarino et al. 2010). Formal nest searches have not been conducted above Diamond Creek since 2004 (Stroud-Settles et al. 2013).

From 1993 to 2004, flycatchers were consistently present during the breeding season at RM 50.5–RM 51.5, but have not been present since 2004 (Ward and Haynes 2007; Northrip et al. 2008). In 2003, 2004, and 2010, the area around RM 28–RM 29 was occupied. Another area of importance in the mid-1990s was RM 71–RM 71.5; however, this area does not appear to have been occupied for the last 17 years. In 2004, the Grand Canyon instituted an emergency closure at two sites. This closure was in effect between May 1 and July 15 and included closure of visitor use, including hiking, camping, and river landings at RM 28.1–RM 28.5, river left, and RM 50.2–RM 50.6, river left. Closures at RM 28 and RM 50 have been put in place intermittently in the past; closure at Cardenas (RM 71) was instituted in the early and mid-1990s.

2.1.4.6 Lower Grand Canyon

Koronkiewicz et al. (2004) reported that the Colorado River in the Grand Canyon downstream of Separation Canyon (RM 234) is strongly influenced by water levels in Lake Mead. Potential southwestern willow flycatcher habitat in this area has changed dramatically in

the last several years as the result of a 105-ft drop in the level of Lake Mead since 2000. Areas that were inundated in the late 1990s are now well above the current water level, and the existing riparian vegetation in many of these areas is dead or dying. A 5-year boost in detections along this stretch of river that occurred from 1997 to 2001 is likely due to favorable water levels of Lake Mead in combination with increased survey effort (Stroud-Settles et al. 2013). The river corridor continues to provide essential habitat for migrating southwestern willow flycatcher (Stroud-Settles et al. 2013).

Southwestern willow flycatchers have been detected in the lower Grand Canyon below RM 234 since 1995 with the exception of 2002, 2003, 2011, and 2012 (Appendix B). In 2004, Koronkiewicz et al. identified approximately 76 hectares of suitable habitat at several sites between RM 239 and RM 275 within the Grand Canyon. These disjunct habitat patches have been inconsistently monitored during the past 11 years for both flycatcher presence and habitat suitability. Suitability ranking of these sites has proven to be largely dependent on current hydrological conditions of the Colorado River. As a result, a habitat assessment survey conducted during one year may result in a habitat ranking that is deemed suitable, but a revisit to the same site during a different year may rank the site as only potential habitat.

2.1.4.7 Life History and Habitat

The southwestern willow flycatcher eats insects and needs riparian habitats to complete its life cycle. It breeds and forages in dense, multi-storied riparian vegetation near saturated soils, slow-moving water, or surface water (Sogge et al. 1995). The southwestern willow flycatcher breeds across the lower Southwest from May through August (Reclamation 2007b). The southwestern willow flycatcher arrives on the breeding grounds throughout May and early June, eggs are generally laid beginning in May, and fledging occurs between June and August (Sogge et al. 1997a, 2010). Occupied sites most often have a patchy interior of dense vegetation or dense patches of vegetation intermingled with openings. Most often, this dense vegetation occurs within the first 3 to 4 m above the ground (FWS 2002c). The structures of occupied patches vary, with a scattering of small openings, shorter vegetation, and open water. Occupied patches can be as small as 2 acres and as large as several hundred acres, but are typically >10 m wide (Reclamation 2007b).

The southwestern willow flycatcher breeds in dense riparian habitats from sea level in California to approximately 8,500 ft in Arizona and southwestern Colorado. Throughout its range, the southwestern willow flycatcher arrives on breeding grounds in late April and May (Sogge and Tibbitts 1992; Sogge et al. 1993; Sogge and Tibbitts 1994; Muiznieks et al. 1994; Maynard 1995; Sferra et al. 1995, 1997). Nesting begins in late May and early June, and young fledge from late June through mid-August (Willard 1912; Ligon 1961; Brown 1988a,b; Whitfield 1990; Sogge and Tibbitts 1992; Sogge et al. 1993; Muiznieks et al. 1994; Whitfield 1994; Maynard 1995). The entire breeding cycle, from egg laying to fledging, is approximately 28 days. Nesting occurs during the spring and early summer months (May 1–August 31) in the Grand Canyon.

Historical egg/nest collections and species descriptions throughout its range identify the southwestern willow flycatcher's widespread use of willow (*Salix spp*.) for nesting (Phillips 1948; Phillips et al. 1964; Hubbard 1987; Unitt 1987; San Diego Natural History Museum 1995). Other habitats are also used, including nonnative species such as tamarisk (*Tamarix spp*.) and Russian olive (*Eleagnus angustifolia*). Throughout the southwestern willow flycatcher's current range, suitable riparian habitats tend to be rare, widely separated small and/or linear locales separated by vast expanses of arid lands.

2.1.4.8 Factors Affecting Distribution and Abundance in the Grand Canyon

The southwestern willow flycatcher has experienced extensive loss and modification of habitat and is also endangered by other factors, including brood parasitism by the brown-headed cowbird (*Molothrus ater*). The southwestern willow flycatcher was listed primarily due to riparian habitat reduction, degradation, and elimination as a result of agricultural and urban development. Other reasons for the decline/vulnerability of the flycatcher include the fragmented distribution and low numbers of the current population; predation; and other events such as fires and floods that are naturally occurring, but have become more frequent and intense as a result of the proliferation of exotic vegetation and degraded watersheds, respectively.

The Grand Canyon does not provide extensive stands of dense riparian habitat suited for breeding southwestern willow flycatchers. The majority of habitat patches in the Grand Canyon lack a consistent, dependable source of water for maintaining moist/saturated soil conditions and/or slow-moving or standing surface water (Stroud-Settles et al. 2013). As a result, the majority of flycatcher habitats in the Grand Canyon are marginal and, unless current hydrological conditions change, these patches will likely continue to decline. Furthermore, the recent arrival of the tamarisk leaf beetle has transformed and will continue to transform the patches of dense tamarisk into unpredictable, diminished patches (Stroud-Settles et al. 2013). Effects of climate change and continued dry basin hydrology may further diminish habitat for the flycatcher due primarily to lower water levels within riparian areas.

2.1.5 Yuma Ridgway's Rail

2.1.5.1 Legal Status

The Yuma Ridgway's rail (*Rallus obsoletus yumaensis*) was listed as endangered on March 11, 1967 (32 FR 4001). A 5-year review of the species was completed in 2006, and currently the 1983 Recovery Plan is in the revision process; a draft was released in 2010 for public review (FWS 2009b), and finalization is expected in 2016. It is categorized as a subspecies with a high degree of threat and low recovery potential due to habitat loss.

2.1.5.2 Recovery Goals and Status

Recovery goals and objectives for Yuma Ridgway's rail are based on the need to achieve and maintain a viable population level and to protect and maintain a sufficient amount of core and other habitats to support the population. The primary threat to the species is that water sources supporting its habitat are not managed and protected, and as a result, habitat may be lost. The draft recovery goal is "To achieve population stability and habitat protection sufficient to downlist and/or delist the Yuma Ridgway's rail" (FWS 2009b).

The 5-year status review for Yuma Ridgway's rail was completed in 2006 (FWS 2006). Based on the review, it was determined that the population in the United States is small, and limited information is available to determine the species' demographic status. Habitat loss in a Mexican population's range and accumulation of selenium in the environment remain significant threats, and thus no change in status was warranted.

2.1.5.3 Historic and Current Range

The Yuma Ridgway's rail occurs along the lower Colorado River and tributaries (Muddy, Virgin, Bill Williams, Lower Gila and Salt Rivers) in Arizona, California, Nevada, and Utah; the Salton Sea in California; and the Cienega de Santa Clara and Colorado River Delta in Mexico (FWS 2009b). Significant breeding areas in the United States include Mittry Lake (Arizona), Imperial Reservoir, Imperial National Wildlife Refuge, Bill Williams River National Wildlife Refuge, Topock Gorge and Topock Marsh in Havasu National Wildlife Refuge, Cibola National Wildlife Refuge along the lower Colorado River and Imperial Wildlife Area, Sonny Bono Salton Sea National Wildlife Refuge at the Salton Sea in California, and the Cienega de Santa Clara in Mexico. There is a small population in southern Nevada/northwest Arizona on the Muddy and Virgin Rivers.

2.1.5.4 Population within the Action Area

McKernan and Braden (1999) reported the presence of Yuma Ridgway's rails between Spencer (RM 246) and the boundary of the Grand Canyon (RM 277); these observations were made while conducting southwestern willow flycatcher surveys in the area. Specifically, McKernan and Braden (1999) report at least one rail observed between May 26, 1996, and June 30, 1996, and they indicate that nesting was confirmed. They report at least one rail observed between May 14, 1997, and June 17, 1997, but indicate that nesting was not confirmed (McKernan and Braden 1999). Surveys for the southwestern willow flycatcher in the lower Grand Canyon from 2003 to 2008 under the Lower Colorado River Multi-Species Conservation Program (LCRMSCP) did not record any incidental detections of Yuma Ridgway's rails (LCRMSCP 2008). GCNP surveys for southwestern willow flycatchers in the lower Grand Canyon in 2010 to 2012 did not have any incidental detection; however, the method of surveying used would be unlikely to pick up rail vocalizations.

The LCRMSCP mapped marsh habitat in the lower Grand Canyon/upper Lake Mead from aerial imagery taken in 2004; that mapping extended from RM 249 (401 km) to RM 277 (446 km), all within the boundary of GCNP. Koronkiewicz et al. (2004) and LCRMSCP (2004) report the presence of live cattails at Spencer Canyon (RM 246) and Burnt Springs (RM 259.5). The persistence of the cattail patches identified in the 2004 imagery and as documented in 2004 and 2005 is unknown. The continuing fall in Lake Mead elevation (60 ft to 18 m from 2004–2015) results in a longer reach of the river, and shallow bays or coves along the channel have become dewatered. Further, within the full-pool of Lake Mead, sediments have built up over time during higher lake elevations forming a delta. The retreating lake flows allows the erosive action of the river to cut through those sediments and move them downstream. The result can be steep eroding banks with riparian and marsh vegetation on top beginning to dry out as the water recedes with the lowered channel as more and more sediment is removed. With these changes, it is not known if cattail marsh habitat is present in sufficient quantity to allow for nesting.

Because of the limited information about the Yuma Ridgway's rail and its habitat in the Grand Canyon, managers must rely heavily upon the limited information available. Given that Yuma Ridgway's rails have been recorded historically at the Grand Canyon but have not been surveyed consistently or recently, managers presume that the Yuma Ridgway's rail may be present in the lower Grand Canyon during the lifetime of the LTEMP.

2.1.5.5 Habitat and Life History

The Yuma Ridgway's rail is a secretive species and is not often seen in the wild; however, it does have a series of distinctive calls and is most often identified by those. This bird inhabits freshwater or brackish stream sides and marshes under 4,500 ft (1,372 m) in elevation. It is associated with dense riparian and marsh vegetation, dominated by cattails (*Typha sp.*) and bulrush (*Scirpus ssp*.) with a mix of riparian tree and shrub species. Yuma Ridgway's rails may climb into a shrub or tree, but overall, they do not perch above the ground (FWS 2009b). Rails are capable of swimming and are also known to dive underwater, and may hold onto submerged vegetation to avoid threats or use its wings to "swim" (Todd 1986; Ripley 1977 cited in Eddleman and Conway 1998). The rail requires a wet substrate such as a mudflat, sandbar, or slough bottom that supports cattail stands of moderate to high density adjacent to shorelines. Other important factors are the presence of vegetated edges between marshes and shrubby riparian habitat (tamarisk or willow thickets) and the amount and rate of water-level fluctuations. Nests are built 3 to 6 in. (8 to 16 cm) above the surface in sloughs and backwaters that support dense stands of bulrush and cattails, and breeding occurs from March to early July. Along the lower Colorado River, males begin calling in February and pair bonding occurs shortly after. Nonnative crayfish provide the primary food base for the rail today; prior to the introduction of crayfish, isopods, aquatic and terrestrial insects, clams, plant seeds, and small fish likely dominated their diet (LCRMSCP 2008).

Eddleman (1989) determined that vocalizations are significantly reduced in winter, and telemetry data indicated that the majority of rails do not migrate. There is evidence that some populations may be more migratory than others, and this could be based on habitat and a stable food source (Eddleman 1989; Corman and Wise-Gervais 2005). Very little is known about the

dispersal of adult or juvenile birds, but the expansion of the population northward along the lower Colorado River (to Lake Mead, the Salton Sea, and up the Gila and Salt Rivers in central Arizona over the last 80 years) indicates that dispersal does occur (FWS 2009b).

2.1.5.6 Factors Affecting Distribution and Abundance in the Grand Canyon

Historically, the primary concentrations of Yuma Ridgway's rails were likely to be found in cattail/bulrush marshes in the Colorado River Delta. Unfortunately, due to diversions from the river for agriculture and municipal uses, the freshwater flows down the lower Colorado River, necessary to maintain marsh habitat, have virtually been eliminated (FWS 2009b). The majority of Yuma Ridgway's rail habitats that exists today are mostly human-made, such as the managed ponds at the Salton Sea (FWS 2009b). Without active management and protection of water resources to address land use changes in floodplains, human activities, environmental contaminants, and reductions in connectivity between core habitat areas, these habitats will be permanently lost to the Yuma Ridgway's rail (FWS 2009b). Effects of climate change and continued dry basin hydrology may further diminish habitat for the Yuma Ridgway's rail due primarily to lower water levels within riparian areas.

Another specific threat to the Yuma Ridgway's rail includes selenium in crayfish, the major prey item of the species. Selenium levels in crayfish collected in Yuma Ridgway's rail habitat were high enough to cause concern for the rail's reproductive success (FWS 2009b). No adverse effects from selenium have been observed; however, due to the rail's secretive nature, nests are very difficult to find and young birds difficult to observe (FWS 2009b).

2.2 BASELINE TAKE RESULTING FROM HANDLING AND GCDAMP RESEARCH

2.2.1 Humpback Chub

Fisheries monitoring and research are important aspects of ongoing research in the Grand Canyon that assesses the impacts of adaptive management and experimental treatments upon humpback chub and other resources. An extensive fisheries monitoring and research program is being implemented by the GCDAMP through the USGS and GCRMC throughout the project area, which will continue under the LTEMP proposed action. While stress upon individual humpback chub may result in occasional fatality, an objective of monitoring is to gather information in order to ensure that LTEMP goals for humpback chub are met.

Stress upon individual humpback chub related to sampling using netting and electro-fishing gears, as well as handling by researchers, is also a potential source of injury or mortality to individuals. No immediate mortality of humpback chub has been documented during tempering prior to release, hoop-netting, or electro-fishing during monitoring associated with NPS translocation projects in Shinumo and Havasu Creeks. Humpback chub were captured and handled 1,068 times between June 2010 and September 2012 in Shinumo and Havasu Creeks (Healy et al. 2014), for example. However, some minimal mortality has occurred during juvenile

collection efforts at the Little Colorado River for translocations and refuge development, although it is generally less than 5% (Van Haverbeke 2012). Five to 10 fish out of 500 to 800 generally die during transport in route to hatchery rearing facilities and during parasite and disease treatments; however, approximately 60 (10%) were lost at a hatchery facility during disease treatments and tagging prior to translocations in 2011. In 2014, approximately 30 out of 600 died during transport to the hatchery facility due to excessive cooling. Mortality of humpback chub captured during monitoring by all management agencies and researchers is reported to the FWS annually.

Incidental fatality was reported to the FWS by the USGS and GCMRC biology program manager (S. VanderKooi) and is summarized here. In 2012, 22 incidental fatalities out of 7,755 total humpback chub captures (0.28% mortality rate from capture) were associated with fish monitoring in the Colorado River using a variety of gear types. Another 4 humpback chub were lost out of 725 captures in the lower sections of the Little Colorado River (0.55%). Incidental mortalities of subadult or juvenile humpback chub (< 200 mm TL) included 88 in 2013 and 36 in 2014. The highest mortality rate was associated with experimental collections and rearing of larval humpback chub to be used in translocations (close to 30% of fish captured). Larval humpback chub collections may continue, or potentially increase slightly, to support translocations and Tier 1-triggered conservation actions included in the proposed action; however, the number collected would be similar to baseline conditions due to hatchery capacity constraints. Larval fish have an extremely low survival rate, and the risk to the humpback chub population of collecting several hundred larval fish is low (Pine. 2013). Nevertheless, collections for translocations or refuge development would be guided by FWS guidance documents (Translocation Framework, Van Haverbeke et al. 2016) and population viability modelling (Pine 2013). While inter-annual variability in incidental fatality due to handling occurs, the research program is not expected to change substantially through the LTEMP, and thus no change in impacts relative to the baseline condition is expected.

2.2.2 Razorback Sucker

Research designed to determine the status of razorback sucker in the lower Grand Canyon has resulted in mortality of larval razorback sucker and other native fish. While the mortality of up to several hundred individual razorback sucker larvae would be expected under the proposed action through collection and sacrifice of larval razorback suckers, with continued monitoring, the population-level impact would be minimal. For example, a single female razorback sucker could produce more than 100,000 larvae. While a final science plan for monitoring razorback sucker has not been developed, given the interest in determining and monitoring the impacts of TMFs and other actions included in the preferred alternative, mortality of larval fish and handling of juvenile fish (if present) may be expected to increase. However, these impacts would not likely impact the population, and monitoring would assist managers in determining the extent of impacts of flows on the species, potentially leading to adjustments in operations to benefit the species, or minimize large-scale impacts on habitat.

3 EFFECTS ANALYSIS OF PROPOSED ACTION

3.1 EFFECTS OF THE PROPOSED ACTION ON KANAB AMBERSNAIL

3.1.1 Direct and Indirect Effects

Aspects of the proposed action that have the potential to affect Kanab ambersnail individuals and habitat include sediment-related experiments (HFEs) and nonnative vegetation management. Other experiments or changes in dam operations included in the proposed action—such as changes in base operations, trout management flows, nonnative fish control, low summer flows, and sustained low flows for invertebrate production—would have no impact on the Kanab ambersnail, because these activities would not occur in locations known to contain populations or habitat. The impacts of changes in base operations, low summer flows, and sustained low flows for invertebrates would be limited to areas within the river channel, where no habitat or individuals occur. Nonnative fish control would occur in the river, in the vicinity of the Little Colorado River inflow, which does not contain habitat for Kanab ambersnail. No fish control would occur in off-channel springs.

3.1.1.1 Effects of Sediment-Related Experiments

Within the Grand Canyon, populations of the Kanab ambersnail occur at Vasey's Paradise and Elves Chasm. Because the Elves Chasm population is located above the 100,000 cfs stage (FWS 2008), this population would not be affected by any of the proposed actions. At Vasey's Paradise, the proposed action will have no effect on the water flow from the side canyon spring that maintains wetland and aquatic habitat at Vasey's paradise. Some Kanab ambersnail habitat could be adversely affected by scouring at Colorado River flows exceeding 17,000 cfs (Kennedy and Ralston 2011). The HFE may reach flows of up to 45,000 cfs. These flows will inundate Kanab ambersnail habitat up to that stage and likely scour the vegetation and carry some snails downstream.

Very little Kanab ambersnail habitat and only a few individuals occur below the 25,000 cfs stage (Meretsky and Wegner 2000; Sorensen 2009). Most Kanab ambersnail habitat is located above the 33,000 cfs stage (Reclamation 2011b). HFEs may scour or inundate portions of Kanab ambersnail habitat. Surveys conducted after HFEs revealed no substantial declines in the Kanab ambersnail population (Kennedy and Ralston 2011). Kanab ambersnails can survive up to 32 hours underwater in cold, well-oxygenated water (FWS 2011a), so as long as they are not washed away, they could survive inundation from short-term HFEs.

Recovery of Kanab ambersnail habitat scoured by HFEs can take up to 2.5 years (Sorensen 2009). Therefore, frequent HFEs may result in long-term loss of Kanab ambersnail habitat (FWS 2011a). Under the proposed action, HFEs would occur more frequently than they would under baseline conditions. Based on modeling results, only five HFEs would occur under the baseline condition, due to the expiration of the HFE protocol (Reclamation 2011b), but an

HFE would be expected to occur almost every year under the proposed action (19.3 HFEs over the LTEMP period). Loss of habitat due to scouring could extend several years beyond the LTEMP period. In addition, impacts on individuals, including fatality, could occur during HFEs, if the individuals are dislodged from habitat and swept into the river. Depending on the elevation of maximum dam discharge during trout management flows, temporary scouring of habitat may occur, but it is unlikely to reach Kanab ambersnail habitat that is above the 30,000 cfs elevation. However, the snail population at Vasey's Paradise survived and persisted through natural pre-dam floods and the 1983 flood, which were much larger in magnitude and longer in duration than the HFEs proposed under the LTEMP (Reclamation 1995; Kennedy and Ralston 2011).The amount of habitat and number of snails that would be unaffected by the proposed action are sufficient to maintain the population.

3.1.1.2 Effects of Vegetation Management

It is possible that vegetation management may occur, on rare occasions, near or within habitat at Vasey's Paradise, which may disturb individuals in small areas. Some nonnative vegetation may encroach on the spring, in which case careful manual removal of the vegetation would occur. To mitigate potential impacts on individual Kanab ambersnails, vegetation biologists would complete surveys and relocate any individuals detected on nonnative vegetation within the treatment areas. It is possible that some individuals could be killed during the treatment, but pre-treatment surveys would minimize this risk.

3.1.1.3 Effects of Climate Change

Climate change has the potential to affect the Kanab ambersnail habitat. The water source at Vasey's Paradise consists of waterfalls emanating from groundwater and emerging from the cliff face. In 2014 and 2015 the flow was noticeably reduced, likely as a result of basin-wide drought. Consequently, the usually dense vegetation at Vasey's Paradise is notably diminished. Climate change and drought will likely diminish the water source supporting Vasey's Paradise and consequently the vegetation and habitat available to the Kanab ambersnail.

Consequently, Reclamation has concluded the proposed action **may affect and is likely to adversely affect the Kanab ambersnail**.

3.2 EFFECTS OF THE PROPOSED ACTION ON HUMPBACK CHUB

The evaluation of potential impacts of the proposed action on humpback chub included consideration of the results of previous investigations conducted below Glen Canyon Dam that examined the status and abundance of native fish (e.g., Coggins and Walters 2009; Albrecht et al. 2014; Gerig et al. 2014; Kegerries et al. 2015), as well as studies of the effects of nonnative fish (Coggins et al. 2011; Yard et al. 2011; Whiting et al. 2014), experimental flows (such as HFEs and other flows), and water temperature on native fish (e.g., Grams et al. 2010;

Makinster et al. 2011; Trammell et al. 2002; Ward 2011; Ward and Morton-Starner 2015; Valdez and Speas 2007).

Several aspects of the proposed action may affect humpback chub directly or indirectly through direct impacts on individuals or habitat; or indirectly by influencing the abundance and distribution of nonnative predators and competitors, or by influencing macroinvertebrate production. Dam operations have the potential to influence river temperatures, the quantity and quality of nearshore rearing habitats (e.g., backwaters), aquatic insects that are food for humpback chub, and nonnative species abundance. These operations may also result in direct fatality to juvenile humpback chub through stranding. Flow-related actions that are analyzed below, which may impact humpback chub, include base operations, operational flexibility incorporated into base operations, sediment-related experiments, and aquatic resource experiments including trout management flows, low summer flows, and sustained low flows for benthic invertebrate production. Other non-flow actions that may impact humpback chub directly or indirectly, and that are analyzed below, include triggered humpback chub conservation actions (Appendix D), mechanical removal of nonnative fish, conservation measures, and continued fisheries research and monitoring under the GCDAMP. Some actions may have negative impacts on individuals, but beneficial effects at a population level.

Sediment monitoring and research and efforts to manage riparian vegetation are not expected to have impacts on humpback chub individuals or habitat. Riparian vegetation management would occur in only small, localized areas within the project area. Although riparian vegetation can play an important role in small stream ecosystems, particularly in providing cover, shade, or habitat for terrestrial invertebrates for fish to feed upon, riparian vegetation is less important for providing cover, shade, or energy inputs in larger rivers (Vannote and Sweeney 1980). Thus, riparian vegetation management would have large impacts on humpback chub and the species' habitat in the Colorado River.

3.2.1 Direct and Indirect Effects

3.2.1.1 Effects of Base Operations

Base dam operations are expected to change with the implementation of the proposed action. Changes will include more consistency across months, and thus more stability throughout the year, in monthly dam release volumes. The daily fluctuation in discharge would be proportional to the volume (i.e., lower fluctuations during lower flows), with a maximum discharge fluctuation range of 8,000 cubic feet/second, which would be the same as the current maximum fluctuation range. The daily downramp rate would be increased, compared to the current condition, by 67% (from 1,500 cfs/hr to 2,500 cfs/hr). Year-round, fluctuating flows throughout the life of the LTEMP period may continue to have detrimental, long-term direct impacts on humpback chub, humpback chub habitat, and aquatic invertebrate prey (food base).

Stranding of fish is a potential outcome of daily hydropeaking (Bunn and Arthington 2002; Nagrodski et al. 2012). Increasing downramp rates under the proposed action

may increase the risk of stranding humpback chub. Stranding could include fish being temporarily (i.e., until flows come back up hours later) restricted to isolated habitats away from the main channel, which may or may not become desiccated, as a result of dropping water levels. Desiccation of these isolated habitats would result in fatality of any juvenile humpback chub present. Factors that may influence the probability of stranding fish in a river with altered flow regimes—such as below hydroelectric plants—include the rate of flow reduction, water temperature, channel geomorphology, and substrate composition, as well as biotic factors including fish life stage and size (as reviewed in Nagrodski et al. 2012). Increasing drawdown rates under the proposed actions will increase the risk of negative impacts; however, humpback chub may be less reliant upon river margin habitats that are sensitive to flow fluctuations (e.g., backwaters; Dodrill et al. 2015) than other native fish, at least in the Little Colorado River inflow reach. The potential for, and the effect of, stranding on individual humpback chub survival has not been directly investigated; however, a summary of stranding literature indicated that fish stranding as a result of hydroelectric and irrigation projects is well documented (Nagrodski et al. 2012).

Daily fluctuating flows will continue to degrade nearshore habitats under the life of the LTEMP, particularly cobble shoals, riffles, and backwaters in wider, sections of the canyon, and where low-angle shorelines susceptible to flow fluctuations are prevalent. For example, cobble riffles and shoals, which are important spawning areas for fish, but also invertebrate production areas, would be dewatered daily. Generally, low catch rates of larval and small-bodied juvenile native fish have been observed in these types of habitats below Lava Falls (Albrecht et al. 2014; Kegerries et al. 2015). Although backwaters were not found to be common in the Little Colorado River inflow aggregation reach during a low steady flow experiment, humpback chub were found at higher densities in these habitats than in others (Dodrill et al. 2015). Backwaters may be more prevalent in other areas of the canyon, outside of the Little Colorado River inflow.

Base operations have been, and will continue to be, characterized as hydropeaking or load-following, which is an operational regime that has been demonstrated to have long-term detrimental impacts on aquatic invertebrates below hydroelectric dams in the western United States (Kennedy et al. 2016). Kennedy et al. (2016) found that hydropeaking was a primary factor implicated in reduced aquatic insect diversity; the Grand Canyon was found to have among the lowest insect diversity and the highest hydropeaking index among 16 dammed rivers. A diverse source of invertebrates colonize the Colorado River among the Grand Canyon's tributaries (Oberlin et al. 1999; Whiting et al. 2014), but hydropeaking and an altered temperature and flow regime will continue to negatively impact the food base for humpback chub over the life of the LTEMP.

Under base operations, through the life of the implementation of the LTEMP proposed action, river temperatures are expected to continue to be more suitable for coldwater nonnative species than for warmwater nonnative fish, particularly closer to the dam. In general, the estimated average main channel temperatures modeled for the LTEMP EIS indicated that temperature conditions would be most suitable for warmwater nonnative species at locations farther downstream from Glen Canyon Dam (e.g., RM 157 and RM 225) compared to upstream locations (e.g., RM 0 and RM 61), where temperatures would be more suitable to cold- or

coolwater nonnative fish (e.g., brown and rainbow trout); this is consistent with past surveys that have found more warmwater nonnative fish species in those areas than upstream.

Colder water temperatures restrict growth of YOY humpback chub, which prolongs the time during which individuals are vulnerable to trout predation (Yackulic et al. 2014). Essentially, juvenile humpback chub do not grow at temperatures under 12°C. Larger, older juvenile humpback chub may be able to avoid, withstand, or escape predation by rainbow trout under warmer and turbid conditions; however, temperature and size did not afford the same advantage in escaping brown trout predation (Ward and Morton-Starner 2015).

Unless the water can be warmed to above 12°C, it should be expected that the reduced water temperatures will result in increased egg incubation time (Hamman 1982), greatly reduced egg and fry survival (Hamman 1982), reduced larval-to-juvenile transition time (Clarkson and Childs 2000), and reduced growth rates of all life stages (Clarkson and Childs 2000; Coggins et al. 2011). From Glen Canyon Dam to the Little Colorado River inflow, water temperatures are generally <12°C. Consequently, there will be little or no spawning of humpback chub in this reach of the mainstem, unless it occurs at isolated locations such as 30-mile springs (RM 30) or springs at RM 34. There is little opportunity for larval fish to grow in Marble Canyon, unless the limited backwaters provide some thermal opportunities. In the Little Colorado River to Diamond reach, backwaters are more prevalent due to the more open geomorphology. Recently, temperatures have reached or exceeded 16°C at about RM 160 during September. This may provide opportunities for mainstem spawning activity and growth.

HFEs build sandbars, which can cause additional—but temporary—backwater habitats. Following the 2014 HFE, 22 sandbars and resultant backwaters throughout the Canyon became larger, 11 sites showed no change, and 5 sites became smaller. Although these sandbars erode within 6 to 12 months, they do not return to the pre-flood stage (Grams 2015). Three fall HFEs have occurred (2012, 2013 and 2014) in November; temperatures are unlikely to significantly increase in backwaters at this time, which is outside the spawning period for humpback chub. Spring HFEs may provide more thermal refuge in backwaters, particularly in the lower Canyon. However, relative densities of humpback chub, based on estimates of backwater prevalence directly after a controlled flood, showed the majority of juvenile humpback chub were found outside of backwaters. This suggests that the role of controlled floods in influencing native fish population trends may be limited (Dodrill et al. 2015).

It is possible that within the LTEMP period uncontrolled warm water releases may occur as a result of the elevation and subsequent water temperature of withdrawals from Lake Powell. Increased temperatures may benefit humpback chub spawning and growth, but would also allow numbers and species of warmwater nonnative species to expand in the system. A new conservation measure for LTEMP will explore new technologies for controlling the temperature of water discharged into the Colorado River and technologies to prevent the passage of fish through the dam.

Reclamation developed a risk assessment model to evaluate effects of a selective withdrawal structure on aquatic resources in the Grand Canyon area. It indicates there may be benefits for all native fishes from warmer water, as well as benefits for many nonnative fish

species that may compete with or prey upon native species. Results also indicate that there may be more suitable conditions for warmwater fish parasites (Valdez and Speas 2007). Species that occur in the Colorado River are listed in Table 5, along with their spawning, incubation, growth, and lethal temperature tolerances.

The impacts of the proposed action on temperature suitability for coldwater nonnative trout were assessed to determine the potential for increased trout populations, and thus increased likelihood of competition or predation upon humpback chub. Using the temperature suitability model, generally, temperature regimes would be suitable—although not optimal—for brown and rainbow trout under the proposed action. Temperature suitability for brown and rainbow trout would be similar to the baseline at most locations downstream of Glen Canyon Dam. However, main channel temperatures at and downstream of RM 61 would be more suitable for trout than at locations closer to the dam. The abundance of trout is lower in those locations because other habitat characteristics (e.g., substrate composition and water clarity) are less suitable at these downstream locations.

Previous studies have shown that rainbow trout recruitment and population size within the Glen Canyon reach appear to be largely driven by dam operations (Avery et al. 2015; AZGFD 1996; McKinney and Persons 1999; McKinney et al. 2001a,b; Makinster et al. 2011; Wright and Kennedy 2011; Korman et al. 2011, 2012). Increases in abundance have been attributed to the changes in flows beginning with interim flows in 1991 and later the implementation of MLFF in 1996. These changes both increased minimum flows and reduced fluctuations in daily flows, which created more stable and productive nursery habitats for rainbow trout in Glen Canyon (McKinney and Persons 1999). Declines in abundance (such as those observed from 2001 to 2007) have been attributed to the combined influence of warmer water releases from Glen Canyon Dam, high abundance, increased intraspecific competition, and periodic dissolved oxygen deficiencies, along with possible limitations in the food base (Makinster et al. 2011). Episodic emigration from the Lees Ferry reach toward the Little Colorado River was likely related to trout density, trout condition, and turbidity during the rainbow trout natal origins study (Korman et al. 2015).

In summary, under base operations, continued hydropeaking flows with increased downramp rates compared to the existing condition under coldwater conditions will continue to degrade nearshore rearing habitats, prevent the establishment of aquatic invertebrates (food base), and increase the risk of stranding juvenile humpback chub over the long term (throughout the life of the LTEMP).

3.2.1.2 Effects of Dam Operational Flexibility

Operational flexibility in dam operations is necessary to account for unforeseen changes in basin-wide hydrologic conditions, dam maintenance needs, water distribution, resource-related issues, or hydropower-related issues. Flexibility in dam operations would not change from the current conditions. These minor operational changes are not expected to measurably impact humpback chub, because no known impacts have been identified related to the current regime.

TABLE 5 Temperature Requirements for Spawning, Incubation, Growth, and Lethality of 36 Native and Nonnative Fish Species of the Colorado River and Its Tributaries in and near the Project Area[a]

	Spawning			Incubation				Growth			Lethal	
Species	Minimum	Maximum	Optimum	Minimum	Maximum	Optimum	Days	Minimum	Maximum	Optimum	High	Low
Black bullhead	19	22	20	21	24	23	6	20	22	21	3	35

[a] All temperatures are in °C. Days are provided as average time for incubation of eggs (Valdez and Speas 2007).

3.2.1.3 Overall Implementation Process for Experiments

As discussed in the preferred action section, an adaptive management approach is being taken to implement all experimental elements of the LTEMP. Prior to the implementation of any experiment, potential impacts on humpback chub (and other resources) would be considered by the DOI, and deliberations would include the FWS and other DOI subject experts. This would help to identify and minimize the risk of impacts on humpback chub as a result of the implementation of an experimental treatment. Each experiment's specific effects on humpback chub and humpback chub habitat are discussed for each set of experiments below.

3.2.1.4 Effects of Sediment-Related Experiments

Experimental flows under the proposed action include: (1) sediment-triggered spring and fall HFEs through 3.2.1.3 the entire 20-year LTEMP period; (2) 24-hr proactive spring HFEs in high volume years (≥10 maf release volume); and (3) extension of the duration of up to 45,000 cfs fall HFEs for as many as 250 hr depending on sediment availability. These experimental flows have the potential to affect humpback chub indirectly by increasing sandbar area and shoreline habitats; however, the importance of these habitats to humpback chub rearing and recruitment is uncertain. The aquatic invertebrate community may also be impacted by sediment experiments (Cross et al. 2011). Recruitment of rainbow trout in Glen Canyon may be affected by spring HFEs, which may potentially indirectly affect humpback chub by increasing competition with, and predation upon, humpback chub.

HFEs under the proposed action were designed to increase and retain fine sediment for ecological purposes in Grand Canyon. Sediment is a fundamental component of the riverine ecosystem, and the sediment regime has been drastically altered by Glen Canyon Dam. Sand deposits were redistributed during pre-dam annual floods, creating substrate for riparian vegetation, and sandbars and backwater habitats for native fish (reviewed in Grams et al. 2010). Slow-water habitats that may be important to native fish, including humpback chub that are dependent upon sand bar development, include backwaters and embayments. For example, relatively high densities of humpback chub were found in backwaters in the Little Colorado River inflow reach (Dodrill et al. 2015), and when 10 habitats were sampled in 2015, more larval humpback chub were caught in embayments than in most other habitat types (Kegerries et al. 2015). However, in 2014, catch rates for larval humpback chub did not differ significantly among habitats sampled in western Grand Canyon (Albrecht et al. 2014). It is uncertain how the availability of these habitats influences juvenile humpback chub survival and recruitment to adult life stages.

HFEs have been shown to build sandbars that substantially increased the total area and volume of backwater habitat (Grams et al. 2010). The increased elevation of backwaters also increased the degree of isolation from the main channel, which would likely result in a higher degree of warming in backwater habitats (Trammell et al. 2002; Vernieu and Anderson 2013), which may be important to native fish in the summer (Albrecht et al. 2014; Kegerries et al. 2015). However, studies of habitat used by juvenile humpback chub have been mainly limited to the Little Colorado River inflow reach, and it is unclear how important

backwater or embayment habitats are to humpback chub throughout other reaches of the Grand Canyon. Beaches and backwaters are not common in the Little Colorado River reach and, although young chub occurred in higher densities in backwaters, their overall abundance in the Little Colorado River reach was higher in talus (Dodrill et al. 2015). Although talus slopes may be important to humpback chub rearing, and are not maintained by sediment deposition expected to occur as a result of HFEs, predation risk to juvenile humpback chub may be higher in talus compared to backwaters under low- and intermediate-turbidity conditions (Dodrill et al. 2016).

Modeling of sediment resources and the impacts of the proposed action focused on areas upstream of RM 87, but literature suggested that the impacts in this area would be indicative of impacts throughout the project area. Sandbars and backwaters cannot be built or maintained without high flows, and sediment-triggered HFEs result in the largest impacts under the proposed action. Substantial improvements in the ability to build and maintain sandbars over the baseline condition are expected for the LTEMP preferred alternative, because no HFEs would occur under the baseline condition after 2020 (existing HFE experimental protocol expires; Reclamation 2011a). The maintenance of backwater, under the proposed action may therefore benefit juvenile humpback chub rearing habitat. However, depending on the frequency and intensity of impacts of TMFs, as described below, and because daily downramp rates will increase under the preferred alternative, the potential for backwater habitats to be dewatered—stranding juvenile humpback chub—remains. In addition, the Near Shore Ecology project concluded that backwaters are likely not important to the Little Colorado River chub aggregation because they are not a significant habitat component in that area (Pine 2011).

HFEs have the potential to affect benthic aquatic invertebrates, which comprises the primary food base for humpback chub, but spring and fall HFE effects may differ. Much of what is known related to the effect of HFEs on the aquatic food base was determined through research in Glen Canyon, but some food base studies have been initiated recently in the Little Colorado River inflow reach. Cross et al. (2011) found that a spring HFE resulted in an overall reduction in invertebrate biomass and production, mainly reflected by declines in two nonnative invertebrates (New Zealand mudsnail, *Gammaris* sp.), but an increase in rainbow trout was also observed; this corresponded with an increase in blackflies and midges, which are prey items for fish. The effects of fall HFEs are less certain, but the aquatic invertebrate community appeared to have responded differently to fall HFEs that were implemented in 2012–2014, compared to effects described in Cross et al. (2011).

Under the proposed action, we could expect there to be 19.3 to 21 HFEs (maximum of 38 HFEs) during the 20-year LTEMP period. The more frequent HFEs are expected to favor blackfly and midge production; however, spring and fall HFEs may differ in their effects, so it is unclear what long-term impacts of annual (i.e., 19.3–21 out of 20 years) HFEs may have on the food base. Under the preferred alternative, up to four of the fall HFEs could be long-duration HFEs (lasting up to 250 hr). These extended-duration HFEs would be of higher magnitude and could increase benthic scouring, compared to short-duration HFEs. Drift from an extended-duration fall HFE may be elevated due to increased biomass of benthic invertebrates that may develop over the summer months The 4 to 5 months between a fall and spring HFE could preclude full recovery of most benthic invertebrate assemblages. A spring HFE following a fall HFE, particularly a long-duration fall HFE, could scour the remaining primary producers and

susceptible invertebrates and further delay the recovery of the aquatic food base. For this reason, implementation of a spring HFE in years that follow an extended-duration fall HFE would be carefully considered.

Due to increased turbidity and other factors at the Little Colorado River inflow that differ from those at Glen Canyon, food base dynamics may not be comparable to those observed in Glen Canyon, and it is unclear what impacts HFEs have had upon the food base at the Little Colorado River. In terms of food base impacts upon humpback chub, recent preliminary USGS unpublished data indicate that as invertebrate drift declines (2014–2015), adult humpback chub body condition may also decline. Cross et al. (2013) found that native fish may be limited by food production, because all of the produced midges and blackflies are consumed. However, it is unclear how declining condition may be reflected in adult humpback chub survival, reproduction, and future recruitment of juveniles. It is possible that skipped spawning may be more prevalent in adults when food is limited, for example.

No current published research is available to show what factors may have correlated to the decline in invertebrate drift at the Little Colorado River in 2014 and 2015, compared to 2012–2013, but flow, temperature, and turbidity are likely factors. However, annual variation in drift since 2012 (potentially related to these factors) is likely much less detrimental to the food base for humpback chub than long-term loss of taxa that has likely resulted from hydropeaking or load-following (Kennedy et al. 2016; see base operations above). Despite the apparent impact on adult humpback chub body condition that may be correlated to food availability, humpback chub population dynamics will likely not respond to variations in food availability in a similar manner to the response shown for rainbow trout (see Cross et al. 2011). Humpback chub evolved in a system with limited autochthonus production due to high turbidity in the pre-dam Colorado River, and thus may have relied more heavily on terrestrial invertebrates or other allochthonous food items washed into the river during floods. In addition, other aspects of the species' life history, including high adult longevity, skip spawning, and higher relative fecundity compared to species in more stable environments, may moderate the effects of highly variable environment, including variation in food availability, on long-term population dynamics of the species. Many fish species evolved in variable environments, with a "boom and bust" life history strategy (see periodic life history strategy: Winemiller and Rose 1992). However, the more stable post-dam environment may also favor nonnative species (Olden et al. 2006; see discussion below). Nevertheless, spring and fall HFEs may not be tested in years when there would appear to be unacceptable risks to key resources including the aquatic food base, and the results of experimental flows will be discussed with FWS prior to implementation to minimize indirect effects on humpback chub.

Proactive spring HFEs would occur in high volume years with planned equalization releases (≥10 maf) in order to protect the sand supply from equalization releases. Fall HFEs longer than 96 hr in duration will be implemented when there is sufficient Paria River sediment input in the fall accounting period (July–October) to achieve a positive sand mass balance in Marble Canyon. Spring HFEs and high and steady flows (Avery et al. 2015), have both demonstrated an increase in rainbow trout production in the Colorado River, especially in the 16-mi reach below the dam (Lees Ferry reach). This increase in survival of juvenile rainbow trout was attributable to an improvement in habitat conditions and food availability in

Glen Canyon for recently emerged trout (Korman et al. 2011). Flows and temperature were modeled over the LTEMP period to assess how rainbow trout recruitment and the potential for emigration downstream toward the Little Colorado River may be impacted by flow experiments. Under the preferred alternative, emigration of trout is expected to increase by 11%, which could increase the likelihood of negative impacts on humpback chub through competition and predation, particularly in cold water release years. To provide a means of controlling trout recruitment following tests of spring HFEs, TMFs would be experimentally implemented and tested for efficacy as early in the LTEMP period as possible. In addition, if a tiered trigger approach to reversing declines in possible humpback chub recruitment fails, mechanical trout control may be implemented at the Little Colorado River inflow. Although both TMFs and mechanical trout control are considered experimental actions, they are expected to offset risks of trout predation upon juvenile chub at the Little Colorado River. In addition, basin-wide drought and the low Lake Powell levels expected to occur occasionally over the next 20 years would result in warmer dam releases, which also mitigate effects of rainbow trout predation upon juvenile humpback chub (Ward and Morton-Starner 2015).

The impacts of spring and fall HFEs on humpback chub are incorporated into the modeling described in the LTEMP EIS. In general, HFE impacts incorporated into the model are focused on influences of the flow and temperature regime changes upon rainbow trout population dynamics and indirect effects on humpback chub as a result of competition and predation. The output of the model for the preferred alternative represents a range of potential outcomes that may occur over the next 20 years for humpback chub, including a "worst-case scenario" that may be defined as colder/coldest dam discharge and high rainbow trout abundance. However, although humpback chub declines may occur during years with cold temperatures and high trout abundance, TMFs and mechanical control of trout are expected to mitigate these negative impacts; therefore, it is unlikely that actual declines in humpback chub would cause the population to reach the low levels displayed by the model (around 1500 individuals) over the life of the LTEMP.

Nonnative brown trout, or warmwater species occurrence or abundance, may also be influenced by the HFEs. Brown trout spawning occurs mostly in tributaries, primarily in Bright Angel Creek (Reclamation 2011a,b); consequently, reproduction would not be significantly affected by the flow operations of the dam. However, recent increases in brown trout recruitment in 2014–2015 have occurred in the Lees Ferry reach of the Colorado River in Glen Canyon (Stewart 2016). Brown trout were observed to be spawning near the 4-mile bar in Glen Canyon during the fall of 2014, and an increase in age-1 brown trout, likely as a result of spawning and recruitment in 2014, was observed in 2015 (Korman et al. 2015). Spawning of brown trout was also observed during October and November of 2015 near the 4-mile bar in Glen Canyon (Korman et al. 2015). It is unclear if flow operations, including recent fall HFEs, caused an increase in brown trout in recent years. The YOY of fall-spawning brown trout would benefit from increased food availability, similar to rainbow trout (Cross et al. 2011), if the fall HFEs' effects on benthic invertebrates are similar to those of the spring HFE. As discussed above, an increase in blackfly and midge production following fall HFEs has not been observed; therefore, it does not appear that recent fall HFEs have resulted in conditions that facilitated increased brown trout reproduction in Glen Canyon.

Although increases in brown trout recruitment do not appear to be related to HFEs, it is possible that the establishment of green sunfish in 2015 in a warmwater slough downstream of Glen Canyon Dam may be related to dam operations. Based on this assumption, and combined with expected occasional warmwater flow release periods during drought years, an increase in the likelihood of warmwater nonnative fish occurrence is expected below Glen Canyon Dam. Rapid increases in dam discharge from baseflow to up to 45,000 cfs during HFE implementation may increase the chance that abundant warmwater nonnative fish near the intakes become entrained in the bypass tubes. The risk would increase during periods of low Lake Powell levels because when this occurs intakes are closer to the surface and lake littoral zones, where smallmouth bass or green sunfish are present. During basin-wide drought years, warmer discharge would increase the risk further, because warm water could facilitate reproduction of these species in the Grand Canyon, potentially near the Little Colorado River inflow. To offset this risk, the conservation measures discussed below were developed. These include the investigation of means to prevent warmwater species' passage through the dam, completion of planning and compliance to make a warmwater slough less hospitable to warmwater nonnative fish, and the development of a rapid response protocol that includes chemical control methods and others not included in the NPS CFMP.

In summary, sediment experiments have the potential to negatively affect humpback chub individuals and habitat by increasing rainbow trout emigration to the Little Colorado River reach. This may increase predation or competition effects, alter the food base, or increase the risk of establishment of warmwater nonnative fish. However, these negative impacts may be offset by conservation actions and triggered mechanical removal of nonnative fish (trout or warmwater nonnative fish) to benefit juvenile humpback chub rearing, the development of a rapid response protocol, and warmwater species' habitat modification. Further, backwaters and embayments created following HFEs may provide warm rearing habitat for juvenile humpback chub, but the benefit may be minimal for the Little Colorado River inflow aggregation. Finally, these sediment treatments will not continue to be tested if they are not effective in achieving their purpose or have unacceptable adverse impacts on the trout fishery, humpback chub population, or other resources.

3.2.1.5 Effects of Trout Management Flow Experiments

TMFs will be implemented when there is predicted high trout recruitment in the Glen Canyon reach, but tests may be implemented when trout are at low densities, early in the LTEMP period. TMFs are designed to cause fatality in YOY rainbow trout by inundating low-angle, nearshore habitats for several days, and then quickly reducing dam discharge, which would strand YOY fish; however, there is also potential for stranding and increased fatality of juvenile humpback chub. Although the Lees Ferry reach trout population is the target of TMFs, an examination of USGS hydrograph data from Lees Ferry (RM 0) and National Canyon (approximately RM 166) indicated there may be little attenuation of stage changes due to flows downstream in the Marble and Grand Canyons. YOY humpback chub are found primarily in the Little Colorado River inflow reach, as well as further downstream, in unknown numbers. Stranding may occur, including stranding of endangered humpback chub and razorback sucker. TMFs are proposed to occur from May through August, in years when the experimental

treatment would be tested or implemented, including up to three cycles per month of high steady flows to draw juvenile fish into shallow nearshore waters, followed by rapid drops in discharge to strand fish.

Modeling conducted for the LTEMP EIS evaluated the number of trout recruits in the Glen Canyon reach, and the numbers of trout and humpback chub in the Little Colorado River reach to determine when TMFs would be triggered under the proposed action. It was estimated that triggers for TMFs would be met approximately every 3 years (32% of years).

Although indirect benefits of TMFs for humpback chub at the Little Colorado River are expected under the proposed action as a result of reduced competition and predation by rainbow trout, an unknown number of YOY humpback chub may also suffer fatality as a result of being stranded during TMFs, including those at the Little Colorado River inflow and downstream in the Grand Canyon. Stranding impacts may be difficult to observe, particularly lesser studied, sublethal impacts upon growth (Nagrodski et al. 2012). However, due to the geomorphological features of the Little Colorado inflow reach, fewer shoreline habitats such as backwaters, which are susceptible to fluctuations, are present, and may support only a small portion of juvenile humpback chub in that reach (Dodrill et al. 2015). It is less likely that TMFs would affect adult or juvenile chub, because they have a greater ability to swim out of confined spaces as flows dropped. Small YOY or larval fish, which already have a high mortality rate, could suffer increased mortality as a result of TMFs. TMFs could occur throughout the summer, overlapping with periods when larval humpback chub are found in nearshore habitats (May–August; Albrecht et al. 2014; Kegerries et al. 2015) and would be susceptible to extreme flow fluctuations under TMFs.

The extent of humpback chub mortality due to stranding and the benefits of reduced trout recruitment in a given year as a result of repeated (every third year) TMFs in Marble and Grand Canyons over the life of the LTEMP are uncertain. These impacts may depend on the quantity of channel margin habitats and their sensitivity to flow changes, the distribution and abundance of humpback chub in sensitive habitats, the timing and number of TMFs, and the degree of attenuation of flows downstream. The beneficial effects of TMFs for humpback chub may depend on the effectiveness of flows in reducing recruitment of YOY trout and emigration to the Little Colorado reach, as well as on the strength of the interaction between humpback chub and rainbow trout, which is mediated by water temperature (see Ward and Morton-Starner 2015). Stranding has not been observed during previous flow experiments, but no studies have been completed, so the degree of stranding is uncertain. The impacts of TMFs throughout GCNP will be monitored to assess effectiveness of the action and the detrimental impacts on native fish and other resources. TMFs will not continue to be tested if there is little or no reduction in trout recruitment after at least three tests, or if there are unacceptable adverse impacts on the humpback chub population or other resources. Consultation with the FWS would be conducted prior to implementation of the experiment. Thus, with “offramps” in place, long-term negative impacts on humpback chub would not be expected.

3.2.1.6 Effects of Triggered Conservation Actions and Mechanical Removal of Nonnative Fish Experiments

Under the proposed action, mechanical removal of nonnative rainbow and brown trout (and other nonnative predators) would be implemented through a triggered, tiered approach (see Appendix D) near the confluence of the Little Colorado River and the Colorado River if conservation actions designed to reverse declines in the Little Colorado River humpback chub aggregation are ineffective. This approach was developed by biologists with the FWS, USGS-GCMRC, AZGFD, NPS, and Reclamation, using the best available science and professional judgement. Conservation actions designed to improve rearing and recruitment of juvenile humpback chub would be implemented when adult humpback chub abundance declines to a threshold, or if recruitment of subadult humpback chub does not meet or exceed estimated adult mortality. Conservation actions would include expanded translocations of YOY humpback chub within the Little Colorado River to grow-out areas (i.e., above Chute Falls, Big Canyon), or larval fish would be taken to a rearing facility and released in the mainstem Little Colorado River inflow area once they reach 150–200 mm. If these conservation actions fail to reverse the declining trends and adult abundance dropped below 7000, mechanical removal of nonnative fish would be implemented in the Little Colorado River inflow area to lessen the effects of competition and predation upon humpback chub by nonnative fish.

Based on a humpback chub population model, which is primarily driven by temperature and rainbow trout population dynamics, it is likely that humpback chub populations may fluctuate over the life of the implementation of LTEMP (20 years). If model assumptions are correct, adult humpback chub populations could decline as low as 1800 individuals, coinciding with cold temperatures and high rainbow trout abundance. For example, expected emigration of rainbow trout from Glen Canyon was estimated to be 11% higher than under the current dam operations. This would increase predation upon juvenile humpback chub, potentially leading to reduced recruitment.

Tier 1 conservation actions would involve collecting 300–750 larvae or YOY—age classes that are vulnerable to predation by nonnative fish and that would naturally have relatively high mortality rates (see Pine 2013)—and rearing them to less vulnerable sizes before releasing them. Alternatively, YOY would immediately be translocated for rearing to areas with few predators, such as Big Spring or above Chute Falls. In the past, fish were successfully translocated within the Little Colorado River and to tributaries; the translocated fish in these locations experienced high survival and/or growth rates (Healy et al. 2014a; Spurgeon et al. 2015; Van Haverbeke et al. 2016), and there is a high likelihood for humpback chub to benefit through augmentation of the adult population as a result of Tier 1 actions. Detrimental effects on humpback chub, including fatality, could occur during handling, transport, or tempering; however, these occurrences are generally low, see Section 2.2.

Mechanical removal of nonnative fish would be implemented at the Little Colorado River inflow if declines in adult humpback chub continued, which would help minimize mortality of juvenile humpback chub. Past studies have indicated that trout predation upon humpback chub could be significant (Yard et al. 2011), and humpback chub are particularly vulnerable to predation at cold water temperatures (Ward and Morton-Starner 2015). It is somewhat uncertain

whether mechanical removal in the vicinity of the Little Colorado River would be successful in reversing declines in humpback chub, because (a) at high immigration rates into the Little Colorado River reach, mechanical removal may not be successful in reducing trout abundance (Coggins et al. 2011), and (b) other factors beyond trout predation and competition may be negatively impacting humpback chub survival and abundance. Past removal efforts appeared to be effective in controlling rainbow trout, and humpback chub recruitment increased; however, the removal effort coincided with a system-wide decline in trout abundance and warming dam discharge, which confounded results (Coggins et al. 2011). Nevertheless, TMFs designed to reduce Glen Canyon rainbow trout recruitment, and thus emigration downstream, would likely result in low immigration rates of trout to the Little Colorado River reach, thereby increasing the effectiveness of mechanical removal and benefitting humpback chub recruitment. The adaptive management approach taken to adjust trout removal targets and thresholds for action would also help ensure the effectiveness of this strategy in stemming humpback chub declines.

As designed, the tiered, adaptive approach to responding to humpback chub declines described here is expected to offset potentially negative impacts of management actions and experiments under the LTEMP. If conservation actions are ultimately successful in improving rearing success, these tools could be implemented proactively, and could potentially lead to long-term beneficial impacts on humpback chub in the Little Colorado River inflow aggregation.

3.2.1.7 Effects of Low Summer Flow Experiments

Low summer flow experiments involve holding flows low (approximately 8,000 cfs) and relatively steady, compared to base operations during warm summer months. Flows may continue to fluctuate 1000 cfs in a day, which would be less fluctuation than under base operations. The goal of the experiment is to achieve warmer river temperatures to benefit humpback chub; however, more stable shoreline habitats may also occur, which could also improve juvenile humpback chub rearing habitat. Lower flows have the potential for more warming via heat transfer from the air compared to higher flows. Low summer flows will be tested when the water temperature has been <12°C for 2 consecutive years, and a target temperature of ≥14°C can only be achieved if flows are dropped with the objective of testing the efficacy of low summer flows on warming and humpback chub growth. Low summer flows will only be tested after the first 10 years, and only under specific, rarely occurring, conditions. This test will not continue if there is no increase in growth and recruitment of humpback chub, if there is an increase in warmwater nonnative species or trout at the Little Colorado River; or if there are unacceptable adverse impacts on the trout fishery, humpback chub population, or other resources.

Under this design (1 to 2 years of testing), the effect of the low flow experiment upon humpback chub growth, rearing, and recruitment will be difficult to determine, because results are likely to be confounded by other factors (variation in annual precipitation, turbidity, etc.). In addition, the tests would be conducted only when humpback chub populations are healthy and stable; this would decrease the test's effectiveness in determining how low flows may improve humpback chub rearing during periods when the population is unhealthy or in decline.

Nevertheless, in addition to benefits associated with warming waters described in previous sections, stable nearshore habitats may benefit rearing, depending on the use of habitats that are sensitive to flow fluctuations (backwaters, embayments, cobble bars, riffles, etc.). The role of backwaters or similar habitats in humpback rearing is discussed in more detail in Section 3.2.1.4. However, reduced fluctuations under the low summer flow experiment would reduce stranding potential for humpback chub, and benefit the food base.

Low summer flows may allow for a prolonged test of the effect of steady flows on the diversity and abundance of aquatic invertebrates, similar to the intent of the low steady weekend flows for macroinvertebrate production experiment (Section 1.2.12). Base operations have been, and will continue to be, characterized as hydropeaking or load-following, which is an operational regime that has been demonstrated to have long-term detrimental impacts on aquatic invertebrates below hydroelectric dams in the Western United States (Kennedy et al. 2016). A diverse source of invertebrates to colonize the Colorado River is found among Grand Canyon's tributaries (Oberlin et al.1999; Whiting et al. 2014), but hydropeaking and an altered temperature and flow regime will continue to negatively impact the food base for humpback chub over the life of the LTEMP. Consistently more stable flows over the summer could result in successful egg-laying and reproduction by sensitive macroinvertebrate taxa (e.g., mayflies), which would also be important prey for humpback chub. However, the experiment may only be implemented 1–3 times in the second year of LTEMP, which would limit the ability of this experiment to benefit humpback chub food base over the long term. Only short-term (within the year of the test) beneficial effects on the food base would be expected.

It is possible that warming as a result of the implementation of low summer flows may increase the risk of warmwater nonnative fish establishment, threatening humpback chub populations. However, these tests are unlikely to increase the risk significantly, because they would occur infrequently (1–3 times out of 20 years), and due to low Lake Powell levels, water temperatures are already within the spawning range of warmwater nonnative species during some part of the year in the lower river (see Kegerries et al. 2015). Basin-wide hydrology that influences the Lake Powell level and dam discharge temperatures would likely overwhelm the effects of dam operations on river temperatures.

Although benefits to humpback chub may be realized as a result of this experiment on habitats and food base, the effect may be of short duration and may be insignificant over the life of the LTEMP (1–3 years out of 20). However, if the experiment has beneficial effects, it may be implemented more frequently beyond the life of the LTEMP period, if additional planning and compliance is completed.

3.2.1.8 Effects of Low Steady Weekend Flows for Macroinvertebrate Production Experiments

Experimental steady flows on weekends, in an attempt to increase invertebrate production and diversity, may benefit nearshore habitats by providing stability and some warming in habitats that are more isolated from the mainstem (low flows would be held steadier plus/minus 1000 cfs fluctuation); however, this would be limited to approximately 34 days over the summer.

This experiment will not be conducted during first 2 years of LTEMP. The goal is to replicate it two to three times to determine its effectiveness.

Kennedy et al. (2016) demonstrated that hydropeaking flows in rivers below hydroelectric facilities may prevent the maintenance of viable populations of many aquatic invertebrates (e.g., mayflies, stoneflies, caddisflies) that would constitute important components of the food base for humpback chub. Many shoreline egg-laying invertebrates were absent from western rivers with higher degrees of hydropeaking fluctuations. This experiment may allow some shoreline egg-laying invertebrates to avoid desiccation, which results in a high degree of egg mortality (Kennedy et al. 2016), and potentially will allow for increased production and possibly diversity of aquatic invertebrates.

In addition to potential benefits of increased aquatic food base production, steady flows on weekends may help to improve the quality of nearshore habitats for juvenile humpback chub. However, it is unclear whether 2 days per week of nearshore habitat stability will result in a measureable impact on juvenile growth, rearing, and recruitment.

Sustained low flows for benthic invertebrate production may benefit humpback chub by providing additional aquatic insect prey. It may also provide stable nearshore habitats for rearing, for 2 days per week. This treatment will be discontinued if there is no observed benefit to the food base, the trout fishery, or native fish; if there is an increase in warmwater nonnative species or trout at the Little Colorado River; or if there is an unacceptable adverse impact on the trout fishery, humpback chub population, or other resources.

3.2.1.9 Effects of Ongoing Conservation Measures

Conservation measures from the 2011 Biological Opinion were evaluated and adapted for the LTEMP, where necessary, and included in the preferred alternative. Some additional conservation measures were developed specifically for the LTEMP and were incorporated into the preferred alternative. The intention of conservation measures is to mitigate or offset potential impacts on ESA-listed species that may result due to the implementation of the LTEMP preferred alternative. These conservation measures were developed in consultation with the FWS and biologists from the NPS. Effects on humpback chub are discussed for each conservation measure below.

Humpback Chub Translocations

Humpback chub translocations were included as conservation measures in the 2008 and 2011 Biological Opinions on the operation of Glen Canyon Dam and on the Nonnative Fish Control and HFE plans, respectively. The preferred alternative includes the continued implementation of humpback chub translocations from the Little Colorado River to other areas in the Little Colorado River or to other tributaries of the Colorado River in the project area in order to (a) improve rearing and growth and provide additional rearing opportunities, or (b) establish additional spawning populations. As discussed in previous sections of this document,

translocations have been conducted above Chute Falls in the Little Colorado River, to Shinumo Creek, and to Havasu Creek. Translocations may result in increased growth or improved rearing and survival of juvenile humpback chub.

Translocations of juvenile humpback chub were first conducted in 2003. They involved moving fish from the lower reaches of the Little Colorado River to areas above Chute Falls (Van Haverbeke et al. 2013). These translocations have continued through recent years. Compared to juvenile humpback chub in the lower Little Colorado River, fish above Chute Falls grew much faster.

Prior to 2014, beginning in 2009, approximately 300 juvenile humpback chub per year were translocated to Shinumo Creek. Estimated growth and survival of translocated humpback chub generally was consistent with, or exceeded, growth and survival estimates of juvenile humpback chub in the Little Colorado River and Colorado River, although emigration rates exceeded 50% (Spurgeon et al. 2015; Healy et al. 2014b). In May of 2014, an NPS-managed fire started by lightning, burned approximately 10% of the Shinumo Creek watershed. Flooding and ash appeared to have extirpated the remaining humpback chub from Shinumo Creek in July and August 2014.

Havasu Creek translocations were initiated in June 2011 and have continued annually through May 2016. Approximately 300 fish were released in Havasu Creek annually. Biannual monitoring of translocated fish indicated that survival and growth objectives were met. In addition, evidence of reproduction, including ripe adult fish and untagged juveniles (age-1+), was observed annually beginning in 2013. Data collected from the May 2016 monitoring trip indicated that multiple year classes of untagged (non-translocated) humpback chub were observed (Nelson et al. 2016).

Through 2016, translocations to Havasu Creek have been limited to the lower 3.5 mi—from the Havasupai Reservation/NPS boundary to the confluence with the Colorado River—on NPS lands. A new effort will be pursued during the LTEMP to conduct initial fish surveys and complete a feasibility study to translocate humpback chub to Havasupai Reservation lands above Beaver Falls. Although the activities are subject to permission and support from the Havasupai Tribe, if habitat is suitable, translocations to this area could lead to an expanded spawning population at Havasu Creek. Larger populations would be more likely to persist in tributaries (Pine 2013).

Genetics management principles outlined in FWS guidance documents (FWS Genetics Management Plan 2010; Van Haverbeke et al. 2016) and the NPS CFMP (NPS 2013) would be followed to maintain genetic diversity and minimize detrimental genetic effects on translocated populations. For example, genetic monitoring would be conducted in tributary spawning populations established through translocations, and new migrants would be introduced occasionally (NPS 2013). As a result, no loss of genetic diversity is expected.

As part of the ongoing humpback chub translocation effort, Reclamation has committed to funding nonnative fish control in tributaries, where necessary, to maximize survival of translocated humpback chub. Control methods would vary depending on the tributary and the

existing nonnative fish species. Complete eradication of a nonnative species would likely provide the most beneficial impact on humpback chub translocated to the tributary; however, no specific plans for chemical piscicides have been identified, and piscicide use would require additional planning and compliance activities.

No detrimental population-scale impacts are expected as a result of translocations. In general, as demonstrated by previous or ongoing translocations, successful rearing and potential additional spawning populations can be developed or augmented through translocation of juvenile humpback chub, thereby benefitting the population. In addition to the continuation of the Chute Falls translocations under the preferred alternative, Havasu, Shinumo, and Bright Angel (pending successful trout control) creeks would continue to be the focus of translocations efforts outside the Little Colorado River. Although translocations can result in mortality of individual juveniles during collection from the Little Colorado River, transport to rearing facilities, disease treatment, or tempering and release (thus far, Chute Falls only), no detrimental population-level impacts on the adult population in the Little Colorado River has been observed. In addition, based on population viability modeling (Pine 2013), collection methods have been further refined to mitigate this risk by targeting life stages (e.g., larval) that would have a high mortality rate in the wild.

Humpback Chub Refuge

A refuge population of humpback chub was established at the FWS SNARRC facility in Dexter, New Mexico. The goal of the refuge is to maintain a genetically diverse population of 1000 humpback chub to be used for propagation in the case of a catastrophic loss of the Grand Canyon population. Impacts would be similar to those described for translocations, in that a small number of larval chub may be lost during collection, transport, and disease treatment; however, no detrimental impacts on the population would be expected.

Mainstem Humpback Chub Aggregations

Conserving mainstem humpback chub aggregations was a focus of past conservation measures related to dam operations. In the LTMEP, Reclamation will continue to assist the FWS, NPS, and GCDAMP to ensure that a stable or upward trend of humpback chub mainstem aggregations can be achieved. Actions include continued monitoring of the Little Colorado River humpback chub aggregation using the juvenile chub monitoring protocol developed following the natal origins project (see Pine et al. 2011); monitoring the mainstem aggregations annually; developing a methodology for locating additional aggregations and individual humpback chub; evaluating "drivers" of recruitment, potential spawning, and natal origins; and exploring a means of expanding humpback chub populations outside the Little Colorado River inflow aggregation.

Mainstem monitoring is critical to understanding how base operations and other experiments under the LTEMP impact humpback chub. Understanding more about the ecology and population dynamics of mainstem aggregations outside the Little Colorado River, including

the impacts of dam operations, may lead to improved management and conservation of those aggregations.

The impacts on individual humpback chub that may occur as a result of monitoring are covered below in Section 2.2. Monitoring under this action would be designed to assess trends in humpback chub in the mainstem Colorado River, and to assess impacts of experimental and management actions on humpback chub. Results of monitoring may allow managers to adapt actions to ensure that projects goals for humpback chub are met.

Disease and Parasite Monitoring

Reclamation intends to fund the GCDAMP to conduct disease and parasite monitoring in humpback chub and other fish in the mainstem Colorado River, in addition to ongoing disease and parasite monitoring conducted by USGS/GCMRC in the Little Colorado River.

It is unclear how this monitoring will be accomplished or how it may benefit humpback chub over the long term; however, understanding the impacts of parasites may inform future conservation actions.

Razorback Sucker Conservation Measures

Studies designed to help understand the status of the razorback sucker population in the Grand Canyon and Lake Mead would continue with the implementation of the preferred alternative. Although the focus of these studies is on razorback sucker, seining for larval and small-bodied YOY and juvenile fish may lead to an increased understanding of juvenile and larval humpback chub habitat use and spawning areas (at a course scale) in the Grand Canyon.

Fatality of individual larval humpback chub would occur as a result of this sampling regime; however, high larval mortality rates are likely in the wild, and thus, this effort would not be expected to impact the adult population. In the first 2 years of the larval and small-bodied fish study conducted from Lava Falls (RM 180) to Pearce Ferry above Lake Mead (RM 280), indicated that reproduction may be occurring (larval humpback chub with yolk sac attached).

No population-scale impacts on humpback chub would be expected, and the study may provide important information for conservation of the species in the western Grand Canyon.

Nonnative Species Conservation Measures

Nonnative fish will continue to threaten humpback chub in the Grand Canyon under the LTEMP preferred alternative. Under the continued colder temperature regimes and clear water that result from dam construction and operations, particularly in Glen and Marble Canyons, nonnative cool-/coldwater species are expected to proliferate and continue to prey upon and compete with humpback chub. Brown trout are a particular threat due to their piscivorous nature

(Yard et al. 2011; Whiting et al. 2014). However, with continued basin-wide drought, and lower Lake Powell levels, warmer water releases from Glen Canyon dam are expected occasionally. For example, in late fall 2015 (November) water released from Glen Canyon dam approached 15°C, which is within the range of suitable temperatures for smallmouth bass spawning. In addition, temperatures in western/lower Grand Canyon reached or exceeded 20°C in 2015. Warmer temperatures may allow for highly piscivorous warmwater nonnative species such as smallmouth bass to proliferate in the project area. Smallmouth bass were identified as a major threat to native fish in the Yampa River, and have caused major declines and extirpation of humpback chub there (Johnson et al. 2008).

Conservation measures that were developed to specifically address nonnative species threats to humpback chub include (a) continued nonnative trout (brown and rainbow) removal efforts at Bright Angel Creek and its inflow, or other areas where expanded populations have been found; (b) feasibility study, and planning, and compliance for chemical piscicide renovation at Bright Angel and Shinumo creeks; (c) study of efficacy of a temperature control device on the dam to address future conditions under climate change; (d) potential research and development of a means to prevent passage of warmwater nonnative fish through Glen Canyon Dam; (e) planning, compliance, and implementation of a plan to address (make less suitable) the suitability of warmwater nonnative fish habitat in a slough below Glen Canyon dam; and (f) completion of a plan for rapid response to nonnative fish invasions, using tools not approved in the NPS CFMP (e.g., chemicals). Finally, the use of flows (e.g., TMFs) to inhibit brown trout spawning and recruitment in Glen Canyon, or other mainstem locations, will be explored over the life of the LTEMP. This measure is necessary to prevent recently detected spawning of brown trout in Glen Canyon from further expanding or increasing in abundance.

Control of brown and rainbow trout in Bright Angel Creek and the Bright Angel Creek inflow reach of the Colorado River would be continued under the proposed action. In 2017, results of control efforts implemented between 2012 and 2017, including trends in abundance of both native and nonnative fish, would be reviewed, and methodology for continued control efforts may be adapted to ensure trout control objectives are met. Brown trout catch-per-unit effort in the Colorado River outside of Bright Angel Creek appears to have declined in recent years (Stewart 2016), concurrent with trout control activities, and declines of brown trout abundance and biomass in Bright Angel Creek (Nelson 2016). Brown trout are defined as high-risk nonnative predators (NPS 2013), and continued control in and around Bright Angel Creek—and in other areas where they expand—would minimize a major threat to humpback chub by reducing predation risk. Long-term beneficial impacts for humpback chub would be expected as a result of continued control of brown trout and reduced predation risk.

The other nonnative fish conservation measures could all lead to beneficial impacts on humpback chub as a result of reduced the risk of invasion and establishment of warmwater nonnative species. The outcome will depend on the effectiveness of the actions, including whether feasible options are developed to manage slough habitat and prevent the passage of warmwater nonnative fish through the dam; no technology currently exists for this.

3.2.1.10 Effects of New Conservation Measures

New conservation measures for humpback chub will explore additional tributaries for potential translocations including consulting with the Havasupai Tribe for potential translocations above Beaver Falls in Havasu Creek. Razorback sucker measures will include continued monitoring of larval and small-bodied fish; these measures will determine the extent of hybridization of flannelmouth and razorback sucker larvae from the western Grand Canyon through genetic analysis. Additional measures to address nonnative fish include evaluation of new technologies for temperature-controlled releases from the dam and methods to prevent fish passage through the dam. Reclamation will support planning and compliance for the development and implementation of a rapid response control effort for new and established nonnative invasive species. This includes modifying the backwater slough at RM 12 to prevent establishment of warmwater invasive species. Reclamation will also explore the use of flow such as TMFs to inhibit brown trout spawning and recruitment in mainstem locations.

3.2.1.11 Effects of Native and Nonnative Plant Management Experimental Actions

Under the proposed action, exotic plant species that are spread or favored by dam operations would be mechanically removed, and potentially treated with herbicides, in selected areas within the project area.

Herbicides may be poisonous to fish and aquatic species; however, standard practices for herbicide application would be followed. This would minimize any risk of impacts on humpback chub or their habitat as a result of contact with the chemicals.

3.2.1.12 Effects of Activities to Preserve and Protect Historic Properties and Cultural Sites

Under the preferred alternative, various mitigation and erosion control measures would be implanted at cultural sites along the river corridor. Sites that would be treated would generally be located above the Colorado River high water mark and outside of humpback chub habitat. Thus, these activities would be expected to have no impacts on humpback chub individuals or habitat.

3.2.1.13 Effects of Climate Change

Climate change and drought have direct influences on hydrologic patterns and water temperature, thus impacting humpback chub. In the Colorado River Basin, hydrologic impacts include lower precipitation and decreased inflow to the reservoir system, resulting in more frequent lower reservoir release volumes, which could potentially impact shoreline habitats and riparian areas. More frequent droughts and warmer atmospheric temperatures have the potential to result in warmer water being released from the dam. Although this may improve thermal suitability for humpback chub, any subsequent benefits may be offset by increased abundance

and expansion of warmwater nonnative fish and aquatic fish parasites (see Section 3.6). Uncontrolled warmer water releases may occur as a result of the elevation and subsequent water temperature of withdrawals from Lake Powell. Increased temperatures may allow numbers and species of warmwater nonnative species to increase in the system.

Springs that supply the Little Colorado River within critical habitat may be vulnerable to basin-wide drought and climate change impacting overall habitat availability and the largest self-sustaining population for the species.

3.3 EFFECTS OF THE PROPOSED ACTION ON RAZORBACK SUCKER

The evaluation of potential impacts of the proposed action on razorback sucker included consideration of the results of previous investigations of the species' ecology (Albrecht et al. 2014; Kegerries et al. 2015), as well as studies of the effects of nonnative fish (Coggins et al. 2011; Yard et al. 2011; Whiting et al. 2014), experimental flows (such as HFEs and other flows) and water temperature on native fish and native fish habitat (e.g., Grams et al. 2010; Makinster et al. 2011; Trammell et al. 2002; Ward 2011; Ward and Morton-Starner 2015).

Several aspects of the proposed action may affect razorback sucker directly or indirectly through direct impacts on individuals or habitat; or indirectly by influencing the abundance and distribution of nonnative predators and competitors, or by influencing macroinvertebrate production. Dam operations have the potential to influence river temperatures, the quantity and quality of nearshore rearing habitats (e.g., backwaters), aquatic insects that are food for razorback sucker, and nonnative species abundance; operations may also result in direct mortality to larval or juvenile razorback sucker through stranding. Flow-related actions are analyzed below that may impact razorback sucker; these include base operations, sediment-related experiments, and aquatic resource experiments including trout management flows, low summer flows, and sustained low flows for benthic invertebrate production. Because identified impacts of operational flexibility under current dam operations have been identified for native fish, no effects are expected that are not considered for other dam operations. Other non-flow actions, which may impact razorback sucker directly or indirectly and are analyzed below, include mechanical removal of nonnative fish, conservation measures, and continued fisheries research and monitoring under the GCDAMP. Some actions may have negative impacts on individuals, but beneficial effects at a population level.

Efforts to manage riparian vegetation, humpback chub translocations, and sediment monitoring and research are not expected to have impacts on razorback sucker individuals or habitat. Riparian vegetation management would occur in only small, localized areas within the project area. Although riparian vegetation can play an important role in small stream ecosystems, particularly in providing cover, shade, or habitat for terrestrial invertebrates for fish to feed upon, riparian vegetation is less important in larger rivers for providing cover, shade, or energy inputs (Vannote and Sweeney 1980). Thus, riparian vegetation management would have large impacts on the razorback sucker and the species' habitat in the Colorado River.

3.3.1 Direct and Indirect Effects

3.3.1.1 Effects of Base Operations

Base dam operations are expected to change with the implementation of the proposed action. Changes will include more consistency across months, and thus more stability throughout the year, in monthly dam release volumes. The daily fluctuation in discharge would be proportional to the volume (i.e., lower fluctuations during lower flows), with a maximum discharge fluctuation range of 8,000 cfs; this would be the same as the current maximum fluctuation range. The daily downramp rate would be increased, compared to the current condition, by 67% (from 1,500 cfs/hr to 2,500 cfs/hr). Under base operations, year-round, fluctuating flows throughout the life of the LTEMP period may have detrimental, long-term direct impacts on juvenile razorback sucker and rearing habitat, razorback back sucker spawning habitat, and aquatic invertebrate prey (food base).

Stranding of fish is a potential outcome of daily hydropeaking (reviewed in Bunn and Arthington 2002; Nagrodski et al. 2012). Increasing downramp rates under the preferred alternative may increase the risk of stranding larval razorback sucker. Thus far, juvenile (older than larval) life stages of razorback sucker have not been sampled in 2 years of study in the Grand Canyon (Albrecht et al. 2014, Kegerries et al. 2015). It is unclear whether larval razorback sucker experience near 100% mortality prior to transformation to juveniles, or if larvae drift to Lake Mead and rear in the lake. Thus, effects are mainly discussed for larval age classes. Stranding could include fish being temporarily (i.e., until flows came back up hours later) restricted to isolated habitats away from the main channel, which may or may not become desiccated, as a result of dropping water levels. Desiccation of these isolated habitats would result in fatality of any larval razorback sucker present. Factors that may influence the probability of stranding fish in a river with altered flow regimes, such as below hydroelectric plants, include the rate of flow reduction, water temperature, channel geomorphology, and substrate composition, as well as biotic factors including fish life stage and size (reviewed in Nagrodski et al. 2012). Larval razorback sucker have limited swimming ability, and thus are at risk of stranding. Increasing drawdown rates under the preferred alternative will increase the risk of fatality. Larval sampling in the lower Grand Canyon found razorback sucker larvae to be distributed throughout most shoreline habitats from Lava Falls to Pearce Ferry from May to July. The highest densities of larvae were found in isolated pools, which composed less than 2% of all habitats sampled. These pools have a high likelihood of desiccation with daily flow fluctuations; however, survival rates among different habitats have not been studied. The potential for, and the effect of stranding on, individual razorback sucker survival has not been directly investigated; however, a summary of stranding literature indicated that fish stranding as a result of hydroelectric and irrigation projects is well documented (Nagrodski et al. 2012).

Razorback sucker spawn on cobble bars and other gravel substrates near or associated with riffles. Riffles and spawning bars may occur in wider, shallower areas of the channel. Therefore, they are susceptible to flow fluctuations. Continued daily flow fluctuations combined with increased downramp rates will likely increase the risk of desiccation of spawning areas and

incubating razorback sucker eggs, leading to increased mortality rates of eggs. Adult razorbacks can swim off of bars as flows decline, and therefore are at less risk.

Under base operations, through the life of the implementation of the LTEMP preferred alternative, river temperatures are expected to continue to be more suitable for coldwater nonnative species than for warmwater nonnative fish, particularly closer to the dam. In general, the estimated average main channel temperatures modeled for the LTEMP EIS indicated that temperature conditions would be most suitable for warmwater nonnative species, as well as native fish such as razorback sucker at locations farther downstream from Glen Canyon Dam (e.g., RM 157 and RM 225) compared to upstream locations (e.g., RM 0 and RM 61), where temperatures would be more suitable to cold or coolwater nonnative fish (e.g., brown and rainbow trout); this is consistent with past surveys that have found more warmwater fish species in those areas than upstream.

Habitat requirements for the endangered razorback sucker, explained in detail in Section 2.1.3, are summarized here. Suitable water temperatures for spawning, egg incubation, and growth range from 14 to 25°C (FWS 2002b), with estimated optimal temperatures of 18°C for spawning, 19°C for egg incubation, and 20°C for growth (Valdez and Speas 2007). Hatching success is temperature dependent, with the potential for complete mortality occurring at temperatures less than 10°C (FWS 2002b). Young razorback suckers require nursery areas with quiet, warm, shallow water such as tributary mouths, backwaters, and inundated floodplains along rivers, and coves or shorelines in reservoirs (FWS 2002b). Razorback sucker are distributed within the project area, from the Colorado River inflow of Lake Mead and at least upstream as far as an area above Lava Falls in Grand Canyon. The upstream distribution of adult razorback sucker is unknown. During May of 2014, razorback sucker larvae were found in the Colorado River as far upstream as RM 173 (upstream of Lava Falls), which is the farthest upstream razorback sucker spawning has been documented in the Grand Canyon (Albrecht et al. 2014). Warm temperatures may be even more critical for larval razorback suckers than other native suckers to transform into juveniles (see Bestgen 2008). Therefore, continued cold temperatures under base operations during the LTEMP implementation period will continue to negatively impact razorback sucker over the long term. However, experimental stable flows may provide some benefit to offset these impacts (see the following sections).

As described for humpback chub, under base operations and fluctuating flows the food base will continue to be degraded throughout the life of the LTEMP.

In summary, under base operations and coldwater conditions, continued hydropeaking flows with increased downramp rates compared to the existing conditions will continue to degrade nearshore rearing habitats, prevent the establishment of aquatic invertebrates (food base), and increase the risk of stranding larval or juvenile razorback sucker in the long term (throughout the life of the LTEMP). In addition, daily fluctuating flows will degrade razorback sucker spawning habitat, river-wide, throughout the life of the plan.

3.3.1.2 Effects of Sediment-Related Experiments and Low Summer Flows

Base flow fluctuations may impact rearing habitat for larval or juvenile razorback sucker. Juvenile fishes in rivers generally rely on low-velocity nearshore environments for rearing. Backwaters potentially created by both HFEs and low summer flows are one such nearshore habitat frequently used by native fishes in the Grand Canyon, and these habitats and their use by native fishes have been a major focus of several investigations. For example, during and after the 2008 HFE physical scientists described the number and area of backwaters that were created during this flood disturbance, and documented how normal operations under MLFF eroded these features to pre-HFE levels within 6 months (Grams et al. 2010). These backwaters, although short lived, may provide ideal rearing conditions for native fishes because water temperatures are often much greater than in the mainstem, particularly when flows are steady. During the 2000 Low Steady Summer Flow experiment, which included steady flows of 8,000 cfs from June through September 2000, mainstem temperatures were 1.4–3°C higher than under previous dam operations, and backwaters were 0.3–5.3°C warmer (Trammell et al. 2002). Similarly, NPS sampling of 47 backwaters distributed from RM 115 to 220 under steady flows in September 2009 showed that at least 21 backwaters were at least 2°C warmer than the adjacent mainstem (Speas and Trammell 2009). The longer residence time of water in nearshore and backwater habitats with steady flows results in warmer temperatures than in the mainstem (Behn et al. 2010), potentially affecting rearing habitat for larval or juvenile razorback sucker.

Although very few studies in the Grand Canyon have specifically investigated razorback sucker habitat, biologists have demonstrated that densities of juvenile native fishes were greatest in backwater habitats compared to other habitats (Dodrill et al. 2015). However, in the Little Colorado River confluence reach where these investigations occurred, backwaters represent a small percentage of available nearshore habitat. Therefore, investigators concluded that maintenance of backwater habitats was not critical to the persistence of the Little Colorado River confluence aggregation of humpback chub. Nonetheless, no studies have evaluated habitat use by larval or juvenile native fishes in downstream reaches where backwaters are larger and more persistent than in the Little Colorado River confluence aggregation (Grams et al. 2010). Few studies have investigated the use of backwaters or other shoreline habitats that may be important to native fish rearing in the western Grand Canyon, where water temperatures are not ideal, but are more suitable for native fish rearing than closer to Glen Canyon Dam. However, shoreline habitats have the potential to provide warmer rearing habitat than the mainstem under certain conditions (Grams et al. 2010; Trammell et al. 2002). It is likely that prolonging the "turnover" of water in nearshore and backwater habitats with steady flows resulted in warmer temperatures than in the mainstem (Behn et al. 2010). Given the need for warm, productive floodplain or backwater habitats for rearing larval and juvenile native fishes, and the lack or low abundance of nonnative fish found in recent backwater sampling (Albrecht et al. 2014; Kegerries et al. 2015), reduced fluctuations, lower flows, or low summer flows may be beneficial for razorback sucker by providing warm and persistent backwater habitats. Thus, low summer flows included under the proposed action as an experiment after the first 10 years of the LTEMP period would likely increase warming and overall stability in these nearshore habitats, thereby benefitting razorback sucker in Grand Canyon. However, the implementation of the experiment may occur only under rare conditions. Benefits to razorback sucker would be minimal if the experiment was implemented only once or a few times in the LTEMP period.

Due to the impact that HFEs and low summer flows have on the creation and maintenance of backwater habitats important to larval or juvenile razorback sucker, these experiments would be expected to benefit razorback sucker in a similar manner to humpback chub. Low summer flows could potentially create or maintain warm backwater habitat beneficial to razorback sucker rearing. Spring HFEs may also create backwater habitat during a time period that may coincide with spawning and emergence of larval fish.

3.3.1.3 Effects of Low Steady Weekend Flows for Macroinvertebrate Production Experiments

Experimental low steady flows on weekends to attempt to increase macroinvertebrate production and diversity may benefit nearshore habitats by providing stability and some warming in habitats that are more isolated from the mainstem (low flows would be held steadier plus/minus 1,000 cfs fluctuation); however, this would be limited to approximately 34 days over the summer. This experiment will not be conducted during first 2 years of LTEMP. The goal is to replicate it two to three times to determine its effectiveness.

The scientific background for this experimental action is discussed in Section 1.2.12 (and see Kennedy et al. 2016). In addition to potential benefits of increased aquatic food base production, steady flows on weekends may help improve the quality of nearshore habitats for larval or juvenile razorback sucker. However, it is unclear whether 2 days per week of nearshore habitat stability will result in a measureable impact on juvenile growth, rearing, and recruitment. Nevertheless, it does not currently appear that razorback sucker are successfully recruiting from the larval to juvenile life stages, possibly due to cold temperatures and lack of stable rearing habitats. Because larval razorback sucker need stable, low-velocity, warm, productive habitats for rearing, a beneficial effect is expected under this experiment, combined with HFEs to build bars and backwaters.

Sustained low flows for benthic invertebrate production may benefit razorback sucker by providing additional aquatic insect prey and stable nearshore habitats for rearing 2 days per week. This treatment will be discontinued if there is no observed benefit to the food base, trout fishery, or native fish; if there is an increase in warmwater nonnative species or trout at the Little Colorado River; or if there are unacceptable adverse impacts on the trout fishery, humpback chub population, or other resources.

3.3.1.4 Effects of Trout Management Flow Experiments

The potential for TMFs to strand and cause mortality in razorback sucker would increase under the proposed action. The extent of mortality due to stranding of razorback sucker in a given year in Marble and Grand Canyons as a result of TMFs is unknown; it may depend on the quantity of channel margin habitats and their sensitivity to flow changes, the distribution and abundance of juvenile fish in sensitive habitats, the timing and number of TMFs, and the degree of flow attenuation downstream. TMFs could be implemented from May through August, which would overlap with the presence of larval razorback sucker. Given that razorback sucker

spawning was documented for the first time in in the study area in 2014 (and continued in 2015; Kegerries et al. 2015) and studies are ongoing, potential impacts on the species are particularly difficult to predict. Larval or juvenile razorback sucker may be particularly sensitive to the drastic and rapid fluctuations associated with TMFs, because those life stages may be more reliant than other native species on low-velocity backwater habitats. For example, in both 2014 and 2015, catch-per-unit-effort of razorback sucker larvae was higher in isolated pools and/or backwaters (Albrecht et al. 2014; Kegerries et al. 2015).

In addition, although the location or habitat preference for spawning adult razorback suckers has not been identified or defined in the Grand Canyon, the species is known to spawn on clean cobble bars in other systems (reviewed in FWS 2002b), and Valdez et al. (2012b) identified potential spawning bars in the Grand Canyon at tributary inflows and canyon mouths including Diamond Creek (RM 226), Spencer Canyon (RM 246), and Surprise Canyon (RM 248.3). These and other shallow cobble bars important for spawning and egg incubation may be sensitive to flow variation under the proposed action. Large fluctuations during the spawning period (February or March to July; Kegerries et al. 2015) associated with TMFs implemented between May and August may impact spawning and incubation habitat by dewatering.

In summary, TMFs will have negative, wide-ranging impacts on razorback sucker juveniles or larvae that would continue to occur for the duration of the action. Similarly to humpback chub, risk to razorback sucker would likely vary by location depending upon the level of stage changes experienced and the steepness of shallow nearshore areas. Monitoring of the impacts of trout management flows throughout GCNP would be implemented to assess the effectiveness of the action, as well as the detrimental impacts on native fish and other resources.

3.3.1.5 Effects of Triggered Conservation Actions and Mechanical Removal of Nonnative Fish Experiments

Under the preferred alternative, mechanical removal of nonnative rainbow and brown trout (and other nonnative predators) would be implemented through a triggered, tiered approach (see Appendix D) near the confluence of the Little Colorado River and the Colorado River if conservation actions designed to reverse declines in the Little Colorado River humpback chub aggregation were ineffective.

Razorback sucker have not been sampled near the Little Colorado River inflow since the 1980s or early 1990s. Although removal of nonnative fish would benefit razorback sucker, this action would likely have limited beneficial impacts on the razorback sucker. Warmer and more turbid waters characterize the lower Grand Canyon where evidence of razorback sucker spawning has been found. These areas are less suitable to trout, so removal of nonnative trout near the Little Colorado River would likely have negligible impacts on razorback sucker.

Similar, Tier 1 conservation actions developed to conserve humpback chub, including actions to enhance rearing and translocations, would have no impact on razorback sucker because actions would occur within the Little Colorado River and its inflow, and no negative impacts of humpback chub upon razorback sucker have been noted.

3.3.1.6 Effects of Conservation Measures

Conservation measures from the 2011 Biological Opinion were evaluated and adapted for the LTEMP, where necessary, and included in the preferred alternative. Some additional conservation measures were developed specifically for the LTEMP, and were incorporated into the preferred alternative. The intention of conservation measures is to mitigate or offset potential impacts on ESA-listed species that may result with the implementation of the LTEMP preferred alternative. These measures were developed in consultation with the FWS and biologists with the NPS. Effects on razorback sucker are discussed for each conservation measure below.

Humpback Chub Translocations, Disease, and Parasite Monitoring (in humpback chub), Humpback Chub Refuge, Mainstem Humpback Chub Aggregations

Humpback chub translocations may result in increased growth or improved rearing and survival of juvenile humpback chub, but would likely have minimal impacts on the razorback sucker. Although adult humpback chub may prey upon larval or juvenile native fish, it is unlikely that a population-level impact would be expected on suckers, including the razorback sucker. For example, as the translocated humpback chub population has grown in Havasu Creek, bluehead sucker have continued to recruit and possibly increase in number (Nelson et al. 2016).

Reclamation intends to fund the GCDAMP to conduct disease and parasite monitoring in humpback chub and other fish in the mainstem Colorado River, in addition to ongoing disease and parasite monitoring conducted by USGS/GCMRC in the Little Colorado River. No impacts on razorback sucker would be expected because no razorback sucker would be targeted for parasite monitoring.

A refuge population of humpback chub was established at the FWS SNARRC facility in Dexter, New Mexico. The goal of the refuge is to maintain a genetically diverse population of 1000 humpback chub to be used for propagation in the case of a catastrophic loss of the Grand Canyon population. As for disease and parasite monitoring, no effects on razorback sucker are expected because they would not be targeted for refuge development.

Conserving mainstem humpback chub aggregations was a focus of past conservation measures related to dam operations. In the LTMEP, Reclamation will continue to assist the FWS, NPS, and GDAMP to ensure that a stable or upward trend of humpback chub mainstem aggregations can be achieved. The impacts on individual razorback sucker that may occur as a result of monitoring are covered in Section 2.2.

Razorback Sucker Conservation Measures

Studies designed to understand the status of the razorback sucker population in the Grand Canyon and Lake Mead would continue with the implementation of the preferred alternative. Actions include (a) studies to determine the extent of hybridization in flannelmouth and razorback sucker larvae collected; (b) studies to determine habitat use and distribution of different life stages of razorback sucker to assist in future management of flows that may help to conserve the species (including identification of habitats sensitive to flow fluctuations), and (c) studies to assess the effects of trout management flows and other dam operations on the species.

Although some fatality of individual razorback sucker may occur as a result of these studies, including fatality of larval fish, as has occurred in 2014 and 2015 related to larval studies (Albrecht et al. 2014; Kegerries et al. 2015), the information gained will be critical to understanding population-level impacts on the species due to dam operations and experimental actions under the preferred alternative. The adaptive management structure of the LTEMP will allow for adjustments in management actions throughout the life of the LTEMP. Thus, negative effects on individuals would likely be offset by population-level benefits that may be expected if adjustments in operations are made as a result of these studies.

Nonnative Species Conservation Measures

Nonnative fish will continue to threaten razorback sucker in the Grand Canyon under the LTEMP preferred alternative. As a result of continued colder temperature regimes and clear water from of dam construction and operations, particularly in Glen and Marble Canyons, nonnative cool-/coldwater species are expected to proliferate and continue to prey upon and compete with native fish. However, razorback sucker may be more at risk from warmwater nonnative fish that may become established because they have been primarily found in the lower river. Warmer temperatures, which have been occurring in the lower river recently, may allow for highly piscivorous warmwater nonnative species such as smallmouth bass to proliferate. Smallmouth bass were identified as a major threat to native fish in the Yampa River, and have caused major declines in native fish (Johnson et al. 2008).

Conservation measures that were developed to specifically address nonnative species threats to humpback chub and, secondarily, to benefit razorback sucker, include (a) continued nonnative trout (brown and rainbow) removal efforts at Bright Angel Creek and its inflow, or other areas where expanded populations have been found; (b) feasibility study, and planning and compliance for chemical piscicide renovation at Bright Angel and Shinumo creeks; (c) study of efficacy of a temperature control device on the dam to address future conditions under climate change; (d) potential research and development of a means to prevent passage of warmwater nonnative fish through Glen Canyon Dam; (e) planning, compliance, and implementation of a plan to address (make less suitable) the suitability of warmwater nonnative fish habitat in a slough below Glen Canyon dam; and (f) completion of a plan for rapid response to nonnative fish invasions, using tools not approved in the NPS CFMP (e.g., chemicals). Finally, the use of flows (e.g., TMFs) to inhibit brown trout spawning and recruitment in Glen Canyon or other

mainstem locations will be explored over the life of the LTEMP. This measure is necessary to prevent recently detected spawning of brown trout in Glen Canyon from further expanding or increasing in abundance.

Among nonnatives present in the project area, rainbow trout recruitment and abundance would be the species most influenced by changes in dam operations. In the context of impacts on the razorback sucker, interactions between rainbow trout would be expected to be less frequent, because habitat for rainbow trout is less suitable where razorback sucker were found recently (Lava Falls to Lake Mead). Nevertheless, critical habitat for razorback sucker extends into Marble Canyon and the Paria River, where rainbow trout are abundant, and where razorback sucker were detected in the 1990s. As described above, trout emigration through Marble Canyon to the Little Colorado River reach may be higher under the proposed alternative. The magnitude of the impacts of rainbow trout on razorback sucker may depend on the extent of the current distribution of razorback sucker in upstream areas of the project area (currently relatively unknown, and habitat is less suitable), the effects of TMFs on trout recruitment, and the effectiveness of triggered mechanical removal in the vicinity of the Little Colorado River. However, TMFs may have a greater negative impact on larval or juvenile razorback sucker that prefer still, warmer, nearshore habitats in areas near Lava Falls and downstream, compared to the potential benefits of reducing rainbow trout through TMFs.

As discussed above for impacts on humpback chub, it is unclear what factors (e.g., potential flow regime changes) have influenced populations of brown trout within the project area and their expansion to Glen Canyon. Brown trout have the potential to impact razorback sucker more than rainbow trout; however, the species is primarily found near Bright Angel Creek, near Tapeats Creek, and recently expanding in Glen Canyon. The continuation of brown trout control efforts, as described under the NPS CFMP, would likely maintain low levels of brown trout near areas where their distribution overlaps with razorback sucker. In addition, because brown trout tend to be far-ranging, it is possible the reductions of brown trout at their source (Bright Angel Creek) could benefit razorback sucker in other areas of the canyon by reducing predation risk slightly. The mainstem area near Tapeats Creek is less suitable for trout due to increased turbidity, and it is unlikely that flow regime changes under the proposed action would influence brown trout in that area.

Warmwater nonnative fish are a primary threat to razorback sucker, range-wide (FWS 2002b). Since the 1990s, a shift in species composition from nonnative to native species for unknown reasons has been noted below Diamond Creek (reviewed in Kegerries et al. 2015). Nevertheless, modeled temperature suitability for warmwater nonnative species in the lower river (RM 157 or 225), where razorback sucker may be spawning, would be expected to change little compared to the baseline condition. Regardless, a response to new or expanded populations of warmwater nonnative fish may become necessary in the lower river in the future. The rapid response plan may allow for additional tools to suppress or remove warmwater nonnative fish, reducing negative impacts due to predation upon razorback sucker.

In summary, the nonnative fish conservation measures could all lead to beneficial impacts on razorback sucker by reducing the risk of invasion and establishment of warmwater nonnative species, or allowing for control of new invasions. The outcome will depend on the

effectiveness of the actions, including whether feasible options are developed for management of slough habitat, and prevention of passage of warmwater nonnative fish through the dam, for which no technology currently exists.

3.3.1.7 Effects of Climate Change

More frequent droughts and warmer atmospheric temperatures as a result of climate change and warmer water being released from the dam are likely to impact razorback suckers in the Grand Canyon. Razorback suckers are currently located in the lower reaches of the canyon where backwater habitat is more available. Warmer water temperatures may create more suitable habitat for larvae and juveniles. However, these effects may be offset by increased abundance and expansion of nonnative fish and aquatic fish parasites. In addition, lower reservoir releases may result in fewer backwater habitats available for spawning and rearing of razorback sucker.

3.4 EFFECTS OF THE PROPOSED ACTION ON SOUTHWESTERN WILLOW FLYCATCHER

The southwestern willow flycatcher nests and forages in habitats ranging from dense, multi-storied riparian vegetation (such as cottonwood/willow stands with a mix of trees and shrubs) to dense tamarisk stands with little layering of vegetation. However, changes in the availability of suitable habitat may not necessarily translate into changes in the southwestern willow flycatcher populations. Despite the abundance of woody riparian vegetation (e.g., tamarisk) since construction of the Glen Canyon Dam, numbers of nesting southwestern willow flycatchers in the Grand Canyon have declined since the 1980s and no nests have been confirmed in the Grand Canyon since 2007 (Stroud-Settles et al. 2013). Consequently, the effect of the proposed action will have no effect on willow flycatchers because they do not occur in the Grand Canyon; however, the proposed action may have effects on habitat the flycatchers could potentially occupy.

The proposed action features several types of HFEs: (a) proactive spring HFEs, (b) sediment-triggered spring HFEs, and (c) sediment-triggered fall HFEs. Proactive spring HFEs in April, May, or June coincide with the nesting period of the southwestern willow flycatcher. However, these flows are only anticipated to occur approximately two times (10%) during the 20-year life of the LTEMP. These HFEs could coincide with the southwestern willow flycatcher nesting period (May and June). However, southwestern willow flycatcher nests in the Grand Canyon have typically been located above the elevation of 45,000 cfs (Gloss et al. 2005), the maximum HFE flow. The action proposes approximately <5 years (<25%) of spring HFEs triggered by sediment loading. However, these HFEs occur in March or April, prior to nest initiation for the southwestern willow flycatcher and would have no direct impact on the species. Both types of HFEs that occur in the fall (sediment triggered and extended duration) occur long after nesting and fledging dates of the southwestern willow flycatcher and would have no direct impact on the species.

This action is not expected to result in important structural changes in riparian habitat or vegetation productivity that could affect the southwestern willow flycatcher. In addition, invertebrates with only terrestrial life stages are not expected to be affected. The action should result in no impacts on the southwestern willow flycatcher's ability to forage effectively and sustain a nest.

Low summer flows, if tested, would occur for 3 months (July, August, and September). This test could overlap with the nesting period (May to August) during the months of July and August. Low summer flows have monthly average low flows of 10,000 cfs or more during the nesting period, which could sustain some inundated riparian nesting habitat, depending on the topography. Low summer flow experiments under this alternative are not expected to have long-term effects on nesting habitat.

The effects of climate change and continued dry basin hydrology may further diminish habitat for the flycatcher, due primarily to lower water levels within riparian areas.

3.5 EFFECTS OF THE PROPOSED ACTION ON YUMA RIDGWAY'S RAIL

Yuma Ridgway's rail nests can be found on small raised mud hummocks, or in the crotches of small shrubs, just above water in dense cattail and tamarisk habitat (Abbott 1940). The Grand Canyon has very little true cattail/marsh habitat, but it does contain considerable stands of dense tamarisk, both near and in the water. However, most potential habitat in the lowest portion of the Grand Canyon where Yuma Ridgway's rails have been detected is now 10 feet or more above the flowing river level; this is a result of Lake Mead water levels dropping in recent years.

Although they are only anticipated to occur approximately two times (10%) during the 20-year life of the plan, this alternative features proactive spring HFEs in April, May, or June that coincide with the nesting period of the Yuma Ridgway's rail. This alternative also proposes approximately <5 years (<25%) of spring HFEs triggered by sediment loading. There is a possibility that these HFEs, when they coincide with the Yuma Ridgway's rail nesting period (April and May), could impact nests and suitable habitat if they are along the river edge. However, it is unlikely that the nests or habitat would be close enough to the river to be impacted by HFEs because HFEs have minimal stage change in this broad floodplain habitat for the rail. Both types of HFEs that occur in the fall (sediment triggered and extended duration) occur long after nesting and fledging dates of the Yuma Ridgway's rail and would have no direct impact on the species. Low summer flows would occur under this alternative. Lower flows during the May to August nesting and fledging period could impact Yuma Ridgway's rail habitat by decreasing the density of vegetation in the marsh habitat within the rail's preferred nesting and predator avoidance areas. Low summer flow experiments under this alternative are not expected to have long-term effects on potential Yuma Ridgway's rail habitat. Designated critical habitat for the Yuma Ridgway rail does not occur in the area of the proposed action. Effects of climate change and continued dry basin hydrology may further diminish habitat for the rail, due primarily to lower water levels within riparian areas.

3.6 CUMULATIVE EFFECTS

Cumulative effects include the effects of future state, local, private, or tribal management actions that may occur in the project area during the duration of the plan (20 years). Future federal actions that have not been previously approved are not included in this section because additional ESA Section 7 consultation would be required. For example, several federal actions are being planned that would require Section 7 consultation including continued permitting of the Navajo Generating Station and the Red Gap Ranch Pipeline. Existing or previously implemented actions are discussed in Section 2. The following projects were considered when analyzing cumulative effects of the proposed action, and other non-federal actions, upon endangered species.

3.6.1 Grand Canyon Escalade

The Navajo Nation has proposed a 420-ac development project, known as the Grand Canyon Escalade, on the Grand Canyon's eastern rim on the western edge of the Navajo reservation at the confluence of the Little Colorado and Colorado rivers. The development would include a 1.4-mi-long, eight-person tramway (gondola) to transport visitors 3,200 ft from the rim to the canyon floor. On the rim, the development would include retail shops, restaurants, a museum, a cultural/visitor center, a hotel, multiple motels, a lodge with patio, roads, and parking for cars and recreational vehicles. It would also include a restaurant, gift shops, an amphitheater, and a riverwalk (with an elevated walkway) along the canyon floor. Analysis for this project has not been conducted, so impacts have not been fully determined; however, the construction and operation of the Escalade project could result in adverse impacts on natural and cultural resources in the areas of the Little Colorado River confluence, wilderness, visual resources, and resources of importance to multiple Tribes. It could also result in beneficial impacts on the local economy through increased tourism and job creation. The Little Colorado River contains critical spawning habitat for humpback chub.

The Grand Canyon Escalade Project and its associated facilities near the confluence of the Little Colorado River could cause both a localized loss of wildlife habitat and source of wildlife disturbance due to human presence. Wildlife species in the Grand Canyon are currently exposed to various sources of man-made noise ranging from human conversation to aircraft flyovers. The potential effects of noise on wildlife include acute or chronic physiological damage to the auditory system, increased energy expenditures, physical injury incurred during panicked responses, interference with normal activities (e.g., feeding), and impaired communication (AMEC Americas Limited 2005). The response of wildlife to noise would vary by species; physiological or reproductive condition; distance; and the type, intensity, and duration of the disturbance. Regular or periodic noise could cause adjacent areas to be less attractive to wildlife and result in a long-term reduction in use by wildlife in those areas. Responses of wildlife to disturbance often involve activities that are energetically costly (e.g., flying or running), altering their behavior in a way that might reduce food intake, communication, and nesting (Hockin et al. 1992; Brattstrom and Bondello 1983; Cunnington and Fahrig 2010; Francis et al. 2009; Maxell 2000).

3.6.2 Uranium Mining on State and Private Lands

Uranium mining peaked in the 1980s in the Grand Canyon region, but there is now a renewed interest due to increases in uranium prices. Increased uranium mining (on state and private lands) could increase the amount of uranium, arsenic, and other trace elements in local surface water and groundwater flowing into the Colorado River (Alpine 2010). Uranium, other radionuclides, and metals associated with uranium mines can affect the survival, growth, and reproduction of aquatic biota.

Aquatic biota and habitats most likely to be affected during mine development and operation are those associated with small, ephemeral, or intermittent drainages. Impacts on aquatic biota and habitats from the accidental release of regulated or hazardous materials into ephemeral drainages would be localized and small, especially if a rapid response to a release is undertaken. The accidental spill of uranium ore into a permanent stream or river such as Kanab Creek would potentially pose a localized short-term impact on the aquatic resources. However, the potential for such an event is extremely low. Most ore solids would settle in the waterbody within a short distance from a spill site (Edge Environmental, Inc. 2009). It is expected that expedient and comprehensive cleanup actions would be required under U.S. Department of Transportation regulations and that an emergency response plan would be in place for responding to accidents and cargo spills (Edge Environmental, Inc. 2009). Overall, the potential for impacts on aquatic biota from an accidental spill would be small to negligible. Spencer and Wenrich (2011) estimated that if an ore load is washed into the Colorado River and is pulverized and dissolved (a scenario that is extremely unlikely to impossible), the uranium concentration in the river would increase from the current 4.0 ppb to only 4.02 ppb (undetectable against natural variations). Predicted no-chemical-effect concentrations for aquatic vascular plants, aquatic invertebrates, and fish are ≥5.0 ppb; the lowest chronic concentrations are well above that concentration (see Hinck et al. 2010). For these reasons, the impacts from uranium mining on aquatic biota in the Colorado River or its major tributaries would be localized and would not reduce the viability of affected resources.

In the past, uranium mining led to localized peregrine falcon nest failures in areas such as Kanab Canyon and its multiple side canyons, where numerous mining claims existed (Payne et al. 2010). Although 684,449 ac of federal land administered by BLM north of GCNP (North and East Parcels) and 322,096 ac of federal land administered by the USFS south of GCNP (South Parcel) was withdrawn from locatable mineral exploration and development (i.e., uranium mining), increased uranium mining on non-federal (state and private) lands remaining open to mining could locally affect wildlife habitat (e.g., habitat loss and fragmentation) and increase the amount of uranium, arsenic, and other trace elements in local surface water and groundwater flowing into the Colorado River (Alpine 2010). Edge habitat associated with uranium mines and associated access roads may provide habitat for brown-headed cowbirds (Payne et al. 2010), which are brood parasites of songbirds. In general, any impacts on wildlife from uranium mining would be localized and should not affect the viability of affected resources, especially with the use of best management practices to control mine discharges and proper mine reclamation.

3.6.3 Increased Municipal and Agricultural Water Demand

As the population in the Basin States grows and expands, municipal, industrial, and agricultural water demand continues to increase. A Reclamation study in 2012 showed that the demand for Colorado River Basin water may exceed demand before 2060 (Reclamation 2012b), which may result in lower Lake Powell levels and changes in flow, sediment, and water temperature regimes in the Grand Canyon.

Population and industrial growth, coupled with climate change, will act in concert to increase water demand in the region (Schindler 2001) and lower flows downstream of Glen Canyon Dam. This could stress existing riparian and wetland vegetation, leading to plant community alterations that would affect both wildlife habitats and the wildlife prey base. Climate change would not affect all wildlife species uniformly. Some species would experience distribution contractions and likely shrinking populations, while other species would increase in suitable areas and thus possibly experience increases in population numbers. Generally, the warmer the current range is for a species, the greater the projected distributional increase (or lower the projected loss) will be for that species due to climate change (van Riper et al. 2014).

3.6.4 Urban and Agricultural Runoff

Urban runoff, industrial releases, and municipal discharges are considered some of the leading nonpoint sources of contaminants to surface waters (EPA 2004). Areas of intensive agriculture can have an adverse effect on the water quality as a result of the salinity, nutrients, pesticides, selenium, and other trace elements that are common constituents in agricultural runoff. For example, elevated selenium found in aquatic organisms in Colorado River in Grand Canyon is thought to be partly due to agricultural runoff from areas with soils containing selenium (Walters et al. 2015). It is unclear how contamination due to agricultural and urban discharge may change in the future.

3.6.5 Nonnative Vegetation and Defoliating Nonnative Insect Expansion

The highly flammable tamarisk has created a fire hazard previously absent along the river. This threatens breeding bird populations, as well as other wildlife. In addition, if native or mixed habitat stands burn, monotypic tamarisk will likely recolonize, eliminating the crucial structure necessary for southwestern willow flycatchers and other nesting birds (e.g., thermal buffering through shading becomes insufficient and will be further exacerbated by warming climate trends) (Schell 2005). Additional factors that could affect riparian wildlife habitat include the tamarisk leaf beetle and splendid tamarisk weevil, which occur along much of the Colorado River below Glen Canyon Dam and result in defoliation and mortality of tamarisk. Widespread tamarisk mortality would likely result in a net loss in riparian habitat for at least a decade or more (Paxton et al. 2011). It seems unlikely that the effects of large-scale defoliation in areas dominated by tamarisk will be compensated for by use of tamarisk beetles as a food resource by birds (Puckett and van Riper 2014).

3.6.6 Cumulative Effects Summary

3.6.6.1 Aquatic Species – Humpback Chub, Razorback Sucker, and Kanab Ambersnail

The incremental effects of the LTEMP proposed action on razorback sucker and humpback chub are not expected to contribute significantly to cumulative impacts along the Colorado River corridor or within the basin at large. Examination of the various hydrologic traces used to model effects of the proposed action on aquatic resources indicated that hydrology (i.e., whether a 20-year trace was drier or wetter on average) had a greater influence on the model results than did the operational differences among alternatives. Similarly, climate change has the potential to have greater effects on fish resources than any of the alternatives because of its direct influences on hydrologic patterns. For example, more frequent droughts and warmer atmospheric temperatures have the potential to result in greater increases in the temperature of water being released from the dam than the operational actions being considered, and this in turn may improve thermal suitability for humpback chub, humpback chub aggregations, and native fish. However, any subsequent benefits may be offset by increased abundance and expansion of nonnative fish and aquatic fish parasites. There are a number of other actions being taken within the Colorado River Basin that could also contribute to significant cumulative effects on fish populations or fish communities. For example, actions to increase the number of self-sustaining populations of humpback chub within the basin (e.g., translocation of humpback chub from the Little Colorado River to other tributaries within the Grand Canyon) have the potential to increase overall numbers of humpback chub and could provide some level of protection against catastrophic events in the Little Colorado River that could greatly reduce or eliminate the population of humpback chub in the Grand Canyon.

3.6.6.2 Wildlife

The effects of the LTEMP proposed action on wildlife are relatively small compared to the effects of other factors, especially future hydrology, and they are not expected to contribute significantly to cumulative impacts along the Colorado River corridor or within the basin at large. The proposed action would have little effect on most wildlife species.

3.6.7 Summary of Climate-Related Changes

The general picture for climate change as it relates to Colorado River Basin hydrology includes decreased inflow to the reservoir system (e.g., lower precipitation) and greater losses (e.g., evapotranspiration associated with higher temperatures and increased demand from the growing population). Climate change is expected to result in more frequent and severe drought conditions in the Southwest. Meeting increasing water needs (e.g., the Lake Powell Pipeline project and the Page-LeChee water supply project) will likely lead to lower reservoir levels in Lake Powell, which may already be affected by increased evaporation associated with higher air temperatures. As discussed in the baseline, the decreasing the elevation of Lake Powell can lead

to warmer water discharges from Glen Canyon Dam and increased water temperatures downstream.

Water discharge from springs supports the vegetative habitat upon which Kanab ambersnail relies. Changes in spring discharge due to reduced snowpack, in addition to impacts of HFEs, may further reduce habitat at Vaseys Paradise. The Southwest is already experiencing the effects of climate change (Garfin et al. 2014). The decade from 2001 to 2010 was the warmest on record, with temperatures almost 1.1°C higher than historic averages (Garfin et al. 2014; World Meteorological Organization 2014). Higher temperatures in the Colorado River Basin have resulted in less precipitation falling and being stored as snow at high elevations in the Upper Basin (the main source of runoff to the river), increased evaporative losses, and a shift in the timing of peak spring snowmelt (and high streamflow) to earlier in the year (NAS 2007; Christensen et al. 2004; Jacobs 2011). Such effects are likely to continue well into the foreseeable future (NAS 2007).

Warmer water temperatures would likely increase production rates of algae and invertebrates (Woodward et al. 2010; FWS 2011c). Lower water levels in Lake Powell may also result in increases in the composition and density of zooplankton downstream of Glen Canyon Dam, because waters would be withdrawn closer to the surface (Reclamation 1995). However, warmer temperatures, particularly in winter, may allow many invertebrate species to complete their life cycles more quickly (Schindler 2001). For example, if stream temperatures are raised by only a few degrees in winter, many aquatic insects that normally emerge in May or June may emerge in February or March and face death by freezing or be prevented from mating because they are inactivated by low air temperatures. In addition, increases in stream temperatures may cause an exaggeration in the separation of the emergence of males and females (e.g., males may emerge and die before females emerge) (Nebeker 1971). Temperatures above the optimum can lead to the production of small adults and lower fecundity (Vannote and Sweeney 1980).

Warmer water temperatures can expand the distribution of nonnative species adapted to warmer temperatures. This includes fish parasites such as the Asian tapeworm, anchor worm, and nonnative crayfish. Increased zooplankton due to climate change may increase abundance of cyclopoid copepods. All cyclopoid copepod species appear to be susceptible to infection by, and therefore serve as intermediate hosts for, the Asian tapeworm (Marcogliese and Esch 1989). Crayfish can prey on fish eggs and larvae and can diminish the abundance and structure of aquatic vegetation such as filamentous algae through grazing (FWS 2011c). Nonnative crayfish are present in Lake Powell (northern or virile crayfish [*Orconectes virilis*]) and Lake Mead (red swamp crayfish [*Procambarus clarkii*]). Warmer temperatures may allow the crayfish to expand into the mainstem of the Colorado River either downstream of Lake Powell or upstream of Lake Mead.

Higher temperatures in the Colorado River Basin have resulted in less precipitation falling and being stored as snow at high elevations in the Upper Basin (the main source of runoff to the river), increased evaporative losses, and a shift in the timing of peak spring snowmelt (and high streamflow) to earlier in the year (NAS 2007; Christensen et al. 2004; Jacobs 2011). These effects in turn have exacerbated competition among users (farmers, energy producers, urban dwellers), as well as effects on ecological systems, during a time when due to a rapidly

rising population water demand has never been higher (Garfin et al. 2014). The combination of decreasing supply and increasing demand will present a challenge in meeting the water delivery commitments outlined in the Colorado River Compact of 1922 (apportioning water between the Upper and Lower Basins) and the United States–Mexico Treaty of 1944 (which guarantees an annual flow of at least 1.5 million ac-ft to Mexico). In 2007, DOI adopted interim guidelines (Reclamation 2007a) to specify modifications to the apportionments to the Lower Basin states in the event of water shortage conditions.

Changes in temperature and precipitation patterns attributed to climate change could also take a toll on the region's rich diversity of plant and animal species (e.g., widespread loss of trees due to wildfires).

As described above, depending on the extent of drought in the Colorado River basin, lower Lake Powell levels may result in the discharge of warmer than anticipated water into Glen and Grand Canyons. This could increase the likelihood that warmwater nonnative predators will become established.

4 CONCLUSIONS AND DETERMINATIONS OF EFFECT

A summary of effects determinations for the five listed species is presented in Table 6. Analysis of effects determination are based 50 CFR 402.02, in which "[e]ffects of the action refers to the direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action, that will be added to the environmental baseline. The environmental baseline includes the past and present impacts of all Federal, State, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early section 7 consultation, and the impact of State or private actions which are contemporaneous with the consultation in process."

4.1 LISTED SPECIES DETERMINATIONS

For the purposes of Section 7 consultation under the ESA, the following definitions are used when determining the level of anticipated effect for each listed species and its habitat (FWS and NMFS 1998a).

No effect: The proposed action will not affect listed species or designated critical habitat.

May affect, but is not likely to adversely affect: Effects of the proposed action on listed species is expected to be discountable, insignificant, or completely beneficial.

- Discountable effects are those extremely unlikely to occur. Based on best judgment, a person would not (1) be able to meaningfully measure, detect, or evaluate insignificant effects; or (2) expect discountable effects to occur.

- Insignificant effects relate to the size of the impact and should never reach the level where incidental take may occur.

- Beneficial effects are contemporaneous positive effects without any adverse effects on the species. In the event that the overall effect of the proposed action is beneficial to the listed species, but also likely to cause some adverse effects, then the proposed action "is likely to adversely affect" the listed species.

May affect, and is likely to adversely affect: Effects of the proposed action on listed species may occur as a direct or indirect result of the proposed action or its interrelated or interdependent actions, and the effect is not discountable, insignificant, or beneficial.

Jeopardize the continued existence of a species: Effects of the proposed action would be expected, directly or indirectly, to appreciably reduce the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species (50 CFR 402.02).

TABLE 6 Summary of Effects Determinations for the Five Listed Species

Determination	Basis for Determination
Humpback chub (*Gila cypha*)	
May affect, is likely to adversely affect	The stranding of young chub could occur during TMFs and downramp rates, but longer-term beneficial impacts on older age classes may result from reduced trout.
	Impacts on habitat include direct, minor, short-term reductions in nearshore habitat could occur in the vicinity of the Little Colorado River with changes in flow stage, but long-term benefit is expected from sand re-deposition that rebuilds and maintains nearshore and backwater nursery habitats. Base operations will continue to degrade the food base.
	Increased predation from expanded population of rainbow trout is expected under cold water discharge, especially with spring or multiple HFEs. Translocations, brown trout control, triggered mechanical removal, triggered proactive conservation actions, and other conservation measures may offset impacts at the population level.
Razorback sucker (*Xyrauchen texanus*)	
May affect, is likely to adversely affect	Potential for creation of warm, productive nursery habitats from increased reshaping of nearshore deposits and backwater development.
	Potential short-term dewatering of spawning areas during TMFs.
	Stranding of larval and young-of-year razorback sucker in nearshore habitats may occur as a result of TMFs and base operations (daily fluctuating flows, including increased downramp rates).
Kanab ambersnail (*Oxyloma kanabensis*)	
May affect, is likely to adversely affect	Potential habitat would be frequently inundated during HFEs that would occur almost annually.
	Proportionally less habitat area would be scoured and fewer snails would be displaced by lower magnitude HFEs.
	Sequential HFEs could re-inundate and scour primary habitat prior to full recovery from previous HFE.
Southwestern willow flycatcher (*Empidonax traillii extimus*)	
May affect, not likely to adversely affect	Not expected to be in the action area during the spring HFE release window (March–April) and high flows of 45,000 cfs or less are not likely to adversely affect their nesting and feeding sites.
Yuma Ridgway's rail (*Rallus obsoletus yumaensis*)	
May affect, not likely to adversely affect	Spring HFEs may flood nesting habitat; however, nesting habitat is rare, and likely above the level HFE effects due to dropping Lake Mead levels.

4.2 HUMPBACK CHUB

Based on the evaluation contained in this BA, Reclamation has determined that the proposed action **may affect and is likely to adversely** affect the humpback chub, and may adversely affect its designated critical habitat. This determination is based on adverse effects on habitat, related to fluctuating flows (increased downramp rates), the potential for increases in negative interactions with rainbow trout, and the potential for TMFs to impact larval and juvenile individuals occupying shallow stream margin habitats. Fluctuating flows under base operations would also continue to limit the diversity and abundance of aquatic invertebrate prey. These combined effects could result in lower survival of young fish and less recruitment to the adult population. The unintended consequence of an increased rainbow trout population that could result from HFEs, especially those in spring, would likely increase downstream dispersal of trout into the vicinity of the Little Colorado River where they could prey on and compete with young humpback chub. This effect would also reduce recruitment of humpback chub and possibly the overall population size. However, TMFs may also reduce negative effects on humpback chub related to downstream emigration and predation or competition by rainbow trout, but their effectiveness is uncertain. Mechanical control of nonnative fish would be initiated if adult or subadult humpback chub abundance declined, and proactive conservation actions to improve rearing fail to reverse population declines downstream of Glen Canyon Dam; this could reduce nonnative trout abundance and their effects on competition with and predation on humpback chub. Trout control in Bright Angel Creek and the Bright Angel inflow is also expected to reduce brown trout in the project area; however, the potential to control brown trout spawning in other areas is less certain.

The HFEs are also expected to have long-term beneficial effects on the humpback chub population. Although periodic high flows would likely temporarily affect habitat and reduce the food base, multiple HFEs would be expected to rebuild and maintain backwater habitats—so long as sufficient fine sediment was available—and stimulate productivity in backwaters and nearshore habitats. Experimental sustained low flows for benthic invertebrate production may improve the food base; however, the success of this experiment is highly uncertain. The number of consecutive HFEs that would benefit the ecosystem (e.g., rebuilding and maintenance of habitat, stimulate food base productivity) or adversely modify or alter the ecosystem from periodic scouring is unknown. In addition to the effects of low flows to benefit the food base, this will be investigated as part of the LTEMP.

Low summer flows could lead to stable, more productive nearshore habitats, increased likelihood of the establishment of a more diverse and productive food base, and warmer water temperatures in the Little Colorado River reach and further downstream, as well as contributing to enhanced growth rates of young humpback chub. However, this experimental treatment would be used only rarely, if a single test in the second 10 years of the LTEMP period proves it to be a useful tool for improving humpback chub habitat. It is thought that the potential benefit of an increase in temperature would be greatest if a water temperature of at least 14°C could be achieved, because these warmer temperatures could favor higher growth rates of humpback chub.

Finally, as described in Section 3.6.7 the potential for increased occurrence of new warmwater nonnative species' introductions may increase in the future as the likelihood of low Lake Powell levels increases with drought and expanded water use, or during LSF experiments. For example, it is likely that the establishment of green sunfish in a backwater slough in Glen Canyon was the result of fish passing through the Glen Canyon Dam (Ward 2015). There is a chance that over the life of the LTEMP, under extreme drought and low Lake Powell levels, dam release temperatures could reach temperatures suitable for reproduction of high-risk nonnative predatory species such as smallmouth bass (15°C). However, current temperatures are already suitable for many warmwater species in the lower river. The river temperature at the Lees Ferry gauge approached 15°C during the fall of 2015 (GCMRC 2016), and reached 20°C below Diamond Creek. Increases in smallmouth bass in the Yampa River have coincided with the decline of the humpback chub population; the threat smallmouth bass pose to humpback chub is thought to be 10 times greater than the threats posed by channel catfish and northern pike (Johnson et al. 2008).

4.3 RAZORBACK SUCKER

Reclamation has also determined that the proposed action **may affect and is likely to adversely** affect the razorback sucker, and may adversely affect its designated critical habitat. This determination is based on potential adverse effects of TMFs stranding juvenile or larval razorback sucker in nearshore habitats, and long-term, river-wide effects as the result of fluctuating flows under base operations, which will continue to compromise the diversity and abundance of aquatic insect prey and degrade nearshore habitats that are important for rearing. Spawning habitat (cobble bars and riffles) is also expected to be negatively affected by base flow fluctuations (including increased downramp rates) and TMFs. TMFs will be less likely to beneficially impact razorback sucker in the western Grand Canyon by reducing trout abundance in Glen and Marble Canyons, and may result in stranding of larval or young-of-year razorback sucker during the summer months. The impacts of TMFs on razorback sucker will be investigated in the LTEMP, and ongoing razorback sucker monitoring in the western Grand Canyon will assist in this investigation. In addition, TMFs could impact spawning habitat and incubating eggs in shallow cobble areas that are most susceptible to changes in flow. Increased downramp rates could also impact razorback sucker young-of-year.

The increased frequency of HFEs could lead to improved sediment conservation and backwater habitat maintenance, benefitting razorback sucker habitat. Increases in sediment load will temporarily increase turbidity, which larvae use as cover from predators (Kegerries et al. 2009). In addition, modeling the hydrology and temperature regime expected during the life of the LTEMP indicated an improvement in temperature suitability compared to the baseline condition at areas inhabited by razorback sucker (i.e., Diamond Creek). Improved backwater habitats, in addition to stability during low summer flows and low steady weekend flows for macroinvertebrate production, could benefit young-of-year as well; however, low summer flows would be implemented only rarely, and invertebrate flows would only be in place for a total of 34 days per summer.

4.4 KANAB AMBERSNAIL

Reclamation has also determined that the proposed action **may affect and is likely to adversely affect the Kanab ambersnail**. Although impacts from the proposed action related to habitat scouring during HFEs will be limited to the habitat near the river, the impact would occur almost annually, which would exceed the rate of habitat recovery (2.5 years). This impact will be limited to one of two populations of Kanab ambersnail. Nevertheless, habitat quality or quantity may decline as a result of the proposed action, in the context of climate change.

There is no designated critical habitat for this species, and this analysis did not evaluate primary constituent elements. This determination is based on short-term adverse effects on habitat and snails located in the inundation zone at Vasey's Paradise. Habitat and snails below the high-water line are expected to be scoured and transported downstream with little or no survival of snails. The proportion of habitat and the number of snails affected would vary with the magnitude of the high release. For the past HFEs, Reclamation has removed habitat and snails from the projected inundation zone. When the habitat was relocated, the vegetation recovered within about 6 months, but when the habitat was not relocated, recovery was delayed about 2.5 years.

4.5 SOUTHWESTERN WILLOW FLYCATCHER

Reclamation has determines the proposed LTEMP **may affect, but is not likely to adversely affect** the southwestern willow flycatcher and southwestern willow flycatcher habitat. This determination is based on the fact that nesting activity, nests, or young are not expected to be in the action area during any of the HFEs except the two proactive spring HFEs. In addition, high flows of 45,000 cfs are not likely to adversely affect the species nesting and foraging habitat. Designated critical habitat for the southwestern willow flycatcher does not occur in the area of the proposed action.

4.6 YUMA RIDGWAY'S RAIL

Reclamation has determined the proposed LTEMP **may affect, but is not likely to adversely affect** the Yuma Ridgway's rail and habitat. Designated critical habitat for the Yuma Ridgway's rail does not occur in the area of the proposed action.

The volume and duration of HFEs is determined by the amount of Paria River sediment that is available. Modeling indicates that the amount of sediment required to trigger spring HFEs will occur in about 26% (5 years) of the 20 years of the LTEMP period. Spring HFEs would occur in April, May, or June and may coincide with the nesting period of the Yuma Ridgway's rail. The Grand Canyon has very little true cattail/marsh habitat and it is unlikely that the nests or habitat would be close enough to the river to be impacted by HFEs because HFEs have minimal stage change in this broad floodplain habitat. In addition, due to dropping levels of Lake Mead, most potential habitat in the lowest portion of Grand Canyon where Yuma Ridgway's rails have been detected is now raised 10 ft or more above the flowing river level, and therefore is out of

reach of fluctuating flows, including HFEs. Any implementation of sediment-triggered spring HFEs will consider resource condition assessments and resource concerns using the interagency process described in Section 1.2.8.

PROPOSED ACTION TRIGGERS FOR THE MANAGEMENT OF HUMPBACK CHUB COLORADO RIVER, GRAND CANYON

This page intentionally left blank

APPENDIX D

DRAFT FINAL

Proposed Action Triggers for the Management of Humpback Chub

Colorado River, Grand Canyon

November 2015

Developed by an Ad Hoc group of Grand Canyon Aquatic Biologists from USFWS, USGS-GCMRC, AZGFD, NPS, USBR (Kirk Young, David Van Haverbeke, Scott VanderKooi, David Ward, Charles Yackulic, Mike Yard, Brian Healy, Melissa Trammel, David Rogowski, Marianne Crawford)

PURPOSE

Mechanical removal of nonnative species is a controversial issue in the Colorado River through Glen and Grand Canyons. A spring 2015 meeting of Grand Canyon biologists (NPS, USFWS, AZGFD, GCMRC) to assess current trout removal triggers resulted in a concept of early conservation measure intervention to maximize conservation benefit to humpback chub (HBC) and minimize the likelihood of mechanical predator removal.

Many factors affect HBC population dynamics such as water temperature, turbidity, and water volume in the Little Colorado River (LCR). This restrains available conservation actions that can be implemented in the event of a declining population of HBC. We can translocate juveniles and young of the year to other areas within and outside the LCR system, juvenile HBC can be head-started at a hatchery, and we can attempt to remove predators. Other conservation tools may include parasite control (although this is unlikely from a population standpoint), non-native fish control in the LCR, and protect from over-utilization for scientific purposes.

Methods to actively manage temperature releases from Glen Canyon Dam sediment augmentation below the Paria River are not included in the Long-Term Experimental Management Program (LTEMP), for Glen Canyon Dam. Inclusion of infrastructure options including these were eliminated from detailed study in the LTEMP alternatives for a variety of reasons. We mention them here because these methods may still represent the most important potential conservation tools that could be used for the long term conservation of HBC in Grand Canyon and the concepts should not be lost.

While healthy wildlife populations are rarely static, trigger objectives include prescribing actions to reverse/ameliorate impacts in order to maintain the LCR HBC population within an acceptable range; and, secondarily to reduce reliance on mechanical removal of predators. For the purposes of these triggers, it is assumed that the primary drivers of HBC population dynamics are interspecific interactions with non-native species, especially rainbow trout, and low water temperature in the mainstem of the Colorado River (Kaeding and Zimmerman 1983; Douglas and Marsh 1996; USFWS 2002; Coggins et al. 2011; Yard et al. 2011). It is suspected that cold water temperatures suppress growth and thus subject young HBC to predation for extended periods of time. The approach described here puts the emphasis on managing humpback chub as opposed to managing predators. Predator removal will only occur if other conservation measures do not appear to be effective in maintaining targeted HBC population levels.

Two Tier Approach

Two tiers of sequential actions were identified; the first would emphasize conservation actions that would take place early during an adult or sub-adult HBC population decline. The second tier would serve as a backstop prescribing predator removal (Threat Reduction) if conservation measures did not mitigate a decline in HBC abundance.

ACTION TRIGGERS

Tier 1 Trigger – Early Intervention Through Conservation Actions:

1a. If the combined point estimate for adult HBC (adults defined ≥200 mm) in the Colorado River mainstem LCR aggregation; RM 57-65.9) and Little Colorado River (LCR) falls below 9,000 as estimated by the currently accepted HBC population model (e.g., ASMR, multi-state).

-OR-

1b. If recruitment of sub-adult HBC (150-199mm) does not equal or exceed estimated adult mortality such that:

1) Sub-adult abundance falls below a three-year running average of 1,250 fish in the spring LCR population estimates.

-OR-

2) Sub-adult abundance falls below a three-year running average of 810 fish in the mainstem Juvenile Chub Monitoring reach (JCM annual fall population estimate; RM 63.45-65.2).

Tier 1 Trigger Response: Tier 1 conservation actions listed below will be immediately implemented either in the LCR or in the adjacent mainstem. Conservation actions will focus on increasing growth, survival and distribution of HBC in the LCR & LCR mainstem aggregation area.

Tier 2 Trigger - Reduce threat using mechanical removal if conservation actions in Tier 1 are insufficient to arrest a population decline:

Mechanical removal of nonnative aquatic predator will ensue:
If the point abundance estimate of adult HBC decline to <7,000, as estimated by the currently accepted HBC population model.

Mechanical removal will terminate if:

Predator index (described below) is depleted to less than 60 RBT/km for at least two years in the JCM reach and immigration rate is low (the long term feasibility of using immigration rates as a metric still needs to be assessed), or

Adult HBC population estimates exceed 7,500 and recruitment of sub-adult chub exceed adult mortality for at least two years.

If immigration rate of predators into JCM reach is high, mechanical removal may need to continue. These triggers are intended to be adaptive based on ongoing and future research (e.g.,

Lees Ferry recruitment and emigration dynamics, effects of trout suppression flows, effects of Paria River turbidity inputs on predator survival and immigration rates, interactions between humpback chub and rainbow trout, other predation studies).

ACTION TRIGGERS BACKGROUND AND RATIONALE

Tier 1 Trigger Target

Adult Humpback Chub population target: 9,000

Using an age-structured mark-recapture (ASMR) model, Coggins and Walters (2009) estimated the adult population of the LCR aggregation of HBC in 2008 was approximately 7,650 fish (6,000-10,000 fish considering a range of assumed mortality rates and ageing error). Using a multi-state model, Yackulic et al. (2014) obtained point abundance estimates of adult HBC between ~11,000-13,000 from 2009 through 2012. This increase in adult abundances roughly coincides with the significant increase of adult HBC that first appeared in the LCR post-2006 (Van Haverbeke et al. 2013). We suggest a population estimate of 9,000 adult fish as a desired future conditions target. Estimates falling below 9,000 would trigger additional conservation actions to increase recruitment until the HBC population recovered to 9,000 adult fish. A 9,000 adult chub target is below the most recent estimate of ~11,000-13,000 individuals and would preclude conservation measures from being initiated immediately, but also provides a "buffer zone" above 7,000 adult fish, at which point mechanical removal is warranted, as prescribed in the 2011 high flow Biological Opinion (USFWS 2011).

LCR and mainstem (LCR aggregation) population targets: 2,000 and 7,000 adult HBC, respectively

We separate the 9,000 total adult target number into an LCR component (2,000 adults), and a mainstem Colorado River component (7,000 adults). It is estimated that ~82% of adult HBC reside in the mainstem Colorado River during the non-spawning season (Yackulic et al. 2014, p. 1015). This proportion was based on estimates obtained during September/October 2011, so this proportion would be expected to vary, possibly considerably, on an annual basis. Nevertheless, objectives to maintain 2,000 adults in the LCR and 7,000 adults in the mainstem during the non-spawning season (i.e., September/October) are proposed. A desired target of 2,000 adults in the LCR is reasonable because the average fall population estimate for adults was 2,380 (SE = 518) from 2007-2014, compared to the average level of 789 adults (SE = 281) from 2000-2006 (Van Haverbeke et al. 2015).

LCR Humpback Chub recruitment target

To maintain a population of 2,000 adult HBC in the LCR during the non-spawning season, there must be sufficient recruitment of sub-adult chub (150-199 mm size class). We estimate that a sub-adult chub population of 1,250 fish annually, as measured during the annual spring spawning season in the LCR is sufficient to maintain the adult HBC target population. This number is derived from an assumption that the annual adult mortality rate in the LCR is estimated at 0.35 (Yackulic et al. 2014, updates Yackulic pers. com). Hence 2,000 x 0.35 = 700 new adults needed annually to replace adult mortality. To annually recruit 700 adults, we estimate that 1,250 sub-adults are annually needed (i.e., not all sub-adults will survive into adulthood). If annual mortality for sub-adults in the LCR is 0.44 (Yackulic et al. 2014, updates Yackulic pers. com.), then 700/(1-0.44) = 1,250 sub-adults needed to offset adult mortality. Hence, if the three-year

running average point population size of sub-adult chub measured during the spring season in the LCR drops below 1,250 fish, additional conservation measures would be triggered (Figure 1).

A three-year running average is used for sub-adults because production of younger life stages of HBC can be highly variable (Van Haverbeke et al. 2013). For long-lived species such as HBC, reduced recruitment of sub-adults in any one year can be compensated in subsequent years with increased recruitment. Three years is considered a reasonable timeframe from which to trigger actions to minimize large changes in adult HBC numbers.

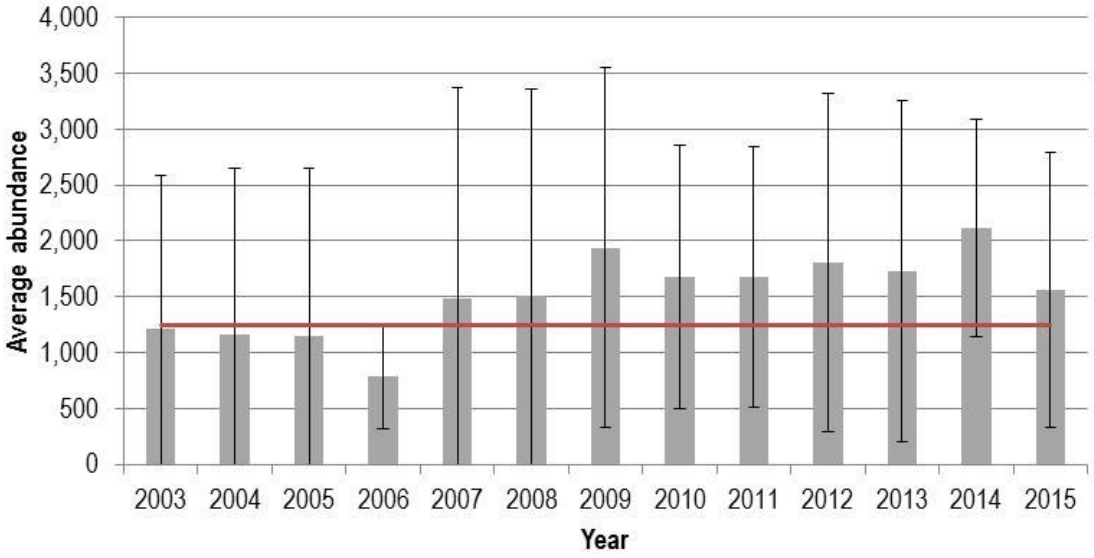

Figure 1. Running three year averages (± 95% CI) of sub-adult humpback chub abundances based on closed spring mark-recapture studies in the Little Colorado River (Van Haverbeke et al. 2013, 2015). For example, the bar for 2003 represents the average abundance of the 150-199 mm size class of humpback chub for 2001, 2002 and 2003 obtained in the Little Colorado River during spring monitoring (note: error bars are large because of typically large annual variability in the abundance of this size class). Additional conservation measures would have been triggered during 2003-2006. The red line represents a trigger value of 1,250 sub-adults, below which conservation measures would be initiated.

Mainstem LCR aggregation recruitment target

To maintain a population of 7,000 adults in the mainstem LCR aggregation reach outside of the spawning season, there must be sufficient recruitment of sub-adult fish (150-199 mm size class). The boundaries of the LCR aggregation in the mainstem traditionally extend from RM 57 (Malagosa Crest) to 65.9 (Lava-Chuar Rapid)(Valdez and Ryel 1995). Since 2009, most mainstem monitoring efforts in the LCR aggregation reach have focused in the JCM (Juvenile Chub Monitoring) reach (RM 63.45-65.2), which is below the LCR and contains ~18% of the adult HBC population found in the mainstem LCR aggregation reach (Yackulic et al. 2014). If ~18% of the population is in the JCM reach, then the desired number of adult chub to maintain in the JCM reach is 7,000 x 0.18 = 1,260 adults. Annual adult mortality in the mainstem LCR aggregation is estimated at 0.15 (Yackulic et al. 2014, updates Yackulic pers. com.). To replace the adults in the JCM reach each year would require 1,250 x 0.15 = 189 adults. Annual mortality of sub-adult chub in the mainstem is estimated at 0.3. Replacing 189 adults annually would require 189/(1-0.3) = 270 sub-adults. Approximately 1/3 of sub-adult chub grow to adult size each year, and accordingly it may take ~3 years1 for a chub in the mainstem to transition from

the sub-adult to the adult size class (Yackulic et al. 2014). Therefore an acceptable target population of sub-adults in the JCM reach each year would be 810 (270 x 3 = 810). As with the LCR component, a running three year average of <810 sub-adults in the JCM reach would trigger conservation actions (Figure 2).

The above scenario assumes that population recruitment dynamics are operating more or less equally throughout the LCR aggregation reach in the mainstem, which is likely not true. Most juvenile chub exiting the LCR are displaced downriver from the confluence (Valdez and Ryel 1995). As such, we might expect that recruitment into adulthood might be more prevalent downstream of the confluence. As such, the proportional number of sub-adults measured in the JCM reach may not reflect the number actually needed to annually replace a total 7,000 adults. In other words, the JCM reach proportional calculation of 810 sub-adults could be low. For example, consider that if the JCM reach harbors a higher than average percent of the mainstem sub-adult chub that recruit into adulthood, then even more than 810 sub-adults in this reach may be needed to maintain a population of 7,000 adults.

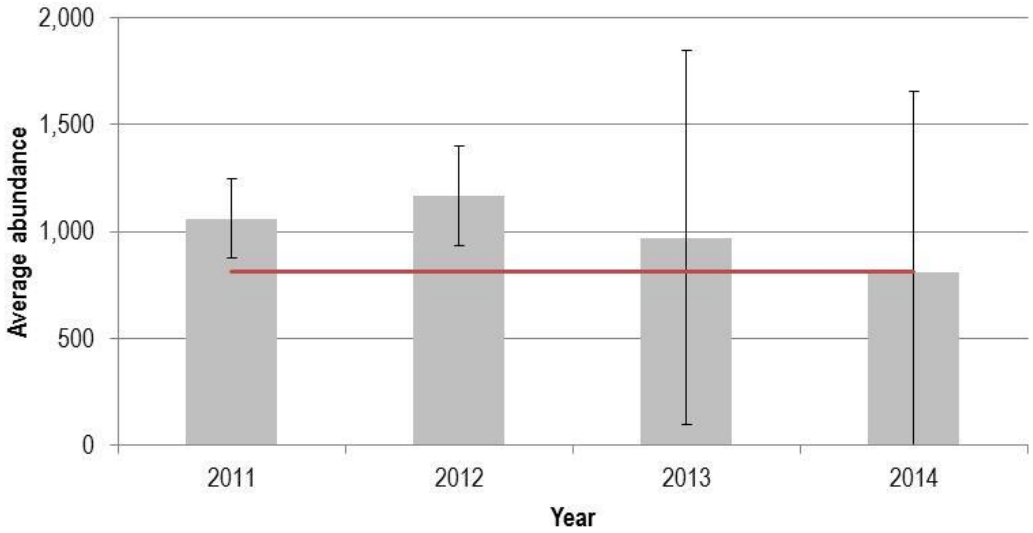

Figure 2. Running three year average abundances (± 95% CI) of sub-adult humpback chub (150-200 mm) abundances based on multi-state model in the mainstem Colorado River in the Juvenile Chub Monitoring reach (data from Yackulic pers. com.). For example, the bar for 2014 represents the average abundance of sub-adult humpback chub in the Juvenile Chub Monitoring reach during 2012, 2013, and 2014. The red line represents the approximate value of a 3-year running average of 810, below which conservation actions would be enacted.

[1]The mainstem LCR population recruitment scenario assumes temperature in the LCR mainstem reach is suitable for growth. If LCR mainstem temperatures are cold (do not exceed 11 oC during the year in the JCM reach), HBC will take longer to reach adulthood, experience greater mortality, and therefore require a larger number of sub-adults targeted to maintain the adult population objective. Target number adjustments will be made prior to implementation of LCR mainstem trigger actions if thought necessary.

Tier 1 Trigger response – HBC Conservation
It is expected that the conservation actions proposed below will assist in ameliorating HBC adult losses or recruitment failures from predation. First, ongoing translocations in the LCR above Chute Falls (~300 fish/year) as well as outside the LCR population (e.g., to Havasu Creek, etc.) will continue, regardless of Tier 1 triggers are met or not. New conservation actions will include expansion of existing activities coupled with experimental actions:

- LCR - Expand translocation actions in the LCR by collecting an additional 300-600 young of the year (YOY) HBC and move to above Chute Falls in October.

- LCR - Assess efficacy of transporting larval HBC (April/May) into Big Canyon and above Blue Springs in the LCR system. Evaluate growth and survival of these transplants;

- Mainstem LCR Aggregation - Larval fish will be removed from LCR (April/May) and head-started at Southwest Native Aquatic Resources and Recovery Center (SNARRC). Once fish reach 150-200 mm they will be translocated to the mainstem LCR reach the following year (currently grow-out space at SNARRC is limited to 750 HBC, use of fish for this purpose would reduce numbers available for other actions, e.g. Havasu, Shinumo.);

- Additional conservation actions as identified and evaluated.

Tier 2 Trigger Targets

Aquatic Predator index
A trout or aquatic predator index is proposed as a means to terminate mechanical removal should it become initiated. Essentially, this is the level (60 predator index fish/km in the JCM reach) at which mechanical removal becomes a futile exercise (i.e., very small return for a high amount of effort). The predator index concept was originally intended to serve as an index whereby mechanical removal would be initiated (e.g., mechanical removal would be initiated once trout levels reached a certain density (~760 index fish/km in the JCM reach). However, because of uncertainty of the actual predation rates of trout on HBC (at differing temperatures, densities, turbidities, etc.), and on its population level effects on HBC, determining an appropriate density of trout at which to initiate mechanical removal is highly uncertain.

A predator index will be developed in the JCM reach to weigh each probable predator by its ability to prey on HBC. The index calculates predator densities by incorporating additional species besides rainbow trout and makes assumptions about their relative predation rates compared to rainbow trout. For example, brown trout are estimated to be about 17 times more predacious on HBC than rainbow trout (Ward and Morton-Starner 2015). Additional predators (e.g., smallmouth bass) could be included through an assignment of their piscivory level relative to rainbow trout. Thus, relative piscivory can be captured in a rainbow trout equivalent predator index (Table 1). For species for which population estimates cannot be estimated with mark/recapture methods, capture probabilities or relative abundance (e.g. catch per unit effort) will be used to estimate the population and incorporate into the density matrix. Also, for certain

species regarded as potentially very piscivorous and dangerous (e.g., small mouth bass, green sunfish), targeted removal efforts for these species may be initiated immediately, regardless of meeting any type of threshold. If initiated, mechanical removal would be terminated once the relative predator index declines to 60 in the JCM reach for two years or HBC recover to a target level. A predator index of 60 in the JCM reach likely represents a point at which there is very diminished return for effort expended, and is roughly equivalent to densities at which mechanical removal was deemed to be not worthwhile as an effective tool to pursue in the past (i.e., mechanical was terminated).

Table 1. Hypothetical predator index. The predator index assigns a relative piscivory rate of 17 to brown trout (Ward and Morton-Starner 2015) and to smallmouth bass (assumed at brown trout rate) and sums the hypothetical numbers of fish. If initiated, mechanical removal would be terminated once the relative predator index declines to 60 in the JCM reach for two years or HBC recover to a target level.

Species	Number	Relative predation factor	RBT equivalent
Brown Trout	21	17	357
Rainbow trout	400	1	400
Smallmouth Bass	1	17	17
Predator index total			774

HBC population level triggers
Continue to use the existing adult HBC population estimate of 7,000, as the trigger for predator removal actions, as stated in the 2011 Biological Opinion (USFWS 2011). Population estimates of sub-adults are not incorporated in Tier 2 triggers, as in Tier 1 triggers.

Tier 2 Trigger response – Threat Reduction.
Mechanical removal of predators from the LCR aggregation reach (& immediate vicinity) will be conducted.

TRIGGER CAVEATS

- If HBC decline and the identified actions are not working, USFWS, in coordination with action agencies and traditionally associated Tribes, will identify future appropriate actions;

- Triggers will be reviewed and modified as necessary (evaluated; new information considered and included; etc.), but no less than every five years;

- Actions and triggers will need to adapt if HBC are found to be impacted by other factors;

- If estimating abundances of small size classes of chub becomes problematic because of population decline (i.e., if numbers get so low capture probability cannot be estimated for

each trip), catch divided by the best estimate of capture probability will be used to estimate abundance.

HIGH-FLOW EXPERIMENT PROTOCOL FOR THE PREFERRED ALTERNATIVE

This page intentionally left blank

APPENDIX P:

HIGH-FLOW EXPERIMENT PROTOCOL FOR THE PREFERRED ALTERNATIVE

High-volume dam releases for sediment conservation are an experimental action that would be implemented under the preferred alternative (Alternative D) of the Glen Canyon Dam Long-Term Experimental and Management Plan (LTEMP). Implementation of high-flow experiments (HFEs) under the preferred alternative would follow the HFE protocol described below for the overall process of implementation of HFEs, including implementation considerations and conditions that would result in discontinuing specific experiments.

HFE releases are restricted to limited periods of the year when the highest volumes of sediment are most likely available for building sandbars. Water year releases would follow the pattern identified for the preferred alternative as adopted by the Secretary of the Interior in the LTEMP Record of Decision (ROD) and the Long Range Operating Criteria (LROC) as currently implemented through the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (Reclamation 2007a). Sediment-triggered HFEs may be made in spring (March or April) or fall (October or November) (Figure P-1). Fall Extended HFEs duration would range from less than 1 hr to 250 hr. Spring and fall HFEs which are not Extended HFEs, would have a duration range from less than 1 hr to 96 hr. Proactive HFEs may be made in spring or early summer (April, May or June), and would have a duration range up to 24 hr. HFE magnitude would range from 31,500 cfs to 45,000 cfs. Frequency of HFEs would be determined by tributary sediment inputs, annual release volumes, resource conditions, and the decision process carried out by the Department of the Interior (DOI) (Sections 2.2.4.3 and 2.2.4.4 of the EIS). Extended-duration fall HFEs are limited to a frequency of 4 times total in a 20 year period.

The HFE protocol uses a "store and release" approach for sediment-triggered HFEs, in which sediment inputs are tracked over two accounting periods, one for each seasonal HFE: spring (December through June) and fall (July through November) (Figure P-1). In addition, the HFE protocol can trigger proactive spring HFEs that would be tested only in years with high annual water volume (i.e., ≥10 maf) when no sediment-triggered HFE occurs. Implementation of an HFE may require reallocating water from other months in order to maintain flows above the required minimum (i.e., 5,000 to 8,000 cfs). The protocol would implement the maximum possible magnitude and duration of HFE that would achieve a positive sand mass balance in Marble Canyon, as determined by modeling.

P.1 DECISION-MAKING PROCESS

The HFE protocol is a decision-making process that consists of three components: (1) planning, (2) modeling, and (3) decision and implementation. The following three subsections describe each of these components.

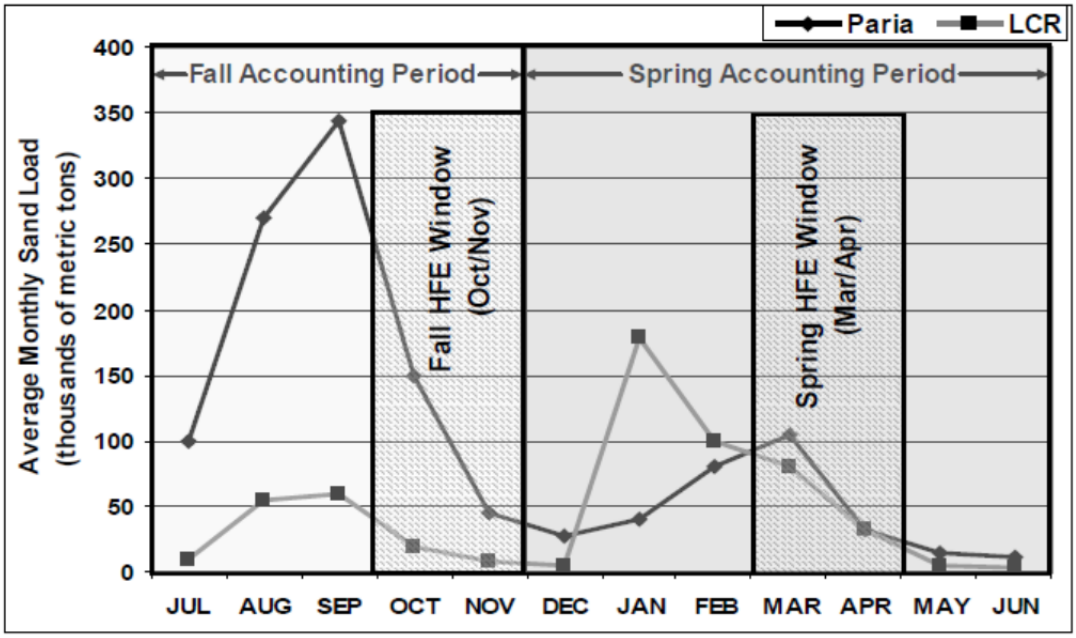

FIGURE P-1 Average Monthly Sand Load from the Paria River and Little Colorado River Showing the Fall and Spring HFE Accounting Periods and Implementation Windows

P.1.1 Planning

The first component of the HFE protocol is planning. An important aspect of planning is the development and implementation of research and monitoring activities appropriate to monitor the effects of the HFEs. The Bureau of Reclamation (Reclamation) would be prepared to conduct an HFE if resource conditions are suitable, there is sufficient sediment input or projected annual release to trigger an HFE, and DOI determines conditions are suitable for proceeding. An annual process prior to a decision on conducting experiments, including an HFE, would evaluate the information on the status and trends of the following resources: (1) water quality and water delivery, (2) humpback chub, (3) sediment, (4) riparian ecosystems, (5) historic properties and traditional cultural properties, (6) Tribal concerns, (7) hydropower production and Western Area Power Administration's (WAPA's) assessment of the status of the Basin Fund, (8) the rainbow trout fishery, (9) recreation, and (10) other resources. Although these resources are listed for consideration on a regular basis, DOI intends to retain sufficient flexibility in implementation of HFEs to allow for response to unforeseen circumstances or events that involve any other resources not listed here. The recent discovery of nonnative green sunfish in the Glen Canyon reach illustrates the need to be responsive to unforeseen conditions.

In implementing HFEs and other experiments, the DOI will exercise a formal process of stakeholder engagement to ensure decisions are made with sufficient information regarding the condition and potential effects on important resources. As an initial platform to discuss potential future experimental actions, the DOI will hold Glen Canyon Dam Adaptive Management Program (GCDAMP) annual reporting meetings for all interested stakeholders; these meetings

will present the best available scientific information and learning from previously implemented experiments and ongoing monitoring of resources. As a follow up to this process, the DOI will meet with the GCDAMP Technical Work Group (TWG) to discuss the experimental actions being contemplated for the year.

The DOI also will conduct monthly Glen Canyon Dam operational coordination meetings or calls with the DOI bureaus (U.S. Geological Survey [USGS], National Park Service [NPS], Fish and Wildlife Service [FWS], Bureau of Indian Affairs [BIA], and Reclamation), Western Area Power Administration (WAPA), Arizona Game and Fish Department (AZGFD), and representatives from the Basin States and the Upper Colorado River Commission (UCRC). Each DOI bureau will provide updates on the status of resources and dam operations. In addition, WAPA will provide updates on the status of the Basin Fund, projected purchase power prices, and its financial and operational considerations. These meetings or calls are intended to provide an opportunity for participants to share and obtain the most up-to-date information on dam operational considerations and the status of resources (including ecological, cultural, Tribal, recreation, and the Basin Fund). One liaison from each Basin State and from the UCRC will be allowed to participate in the monthly operational coordination meetings or calls.

P.1.2 Modeling

Mathematical models are used to make recommendations for future sediment-triggered HFEs using contemporary sediment data and forecasted hydrologic data to determine whether suitable sediment and hydrology conditions exist for a sediment-triggered HFE.

The two basic inputs for the modeling are the water input or hydrology, which is taken from the Colorado River Simulation System (CRSS) (Reclamation 1988, 2007b) and the sediment input, which in this case is restricted to inputs from the Paria River. A flow routing model (Wiele and Smith 1996) is used to simulate water passing downstream. A sediment budget model (Wright et al. 2010) is used to integrate the flow routing with the sediment inputs and outputs to determine whether or not a sediment mass balance is achieved for sediment-triggered HFEs (Russell and Huang 2010).

The sand budget is the net amount of sand in metric tons that has accumulated in the river channel over some period of time. In the Paria River, the two primary sand input periods are July through October and January through March (Figure P-1). During these two periods, sand is being accumulated at a higher rate than in other months. In order to accommodate the decision process and to address other resource needs or concerns, the sediment-triggered HFE windows are two-months long (October–November and March–April).

The sand budget model would use the sediment inputs and estimates the outputs for three river reaches where sand is tracked: (1) Lees Ferry/Paria River (RM 0) to RM 30, (2) RM 30 to Little Colorado River (RM 61), and (3) Little Colorado River to RM 87. The first two reaches would be used to estimate the maximum possible magnitude and duration of an HFE that will not create a negative sand mass balance in Marble Canyon (RM 0 to RM 61).

Hydrologic data for implementation would be based on forecasted monthly inflow volumes from the National Weather Service's Colorado Basin River Forecast Center and Reclamation's 24-month study projected storage conditions. The 24-month study computer model projects future reservoir conditions and potential dam operations for the system reservoirs given existing reservoir conditions; inflow forecasts and projections; and a variety of operational policies and guidelines. Monthly volumes would be apportioned to daily dam releases by WAPA. Water supply forecasts and models would be needed to make these projections and uncertainty associated with these projects would need to be considered in the decision-making process (Grantz and Patno 2010). The sediment data used would be real-time accumulated inputs estimated from the Paria River streamflow gages.

Sand availability at the onset of each release window is determined by the amount of sand received from the Paria River during the accumulation period less the amount transported downstream to the Little Colorado River as estimated by the sand routing model. Sand in Grand Canyon received from the Little Colorado River is viewed as an added benefit to the amount received from the Paria River. The Little Colorado River input cycle largely follows the same accrual periods as the Paria River; however, only sand inputs from the Paria River would be used in HFE modeling recommendations.

Each run is evaluated against 16 different HFE magnitudes and durations to determine their possible occurrence in the sediment-triggered HFE window months (Table P-1). The magnitude and duration of an HFE would be determined from the stored sand mass available on October 1 and March 1 of each water year, and the forecasted hydrology. The model evaluates each of the 16 sediment-triggered HFE types sequentially starting with the highest magnitude and duration of release. For example, the initial run determines if there is enough sediment available to achieve a positive sand mass balance in Marble Canyon for a release of 45,000 cfs for 250 hours. A positive sand mass balance is defined as a condition in which the amount of sediment being delivered by tributaries into the system exceeds the amount being exported from the system by ongoing dam operations and HFEs in the accounting period under consideration.

If the model run concludes that enough sediment is not available to achieve a positive sand mass balance, the next lower magnitude or duration sediment-triggered HFE is evaluated by the model. This is repeated until a sediment-triggered HFE scenario is reached that can be implemented with the available sediment or it is determined that a sediment-triggered HFE cannot be implemented. If it is determined that a sediment-triggered HFE cannot be implemented and the projected annual volume is greater than or equal to 10 maf, a proactive spring HFE would be triggered.

TABLE P-1 List of HFEs Available for Sediment-Triggered Experiments (fall, extended-duration fall and spring) under the Preferred Alternative

HFE ID	Peak Discharge (cfs)	Duration at Peak (hours)
1	45,000	250
2	45,000	192
3	45,000	144
4	45,000	96
5	45,000	72
6	45,000	60
7	45,000	48
8	45,000	36
9	45,000	24
10	45,000	12
11	45,000	1
12	41,500	1
13	39,000	1
14	36,500	1
15	34,000	1
16	31,500	1

The modeling component is based on four key analysis phases associated with the two sand budget accounting periods and the two sediment-triggered HFE windows:

- Phase 1: Fall Accounting Period. The fall accounting period is from July 1 to November 30. Beginning on July 1 of each year, monitoring data would be used to track the sand storage from Paria River inputs in Marble Canyon.

- Phase 2: October-November HFE Window. Beginning October 1, sand storage and forecast hydrology would be evaluated using the sediment budget model to determine whether conditions are suitable for an HFE. The model determines what magnitude and duration of the HFE, if any, would produce a positive sand mass balance at the end of the accounting period. If the model produces a positive result, the largest HFE that would result in a positive sand mass balance is forwarded to the decision and implementation component (see below), which also allows for other factors to be considered in the planning process (see Section P.1.1). During the decision process, sediment input would continue to be measured, the model would continue to be run and results or output would be forwarded to decision-makers to allow for refinement of the previously recommended magnitude and duration of the HFE. If the model produces a negative result, the model would be rerun using more recent sediment input to determine whether a positive sand mass balance would be reached in time to have an HFE in the release window.

- Phase 3: Spring Accounting Period. The spring accounting period is December 1 to June 30. As with the fall accounting period, monitoring data would be used to track the sand storage conditions in Marble Canyon during this time period. This accounting would be conducted regardless of whether or not a previous October or November HFE was conducted such that two HFEs could theoretically occur in the same year. The exception to this would be following an extended-duration fall HFE, as there would be no spring HFE following an extended-duration fall HFE. The accounting would continue to consider sand storage conditions present at the end of Phase 2, whether or not an HFE has occurred.

- Phase 4: March-April sediment-triggered HFE Window. The evaluation in this phase is the same for the October-November HFE window (see Phase 2) with the model output being forwarded to the decision and implementation component. The model output would be used in the same way as for the October-November determination. Whether or not a spring HFE is scheduled, sediment inputs would continue to be monitored through the end of the spring accounting period for use in the next accounting period. Note that proactive spring HFEs (see Section P.3.2), which are triggered by water volume and not sediment inputs, could occur in April, May, or June. In addition, spring HFEs would not be tested in years when there had been an extended-duration fall HFE earlier in the same water year.

P.1.3 Decision and Implementation

The third component of the HFE protocol is decision and implementation. This component could span a portion or most of the HFE window, depending on when conditions are deemed suitable for an HFE. The output from the model runs described above is used to determine if sediment and hydrology conditions are suitable for an HFE of a given magnitude and duration. For example, if the scenario that is identified by the model cannot be implemented because of facility limitation (e.g., if one or more turbines are out of service), managers would assess the need to modify the range of magnitude and duration of the HFE. Because this EIS has considered the effects of 45,000 cfs HFEs for 1 to 250 hours, it also serves to analyze the effects of HFEs at lower magnitudes and equivalent durations.

Because the model only considers water and sediment, an added purpose of the decision and implementation component is to consider potential effects on other resources. To determine whether conditions are suitable for implementing or discontinuing HFEs, the DOI will schedule implementation meetings or calls with the DOI bureaus (USGS, NPS, FWS, BIA, and Reclamation), WAPA, AZGFD, and one liaison from each Basin State and from the UCRC, as needed or requested by the participants. The implementation group will strive to develop a consensus recommendation to bring forth to the DOI regarding resource issues as detailed at the beginning of this section as well as including WAPA's assessment of the status of the Basin Fund. The Secretary of the Interior will consider the consensus recommendations of the

implementation/planning group, but retains sole discretion to decide how best to accomplish operations and experiments in any given year pursuant to the ROD and other binding obligations.

DOI also will continue separate consultation meetings with the Tribes, AZGFD, the Basin States, and UCRC upon request, or as required under existing RODs.

If the decision is made to conduct an HFE, staff of the USGS's Grand Canyon Monitoring and Research Center (GCMRC) would prepare to conduct monitoring and research in cooperation with other agencies. If not, the process would be repeated during the next accounting window. For each HFE, GCMRC staff would analyze results and integrate information from other HFEs for use in future HFE decisions.

The decision process could result in a sediment triggered HFE being considered whether or not a positive sand mass balance is projected for that release, since the decision must be made in advance of the actual sediment-triggered HFE release and there is an admitted uncertainty in the modeled forecast for both sediment input and dam releases. Caution would be exercised; however, because the sand mass balance only accounts for the difference between inputs and outputs, and does not adequately portray the erosion of sand in the river channel. Successive HFEs or intervening periods of erosion without HFEs could negatively affect the ability of future HFEs to form sandbars and beaches. Furthermore, this erosion could impact other resources and it is advisable to ensure that the net amount of sand in the river channel not be depleted so as to compromise other ecosystem components and functions. The output of the model would be integrated with an assessment of the status and trend of other resources, as an acknowledgement that the decision cannot be focused solely on the condition of the sediment to ensure that the decision encompasses the impacts on the resources identified above in P-1.1.

P.2 OPERATION OF GLEN CANYON DAM UNDER THE HFE PROTOCOL

The scenarios considered below describe how Reclamation would modify the operation of Glen Canyon Dam to reallocate monthly volumes when necessary to achieve HFEs as called for under this protocol. Implementation of the protocol will be done in concert with coordinated river operations. Since 1970, the annual volume of water released from Glen Canyon Dam has been made according to the provision of the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs (LROC) that includes a minimum objective release of 8.23 maf.

The 2007 Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Power and Lake Mead (Reclamation 2007a) for lower basin shortages and the coordinated reservoir operations (Reclamation 2007b) implements relevant provisions of the LROC for an interim period through 2026. This allows Reclamation to modify these operations by allowing for potential annual releases both greater than and less than the minimum objective release under certain conditions. A more thorough description of Reclamation's process for determining and implementing annual release volumes is available in the 2007 EIS and Record of Decision (Reclamation 2007a and 2007b).

Pursuant to the 2007 Colorado River Interim Guidelines, the annual release volume from Lake Powell is projected and updated each month in response to the monthly 24-month study model run. This projected annual release volume is allocated to produce projected monthly release volumes and becomes the basis for scheduled monthly releases from Glen Canyon Dam. It is important to note that, regardless of the timing of releases, implementation of the HFE protocol would not affect annual release volumes.

HFEs could require more water than what is scheduled for release through the coordinated operation process described above. In order to perform these HFEs, reallocation of monthly releases from Glen Canyon Dam may be necessary. Monthly reallocations for an HFE would not affect annual release volumes.

P.2.1 Potential Operation of Glen Canyon Dam during the Fall HFE Implementation Window

Reclamation would attempt to implement fall HFEs by lowering the remaining days within the fall HFE period to the degree practicable up to as low as allowed under the LROC and LTEMP ROD in order to release the projected October and November volumes in the 24-month study. If a fall high-HFE could be achieved within the release volumes projected for October and November, no reallocation of the monthly volumes from other months would need to be performed.

If, however, a fall HFE could not be achieved within the release volumes projected for October and November, Reclamation would reduce the projected monthly release volumes as necessary through the remainder of the water year. The reallocation would be determined in consultation with WAPA to minimize adverse impacts on hydropower. Reallocation would only be conducted up to the amount necessary to result in the projected monthly volume for October and November being sufficient to conduct the HFE.

P.2.2 Potential Operation of Glen Canyon Dam during the Spring HFE Implementation Window

Reclamation would attempt to achieve spring HFEs by lowering the remaining days within the spring HFE period to the degree practicable up to as low as allowed under the LROC and LTEMP ROD in order to release the projected March and April volumes in the 24-month study. If the sediment-triggered spring HFE could be achieved within the release volumes projected for March and April, no reallocation of the monthly volumes from other months would need to be performed. Note that proactive spring HFEs (see Section P.3.2) would not require reallocation of water outside of the month in which they occurred because they would be 24 hours or less in duration.

If, however, Reclamation determined that it would not be possible to achieve the sediment-triggered HFE within the monthly release volumes projected for March and April, Reclamation would reduce the projected monthly release volumes as necessary through the

remainder of the water year. The reallocation would be determined in consultation with WAPA to minimize adverse impacts on hydropower. The reallocation process would only be conducted up to the amount necessary to result in the projected monthly volume for March and April being sufficient to conduct the sediment-triggered HFE. If additional reallocation of the monthly volumes is required to achieve the sediment-triggered HFE, Reclamation would attempt to do so while maintaining the projected July and August release volumes in the 24-month study.

P.3 HIGH FLOW EXPERIMENTS TO BE EVALUATED UNDER THE PREFERRED ALTERNATIVE

Sediment-related experiments under the preferred alternative include (1) sediment-triggered spring and fall HFEs up to 96-hr duration; (2) short-duration (24-hr) proactive spring HFEs in high-volume equalization years (>=10 maf) prior to equalization releases; and (3) implementation of up to four extended-duration (>96 hr) HFEs, up to 250 hr long, depending on sediment conditions. The pattern of transferring water volumes from other months to make up the HFE volume would be discussed in the monthly Glen Canyon Dam operational coordination meetings described in Section P.1.

If sediment resources are stable or improving, the combination of base operations, HFEs, and other treatments would continue as prescribed for the preferred alternative. If sediment resource conditions decrease to unacceptable levels during the LTEMP period, operations may be modified to the extent allowable under the LTEMP ROD or would be evaluated and considered under a separate NEPA process, potentially including additional studies of sediment augmentation or other actions.

For all sediment experiments, testing would be modified or temporarily or permanently suspended if (1) experimental treatments were ineffective at accomplishing their objectives, or (2) there were unacceptable adverse impacts on resources. Monitoring results would be evaluated to determine whether additional tests, modification of experimental treatments, or discontinuation of experimental treatments were warranted.

Implementation of HFEs would consider resource condition assessments and resource concerns using the annual processes described in Sections P.1. HFEs may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section P.1. In addition, there is uncertainty associated with cumulative impacts from sequential HFEs. These cumulative impacts would be considered before implementing an HFE.

P.3.1 Sediment-Triggered Spring HFEs

Under the preferred alternative, sediment-triggered spring HFEs would be implemented after an initial 2-year delay in order to enable testing of the effectiveness of trout management flows and address concerns raised by the apparent positive response of trout to the 2008 spring HFE (Korman et al. 2011; Melis et al. 2011). After the first 2 years of the LTEMP period, spring HFEs would be implemented when triggered by sediment conditions, except in water years when

an extended-duration fall HFE (see description in Section P.3.4) was conducted. Modeling indicates that there may be sufficient sediment input for spring HFEs in about 26% of the years in the LTEMP period. Sediment-triggered spring HFEs would be implemented when triggered during the entire LTEMP period unless new information indicated they were not effective in building sandbars, or there were unacceptable adverse effects on resources (Section P.1).

Implementation of sediment-triggered spring HFEs would consider resource condition assessments and resource concerns using the processes described in Section P.1. Spring HFEs may not be tested when there appears to be the potential for unacceptable adverse impacts on the resources listed in Section P.1. In addition, there is uncertainty associated with the cumulative impacts of sequential HFEs on sediment, aquatic, and potentially other resources. These cumulative impacts would be considered before implementing a spring HFE particularly if a fall HFE had been implemented in the same water year.

P.3.2 Proactive Spring HFEs

GCMRC scientists identified proactive spring HFEs as a potential experimental treatment to transport and deposit in-channel sand at elevations above those of equalization flows. Proactive spring HFEs would be tested only in years with high annual release volume (i.e., ≥10 maf). A first test would be a 24-hr 45,000-cfs release conducted in April, May, or June. Duration in subsequent tests could be shortened depending on the observed effects during the first tests. It would be preferable to test proactive spring HFEs at least two to three times in the 20 year LTEMP period, but being able to do so will be dependent upon annual hydrology. Modeling indicates that proactive spring HFEs would be triggered in about 10% of the years in the LTEMP period.

Proactive spring HFEs would not be tested in the first 2 years of the LTEMP. In addition, proactive spring HFEs would not be tested in years when there had been a sediment-triggered spring HFE or an extended-duration fall HFE earlier in the same water year. Proactive spring HFEs could be performed in the same water year as a 96-hr or shorter sediment-triggered fall HFE, although prior to implementation, the potential effects of these HFEs would be carefully evaluated using the processes described in Section P.1. The first test would be carefully evaluated to determine whether additional tests were warranted based on the efficacy of building and maintaining sandbars. If initial tests show positive results without unacceptable adverse effects on the resources listed in Section P.1, proactive spring HFEs would be implemented when triggered during the entire LTEMP period.

Implementation of proactive spring HFEs would consider resource condition assessments and resource concerns using the processes described in Section P.1. Proactive spring HFEs may not be tested when there appears to be the potential for unacceptable impacts on the resources identified in Section P.1. The cumulative impacts of sequential HFEs would be considered before implementing a proactive spring HFE.

P.3.3 Sediment-Triggered Fall HFEs

Under the preferred alternative, sediment-triggered fall HFEs could be implemented throughout the 20-year LTEMP period unless new information indicated fall HFEs were not effective in building sandbars, or there were unacceptable adverse effects. Modeling indicates fall HFEs would be triggered in about 77% of the years in the LTEMP period.

Implementation of sediment-triggered fall HFEs would consider resource condition assessments and resource concerns using the processes described in Section P.1. Fall HFEs may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section P.1. The cumulative impacts of sequential HFEs would be considered before implementing a sediment-triggered fall HFE.

P.3.4 Extended-Duration Fall HFEs

The HFE EA (Reclamation 2011) had a limit of 96-hr duration HFEs at various release levels. Under the preferred alternative, sediment-triggered fall HFEs with durations longer than 96 hr (up to 250 hr) would be tested. The duration of these extended-duration fall HFEs would be based on the amount of sediment delivered from the Paria River during the fall accounting period and would be no more than the maximum magnitude and duration of HFE that would achieve a positive sand mass balance in Marble Canyon, as determined by modeling. Based on examination of the observed historical sediment input from the Paria River, it was determined that HFEs up to 10.4 days in length (250 hr) could be supported before exhausting seasonal sediment inputs and affecting water delivery requirements. GCMRC scientists have suggested that increasing the duration of HFEs when sediment supply can support a longer duration may lead to more sand being deposited at higher elevations, resulting in bigger sandbars. Modeling indicates the sediment trigger for this treatment may be reached in 25% of the years in the LTEMP period. There would be no more than four extended-duration fall HFEs allowed over the 20-year LTEMP period.

The duration of the first implementation of an extended-duration HFE would be limited to no more than 192 hr (twice as long as the 96-hr limit). This duration is considered long enough to produce a measurable result if the treatment represents an effective approach to building sandbars under enriched sediment conditions. The duration of all tests would be based on available sediment, current hydrology, reviews of available information, the expert opinion of GCMRC and other Grand Canyon scientists, and consideration of potential effects on other resources listed in Section P.1. If feasible, monitoring would include real-time observations of sediment concentrations to determine if sediment deposition continues throughout the duration of the extended HFEs.

Implementation of extended-duration fall HFEs would consider resource condition assessments and resource concerns using the processes described in Section P.1. Extended-duration fall HFEs may not be tested when there appears to be the potential for unacceptable impacts on the resources listed in Section P.1. Because the effects of extended-duration HFEs on Lake Mead water quality are a concern, DOI will coordinate with relevant water quality

monitoring programs or affected agencies prior to implementing any test of extended-duration HFEs. The cumulative impacts of sequential HFEs would be considered before implementing an extended-duration fall HFE.

Another important concern that results from the large volume of water bypassed during an extended-duration HFE is water delivery. Water delivery issues would be considered before deciding to implement an extended-duration fall HFE. An extended-duration HFE would not be implemented if annual release volume would be affected. It is possible that in lower volume years there would not be sufficient water available to support an extended-duration HFE. A 250-hr extended-duration HFE would result in a monthly total release of approximately 1.2 maf. In lower volume release years (e.g., 7.0 maf or 7.48 maf), the maximum duration may be less than 250 hr. In addition, a sediment-triggered spring HFE or proactive spring HFE would not be conducted in the same water year as an extended-duration fall HFE. If an extended-duration fall HFE was triggered but not implemented for any of the reasons described above, a fall HFE 96 hr or less in duration could be implemented instead. Implementation would necessitate reducing water volume in other months of the same water year.

In order to fully test the efficacy of these longer HFEs, several replicates would be desirable in the 20 year LTEMP period. Extended-duration HFEs would be considered successful and would be continued up to a total of four times in the 20-year LTEMP period as part of an adaptive experimental treatment if there was a widespread increase in bar size relative to ≤96-hr HFEs, and if sand mass balance was not significantly compromised relative to the ability to maintain a long-term equilibrium. Extended-duration HFEs would not continue to be tested if they were not effective in building sandbars, if resulting total sandbar volumes were no bigger than those created by shorter-duration HFEs, or if unacceptable adverse impacts on resources listed in Section P.1 were observed.

APPENDIX Q:

RESPONSES TO PUBLIC COMMENTS ON THE GLEN CANYON DAM LONG-TERM EXPERIMENTAL AND MANAGEMENT PLAN DRAFT ENVIRONMENTAL IMPACT STATEMENT

The U.S. Department of the Interior (DOI), through the Bureau of Reclamation (Reclamation) and National Park Service (NPS), proposes to develop and implement a Long-Term Experimental and Management Plan (LTEMP) for operations of Glen Canyon Dam. The LTEMP would provide a framework for adaptively managing Glen Canyon Dam operations over the next 20 years, consistent with the Grand Canyon Protection Act of 1992 (GCPA) and other provisions of applicable federal law. The LTEMP would determine specific options for dam operations, non-flow actions, and appropriate experimental and management actions that will meet the GCPA's requirements and minimize impacts on resources within the area impacted by dam operations, including those of importance to American Indian Tribes.

On January 8, 2016, the LTEMP DEIS was filed with Region 9 of the U.S. Environmental Protection Agency (EPA); a Notice of Availability and Notice of Public Meetings were published in the *Federal Register* (81 FR 963); and an email notification of the availability of the DEIS for download from the project website (www.ltempeis.gov) was sent to approximately 600 members of the public who had signed up for notification during the scoping period. Prior to this date, the DEIS was sent to each of the Governors, Senators, and Representatives from relevant congressional districts of the seven Colorado River Basin States (Arizona, California, Colorado, Utah, Nevada, New Mexico, and Wyoming).

In addition to making the DEIS available on the public website, 84 compact disc copies of the DEIS were mailed to individuals at their request; 46 copies were picked up at public meetings held for the DEIS; and copies were made available for public review after the DEIS was published at the following locations:

- J. Willard Marriott Library, University of Utah, 295 South 1500 East, Salt Lake City, Utah 84112.
- Cline Library, Northern Arizona University, 1001 S. Knoles Drive, Flagstaff, Arizona 86011-6022.
- Burton Barr Central Library, 1221 North Central Avenue, Phoenix, Arizona 85004.
- Page Public Library, 479 South Lake Powell Boulevard, Page, Arizona 86040.
- Grand County Library, Moab Branch, 257 East Center Street, Moab, Utah 84532.
- Sunrise Library, 5400 East Harris Avenue, Las Vegas, Nevada 89110.

- Denver Public Library, 10 West 14th Avenue Parkway, Denver, Colorado 80204.

- Natural Resources Library, U.S. Department of the Interior, 1849 C Street NW, Main Interior Building, Washington, D.C. 20240-0001.

The original 90-day public comment period was extended an additional 32 days (122-day total) to May 9, 2016, after several requests were received from the public and Cooperating Agencies. During the comment period, two in-person meetings and two Internet-based webinars were held to provide the public with information about the content and findings of the DEIS and to receive written comments on the DEIS. The meetings and webinars were held on the following dates:

- Webinar—Tuesday, February 16, 2016, at 6:30 p.m. Mountain Standard Time (MST);

- Meeting—Monday, February 22, 2016, at 6:00 p.m. MST, Flagstaff, Arizona;

- Meeting—Thursday, February 25, 2016, at 6:00 p.m. MST, Phoenix, Arizona; and

- Webinar—Tuesday, March 1, 2016, at 1:00 p.m. MST.

At these meetings, LTEMP staff were available to take comments and answer questions before and after presentations were made on the DEIS.

During the public comment period, the public was encouraged to submit comments electronically through the NPS Public, Environment, and Public Comment (PEPC) website. Comments were also received, however, through the mail or using a public comment form provided at the public meetings. More than 3,000 individual comment documents were received on the DEIS.

Comments were determined to be substantive or nonsubstantive in nature. NEPA regulations require that responses be provided to substantive comments. Comments are considered substantive if they:

- Challenge accuracy of analysis

- Dispute information accuracy

- Suggest different viable alternatives

- Provide new information that makes a change in the proposal In other words, they raise, debate, or question a point of fact or policy.

Comments in favor of or against the proposed action or alternatives, or comments that only agree or disagree with co-lead agency policies, are not considered substantive. Substantive comments were summarized and are presented, along with a response, per issue or impact topic in this appendix. Substantive comments were used to make changes to the DEIS when deemed appropriate and justified. Comment issues and the pages on which responses are located are presented in Table Q-1.Commenters, their affiliation (if any), and the section(s) where responses to their substantive comments are located are presented in Table Q-3, in Section 15.

Nonsubstantive comments are comments that offer opinions or provide information not directly related to issues or impact analyses. Nonsubstantive comments have been considered by the joint leads, but do not require a formal response.

PUBLIC COMMENT SUBMITTAL METRICS

Comment documents were received from 3,035 individuals; organizations (including environmental groups and other special interest groups); Tribes, private businesses (including recreational companies) and industry; and local, state, and federal agencies. Submissions were received from all 50 states plus the District of Columbia. About 12% of the submissions were from Arizona. Most submissions were received from California, at 19%. Table Q-2 shows the percentages for the five states with the most comments. Additional states that submitted more than 100 comments included Illinois, Pennsylvania, Texas, and Washington. Over 2,900 submissions were received via the LTEMP public website, and about 30 were received via postal mail. Another 20 were submitted using a comment form distributed at the Public Meetings. One petition included approximately 400 signatures.

FORM LETTERS

Over 1,400 of the 3,035 comment letters received were submitted as form letters that included the same comment language. Ten form letters were received, with submittals numbering: 15, 17, 21, 21, 24, 24, 29, 100, 166 and >1,000. Also, as noted above, one letter, a petition to enhance the Lees Ferry rainbow trout fishery, was signed by 404 individuals. The vast majority of the form letters expressed support for the preferred alternative. The form letter with over 1,000 submittals read as follows:

"Thank you for the opportunity to provide comments on the future of the Colorado River below Glen Canyon Dam. I support the preferred management plan (Alternative D) for Glen Canyon Dam, including experimental high flow releases, for the next 20 years. The Grand Canyon's native fish, recreational experiences, and other natural and cultural resources deserve this best option. It is especially important to keep daily water release fluctuations capped at 8,000 cfs. This will help preserve natural resources that provide habitat for endangered fish and the re-building of beaches along the Colorado River. Thank you for including efforts to restore riparian vegetation, which would otherwise degrade under any of the other alternatives."

TABLE Q-1 Comment Issues and Location in the Report

1 AIR QUALITY AND CLIMATE CHANGE Q-13

1.1 Delete "negligible" because it is Subjective Q-13
1.2 Minimize Potential Impacts by Comparing Project-Related GHG Emissions with Regional Total and US Total Q-13
1.3 Consider Effects of HFE on GHG Emissions Q-13
1.4 Display Greenhouse Gas (GHG) Emissions Increase in Everyday Terms Q-13
1.5 Alternative D increases GHG Emissions, Nearly Four Times the Level Associated with Alternative A Q-14
1.6 Methane Emissions from Lake Powell that Contribute to Climate Change Q-14

2 ALTERNATIVES Q-15

2.1 EIS Does Not Comply with NEPA Q-15
2.1.1 The DEIS Did Not Evaluate All Reasonable Alternatives Q-15
2.1.2 No Alternative Featured Greatly Increased Hydropower Q-16
2.1.3 Experiments are not Adequately Defined or Analyzed Q-16
2.2 EIS Does Not Comply with ESA Q-17
2.3 EIS Does Not Comply with CRSPA Q-20
2.4 Support Alternative D Q-22
2.5 Support Alternative D with Caveats Q-22
2.6 Support Alternative B Q-25
2.7 Support Alternative A Q-27
2.8 Support Alternatives Considered but Rejected (Fill Mead First, Decommission Dam) Q-28
2.9 EIS Should Have Considered Infrastructure Additions/Modifications Q-30
2.10 Alternative D ignores (or does not meet) Hydropower Objective Q-31
2.11 EIS Did Not Consider a Full Range of Alternatives Q-32
2.12 Flows Should Not Drop Below 8,000 cfs Q-33
2.13 8,000 CFS Fluctuation Limit Q-34
2.14 EIS Did Not Adequately Consider the Effects of Climate Change Q-35
2.15 Geographic Scope of the EIS Q-36
2.16 Monitoring to Support Adaptive Management Q-37
2.17 Include a Summary of Experimental and Management Actions for the Rainbow Trout Fishery Q-37
2.18 Glen Canyon Dam Safety and Security Q-37
2.19 Experimental Uncertainty Q-37
2.20 Impacts on Basin Fund Q-38
2.21 Due Consideration of Hydropower Q-39
2.22 Support Alternative F Q-39

3 AQUATIC ECOLOGY Q-40

3.1 Alternatives Adequate Will Not Protect Colorado River Ecosystem Q-40
3.2 Impacts of Fall HFEs on Fish and Aquatic Food Base Q-40

TABLE Q-1 (Cont.)

3.1 None of the Alternatives Adequate to Change and Protect Colorado River Ecosystem ... Q-40
3.2 Impacts of Fall HFEs on Fish and Aquatic Food Base ... Q-40
3.3 Reduce Number of HFEs to Improve the Aquatic Food Base ... Q-41
3.4 Impacts of Minimum Flows Before and After HFEs ... Q-41
3.5 Provide Additional Information on Most Recent Fall HFEs ... Q-42
3.6 Support Careful Testing of TMFs ... Q-42
3.7 Quagga Mussels ... Q-43
3.8 Provide Additional/Updated Information on Aquatic Resources and Species ... Q-43
3.9 AZGFD Management Plan ... Q-44

4 CULTURAL RESOURCES ... Q-45

4.1 Applicability and Composition of Cultural Resource Metrics ... Q-45
4.1.1 Wind Transport ... Q-45
4.1.2 Time Off River ... Q-45
4.1.3 Glen Canyon Flow Effect Metric ... Q-46
4.2 Area of Potential Effects ... Q-46
4.3 Landmark Status for Grand Canyon and its Resources ... Q-46

5 CUMULATIVE IMPACTS ... Q-47

5.1 Additional Foreseeable Actions (Including Management Plans) to be Included ... Q-47
5.2 Refinement of Description and/or Impact Assessment for Foreseeable Actions Considered ... Q-47

6 HYDROPOWER ... Q-48

6.1 Scope of Analysis and Study Elements ... Q-48
6.1.1 Hydropower Goals and Objectives ... Q-48
6.1.2 Generation at Hoover Dam ... Q-48
6.1.3 Cumulative Impacts on Power Systems ... Q-48
6.1.4 Analysis of Impacts on Basin Fund ... Q-48
6.1.5 Consideration of Impacts on Basin Fund ... Q-49
6.1.6 Power System Impacts on Climate Change ... Q-49
6.1.7 Sensitivity Analysis of Fuel Prices ... Q-49
6.1.8 Clean Powerplant Legislation ... Q-49
6.2 General Overarching Comments on the Power Systems Analysis ... Q-50
6.2.1 Adequacy of Power Systems Analysis ... Q-50
6.2.2 Ratepayer Analysis Flawed ... Q-50
6.2.3 Inputs to Capital Costs Analysis ... Q-51
6.3 Legal Issues ... Q-52
6.3.1 HFEs as Part of Long-Term Operations ... Q-52
6.3.2 Irretrievable Loss of Hydropower ... Q-52

9.4 Adoption of MLFF Flows Corresponded with Degradation of the Lees Ferry Fishery Drop in Visitations Q-74

10 TRIBAL RESOURCES Q-75

10.1 Opposition to Mechanical Removal of Trout and Trout Management Flows Q-75
10.2 Lack of Tribal Representation in Development of EIS Q-75
10.3 Metric Should Not Be Used to Analyze Impacts to Cultural and Tribal Resources Q-76
10.4 Cultural Landscapes and Traditional Cultural Properties not Thoroughly Discussed Q-76
10.5 Tribal Lands and Resources on Tribal Lands Not Taken Into Consideration Q-77
10.6 Impacts to Hualapai Tourism Operations Not Thoroughly Analyzed Q-77
10.7 Tribal Perspectives on Components of the Colorado River Ecosystem Q-77
10.8 Editorial Comments Q-78

11 SEDIMENT Q-79

11.1 Concern Over Erosion of Sandbars and Beaches following High Flows (i.e., HFEs) Q-79
11.2 Spring HFEs—Uncertainty and Concern Over Impacts; More Testing Is Needed Q-79
11.3 Equalization Flows—Concern Over Increased Erosion and Higher Rate of seDiment Transport Q-79
11.4 Sediment Should Be Considered a "secondary" Resource Q-80
11.5 Concern Over Sediment Accumulation in Lake Powell and Behind the Dam Q-80

12 SOCIOECONOMICS AND ENVIRONMENTAL JUSTICE Q-81

12.1 Regional Economic Impacts Associated with Boating Visitor Expenditures Q-81
12.2 Regional Economic Impacts Associated with Angler Visitor Expenditures, in Particular Impacts of HFEs Q-81
12.3 Use Values Associated with Angling and Boating Trips Q-81
12.4 Non-Use Values Associated with Fishing Resources Q-81
12.5 Economic Impacts on Tribes Q-82
12.6 Impact on Water Provision Q-82
12.7 Regional Electric Power Economic Impacts Q-82
12.8 Economic Impacts of Activities of Confluence Partners Out of Scope of EIS Q-82
12.9 Depth of Literature review on Use Valuation in Appendix I Q-83
12.10 Mechanical Removal and Trout Management Flows Q-83

13 WATER Q-84

13.1 Consideration of Climate Change Effects Related to Water Supply Reductions, Evaporation, and Operational Levels of Lake Powell Q-84
13.2 Consideration of Climate Change Impacts on Water Availability, Increased Demand, and Greater Depletion Q-84
13.3 Influence of Tributaries and Lake Powell on Main Stem and Lake Mead Salinity Levels Q-84
13.4 Editorial Comments Q-85

14 WILDLIFE Q-86

14.1 Averting the Responsibility to Protect Native Species Q-86
14.2 HFE IMPACTS on Kanab Ambersnail Q-86

TABLE Q-1 (Cont.)

14.3 Operate Glen Canyon Dam in a Way that Protects All Wildlife (Including Listed Species) Q-87

TABLE Q-2 Commenter Distribution by State

State	Percentage
AZ	12
CA	19
CO	5
FL	5
NY	5
All others	53

The form letter with 166 submittals and the petition with 404 signatures had nearly identical language, which recommended that the LTEMP should:

- Explicitly recognize that the Lees Ferry tailwater trout fishery as priority resource "value" for which Glen Canyon Dam should be operated as provided for in the Grand Canyon Protection Act.

- Incorporate the goals and objectives of the Arizona Game and Fish Department's Fishery Management Plan for the Lee Ferry Trout Fishery as stated goals and objectives of the LTEMP.

- Fully consider the impacts of repeated fall high flow experiments on the aquatic food base, rainbow trout, and invasive species in Glen and Marble Canyons.

- Place more emphasis on conducting high flow experiments in the spring to benefit a variety of resources besides sediment/sandbars including the aquatic food base, native fish, rainbow trout and riparian vegetation.

- Test the use of sustained low steady flows (also known as "macroinvertebrate production flows") to increase the production and diversity of the aquatic insects in the Colorado River below Glen Canyon Dam.

- Carefully test the use of Trout Management Flows (TMF), but only when there is an identified need to reduce the number of young of the year rainbow trout in Lee Ferry.

The form letter with 100 submittals simply endorsed "DOI's plan to operate the Glen Canyon Dam in a way that will best protect Grand Canyon National Park." Conversely, the form letter with 29 submittals stated that the "DEIS fails to adequately analyze the impacts of climate change on the entire Colorado River water supply system" and "should have considered a wider range of reasonable alternatives that fully take climate change into account." The remaining form letters were variations on the themes of protecting the Lees Ferry trout fishery or endorsing DOI's plan. Substantive issues raised in the form letters and in individual letters submitted are addressed in the following sections.

SUMMARY OF ISSUES RAISED IN COMMENTS ON THE DEIS AND DOI'S RESPONSES

Comment letters received on the public draft of the LTEMP EIS raised substantive issues in a number of technical areas related to the analyses presented in the EIS and in non-technical areas related to the requirements of preparing the EIS under NEPA. Comments ranged from support of the preferred alternative as is, to support with qualifications, to support of other alternatives. Some commenters disagreed with the exclusion of some proposed alternatives as not meeting the purpose and need of the proposed action, including decommissioning of the dam. Other comments questioned the adequacy of the EIS under NEPA and ESA and in addressing the effects of climate change. Many comments addressed the proposed experiments that are a part of the preferred alternative and other alternatives, their triggers, their potential effectiveness, and their potential effects on other resources not targeted by the experiments. Other comments addressed the modeling conducted to analyze effects of dam operations on resources and on the metrics produced by the models to assess impacts. A number of comments concerned the effects of daily fluctuations and minimum river flows downstream of the dam resulting from dam operations under the various alternatives. Many comments addressed the use of HFEs, their timing, potential benefits and effects on hydropower generation. These and other substantive issues are outlined in the following section. Following the outline is a section that presents a summary of each issue as raised in comments and DOI's response. Finally, an index of all comment letters submitted, the names of the commenters, and their affiliation is presented following the issues and responses section.

Comment Categories, Comment Issues, and Location Where Responses are Found

Comments issues were categorized according to a number of technical and non-technical areas based on the substantive content of the letters submitted. In addition, a large number of editorial comments were received, and we have updated the text where appropriate in response to these comments. These comments refer to specific page numbers and line numbers in the DEIS. Because the overall document pagination has changed from the DEIS to the FEIS, including the specific location of each change would have limited utility and be cumbersome. Accordingly, we have not included the specific locations of each change in this Appendix. The EIS was revised appropriately to address all substantive editorial comments, to correct typographical errors, and to add specific language submitted by Tribes.

The following outline presents the comment categories, a brief description of the issues raised, and the location in the following section where each issue is summarized and DOI's response is presented.

LTEMP CONSOLIDATED ISSUES AND RESPONSES

1 AIR QUALITY AND CLIMATE CHANGE

1.1 DELETE "NEGLIGIBLE" BECAUSE IT IS SUBJECTIVE.

Summary Comment: Commenters expressed that the term "negligible" is a biased, subjective term.

Response: For emissions of SO2 and NOx presented in Section 4.15, the term "negligible" was used to describe impacts, but the actual projected emissions (in tons/yr) and percentage change relative to Alternative A also were provided. No change was made to the text. In Section 4.16, the text was edited to remove the term negligible and only the actual projected emissions of greenhouse gases (in tons/yr) and percentage change relative to Alternative A, and current conditions in the 11-state region and the United States were provided.

1.2 MINIMIZE POTENTIAL IMPACTS BY COMPARING PROJECT-RELATED GHG EMISSIONS WITH REGIONAL TOTAL AND US TOTAL

Summary Comment: Commenters expressed that the effects of increases in GHG emissions for the alternatives should be presented on a local or regional basis, and not at a national level.

Response: Text was updated to show project-related GHG emissions compared to total regional (11 states) while still retaining U.S. GHG emissions as that level is a conventional way of assessing their impacts.

1.3 CONSIDER EFFECTS OF HFE ON GHG EMISSIONS

Summary Comment: Commenters suggested that strong consideration should be given to the air emission impacts resulting from HFEs.

Response: The analysis considered the effects of HFEs on air quality in Section 4.15 and on greenhouse gas emissions in Section 4.16. The modeling results presented in these sections included HFEs in all of the alternatives.

1.4 DISPLAY GREENHOUSE GAS (GHG) EMISSIONS INCREASE IN EVERYDAY TERMS

Summary Comment: Commenters recommended that increases in GHG emissions be expressed as an equivalent mass of coal burned using the EPA's "Greenhouse Gas Equivalencies Calculator," rather than just presenting GHG emissions in metric tons.

Response: In Table 4.16-1, we added a footnote which states, "Using an online tool from the EPA (https://www.epa.gov/energy/greenhouse-gas-equivalencies-calculator), one can express a given amount of GHG emissions in MT in everyday terms. For example, 1 million MT/yr is estimated to be equivalent to the amount of CO_2 that is emitted as a result of the electricity use of 148,000 households. However, because the EPA cautions that these estimates are approximate and should not be used for emission inventory or formal carbon footprinting exercises" the authors felt it was not appropriate to report the results in this document using that conversion.

1.5 ALTERNATIVE D INCREASES GHG EMISSIONS, NEARLY FOUR TIMES THE LEVEL ASSOCIATED WITH ALTERNATIVE A

Summary Comment: Commenters noted that Alternative D, which averages more than 1 HFE per year for the 20-year DEIS period, increases GHG emissions by 22,908 metric tons per year, nearly four times the level associated with Alternative A, which is the lowest GHG-producing Alternative due to the lowest frequency of HFEs.

Response: While the commenter is correct that Alternative D increases GHG by 22,908 metric tons per year (MT/yr), the EIS analysis found that the level of emissions for Alternative A was 55,177,668 MT/yr and the level of emissions for Alternative D was 55,200,576 Mt/yr and so the difference from Alternative A would be only 0.042%.

1.6 METHANE EMISSIONS FROM LAKE POWELL THAT CONTRIBUTE TO CLIMATE CHANGE

Summary Comment: Commenters state that preliminary estimates of methane emissions from the operation of Glen Canyon Dam and Lake Powell indicate that the combined life cycle GHG equivalents may be as high as one-third of a natural gas power plant.

Response: Because no studies on GHG emissions from Lake Powell and Grand Canyon Dam have been made, GHG emissions, such as CO_2, CH_4, and N_2O, from the reservoirs were discussed qualitatively in Section 4.16.2.1. Reservoirs such as Lake Powell would be expected to produce some amount of GHG emissions consistent with levels reported for reservoirs in the semiarid Western U.S. (Tremblay et al. 2004 and http://www.ipcc-nggip.iges.or.jp/public/2006gl/pdf/4_Volume4/V4_p_Ap3_WetlandsCH4.pdf). However, GHG emissions from these sources and associated climate change are not anticipated to be different among the alternatives.

2 ALTERNATIVES

2.1 EIS DOES NOT COMPLY WITH NEPA

2.1.1 The DEIS Did Not Evaluate All Reasonable Alternatives

Summary Comment: Citing 40 CFR 1502.14 requiring agencies to "[r]igorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study briefly discuss the reasons for their having been eliminated." Commenters stated that the LTEMP EIS process does not appear to comply with NEPA because Reclamation and NPS (i) did not objectively evaluate all reasonable alternatives, (ii) failed to assess mitigation measures regarding sediment issues, and (iii) appeared to utilize a partial decision making process.

Response: The LTEMP EIS carried forward a range of reasonable alternatives that were developed based on the input of DOI experts, Cooperating Agencies, stakeholders, Tribes and the public. Early alternative concepts were provided to cooperators and stakeholders for input and a public meeting was held on in April of 2012 to further explore and characterize those concepts. Mitigation measures within the scope of this EIS that fit the purpose and need were considered. The decision making process for this EIS conforms with the established NEPA process and considered input from the public, cooperators, stakeholders and Tribes. This NEPA document provides detailed analysis for a broad range of alternatives ranging from those proposed for ecological purposes, and those proposed by hydropower interests and focused on hydropower generation to, and those proposed to strike different a balances among all resource areas.

Alternatives F and G, the seasonally adjusted steady flow and year round steady flow alternatives were proposed by members of the public and interest groups during scoping. These alternatives were similar to ones considered in the 1996 EIS as well. These alternatives considered as part of a range of reasonable alternatives and these showed many positive and negative impacts on a variety of resources as were disclosed in the draft impact statement. The preferred alternative showed a better balance between resources to achieve the purpose and need.

Full powerplant capacity operations were considered and eliminated as an alternative as discussed in Section 2.3.10 because fluctuation levels to the degree proposed would have adverse impacts on many downstream resources and would not meet the purpose and need for this EIS. Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range compared to the No Action alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the DEIS. The preferred alternative showed a better balance among resources to achieve the purpose and need. [519951]

DOI believes the EIS is in full compliance with NEPA regulations. The USEPA reviewed the DEIS and determined that, based on their review, rated the preferred alternative as "Lack of Objections-Adequate," the highest rating possible.

2.1.2 No Alternative Featured Greatly Increased Hydropower

Summary Comment: Commenters stated that, none of the alternatives feature greatly increased (hydropower) flexibility and that the Agencies should provide more explanation regarding why an alternative with even more daily flexibility was not considered. Others stated that the LTEMP EIS preferred alternative does not meet the renewable resource goal of NEPA Section 101 (b) 6 or the hydropower resource goal established by the DOI for the LTEMP EIS process due to restrictions on the utilization of Glen Canyon Dam for hydropower production under the preferred alternative

Response: Full powerplant capacity operations were considered and eliminated as an alternative as discussed in Section 2.3.10 because fluctuation levels to the degree proposed would have adverse impacts on many downstream resources and would not meet the purpose and need for this EIS. Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range compared to the No Action alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the DEIS. The preferred alternative showed a better balance between resources to achieve the purpose and need.

The analysis performed in this EIS is fully consistent with both the hydropower resource goal in Section 1.4 and the goal set forth in the "policies and goals" subchapter of NEPA, including the cited goal in Section 101(b)(6). Hydropower impacts and consistency with the hydropower resource goal are discussed in Section 4.13. Regarding Section 101(b)(6) of NEPA, this is a general statutory statement that Congress that cannot be read in isolation. Instead, it must be read in connection with the Law of the River, the GCPA, and other statutory provisions specific to operations of Glen Canyon Dam. When these authorities are read together, Congress has established specific requirements for the operation of Glen Canyon Dam. This EIS considers those specific requirements and identifies a preferred alternative that meets the purpose and need and achieves an appropriate balance for meeting the objectives

2.1.3 Experiments are not Adequately Defined or Analyzed

Summary Comment: One commenter stated that Alternative D violates the requirements of NEPA because it contains experiments or other proposed actions that are not adequately defined or analyzed. Another commenter stated that "poorly defined experimental conditions, coupled with the unquantified discretion of the DOI to determine whether there are "adverse effects" on "other resources" renders the EIS legally inadequate because it does not contain the required "hard look" at the environmental and other impacts of the proposed action."

Response: The co-lead agencies feel that this NEPA process takes a comprehensive "hard look" at the proposed action and alternatives to determine whether there are "adverse effects" on "other resources" and is fully consistent with NEPA. As stated in Section 2.2.4.3, This EIS analyzed a wide range of conditions that could occur and states the potential effects in the document.

DOI disagrees with the statement that experiments or other proposed actions are not adequately defined or analyzed. Extensive detail on the costs of experiments appears in Appendix K and text was added to Section 4.13.2.3 to more fully describe effects to hydropower from all experiments. The LTEMP EIS describes experiments to be conducted under different alternatives in sufficient detail to allow for a full analysis of their effects. Extensive modeling of the effects of these alternatives on a full set of resources was conducted and formed the basis of the assessment presented in the EIS. These modeling results were supplemented with qualitative assessments of effects based on existing literature and observations. An assessment of the cumulative impacts of LTEMP alternatives in combination with other past, present, and reasonably foreseeable future impacts is presented in Section 4.17 of the EIS. GCMRC has developed a science plan that describes the information that will be gathered during implementation of the LTEMP, and how that information would be used in an adaptive management context.

The adaptive management process and triggers are adequately addressed in this NEPA document. Section 4.1 and Appendices C and K of the LTEMP DEIS have detailed information on the extensive modeling that was performed with a variety of long term strategies and referring to uncertainties explicitly. The range of adaptations are also well defined and analyzed in the EIS. Text was added between the DEIS and the FEIS to further define this and state specifically under each experiment how magnitudes, duration or frequencies of components of the experiments may change. The long term strategies were variations of the alternatives that turned various experiments "off" or "on" to model different combinations and frequencies of experiments under a variety of hydrologic inflow conditions. This extensive modeling was coupled with extensive literature review and subject matter expert input to provide thorough analysis. This is sufficient for a NEPA analysis. Additional details of experiments and monitoring will be developed through the AMP annual work plans.

DOI believes the EIS is in full compliance with NEPA regulations. The USEPA reviewed the DEIS and determined that, based on their review, rated the preferred alternative as "Lack of Objections-Adequate," the highest rating possible

2.2 EIS DOES NOT COMPLY WITH ESA

Summary Comment: Commenters stated that the LTEMP EIS does not comply with the Endangered Species Act because considered experiments, operations or management actions are quite likely to result in negative impacts to an endangered species.

(1) In addition, DOI should seek input from AMWG and TWG representatives on the draft Biological Assessment under the ongoing Species Status Assessment for HBC, which could improve and refine experimental treatments in the Preferred Alternative and clarify triggers, off ramps, monitoring and definitions of success.

(2) Further, Alternative D is incompatible with the ESA, in part because there are no binding obligations or criteria or required mitigation that protect the endangered HBC.

(3) Because the DEIS fails to define "annual implementation considerations" and "off-ramps," so nearly every experimental treatment will be undertaken unless there are "potential unacceptable impacts" on certain defined and undefined resources.

(4) A commenter stated that the failure of the DEIS to include and consider the cumulative impacts all of the HFEs, including the effects on rainbow trout recruitment and humpback chub from the 2013 and 2014 HFEs, represents a significant analytical flaw, and that it is inappropriate to consider 250 hour long HFEs due to erosion concerns.

(5) A number of people commented that the EIS did not consider or should have considered more the restoration of extirpated species and recovery implementation plans for all species known to be native to Grand Canyon prior to the operation of Glen Canyon Dam.

(6) With respect to proposed low summer flows, one commenter supports convening a panel of experts to analyze existing science on low summer flows within the first 5 years of the LTEMP period.

(7) With respect to sustained low flows for benthic invertebrate production, a commenter requested a comprehensive review of these flows by a scientific panel during the first several years of the LTEMP period to determine their cost, efficacy, and impact on native and nonnative fish.

Response: DOI has consulted with the U.S. Fish and Wildlife Service and developed conservation measures and alternative-specific experimental actions to avoid, minimize, and mitigate adverse impacts on endangered species and critical habitat potentially affected by the proposed action. The Biological Assessment is found in Appendix O in the final EIS. [519929] DOI has been consulting with FWS throughout the 5-year EIS process. The LTEMP EIS used the best available science and peer-reviewed modeling in its analysis of the effects of the proposed action and alternatives on endangered species and critical habitat.

(1) In developing the Biological Assessment for LTEMP, Reclamation convened an ad hoc group of Grand Canyon aquatic biologists from FWS, GCMRC, AZGFD, NPS, and Reclamation to develop the conservation measures, experimental actions, and trigger levels for those actions to be included in the EIS. GCMRC scientists have been involved since scoping with development of LTEMP alternatives and have provided information, research results, and expert opinions regarding the effects of the proposed action on endangered species and critical habitat throughout the EIS process. Also several Cooperating Agencies, including Tribes and Western Area Power Administration were given a chance to review the Biological Assessment and the proposed conservation measures were presented to the AMWG members at the August 2016 AMWG meeting. The Biological Assessment was updated to incorporate feedback and input resulting from these reviews.

The FWS humpback chub species status assessment that the commenter refers to is in process and will not be completed until well after the publication of the LTEMP FEIS. It is

not required to be complete for the FEIS or the record of decision, and is therefore independent of this NEPA process.

Greater specificity regarding triggers for HFE implementation and humpback chub actions have been added to the EIS (Appendices O and P).

(2) Formal consultation with FWS has resulted in a Biological Assessment and Biological Opinion on the effects of the proposed action on listed species and designated critical habitat, as presented in Appendix O of the EIS. DOI has worked closely with FWS throughout the 5-year EIS process to ensure that the appropriate experiments, dam operations, and non-flow actions were identified in the proposed action or as conservation measures. LTEMP EIS alternatives include experiments that are intended to improve conditions for ESA-listed species and other special status species. The LTEMP EIS team used the best available science and peer-reviewed modeling to determine the potential effects of these alternatives on these species.

Throughout the LTEMP DEIS drafting process, the parties to the DEIS have consistently prioritized the conservation of humpback chub and its habitat. FWS, the expert agency on endangered species issues, has been involved in the DEIS process from its inception. GCMRC scientists, who specialize in studying HBC and its habitat, have also provided valuable input regarding HBC during this process.

(3) The LTEMP EIS did consider and define "annual implementation considerations" and "off-ramps" for experiments. The implementation framework for Alternative D (Section 2.2.4.3 of the EIS) explicitly calls for the consideration of key resources (including endangered and threatened species and their designated critical habitat) when determining which experiments to conduct in any given year. The framework also establishes off-ramps that would identify when experiments should no longer be conducted if it was established there were potential unacceptable adverse impacts to endangered species and critical habitat. As described in Section 2.2.4.4, DOI will also exercise a formal process of stakeholder engagement to ensure decisions are made with sufficient information regarding the condition and potential effects on important resources. GCMRC has developed a science plan that describes the information that will be gathered during implementation of the LTEMP, and how that information would be used in an adaptive management context in order to promote the conservation of humpback chub and other species of concern.

(4) The LTEMP EIS did fully consider direct, indirect and cumulative effects of HFEs. Descriptions of the observed effects of HFEs conducted in 2012, 2013, and 2014 have been added to the EIS. The impacts of HFEs on other resources, including endangered species and hydropower, were fully analyzed in the EIS. The EIS acknowledges that experimental testing may provide new information about the effects of extended-duration fall HFEs on endangered species and their habitat. If that experimentation results in significant new information about potentially adverse impacts, outside of what was analyzed in this NEPA process then additional NEPA reviews would be completed as appropriate. These HFEs would only be conducted in years of very large sand input from the Paria River during the fall accounting period and the duration would be adjusted to be compatible with the magnitude of the sand input. Extended-duration fall HFEs would only be allowed in 4 of the

20 years of the LTEMP period and spring HFEs would not be allowed in the same water year to mitigate the cumulative impact of sequential HFEs. In addition, consideration would be given to their effects on key resources including water delivery, the Basin Fund, endangered species, and sediment.

(5) The reintroduction of extirpated species was outside the scope of this EIS and is discussed in Section 1.5.3.

LTEMP EIS alternatives include experiments that are intended to improve conditions for ESA-listed species and other special status species. The LTEMP EIS team used the best available science and peer-reviewed modeling to determine the potential effects of these alternatives on these species. DOI has worked closely with FWS throughout the 5-year EIS process to ensure that the appropriate experiments, dam operations, and non-flow actions were identified as conservation measures. Formal consultation with FWS has resulted in a Biological Assessment and Biological Opinion on the effects of the proposed action on listed species and designated critical habitat, as presented in Appendix O of the EIS.

The original notice of intent to prepare the LTEMP EIS identified the need to determine whether to establish a recovery implementation program for endangered fish species below Glen Canyon Dam. The LTEMP team found that identifying the need to determine whether to establish a recovery implementation program (RIP) for endangered fish species below Glen Canyon Dam did not meet the purpose and need for the action.

(6) Additional description of the implementation process for low summer flows has been added to the EIS (Section 2.2.4.6) including convening a scientific panel that includes independent experts prior to the first potential use of low summer flows to synthesize the best available scientific information related to low summer flows. Based on input from GCMRC, FWS, and joint-lead experts, we feel the additional restriction of only implementing the first test of low summer flows if humpback chub population status is robust is not needed because any test of low summer flows would consider the possibility for unacceptable adverse impacts to endangered species and critical habitat, and implementation of such a test may be delayed until conditions were suitable and unacceptable adverse impacts were minimized.

(7) We acknowledge that testing may be needed to determine the efficacy of macroinvertebrate production flows in this ecosystem, but find there is sufficient evidence for testing this tool experimentally. We acknowledge the potential for macroinvertebrate production flows to lead to increases in trout numbers. As described in Section 2.2.4.6, the "effects of the test would be evaluated…" and "…could be discontinued if there were unacceptable effects on other resources." Furthermore, we have consulted with FWS and GCMRC, and they both regard the experiment as low risk to the humpback chub population.

2.3 EIS DOES NOT COMPLY WITH CRSPA

Summary Comment: Several commenters have stated that the DEIS has improperly excluded hydropower enhancing alternatives and that the preferred alternative runs counter to the Grand Canyon Protection Act, the implementation of which is subject to and must be consistent with

Colorado River Storage Project Act (CRSPA). Under Section 7 of CRSPA, hydroelectric power plants are under CRSP A are to be operated "so as to produce the greatest practicable amount of power and energy that can be sold at firm power and energy rates." Alternative B outperforms Alternative D in this regard, while Alternative D provides no experiments to benefit hydropower, which would benefit HBC. Commenters state that the DEIS considers only the water management aspects of CRSPA and disregards the hydropower enhancement aspects and that the GCPA and CRSPA must be considered together, giving full consideration to each and that hydropower enhancement was disregarded because it did not conform to the agencies preconceived notion of where the program was to go. Finally, one commenter stated that the LTEMP is deficient as a management program because ignores the legal responsibility to explore mitigation strategies that would allow the use of the dam for its hydropower generating purposes as originally intended and that mitigation strategies are available that will benefit the trout fishery, reduce mechanical removals, stabilize sediment, and enhance river running while providing hydropower in a load following context. One commenter stated that environmental studies thus far completed and proposed do not support disruptions to continued dam management for water and power with either only negligible or zero species improvements and in the absence of reliably identifiable cause/effect and resulting benefit correlations, they urged prioritization of CRSP hydroelectric power purposes for the Glen Canyon Dam operations.

Response: Contrary to statements in the comment, the LTEMP EIS did evaluate and present the results for an alternative that increased hydropower generation. Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range compared to the No Action Alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the EIS. The preferred alternative showed a better balance between resources to achieve the purpose and need of the proposed action.

DOI formulated the characteristics of the preferred alternative based on initial modeling of a set of 6 alternatives. There were several characteristics that were chosen to specifically reduce cost to the hydropower resource including increasing the fluctuation factor from 7 to 10 in high demand months, adjusting the monthly release pattern to match WAPA's Contract Rate of Delivery, increasing the volume of water in the high demand month of August from 750 to 800 kaf in 8.23 maf years, and eliminating steady flows after HFEs. Many objectives and resource goals were considered in the LTEMP EIS. No one alternative was found which met all goals and objectives. Alternative D performed the second best out of the action alternatives on the hydropower metrics while also meeting the purpose and need and providing the best balance of resource impacts to comply with the Grand Canyon Protection Act and protect, mitigation and improve downstream resources. The preferred alternative was identified as the best balance for meeting the purpose and need of the LTEMP EIS.

Full powerplant capacity operations were considered and eliminated as an alternative as discussed in Section 2.3.10 because fluctuation levels to the degree proposed would have adverse impacts on many downstream resources and would not meet the purpose and need for this EIS.

The DEIS is consistent with both Section 7 of CRSPA and the GCPA. The CRSPA and the GCPA are both statutes that concern operation of Glen Canyon Dam, and the GCPA expressly acknowledges that the Secretary shall implement the GCPA "in a manner fully consistent with and subject to the Colorado River Compact, the Upper Colorado River Basin Compact, the Water Treaty of 1944 with Mexico, the decree of the Supreme Court in Arizona v. California, and the provisions of the Colorado River Storage Project Act of 1956 and the Colorado River Basin Project Act of 1968 that govern allocation, appropriation, development, and exportation of the waters of the Colorado River basin." Accordingly, the Secretary has considered both statutes in this NEPA process analyzing the operation of Glen Canyon Dam. Regarding the "Full-Powerplant Capacity Operations Alternative", as explained in the EIS (see Section 2.3.10), this alternative was rejected because it would not meet the purpose, need, and objectives of the LTEMP including compliance with the GCPA. However Alternative B described in Section 2.3.2 and analyzed in Chapter 4 includes a test of "hydropower improvement flows" that featured wide daily fluctuations (up to 20,000 cfs in some years and months).

2.4 SUPPORT ALTERNATIVE D

Summary Comment: Numerous commenters support Alternative D, the preferred alternative, some noting that Modulated flows as set out in Alternative D will better accomplish the stated objective- "...to protect, mitigate adverse impacts on, and improve the values for which GCNP and GCNRA were established, including, but not limited to natural and cultural resources and visitor use.

Response: Alternative D was identified as the preferred alternative because it met the purpose and need of the proposed action while achieving the best balance between downstream resource protection and hydropower production. It was the second best of the action alternatives in terms of hydropower performance.

2.5 SUPPORT ALTERNATIVE D WITH CAVEATS

Summary Comment: A number of commenters support Alternative D with some changes or caveats:

(1) Modify the HFE trigger to allow for more frequent spring HFEs that are aimed at benefitting a variety of priority resources besides sediment/sandbars, including aquatic food base, the endangered humpback chub and razorback sucker, other native fishes, the rainbow trout fishery, and riparian vegetation.

(2) Support and opposition to low summer flows.

(3) Support testing of sustained low steady flows (macroinvertebrate production flows) designed to increase the production and diversity of the aquatic insects in the Colorado River below Glen Canyon Dam and recommend testing of macroinvertebrate production flows very early in the 20-year implementation process.

(4) Prefer fewer HFEs in general, as many fishermen and fishing guides believe that repeated/frequent fall HFEs may be adversely impacting the rainbow trout fishery and the aquatic food base.

(5) Support continued testing of fall HFEs, but noting that extended duration HFEs up to 10 days in length, need to carefully consider potential impacts to the aquatic food base, rainbow trout, and invasive species in both Glen and Marble canyons

(6) The alternative should employ actions to prevent low dissolved oxygen levels that could be harmful to fish. In general, flows below 8000 cfs should be avoided if the condition of trout or food base is poor, water temperatures are above average, and DO levels are below average.

(7) Support careful testing of Trout Management Flows (TMFs) when there is an identified need to reduce the number of young of the year rainbow trout in Lee Ferry agreement is reached with AZGFD that the trout population can withstand a TMF experiment that has the potential to eliminate a recruitment year class.

(1) Response: The implementation framework for Alternative D (Section 2.2.4.3 of the EIS) explicitly calls for the consideration of key resources, including the trout fishery, when determining which experiments to conduct in any given year. The framework also establishes off-ramps that would identify when experiments should no longer be conducted due to unacceptable adverse impacts. As described in Section 2.2.4.4, DOI will also exercise a formal process of stakeholder engagement to ensure decisions are made with sufficient information regarding the condition and potential effects on important resources.

The EIS discloses effects related to the frequency of spring HFEs. Based on modeling and analysis, there are potential positive and negative benefits to downstream resources from spring HFEs. DOI has reviewed the parameters under which spring HFEs are conducted and the way in which the accounting periods are applied. Under the preferred alternative, there would be 4-7 spring HFEs on average over the 20 year period, and there would testing and monitoring of impacts. Under the preferred alternative, spring HFE's are triggered based upon sediment or hydrology triggers. GCMRC was consulted on the potential to modify the accounting periods and the scientists most familiar with the protocol did not believe it warranted a change in accounting periods. The DOI feels that the frequency of spring HFEs in the preferred alternative provides the appropriate balance between potential positive and negative impacts.

(2) The EIS discloses effects related to low summer flows. Positive benefits include potential warming that could help with humpback chub spawning in the mainstem, and negatives include hydropower impacts and potential concerns related to trout recruitment, water quality, recreation and other concerns. The FEIS includes additional language regarding the review of scientific information that would occur prior to use of this tool in the second ten years of the LTEMP experimental period. DOI feels that the preferred alternative provides an appropriate balance between those positive and negative impacts.

(3) The preferred alternative would allow for the possibility of testing macroinvertebrate production flows early in the LTEMP period. The decision would be based on the recommendations from GCMRC for the conditions of the year and for good experimental design including avoiding confounding results based on the experiments. The process under the preferred alternative includes communication and input from agencies including AZGFD. The impact of these flows on the aquatic food base, trout, and other species are discussed in the EIS.

(4) The EIS discloses effects related to the frequency of HFEs. The frequency of HFEs varies between alternatives and further modeling and evaluation was performed on long term strategies that has HFEs "turned on" or "turned off" for various modeling runs. Based on evaluation of these modeling results, on analyses of published studies and on input from cooperators and the public, the DOI feels that the preferred alternative provides an appropriate balance between those positive and negative impacts.

(5) The best available science related to the potential effects of extended duration HFEs on trout and other resources were incorporated into the analysis. The experiments include various "off ramps" in order to respond to potential impacts in the basin, including unacceptable adverse impacts outside of what was analyzed in the EIS to the rainbow trout fishery. In addition, impacts to recreation economics and other resources were included in the EIS. Consideration of unacceptable effects of sequential HFEs, including extended-duration fall HFEs, is explicitly identified in the EIS as a concern to be addressed before implementation. DOI feels that the preferred alternative includes an appropriate level of caution and consideration regarding the use of extended duration HFEs.

(6) The preferred alternative does not include flows to address low dissolved oxygen levels in the Lees Ferry area. This concern has only been documented as occurring in one year and the recommendations from GCMRC at this time are to monitor this issue to learn more about those potential conditions prior to considering experimental actions. The joint leads recommended to GCMRC to include this consideration of monitoring in their science plan to accompany the LTEMP.

(7) The use of TMFs has been designed as a tool for managing the trout population with respect to downstream endangered fish concerns but would also be expected to result in a healthier trout fishery with less population oscillation due to density dependence. Regardless of purpose, the trigger for this tool would be a large predicted trout recruitment event. Under these circumstances, TMFs would be expected to have positive benefits for endangered species and the stability and health of the trout fishery. Under the preferred alternative, AZGFD would be involved in annual implementation and planning discussions and Tribes would be consulted regarding the use of this tool. DOI feels that the preferred alternative includes an appropriate level of caution and consideration regarding the use of trout management flows.

2.6 SUPPORT ALTERNATIVE B

Summary Comment: Commenters expressed a preference for Alternative B, stating that Alternative B outperforms all other action alternatives for nearly all resources, and is the only action alternative that addresses the stated hydropower objective of the LTEMP EIS. In addition, DOI should consider eliminating the 8,000 cfs cap on daily fluctuations, eliminate low summer flow experiments, reduce HFE experiments to no more than one every other year, and allow operation at full power plant capacity. In comparison to Alternative D, commenters stated that Alternative B has lower air emissions and performs better than Alternative D across a wide range of resources considered in the LTEMP DEIS - humpback chub, air emissions, archeological resources, recreation value, retail power rates, hydropower value, increase in native vegetation, and water quality among others. In addition, Alternative D proposes a series of treatments which appear to be counterproductive and which would require subsequent treatments that would otherwise be unnecessary, specifically, as noted on p. 4-67, that subsequent HFEs erode the sandbars potentially benefitted by earlier HFEs. Further, Alternative D maintains an artificial intraday fluctuation cap of 8,000 cubic feet per second (cfs), while DOI has failed to show that the same cap under current operations benefits other resources. Finally, the DEIS reveals a bias towards the sediment resource, but is flawed because it considers flows as the only available method for improving the sediment resource.

Response: Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range of water flows compared to the No Action Alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the EIS. The preferred alternative, Alternative D, showed a better balance of effects to resources to achieve the purpose and need of the proposed action. Alternative D performed the second best out of the action alternatives on the hydropower metrics while also meeting the purpose and need and providing the best balance of resource impacts to comply with the Grand Canyon Protection Act and protect, mitigate and improve downstream resources.

As stated in Section 2.4.1, DOI considers sediment augmentation to be outside the scope of the LTEMP EIS because it is currently economically infeasible and would require additional congressional authorizations.

Modeling and NEPA analysis indicates that Alternative B would perform better than other alternatives for hydropower, however the joint leads identified Alternative D as the preferred alternative because it better satisfies the purpose and need of the proposed action and performed better than Alternative B for most other resources.

Note that the wording of the hydropower objective as presented in the EIS is "Maintain ***or*** increase Glen Canyon Dam electric energy generation, load following capability, and ramp rate capability, and minimize emissions and costs ***to the greatest extent practicable, consistent with improvement and long-term sustainability of downstream resources*** [emphasis added]." With this definition, all of the alternatives considered in the EIS satisfy the hydropower objective; however, the performance varies by alternative. It should be noted that Alternative D performed second best for hydropower out of all the action alternatives.

As stated in Section 4.5.2.3, "The average minimum number of adult humpback chub was highest for Alternatives B, D, and E, slightly lower under Alternatives A and C, and lowest under Alternatives F and G (Figure 4.5-8). These results indicate that although there are small differences among the alternatives with regard to the predicted minimum number of adult humpback chub in the Little Colorado River aggregation, all alternatives would maintain the population above at least 1,000 adults throughout the 20-year LTEMP period." It should be noted that the modeling for Alternative D showed improvement for humpback chub abundance; slightly higher abundance than No Action. Alternative D also includes macroinvertebrate production flow experiments which are expected improve the food base for humpback chub.

As stated in Section 4.15.2, "For both SO_2 and NO_x, steam turbine (coal plant) emissions are slightly lower under Alternatives F and G…. even though these two alternatives generate <2% less Glen Canyon Dam energy than the fluctuating flow alternatives…" such as Alternative B. "Net NO_x emissions related to spot market sales and purchases are lowest (greatest negative value) for the steady flow Alternatives F and G, and highest for the fluctuating flow Alternatives B and A. Net SO_2 spot market emissions are essentially the same across alternatives." However, "Given the very small differences in the estimated emissions after considering all of the factors discussed above and in light of the uncertainty of emissions modeling, it may be concluded that emissions would be similar under all of the alternatives."

As stated in Section 4.16.3, "There are expected to be some differences in the emissions of GHGs among the LTEMP alternatives." All differences were less than 0.1% of the total emissions and less than 0.0005% at the 11-state regional scale and less than 0.0001% at the US scale. The minor differences among alternatives are reported in Section 4.16.3.

The 8,000 cfs maximum daily fluctuation cap that is currently in place has been in place since 1996. The cap is present in both No Action and the preferred alternative. It was put in place in 1996 to address safety, recreation and sediment concerns. The LTEMP EIS analysis has found that the same concerns still apply. The 8,000 cfs maximum daily fluctuation is based on the 1995 Bishop study, which was reviewed by DOI experts and found to still be the best available information and appropriate for this EIS. The Bishop study surveyed both the river guides and the general public regarding preferences and the river guides reported a preference for a maximum of 8,000 cfs daily change for a "tolerable recreation experience" under relatively high average daily flows. See Appendix J, where table J-1 has been updated to show the survey responses at a range of flow levels. The 8,000 cfs maximum daily fluctuation in the preferred alternative is consistent with the over 1,000 comment letters received from river guides and members of conservation groups on the DEIS specifically stating the preference for retaining the 8,000 cfs maximum daily fluctuation in the preferred alternative that is currently in place for No Action.

Under Alternative D, low summer flows are only considered in the second ten years as an experiment and would only be performed more than once if the first test was shown to be successful in terms of effects to the humpback chub population. As disclosed in the DEIS, there are potentially negative impacts of lower summer flows to hydropower, bacteria/pathogens, vegetation, and food base/aquatic invertebrates. In terms of positive benefits, the modeling showed potential modest temperature increases which may be beneficial to humpback chub

populations under certain conditions. When considering individual model traces, variations in downstream temperatures were generally greatest in July (nearly 3°C warmer for low summer flows) and least in September (about 1°C warmer for low summer flows), with August falling in the middle (approximately 2°C warmer for low summer flows). In many meetings and consultations, GCMRC and FWS staff have expressed their expert opinions that LSFs are considered a low risk experiment to endangered fish and a potentially useful tool worthy of experimental testing because of the potential improvement to humpback mainstem spawning.

As determined by the modeling conducted for Alternative B, a reduction in HFE frequency to no more than one every other year would reduce sandbar building with potential negative impacts on camping and riparian species. Implementation of full powerplant capacity operations ("hydropower improvement flows" of Alternative B) would have adverse impacts on a number of downstream resources including aquatic food base, native fish, riparian vegetation, wildlife, cultural resources, and recreation.

Full powerplant capacity operations were considered and eliminated as an alternative as discussed in Section 2.3.10 because fluctuation levels to the degree proposed would have adverse impacts on many downstream resources and would not meet the purpose and need for this EIS. Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range of water flows compared to the No Action alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the DEIS. The preferred alternative showed more positive than negative effects to resources, as compared to Alternative B, to achieve the purpose and need.

Although Alternative D was projected to increase greenhouse gas emissions relative to Alternatives A and B, this difference was 22,908 "metric" tons not "million" tons. This increase represents a very small percentage (0.042%) of the greenhouse gas emissions that would result from the actions considered in Alternative A. The analysis for the EIS determined that under Alternative D, there would be a 152% increase in the sand load index (a measure of sandbar building potential) and a 47% decrease in the sand mass balance index, the lowest decrease of all the action alternatives. No one alternative was found which performed best for all goals and objectives. The preferred alternative was identified as the best balance for meeting the purpose and need of the LTEMP EIS.

2.7 SUPPORT ALTERNATIVE A

Summary Comment: Commenters expressed support for Alternative A, the no-action alternative, noting that Alternative A outperforms Alternative D with respect to a number of resource interests, and that Alternative A and Alternative B are the only two alternatives that meet the goal to "maintain or improve hydropower production." Some of the commenters acknowledged that the Preferred Alternative (Alternative D) has been changed to improve hydropower compared to how it was originally proposed, with more volume in the peak power month of August and more fluctuation in general, and could conditionally support it with the following changes: (i) increased daily fluctuations to 12 times monthly volume (in kaf) in June-August., and 10 times monthly volume (in kaf) in other months; (ii) removal of the 8,000 cfs fluctuation

cap; (iii) inclusion of hydropower improvement flow experiments; (iv) limitation of HFEs to a maximum of one occurrence per calendar year, and (v) exclusion of low summer flow experiments.

Response: DOI formulated the characteristics of the preferred alternative based on initial modeling of a set of 6 alternatives. There were several characteristics that were chosen to specifically reduce cost to the hydropower resource including increasing the fluctuation factor from 7 to 10 in high demand months, adjusting the monthly release pattern to match WAPA's Contract Rate of Delivery, increasing the volume of water in the high demand month of August from 750 to 800 kaf in 8.23 maf years, and eliminating steady flows after HFEs. Many objectives and resource goals were considered in the LTEMP EIS. No one alternative was found which met all goals and objectives. Alternative D performed the second best out of the action alternatives on the hydropower metrics while also meeting the purpose and need and providing the best balance of resource impacts to comply with the Grand Canyon Protection Act and protect, mitigate and improve downstream resources. The preferred alternative was identified as the best balance for meeting the purpose and need of the LTEMP EIS.

The increases in fluctuation described in the comment were all analyzed in the document in association with other alternatives and showed a number of positive and negative impacts to resources that led to those other alternatives not being identified as the preferred alternative. The preferred alternative performed the best with the fluctuation levels it currently has to address the concerns of endangered species, sediment, hydropower and other related resources.

Note that the wording of the hydropower objective as presented in the EIS is "Maintain or increase Glen Canyon Dam electric energy generation, load following capability, and ramp rate capability, and minimize emissions and costs to the greatest extent practicable, consistent with improvement and long-term sustainability of downstream resources [emphasis added]." With this definition, all of the alternatives considered in the EIS satisfy the hydropower objective; however, the performance varies by alternative. It should be noted that Alternative D performed second best for hydropower out of all the action alternatives.

2.8 SUPPORT ALTERNATIVES CONSIDERED BUT REJECTED

Summary Comment: Commenters expressed support for alternatives that were considered but rejected, specifically for the "Fill Lake Mead First, "Run of the River," and Decommission Glen Canyon Dam" alternatives. None of the retained alternatives, the commenters state, would be viable in the event of catastrophic reductions in Colorado River flows due to climate change, would adequately address the impacts of Glen Canyon Dam in driving the decline of Lake Mead, is capable of curtailing and reversing and the harm caused by to Glen Canyon under Lake Powell reservoir, or alleviates the effects of the dam's holding back sediment. DOI's justification for rejecting the alternatives is obsolete in the context of dramatic climate change impacts, while the current infrastructure for providing municipal water supplies through Glen Canyon Dam in unsustainable. Commenters also requested the analysis of a new alternative employing a historically based hydrograph alternative that attempts to restore hydrological functions that would benefit vegetation and possibly beaches. Other commenters stated that the LTEMP

alternatives would not be viable under catastrophic reductions in Colorado River flows due to climate change, nor adequately address the impacts of Glen Canyon Dam in driving the decline of Lake Mead. DOI's rationale for rejecting the proposed The "Fill Mead First Alternative" and "The Run-of-the-River Alternative" would be obsolete under severe climate change. Further, none of the alternatives analyzed the possibility that continued decline of Lake Mead could trigger a "shortage declaration" under the 2007 Interim Guidelines or an even more extreme "Compact Call," under which lower Colorado River basin states would legally compel the upper basin states to deliver their water allocation under the Law of the River.

Response: The LTEMP team developed a set of alternatives that represented the full range of reasonable experimental and management actions; met the purpose, need, and objectives of the proposed action; and were considered within the constraints of existing laws, regulations, and existing decisions and agreements. Other alternatives such as the "Fill Mead First," "Run-of-the River" and "Decommissioning the Dam" proposals were not included in the EIS because they would not meet the purpose, need, or objectives of the proposed action (see Sections 2.3.9 and 2.3.10). These alternatives would not allow compliance with water delivery requirements including the Law of the River and 2007 Interim Guidelines (Reclamation 2007a,b), and would not comply with other federal requirements and regulations, including the GCPA.

The EIS presented an analysis of historical hydrographs to determine how the alternatives would perform under the drier conditions of climate change conditions, and found that, although the resource impacts under climate change would be different from those under historic hydrology, the relative performance of alternatives would be consistent relative to each other. This indicated that Alternative D would continue to be the best of the alternatives under a changed climate.

The "Fill Mead First" proposal was not included in the DEIS because it would not meet the purpose, need, or objectives of the proposed action (see Section 2.3.9). The alternative would not allow compliance with water delivery requirements including the Law of the River and 2007 Interim Guidelines (Reclamation 2007a,b), and would not comply with other federal requirements and regulations, including the GCPA.

Regarding whether the annual volume of water moving from the Upper Colorado River Basin to the Lower Colorado River Basin should be changed for the purpose climate change considerations, annual volume determinations are presently implemented through the LROC as currently implemented through the 2007 Interim Guidelines. Consistent with the GCPA, and the purpose and need for this proposed action, any changes to annual volume determinations are beyond the scope of this NEPA analysis. Accordingly, the Proposed Action in the draft EIS does not require the Federal agencies (NPS and BOR) to either create a plan for providing water to the Colorado River in Grand Canyon during extended drought periods or develop a basin wide plan for the operations of all dams.

In December 2012, Reclamation and agencies representing the seven Colorado River Basin States completed the Colorado River Basin Water Supply and Demand Study (Reclamation 2012e). The purpose of the Study was to define future imbalances in water supply and demand in the Basin through the year 2060, and to develop and analyze options and strategies to resolve those imbalances. The study used several different scenarios for both supply and demand to capture a range in potential future conditions.

The LTEMP EIS includes an analysis of meeting water delivery requirements under historic hydrology (Section 4.2.2.1) and climate change scenarios (Section 4.16.2.2). This analysis demonstrated that, although there were differences in the performance of alternatives under historic and climate change scenarios, the same relative performance of alternatives was observed under the two scenarios. The analysis also demonstrated that all alternatives could continue to meet Compact requirements.

2.9 EIS SHOULD HAVE CONSIDERED INFRASTRUCTURE ADDITIONS/MODIFICATIONS

Summary Comment: Commenters disagree with DOI's decision to exclude some forms of infrastructure additions, or modifications, mainly involving temperature control of dam discharges or sediment augmentation below the dam, or with DOI's definition of sediment augmentation as an infrastructure addition or modification. Commenters stated that the DEIS dismissed any augmentation outright as deeming them economically unfeasible, request that DOI provide additional information as to the decision making process used to eliminate sediment augmentation from consideration because it is "infeasible," and note that no cost evaluation or studies were performed to determine whether the installation of temperature control devices would be an appropriate alternative to analyze. Options are available to deliver trapped sediment upstream of the dam downstream, to reposition bed-load sand to beaches and/or enhance supplies from the Paria, including the use of dredges. Dredging and beach building is not new infrastructure, but a possible alternative to HFEs that should be considered.

Response: As stated in Section 2.4.1, DOI considers any infrastructure modifications or additions to be outside the scope of the LTEMP EIS because they are currently economically infeasible and would require additional congressional authorizations (16 U.S.C. § 460l-19). However, the DOI does not rule out future new infrastructure if resource conditions warrant. Any infrastructure addition or modification would require additional time and study. Future potential infrastructure modifications would need to be evaluated in NEPA assessments (EAs or EISs) that fully considered the environmental impacts of construction and operation. These assessments and the construction of the infrastructure would necessarily result in some delay from the time of the LTEMP ROD and actual start of operation of the infrastructure. It could take as many as 10 years or more to evaluate and construct a TCD or sediment augmentation. Sediment augmentation was also determined to be outside the scope of the 1995 EIS. The EIS has demonstrated how the preferred alternative is designed to meet as many of the environmental conditions as possible as mandated by the GCPA.

The analysis for the EIS determined that under Alternative D, there would be a 152% increase in the sand load index (a measure of sandbar building potential) and a 47% decrease in the sand mass balance index, the lowest decrease of all the action alternatives.

Sediment is an important resource in the Grand Canyon and supports aquatic and riparian ecosystems, cultural resources, and recreation. Options for how to mitigate sediment impacts have been intensively studied for more than 20 years by the Grand Canyon Research and Monitoring Center (GCMRC) as well as by many academics and DOI bureau staff. Many options were considered throughout the LTEMP EIS process to address this problem. Options for

sediment augmentation were considered originally but after evaluation were considered economically infeasible at this time. Without augmentation, HFEs are considered the most feasible and potentially beneficial approach to building sandbars with the limited sand supply available downstream of Glen Canyon Dam.

2.10 ALTERNATIVE D IGNORES (OR DOES NOT MEET) HYDROPOWER OBJECTIVE

Summary Comment: Commenters state that the LTEMP EIS preferred alternative does not meet the renewable resource goal of NEPA Section 101 (b) 6 or the hydropower resource goal established by the DOI for the LTEMP EIS, that power production be "maintain[ed] (or/and) improve[d]," as stated in the Purpose and Need Statement (76 FR 129, July 6, 2011. Alternative D, places restrictions on the utilization of Glen Canyon Dam for hydropower production that are in addition to the restrictions that were established as a result of the 1996 Record of Decision (ROD). As a result, the renewable hydropower resource objectives of NEPA and the LTEMP EIS process will not be met if the preferred alternative is selected. In addition, low steady flow in July, August and September would result in a detrimental impact to hydropower production and would not meet the hydropower DFC objective.

Response: Hydropower production was one of the key resources thoroughly evaluated in the EIS. Many objectives and resource goals were considered in the LTEMP EIS. No one alternative was found which met all goals and objectives. Alternative D was identified as the preferred alternative because it met the purpose and need of the proposed action while achieving the best balance between downstream resource protection and hydropower production. It was the second best of the action alternatives in terms of hydropower performance.

DOI formulated the characteristics of the preferred alternative based on initial modeling of a set of 6 alternatives. There were several characteristics that were chosen to specifically reduce cost to the hydropower resource including increasing the fluctuation factor from 7 to 10 in high demand months, adjusting the monthly release pattern to match WAPA's Contract Rate of Delivery, increasing the volume of water in the high demand month of August from 750 to 800 kaf in 8.23 maf years, and eliminating steady flows after HFEs.

Note that the wording of the hydropower objective as presented in the EIS is "Maintain ***or*** increase Glen Canyon Dam electric energy generation, load following capability, and ramp rate capability, and minimize emissions and costs **to the greatest extent practicable, consistent with improvement and long-term sustainability of downstream resources** [emphasis added]." With this definition, all of the alternatives considered in the EIS satisfy the hydropower objective; however, the performance varies by alternative. It should be noted that Alternative D performed second best for hydropower out of all the action alternatives.

Several commenters provided letters addressing the role of hydropower in the purpose and need of this NEPA process. The joint leads feel the purpose and need as drafted reflects the appropriate role of hydropower given the authorities surrounding the operation of Glen Canyon Dam. In certain places we have edited the text to clarify the role of GCPA downstream resource priorities and hydropower. Water delivery and hydropower are fundamental principles that show

up as the first objectives of the LTEMP. The joint leads worked hard with the stakeholders to ensure representation of all interests. The GCPA is clear in its goals and the objectives that were outlined for the LTEMP reflect the goals of GCPA and the goals reflected in the "Law of the River". Please see the resource and objective goals outlined in the EIS.

2.11 EIS DID NOT CONSIDER A FULL RANGE OF ALTERNATIVES

Summary Comment: Commenters expressed disappointment that no alternative increased daily hydropower flexibility and expressed a desire to allow operation at full power plant capacity (with mitigation). Commenters disagreed with DOI's rationale for excluding the Full-Powerplant Capacity Operations Alternative - that it "would not meet the purpose, need, and objectives of the LTEMP including compliance with the GCPA."

Response: Contrary to statements in the comment, the LTEMP EIS did evaluate and present the results for an alternative that increased hydropower generation. Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range compared to the No Action Alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the EIS. The preferred alternative showed a better balance between resources to achieve the purpose and need of the proposed action.

As determined by the modeling conducted for Alternative B, a reduction in HFE frequency to no more than one every other year would reduce sandbar building with potential impacts on camping and riparian species. Implementation of full powerplant capacity operations ("hydropower improvement flows" of Alternative B) would have adverse impacts on a number of downstream resources including aquatic food base, native fish, riparian vegetation, wildlife, cultural resources, and recreation.

Regarding the "Full-Powerplant Capacity Operations Alternative", as explained in the EIS (see Section 2.3.10), this alternative was rejected because fluctuation levels to the degree proposed would have adverse impacts on many downstream resources and would not meet the purpose, need, and objectives of the LTEMP including compliance with the GCPA. However Alternative B described in Section 2.3.2 and analyzed in Chapter 4 includes a test of "hydropower improvement flows" that featured wide daily fluctuations (up to 20,000 cfs in some years and months).

Full powerplant capacity operations were considered and eliminated as an alternative as discussed in Section 2.3.10 because fluctuation levels to the degree proposed would have adverse impacts on many downstream resources and would not meet the purpose and need for this EIS. Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range compared to the No Action Alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the DEIS. The preferred alternative showed a better balance between resources to achieve the purpose and need.

The EIS presented an analysis of historical hydrographs to determine how the alternatives would perform under the drier conditions of climate change conditions, and found that, although the resource impacts under climate change would be different from those under historic hydrology, the relative performance of alternatives would be consistent relative to each other. This indicated that Alternative D would continue to be the best of the alternatives under conditions resulting from climate change.

2.12 FLOWS SHOULD NOT DROP BELOW 8,000 CFS

Summary Comment: Commercial rafters note that it is critical to their operations and public safety that the actual, not mean, daily minimum flow never drops below 8000cfs. Minimum flows of 5000 cfs from 7pm-7am for Alternative D indicated in Table 2.1 (page 2-9) are inadequate and dangerous. Navigational safety for boating is compromised when actual flows drop below 8000 cfs due to exposed rocks and increased difficulty in navigating the channel. Further, rafters are concerned with the minimum water level over the entire 24-hour day period; water released overnight will have an effect on many boaters downstream in the subsequent daytime hours. Also, low flow minimums below that of the 8,000 cfs level will restrict the time off-river by slowing the on-river pace and in turn diminish the overall experience for the visitor.

Response: Under the No Action Alternative, current minimum releases from the dam are set at 8,000 cfs from 7 am to 7 pm and 5,000 cfs from 7 pm to 7 am. This flow pattern, averaging a minimum over 24 hours of 6,500 cfs, has been in place since the 1996 Record of Decision was signed. Lower flows travel at a slower rate of speed and flows attenuate as the water moves downstream. The current minimums that have been in place for 20 years would be continued under the preferred alternative. Additionally, monthly volumes in the preferred alternative represent a relatively even pattern, allowing for more predictable and stable flow patterns throughout the year, including the high visitation summer months.

The EIS evaluates impacts on recreation related to navigation, fluctuations, and safety. These evaluations considered the minimum flow during each 24-hr period and the maximum daily fluctuation of each alternative. The preferred alternative is very similar to the No Action Alternative with regard to navigation, fluctuation level, and safety. As for all experiments, the implementation of low summer flows, TMFs, and macroinvertebrate production flows would take into account unacceptable adverse impacts on key resources including recreation. If unacceptable adverse impacts on key resources were anticipated, the minimum flow for both of these experiments could be adjusted.

The EIS acknowledges that low flows would reduce the amount of time boaters could spend off river, and assesses the impacts of each alternative using a “time off river“ index. The preferred alternative is expected to result in a very small decrease (<2%) in this index relative to the No Action Alternative.

2.13 8,000 CFS FLUCTUATION LIMIT

Summary Comment: Many commenters expressed a preference to keep daily water release fluctuations capped at 8,000 cfs, stating that this will help preserve natural resources that provide habitat for endangered fish and the re-building of beaches along the Colorado River. High fluctuations, some also note, can diminish or reverse some of the benefits of the HFEs and make it very difficult on river rafters and guides as they manage and plan river trips and manage boats on the shoreline. Other commenters support removing the 8,000 cfs cap, stating that it is unsupported by the scientific literature and restricts the hydropower resource without regard to CRSPA provisions to the contrary, and that DOI has failed to show that it benefits other resources.

Response: Alternative B was originally crafted and submitted by CREDA, a power utility stakeholder. It has a greatly increased daily range compared to the No Action Alternative and it includes an experimental implementation of maximum powerplant capacity releases. This alternative showed a number of positive and negative impacts on a variety of resources as were disclosed in the EIS. The preferred alternative showed a better balance between resources to achieve the purpose and need of the proposed action.

The 8,000 cfs maximum daily fluctuation cap that is currently in place has been in place since 1996. The cap is present in both No Action and the preferred alternative. It was put in place in 1996 to address safety, recreation and sediment concerns. The LTEMP EIS analysis has found that the same concerns still apply. The 8,000 cfs maximum daily fluctuation is based on the 1995 Bishop study, which was reviewed by DOI experts and found to still be the best available information and appropriate for this EIS. The Bishop study surveyed both the river guides and the general public regarding preferences and the river guides reported a preference for a maximum of 8,000 cfs daily change for a "tolerable recreation experience" under relatively high average daily flows. See Appendix J, where table J-1 has been updated to show the survey responses at a range of flow levels The 8,000 cfs maximum daily fluctuation in the preferred alternative is consistent with the over 1,000 comment letters received from river guides and members of conservation groups on the DEIS specifically stating the preference for retaining the 8,000 cfs maximum daily fluctuation in the preferred alternative that is currently in place for No Action.

Implementation of full powerplant capacity operations ("hydropower improvement flows" of Alternative B) would have adverse impacts on a number of downstream resources including aquatic food base, native fish, riparian vegetation, wildlife, cultural resources, and recreation.

The increases in fluctuation described in comments were analyzed in the document in association with various alternatives and showed a number of positive and negative impacts to resources that led to those other alternatives not being identified as the preferred alternative. The preferred alternative performed the best with the fluctuation levels it currently has to address the concerns of endangered species, sediment, hydropower and other related resources.

Modeling also indicated that the higher fluctuation levels under Alternative B or E would result in a number of adverse impacts including impacts on sediment, aquatic food base, vegetation, and recreation.

2.14 EIS DID NOT ADEQUATELY CONSIDER THE EFFECTS OF CLIMATE CHANGE

Summary Comment: Commenters expressed that the DEIS fails to take climate change seriously, fails to analyze the impacts on the water supply system of climate change for the entire Colorado River including the ecology in the Grand Canyon due to the operation of Glen Canyon Dam and Lake Powell, fails to analyze the likelihood of a "Compact Call" on the Colorado River due to the water lost by evaporation and seepage due to the operation of Glen Canyon Dam and Lake Powell, and fails to analyze a full range of alternatives that should be considered due to climate change including the decommissioning of Glen Canyon Dam and the draining of Lake Powell, stating that the criteria used to eliminate these alternatives would be obsolete in the face of catastrophic reductions in Colorado River flows caused by climate change, while none of the current alternatives would be viable under such conditions.

Response: The LTEMP utilized the best available science provided through the peer reviewed Basin Study (Reclamation 2012) regarding climate change projections in the Colorado River. The hydrological traces generated for the Basin Study were utilized as described in Section 4.16.1 and Appendix C.

This EIS used 21 reconstructed historical hydrological traces that were reweighted based on the 112 climate change traces to represent the best current understanding of what might happen under the drier conditions of climate change. Based on this analysis, the weights on the hydrological traces had a small effect on the aggregate performance but did not change the rankings of alternatives. This result suggests the relative performance of the alternatives would be consistent regardless of the uncertainty of the effects of climate change, and that Alternative D would continue to be the best of the alternatives under a changed climate.

The LTEMP team developed a set of alternatives that represented the full range of reasonable experimental and management actions; met the purpose, need, and objectives of the proposed action; and were considered within the constraints of existing laws, regulations, and existing decisions and agreements. Other alternatives such as decommissioning of Glen Canyon Dam, "Fill Mead First" and "Run-of-the River" proposals were not included in the EIS because they would not meet the purpose, need, or objectives of the proposed action (see Sections 2.3.8, 2.3.9 and 2.3.10). These alternatives would not allow compliance with water delivery requirements including the Law of the River and 2007 Interim Guidelines (Reclamation 2007a,b), and would not comply with other federal requirements and regulations, including the GCPA. The performance of these alternatives under climate change during the 20-year LTEMP period was discussed in Section 4.16.2.

Regarding whether the annual volume of water moving from the Upper Colorado River Basin to the Lower Colorado River Basin should be changed for the purpose climate change considerations, annual volume determinations are presently implemented through LROC as currently implemented through the 2007 Interim Guidelines. Consistent with the GCPA, and the purpose and need for this proposed action, any changes to annual volume determinations are beyond the scope of this NEPA analysis. Accordingly, the Proposed Action in the draft EIS does not require the Federal agencies (NPS and BOR) to either create a plan for providing water to the

Colorado River in Grand Canyon during extended drought periods or develop a basin wide plan for the operations of all dams.

The Basin Study (Reclamation 2012) was peer reviewed and is the best available science regarding climate change projections in the Colorado River Study. The hydrological traces generated for the Basin Study were utilized as described in Section 4.16.1.2 and Appendix C. This EIS did not model the 112 climate change hydrologic traces generated as part of the Basin Study due to insufficient data to drive the complex suite of models. We used 21 reconstructed historical hydrological traces that were reweighted based on the 112 climate change traces to represent the best current understanding of what might happen because of climate change. Based on this analysis, the weights on the hydrological traces had a small effect on the aggregate performance but did not change the rankings of alternatives. This result suggests the alternatives are robust to uncertainty about climate change.

By utilizing historic hydrology information and climate change-weighted hydrology information, we evaluated the effects of alternative operations over the 20-year LTEMP period under a wide-range of hydrologic and sediment conditions. We used a complete set of integrated models to evaluate effects of these changes in hydrology and sediment on the full range of resources including aquatic resources, terrestrial vegetation and wildlife, endangered species, cultural resources, Tribal resources, recreation, and socioeconomics. We modeled scenarios where the pool elevation dropped below the estimated minimum power pool (3,490 ft) and the results showed that there was no significant difference in the relative performance of the alternatives (Section 4.2). As stated in Section 4.2.2 of the EIS, "For Lake Powell elevations, all alternatives show very similar percentages for elevations that are ≤3,490 ft. The percentage of traces ranges between 0 and 5 and remains relatively constant throughout the 20 year period." In addition, we looked at the cumulative impacts of LTEMP in combination with other past, present, and future projects. We determined that the alternatives were robust to projected climate change-related hydrologies and could operate within the constraints of each alternative over the 20-year LTEMP period.

2.15 GEOGRAPHIC SCOPE OF THE EIS

Summary Comment: One commenter stated that the DEIS fails to clearly distinguish between 1) the scope of the proposed activity, i.e., Colorado River Ecosystem, and 2) the area of impact associated with implementing any activity proposed under LTEMP, and that it is unclear why some resources are discussed beyond the specific geographic limitations of the Colorado River Ecosystem and other resources are not. The DEIS should remain consistent with the geographic scopes intended for the proposed activities and impacts identified throughout its discussions and analyses.

Response: The text of the EIS has been revised to better clarify the geographic scope (See Section 1.5.1). It should be noted that the areas of potential impact vary by resource by necessity to evaluate the impacts. For instance, the effects of dam operations on vegetation or sediment are much more limited geographically than the effects on air quality or hydropower. In the cumulative analysis section (4.17), the region of influence for each resource is defined in the second column of Table 4.17-2.

2.16 MONITORING TO SUPPORT ADAPTIVE MANAGEMENT

Summary Comment: Commenters on this issue requested that the lead agencies conduct long-term resource monitoring to support adaptive management and to measure progress toward achieving goals and desired future condition.

Response: Long-term-monitoring for adaptive management will continue under the LTEMP. GCMRC has developed a Science Plan for the LTEMP that will guide these monitoring activities.

2.17 INCLUDE A SUMMARY OF EXPERIMENTAL AND MANAGEMENT ACTIONS FOR THE RAINBOW TROUT FISHERY

Summary Comment: Commenters on this issue requested that the selected alternative and/or the Record of Decision include a summary of experimental and management actions that are proposed to benefit the Lees Ferry rainbow trout fishery.

Response: The FEIS includes descriptions of all experimental and management actions for the alternatives in Chapter 2. There is not a summary of trout related experiments for all alternatives in one section, however all aquatic resource experiments for Alternative D can be found in Table 2-9 and Section 2.2.4.6.

2.18 GLEN CANYON DAM SAFETY AND SECURITY

Summary Comment: A commenter stated that Reclamation's misrepresentation of the growing risks associated with GCDs operational safety, the security of its water storage and hydropower generation benefits, as well as threats to water quality, not only renders its suite of alternatives and assessments thereof, incomplete, but renders an injustice to the Colorado River society as a whole by denying the public a truthful and up-to-date assessment of the known risks associated with the continued operations of GCD and the implied benefits therein.

Response: It is not clear what safety risks this comment is referring to. Dam safety is a priority of the Bureau of Reclamation and is evaluated comprehensively through Reclamation's Dam Safety program on an -ongoing basis. These on-going evaluations are wholly independent of LTEMP and beyond the scope of this NEPA analysis. The co-lead agencies feel that this NEPA process takes a comprehensive "hard look" at the proposed action and alternatives that is fully consistent with NEPA.

2.19 EXPERIMENTAL UNCERTAINTY

Summary Comment: Commenters stated that the experimental framework included in Alternative D fails to provide any meaningful level of certainty, there is insufficient detail and information regarding experimental triggers, baselines, off-ramps, hypotheses, unacceptable adverse impact, and metrics to determine success, or adaptively managing under LTEMP, and

the framework vests sole discretion in the DOI to determine whether a given experiment will be conducted.

Response: Triggers for experiments are clearly articulated. For several fish experiments triggers were developed and defined through the consultation process with FWS with information provided from GCMRC another experts and cooperators. GCMRC also developed a science plan and will be intimately involved in the implementation of LTEMP experiments through the GCDAMP triennial budget process and on-going monitoring, evaluation and reporting. The Colorado River Ecosystem is a dynamic system with complex interactions and changing conditions from year to year. The preferred alternative established a balance between structure and flexibility for experimentation to be able to allow for adaptive management in response to both changing conditions and new information gathered from experimentation. The preferred alternative has a number of annual steps built into the process to coordinate with GCMRC, agencies and stakeholders to consider the conditions of the year and the appropriate experiments given those conditions. Triggers and 'off-ramps' are defined. The triggers for HFEs and LSFs are well defined. Many of the triggers for tools for fish management have intentionally been left to be more flexible in the EIS as those have been defined during the consultation process with the FWS and will be more clearly stated in the FEIS. Greater specificity regarding triggers for HFE implementation and humpback chub actions have been added to the EIS (Appendices O and P).

The implementation framework for Alternative D (Section 2.2.4.3 of the EIS) explicitly calls for the consideration of key resources when determining which experiments to conduct in any given year. The framework also establishes off-ramps that would identify when experiments should no longer be conducted due to unacceptable adverse impacts. As described in Section 2.2.4.4, DOI will also exercise a formal process of stakeholder engagement to ensure decisions are made with sufficient information regarding the condition and potential effects on important resources. GCMRC has developed a science plan that describes the information that will be gathered during implementation of the LTEMP, and how that information would be used in an adaptive management context. Appendix O includes information regarding triggers for fish actions.

2.20 IMPACTS ON BASIN FUND

Summary Comment: A commenter stated that impacts to the Upper Colorado River Basin Fund must be assessed and considered.

Response: In Section 4.13 and appendix K of this EIS there is extensive analysis of the revenues from Glen Canyon hydropower production contributing to the Basin Fund. There are other factors that affect the balance of the Basin Fund that are outside the scope of the actions analyzed in this EIS, however those would not vary by alternative so they were not analyzed in the LTEMP EIS.

2.21 DUE CONSIDERATION OF HYDROPOWER

Summary Comment: Commenters stated that the Department of Interior must balance numerous important, and often competing, factors in developing the final LTEMP. Commenters urged that due consideration and weight be given to the importance of hydropower in this process.

Response: Many objectives and resource goals were considered in the LTEMP EIS. Hydropower production was one of the key resources thoroughly evaluated in the EIS. No one alternative was found which met all goals and objectives. Alternative D performed the second best out of the action alternatives on the hydropower metrics while also meeting the purpose and need and providing the best balance of resource impacts to comply with the Grand Canyon Protection Act and protect, mitigate adverse impacts to, and improve downstream resources. The preferred alternative was identified as the best balance for meeting the purpose and need of the LTEMP EIS.

2.22 SUPPORT ALTERNATIVE F

Summary Comment: One commenter expressed a preference for Alternative F, seasonally adjusted steady flows, because it would mimic natural conditions, and thus improve tailwater temperature and sediment conditions and riparian ecosystems downstream. Peaking power provided by fluctuating flows could be replaced by utility scale photovoltaic solar power.

Response: Alternative D was chosen as the preferred alternative because it met the purpose and need of the proposed action while achieving the best balance between downstream resource protection and hydropower production. This analysis considered the means and costs of alternate sources of peaking capacity as applicable under the various LTEMP alternatives

3 AQUATIC ECOLOGY

3.1 ALTERNATIVES WILL NOT PROTECT COLORADO RIVER ECOSYSTEM

Summary Comment: Commenters noted that Bureau of Reclamation (BOR) and NPS are setting themselves up for failure by attempting to restore an entire ecosystem based on responses to sediment inputs, temperature, and power grid needs alone instead of basing Glen Canyon Dams hydrograph on historic flow magnitude, frequency, duration, timing, and rate of change. In addition, there is a growing body of evidence on life history adaptations that indicate that several species depend on very localized hydrological conditions for their survival and reproduction. The Colorado River Ecosystem is continually changing, and novel, unanticipated ecosystem developments occur nearly every year. Many environmental and economic uncertainties, both recognized and unknown, complicate future adaptive management of the Dam and the Colorado River Ecosystem. Ensuring flexibility and administrative responsiveness is essential. Also, contingency planning is needed on a regular (annual) basis to deal with surprise events or processes, such as the sudden eruption of non-native green sunfish in Glen Canyon in 2015. Other commenters stated that adaptive management is based on the strategy of not placing the entire ecosystem at risk to answer management questions. Many management questions should be explored through small-scale field experiments or through modeling, rather than subjecting the entire ecosystem to an experiment that might jeopardize component species or processes. Only in cases where whole-ecosystem experiments are known to work, should they be conducted (e.g., testing the impacts of springtime HFEs on fluvial geomorphology and river biota).

Response: The purpose and need for LTEMP clearly align with the Grand Canyon Protection Act, whose goal is “to protect, improve and mitigate adverse impacts to natural and cultural resources and visitor use for which both park units were established”. All alternatives, including the preferred alternative (Alternative D), have positive and negative impacts which are disclosed in the EIS analyses. The Colorado River Ecosystem is a dynamic system with complex interactions and changing conditions from year to year. The preferred alternative established a balance between structure and flexibility for experimentation to be able to allow for adaptive management in response to both changing conditions and new information gathered from experimentation. The preferred alternative has a number of annual steps built into the process to coordinate with GCMRC, agencies and stakeholders to consider the conditions of the year and the appropriate experiments given those conditions. The joint leads have concluded that Alternative D has more positives than negatives and provides the best balance to meet the purpose and need for this project and to comply with the Grand Canyon Protection Act and the Law of the River. For a summary of impacts among alternatives, see Table 2-14.

3.2 IMPACTS OF FALL HFEs ON FISH AND AQUATIC FOOD BASE

Summary Comment: A number of commenters believed that repeated/frequent fall HFEs may be adversely impacting the rainbow trout fishery and the aquatic food base. Others stated that HFEs should be either deferred or only conducted in the spring if the condition of trout or the food base in Lees Ferry is poor. Others stated that the effects of sediment-triggered fall HFEs on trout recruitment are uncertain, but fall HFEs are expected to have less effect on trout production than

spring HFEs. Some commenters believed that a connection could be made between three consecutive fall HFEs and an increase in brown trout recruitment. In addition, the Havasupai requested the development of a monitoring site to study the impacts from the backflow of the HFE into Havasu Creek as well as impacts on the endangered fish naturally occurring and introduced at this location.

Response: The effects of HFEs on aquatic resources were fully analyzed in Section 4.5. This section reports that fall HFEs have not been found to have negative impacts to the food base, to trout recruitment or to native or non-native fish generally. There is no evidence of the frequency of HFEs being related to brown trout recruitment. Prior to the implementation of any HFEs, there would consideration of conditions related to humpback chub, trout, and aquatic food base. The HFE implementation process includes meetings with the GCMRC, FWS, AZFGD and other partners to take into consideration annual conditions as well as any new information. If unacceptable adverse impacts are predicted or observed, then experiments may be discontinued or additional NEPA processes may be conducted.

DOI will discuss the idea of a Havasupai monitoring site near Havasu Creek with GCMRC to be considered in the science plan or the monitoring implementation details.

3.3 REDUCE NUMBER OF HFEs TO IMPROVE THE AQUATIC FOOD BASE

Summary Comment: Commenters expressed concern regarding the continuation and expansion of HFEs, both in terms of frequency and duration. HFEs scour and remove the aquatic food base resulting in the loss of the main food source for trout and downstream humpback chub. Studies suggest that it takes 1 to 1.5 years for the food base to recover to pre-HFE levels after any HFE event. This indicates that if HFEs are implemented one or more times annually, there will be little opportunity for the food base to recover which will increase stress on the endangered native fish. Therefore, any selected alternative should include no more than one HFE every other year.

Response: Flow effects (including HFEs) on the aquatic food base are discussed in Section 4.5.2.1, with a more detailed discussion in Section F.2.2.1 (Appendix F). Reducing the number of HFEs (e.g., no more than one HFE every other year) is not supported by the analysis presented in the EIS. As discussed in Section F.2.2.1 (Appendix F), repeated HFEs are expected to result in a more productive aquatic food base. Such results do not occur from infrequent HFEs. Nevertheless, the HFE‘s are experimental in nature and allow for some adaptation over time based on results within the bounds of environmental compliance. If the HFEs cause unacceptable adverse impacts, there is a process defined in the EIS to suspend the HFEs.

3.4 IMPACTS OF MINIMUM FLOWS BEFORE AND AFTER HFEs

Summary Comment: Several commenters support the idea of keeping flows low and stable before and after HFEs. The health of the rainbow trout fishery and the aquatic food base, water temperatures, and dissolved oxygen levels should all be considered when determining the minimum flow that will precede and/or follow a fall high flow experiment (HFE). In general,

flows below 8000 cfs should be avoided if the condition of trout or food base is poor, water temperatures are above average, and dissolved oxygen levels are below average

Response: The issues the commenter raises, the health of the rainbow trout fishery, the aquatic food base, water temperature, and dissolved oxygen levels would be considered as part of the assessment of resources listed in Section 2.2.4.3 that will be considered when determining the flows that would precede or follow an HFE. Though the LTEMP EIS analysis did not find that steady flows after fall HFEs present a risk to the humpback chub population, that experiment has been removed for a number of other reasons including that it would be difficult to measure the results.

3.5 PROVIDE ADDITIONAL INFORMATION ON MOST RECENT FALL HFEs

Summary Comment: Commenters requested the inclusion of results from the recent HFEs (2012, 2013, and 2014) throughout the LTEMP DEIS including the portion of Section of 4.5 which addresses flow effects on benthic invertebrates. Given the impact to the endangered species, hydroelectric capacity and environmental ramifications of purchased power to replace the effects of HFEs; the failure of the DEIS to include and consider all of the HFEs and the cumulative impacts represents a significant analytical flaw. In addition, the DEIS fails to, but must include an analysis of the results of the 2013 and 2014 HFEs on rainbow trout recruitment and humpback chub.

Response: Preliminary results of the more recent HFEs have been added to Sections 3.5 and 4.5 of the EIS.

3.6 SUPPORT CAREFUL TESTING OF TMFs

Summary Comment: A number of commenters support the careful testing trout management flows (TMF), but only when there is an identified need to reduce the number of young of the year rainbow trout in Lees Ferry; while recognizing Tribal opposition to TMFs. A TMF should only be tested if AZGFD is in agreement that the trout population can withstand a potentially very successful TMF experiment that eliminates a recruitment year class. Testing TMFs when young trout are not abundant may adversely affect the Lees Ferry trout fishery, is contrary to the "condition dependent" adaptive management approach, and may not lead to conclusive results on the effectiveness of TMFs as a management tool.

Response: The DOI considers TMFs as an important tool for minimizing risk to downstream endangered fish from trout regardless of the cause of trout population increases or migration. Text has been added to Section 2.2.4.6 to clarify that implementation of TMFs would consider resource condition assessments and resource concerns. Early tests of TMFs would be used to determine the effectiveness of TMFs and a best approach to trout management. TMFs may not be tested when there appears to be the potential for unacceptable adverse impacts to specific resources such as humpback chub. Triggers for the implementation of TMFs would be developed in consultation with the AZGFD and other stakeholders to determine the implementation based on resource conditions in the given year. For Alternative D (the preferred alternative), trout

management flows are triggered by the prediction of high recruitment of young-of-year trout regardless of the cause of trout population increases or migration.

Based on the best available information, extensive modeling and extensive dialog with subject matter experts, the joint leads believe there would be concerns associated with testing TMFs when the trout population and trout recruitment is too low as that might not provide the best conditions for testing this tool. The text in the EIS has been edited to reflect this concern. Experimentally, the best conditions for testing TMFs are when high trout recruitment is expected, such as during a high release volume/equalization year or after a spring HFE, however the conditions for both of these are somewhat unpredictable and infrequent. Also DOI recognizes the concern of several Tribes related to conducting TMFs and the concerns of trout fisherman about the status of the trout fishery when TMFs are tested. DOI has designed the process for experiments to include a detailed evaluation of the resource conditions for the year and an extensive coordination process to hear from Tribes, agencies and the AMWG stakeholders about the concerns present at the time of implementing the experiments

3.7 QUAGGA MUSSELS

Summary Comment: A few commenters expressed concern that a potential infestation of quagga mussels below Glen Canyon Dam will have an adverse environmental impact. Because of the range of alternatives were developed before quagga mussel infestation occurred, it will be critical to study how best to mitigate the environmental damage it may cause. It was believed that there is a high probability that quagga mussels will change the food base chain and conflict with the proposed need for low summer flows to improve the aquatic food base. It is unclear what will happen to productivity in the Glen Canyon Reach if organic matter is reduced as a result of quagga mussels becoming established in Lee‘s Ferry.

Response: Quagga mussels continue to be found in the Colorado River below Glen Canyon Dam. Their distribution is patchy and highly influenced by location-specific flow regimes. While the potential impact from quagga mussels is uncertain, their management is beyond the scope of the EIS. If required, they would be managed through other actions conducted by the NPS. The Kennedy (2007) report cited in the EIS points out that negative ecological impacts appear to be low and that moderate densities of quagga mussels may increase food available to fish, increase the complexity of habitat and stimulate additional benthic production. (A link to the report can be found at http://pubs.usgs.gov/of/2007/1085/.)

3.8 PROVIDE ADDITIONAL/UPDATED INFORMATION ON AQUATIC RESOURCES AND SPECIES

Summary Comment: Several commenters wanted to see additional or updated information on a particular aquatic resource or species. These included wanting the EIS to provide more recent information regarding the status of razorback suckers in Lake Mead and the Lower Grand Canyon. Another commenter wanted the EIS to include the most recent data on brown trout recruitment in the Lee’s Ferry section of the Colorado River. One commenter requested that the connection between mayflies, stoneflies and caddisflies and the fish community be more

thoroughly addressed. Another commenter was concerned about predation of larval humpback chub by juvenile and adult humpback chub, as this could be a significant factor in year-to-year recruitment. One commenter noted that to fulfill the requirements of the Endangered Species Act, the best scientific and commercial data available needs to be used.

Response: The assessment of potential impacts from LTEMP activities on aquatic resources and species in the EIS is based on an extensive review of the scientific literature and other available data; as well as input from federal and state agencies (including the FWS and AZGFD) and other interested stakeholders. Recent literature and information on the aquatic resources and species made available since publication of the DEIS has been incorporated into the EIS. In regards to listed fish species, the recently completed Biological Assessment (BA) for the LTEMP is included as Appendix 0 of the EIS. The aquatic ecology sections (Sections 3.5 and 4.5) have been modified to include information from the BA.

3.9 AZGFD MANAGEMENT PLAN

Summary Comment: Commenter wanted information added describing the Arizona Game and Fish Departments Fisheries Management Plan, Colorado River-Lees Ferry 2015-2025 (Rogers 2015). The plan includes implementing actions that may be considered ongoing actions. The AZGFD refined the goals and objectives for the Lees Ferry Fishery in that plan. The purpose of the plan was to set measurable goals and identify several strategies to reach these goals. This differs from the NPS comprehensive fisheries management plan which focused on stocking triggers for Lees Ferry in the event the fishery returned to conditions prior to MLFF where it was primarily supported by stocking. A key concern which is addressed in the AZGFD plan, and not in the NPS comprehensive fish management plan, is the definition and response to a catastrophic loss of the fishery. The AZGFD plan is a proactive approach that aligns with the NPS Comprehensive Fisheries Management Plan that seeks to avoid a catastrophic loss and to ensure that the highly valued recreational trout fishery is sustained or enhanced while minimizing impacts to humpback chub.

Response: The AZGFD management plan and NPS's Comprehensive Fisheries Management Plan are independent of the LTEMP EIS. Currently, there are aspects of the AZGFD plan that are not in agreement with the LTEMP or with the Comprehensive Fisheries Management Plan. These issues include HFEs triggered by dissolved oxygen conditions or trout population levels, and details related to stocking conditions. Because of these differences, at this time, the joint leads cannot include these objectives or reference this plan in its current form because several of the actions in the plan do not meet the purpose and need of the LTEMP or do not agree with the Comprehensive Fisheries Management Plan. The NPS is continuing to work with AZGFD to work toward agreement on these concerns.

4 CULTURAL RESOURCES

4.1 APPLICABILITY AND COMPOSITION OF CULTURAL RESOURCE METRICS

4.1.1 Wind Transport

Summary Comment: Commenters expressed concern with how effectively this metric captures the potential for wind transported sediment to help preserve archaeological sites along the Colorado River. The comments ranged from requests to remove the metric from the analysis to clarifications on how the components of the metric were developed.

Response: The text in the EIS was updated to include the results of several recently published studies on the extent and range that wind transported sediment can be distributed. The text was also modified to indicate that some Tribal members may not consider the reburial of sites by wind transported sediment to be a positive effect.

4.1.2 Time Off River

Summary Comment: Commenters expressed that the time-off-river metric, a measure of the time available to rafters for shore exploration during river trips and a function of river flow levels, is a poor measure of potential impacts on archaeological sites and should not play an important role in the EIS analyses. Commenters noted that while the metric is a logical construct, there is no evidence that more time off river leads to greater visitation because visitors have many other options for exploration and, further, that respectful visitation of Class I sites is actually expected and encouraged.

Response: In the cultural section, 4.8, this metric is presented as a **potential** for increased effects, rather than as a direct link to increased effects, because the monitoring of these sites which NPS has performed over the last 20 years has not shown a strong correlation or a cause and effect relationship. The metric was developed in response to concerns from the Tribes who have noted negative effects at archaeological sites due to visitors and their observations that additional time off river allows for boating parties to spend more time hiking and visiting sites. The value of the metric for cultural resources varied little among the LTEMP alternatives as noted in Section 4.8.

In the recreation analysis in Section 4.11, this metric measures the potential effects of alternate flow regimes on recreation and therefore is the most pertinent means of evaluating the LTEMP alternatives with respect to effects on recreation. In the recreation analysis, more time-off-river was considered a positive for recreation as it was used to "evaluate the opportunity for onshore exploration." The value of the metric varied little among the LTEMP alternatives (Figure 4.10-1), and thus had little value in differentiating them as noted in Section 4.11.2.

4.1.3 Glen Canyon Flow Effect Metric

Comment Summary: Commenters raised concerns with the choice of Ninemile Terrace as a proxy for other historic properties in GCNRA and also questioned the effectiveness of the metric as a predictor of erosion at archaeological sites in GCNRA because of a lack of direct studies on this topic.

Response: Text was added in Appendix H to further clarify why Ninemile Terrace is an effective proxy for other archaeological sites in GCNRA. The components of the metric are based on direct observations of effects from past HFEs on the terrace.

4.2 AREA OF POTENTIAL EFFECTS

Request disclosure on how APE was determined. Do not support the rim to rim application of the APE.

Summary Comment: Several commenters inquired about the Area of Potential Effect (APE) for the Section 106 of the National Historic Preservation Act review for LTEMP. The DEIS contained general language on this topic as consultation was on going when the DEIS was issued. Specifically they were seeking information on how the APE was determined and which historic properties were being included. There was a commenter who disagreed with defining the APE to include all historic properties within the canyon.

Response: Text in Chapters 3 and 4 has been updated to explain the differences between the analysis of potential effects between NEPA and NHPA Section 106. Reclamation and the NPS are developing a new programmatic agreement for the NHPA Section 106 process and to help guide management of cultural resources along the Colorado River. These consultations are on-going. Once the Cultural Programmatic Agreement is complete the information on the APE will be provided to the public.

4.3 LANDMARK STATUS FOR GRAND CANYON AND ITS RESOURCES

Summary Comment: Comments were received suggesting that the cultural resources found within the Grand Canyon warrant consideration as a National Historic Landmark and that nomination of the resources as a National Historic Landmark begin soon.

Response: The NPS is continuing consultations with the Tribes concerning future nominations for listing of resource in the National Register of Historic Places. However, the nomination of the canyon as a National Historic Landmark is beyond the scope of the LTEMP EIS.

5 CUMULATIVE IMPACTS

5.1 ADDITIONAL FORESEEABLE ACTIONS (INCLUDING MANAGEMENT PLANS) TO BE INCLUDED

Summary Comment: Commenters requested that additional foreseeable actions be included in the cumulative impacts analysis. Among them were the MLFF alternative (1996 ROD), releases of contaminated water into Lake Powell (related to mines), the AZGFD fisheries management plan, and the Flaming Gorge Dam and Aspinall Unit EISs.

Response: The cumulative impacts analysis was revised to include the additional foreseeable actions as requested and to account for the effects of these actions on various resources, as warranted.

5.2 REFINEMENT OF DESCRIPTION AND/OR IMPACT ASSESSMENT FOR FORESEEABLE ACTIONS CONSIDERED

Summary Comment: Commenters requested revisions to modify or update the descriptions of foreseeable actions identified; e.g., to flesh out the implications of the 2007 Guidelines to water resources or to update the status of the Clean Power Plan proposed rule. Other requests pertained to defining terms (e.g., the region of influence or the term "future projects"). Commenters also requested that descriptions of power plants (Four Corners and San Juan Generating Station), listed as foreseeable actions, be revised to reflect the current and scheduled modifications at those plants and that the implications of these changes to regional hydropower generation be addressed.

Response: The cumulative impacts analysis was revised to update descriptions of foreseeable actions and to account for the effect of these changes on water resources and hydropower, as warranted. Definitions of terms such as "region of influence" and "future projects" were added in Section 4.17.

6 HYDROPOWER

6.1 SCOPE OF ANALYSIS AND STUDY ELEMENTS

6.1.1 Hydropower Goals and Objectives

Summary Comment: Hydropower goal and objectives are not clear and use conflicting language in the various sections of the report.

Response: Text has been revised to make consistent throughout EIS.

6.1.2 Generation at Hoover Dam

Summary Comment: Analysis of changes in generation at Hoover Dam is beyond the scope of LTEMP because Hoover and Glen Canyon are statutorily separate.

Response: Although Glen and Hoover are statutorily separate and effect different entities, the power systems economic analysis focuses on power production costs and capacity expansion related expenditures for the grid as a whole not on the financial impacts for specific entities. Economic impacts on Lake Mead and Hoover Dam are the result of changes in monthly water release patterns from Lake Powell. These changes to impacts on power economics have been identified and therefore were included in the FEIS.

6.1.3 Cumulative Impacts on Power Systems

Summary Comment: Cumulative impacts on power systems were not adequately addressed.

Response: Text has been added to the EIS to address this concern in Section 4.17.

6.1.4 Analysis of Impacts on Basin Fund

Summary Comment: The impacts on Upper Colorado Basin Fund, cash flow and its ability to fund important research should be studied in more detail.

Response: Section 3.13.1.2 includes a description of the Basin Fund and states “Most of the revenues come from sales of hydroelectric power and transmission service.” This EIS did analyze revenues from Glen Canyon hydropower production and their contribution to the Basin Fund. See the extensive hydropower analysis in 4.13 and Appendix K. There are other factors that affect the balance of the Basin Fund; however, they are outside the scope of the actions analyzed in the LTEMP EIS and would not be affected by the LTEMP alternatives. It should also be noted that consideration of unacceptable adverse impacts on the Basin Fund is one of the considerations included in Section 2.2.4.3 as part of the implementation process for experiments that may affect hydropower.

6.1.5 Consideration of Impacts on Basin Fund

Summary Comment: Impact on Upper Colorado Basin Fund should be a secondary consideration when selecting a preferred alternative.

Response: DOI considers the Upper Basin Fund important to the LTEMP given its role in funding environmental activities. Consideration of unacceptable adverse impacts on the Basin Fund is one of the considerations included in Section 2.2.4.3 as part of the implementation process for experiments.

6.1.6 Power System Impacts on Climate Change

Summary Comment: Potential climate change impacts on LTEMP alternatives were not incorporated in the power systems analysis.

Response: Climate change effects on hydropower generation results are presented in Section 4.16.3. The LTEMP climate change analysis was based on the Basin Study (Reclamation 2012), which was peer reviewed and is the best available science regarding climate change projections in the Colorado River Study. The hydrological traces generated for the Basin Study were utilized as described in Section 4.16.1.2 and Appendix C. The Basin Study used 112 climate change hydrologic traces generated as part of the Basin Study, however due to insufficient data to drive the complex suite of models, we used a subset of 21 traces out of the 112 for the LTEMP EIS. These 21 reconstructed historical hydrological traces were reweighted based on the 112 traces to represent the best current understanding of what might happen because of climate change. Based on this analysis, the weights on the hydrological traces had a small effect on the aggregate performance but did not change the rankings of alternatives. This result suggests the alternatives are robust to uncertainty about climate change.

6.1.7 Sensitivity Analysis of Fuel Prices

Summary Comment: A sensitivity analysis using a range of projected utility fuel prices should have been conducted because natural gas prices are currently very low.

Response: Text was added to the EIS text acknowledging the possible effects of the currently low natural gas prices on results.

6.1.8 Clean Powerplant Legislation

Summary Comment: Clean powerplant legislation was not considered in the analysis.

Response: Information about clean powerplant legislation is included in the cumulative impacts Section 4.17, but that legislation is currently in draft form. In February 2016 the Supreme Court ordered EPA to stop enforcement until a lower court rules on a lawsuit. A ruling on the lawsuit will most likely not come until after the 2016 presidential election and enforcement may depend upon the results of the election as well. Because specifics are unknown at this time and it may be

tied up in litigation for many years, it was not appropriate to analyze it further than this in this EIS.

6.2 GENERAL OVERARCHING COMMENTS ON THE POWER SYSTEMS ANALYSIS

6.2.1 Adequacy of Power Systems Analysis

Summary Comment: The analysis is strongly biased against hydropower resources, incomplete, and significantly underestimates costs in all cases using simplified models and metrics for hydropower resource rendering it inadequate.

Response: The commenter has provided no evidence to support these conclusions. Therefore, we have no basis to determine whether or not they are accurate. We do not believe that the analysis is biased against hydropower resources, is incomplete, or underestimates costs. LTEMP used economic measures that are consistent with the ones used in other Upper Colorado River Basin environmental studies. The level of technical detail that was used to support the computation of these measures has in general exceeded the ones used in other studies, some of which only applied the GTMax-lite model. For the LTEMP analysis we also used the AURORA model to explore grid-wide interactions. All major assumptions are both noted and documented and rely on publically available sources such as those published by the U.S. Energy Information Administration (EIA) and the Federal Energy Regulatory Commission. There were several sensitivity analyses included in Appendix K to explore possible additional sources of costs. In response to utility cooperator comments on the DEIS, an additional analysis was added to Appendix K looking at a different mix of powerplant replacement technologies which could result in a higher estimate of capacity replacement costs. The text in Chapter 4 Section 4.13 was also updated to include a summary of those sensitivity analyses.

6.2.2 Ratepayer Analysis Flawed

Summary Comment: The retail ratepayer analysis that was included within the draft LTEMP EIS report is flawed because the agencies that conducted the analysis do not provide retail electric service, do not deal with issues that are directly related to the provision of retail electric service, do not have expertise with respect to retail electric rate making, and did not consult with retail electric service providers such as SRP when conducting the analysis.

Response: Retail rate analyses were primarily conducted by Edward Bodmer who led retail electricity rate and utility financial viability analyses for Western's Electric Power Marketing EIS. He is an experienced financial consultant who develops complex corporate project finance and simulation models. He provides expert testimony on financial issues before regulatory agencies and has taught customized in-house courses for Shell Oil, General Electric, HSBC, Citibank, CIMB, Lindlakers, Saudi Aramco and many other energy and industrial clients around the world. He also worked for a regulatory commission and has testified approximately 40 times on rate making issues both from a financial perspective and a rate allocation perspective. The

rate impacts were reviewed by experts in the field who had no problems with the overall approach. Formerly, Bodmer was the Vice President at the First National Bank of Chicago, where he directed created financial modeling techniques used in advisory projects. With respect to the comment that we did not consult with entities such as SRP, this is simply incorrect. We received comments, letters and made presentations where ratemaking entities were present. In addition, we did extensive research on the financial structure of the entities and reviewed financial data in the context of rate setting. In addition, the ratepayer methodology and results report were peer reviewed by three independent reviewers as well as by GCMRC.

6.2.3 Inputs to Capital Costs Analysis

Summary Comment: Capital costs should have been supplied by CREDA members since they actually build new powerplants and entities such as Argonne and Energy and Environmental Economics, Inc. (E3) do not.

Response: LTEMP assumptions regarding the characteristics of all capacity expansion candidates including capital investment costs are noted and documented in K.1.6.2. These costs are based on Energy Information Administration (EIA) data that are used for the EIA Annual Energy Outlook. This section discusses these costs and compares these to other estimates including those used by Western Electricity Coordinating Council (WECC) and those supplied by CREDA for a previous Upper Colorado River Basin EIS. LTEMP hydropower analysts are both well qualified and have extensive experience in applying these costs for economic analyses. We note that a very similar approach that also used EIA data sources was used by E3 for a study conducted for WECC.

As stated in Chapter 4, Section 4.13.1 "The LTEMP hydropower resources impact analysis was largely an economic analysis rather than a financial analysis. A financial analysis focuses on the revenues and costs accrued by a particular entity, including transfer payments, such as power transactions, taxes, and insurance. It also includes payments made by individual entities for previous investments. In contrast, an economic analysis focuses on societal costs and benefits. Transfer payments among entities are excluded because the total net change to society of these transactions is zero; that is, the amount paid by the buying entity equals the amount received by the selling entity. Also excluded from economic costs are past investments, such as those to construct power plants, because these expenditures have already been incurred on society and cannot be recovered. Similar to other power systems EIS analyses performed by Argonne, the economic analysis performed for LTEMP estimates changes to the U.S. economy as the result of altering operating criteria at Glen Canyon Dam. These economic costs include expenditures to build and operate new capacity in the future to replace Glen Canyon Dam Powerplant lost capacity and both fuel and variable operation and maintenance (O&M) costs associated with altering the dispatch of Western Interconnection generating units. A financial analysis was performed for the LTEMP EIS to estimate the wholesale (see Section 4.13.1.2) and retail rate impacts (see Section 4.13.1.3) on individual affected entities (e.g., individual FES utilities and their retail customers)."

6.3 LEGAL ISSUES

6.3.1 HFEs as Part of Long-Term Operations

Summary Comment: Bypass releases associated with HFE's that are conducted on a routine basis as part of a long-term operational plan are inconsistent with the "Law of the River" and that have not been addressed from a legal perspective.

Response: These releases are experimental and are being implemented in compliance with the Law of the River and specifically in compliance with laws related to the operations of Glen Canyon Dam. Experimental releases only change the monthly and hourly releases with annual volumes still complying with the LROC as currently implemented through the 2007 Interim Guidelines.

6.3.2 Irretrievable Loss of Hydropower

Summary Comment: Experiments cause an irretrievable loss of hydropower production, but there is no analysis included which would meet the requirement of 40 CFR 1506.1

Response: To the extent there is a loss of hydropower production in the future as a result of implementing the preferred alternative, this potential loss has been analyzed in the EIS. Analysis has been added to Section 4.17, and a discussion provided in Section 4.20.

6.4 TECHNICAL POWER SYSTEM ISSUES

6.4.1 Discount Rate

Summary Comment: Discount rate used in the analysis is too high and capital costs have not been escalated resulting in an underestimate of negative power impacts

Response: By policy, Reclamation is required to use the Principles and Guidelines (P&G) discount rate which is currently 3.375%. A rate of 1.4% was used in a sensitivity study, the results of which have been documented. Also, Reclamation P&Gs do not allow real capital cost escalation.

6.4.2 Capital Costs

Summary Comment: Capital costs are too low; all cost considerations for constructing a new generating plant were not included in developing capital and O&M costs.

Response: The economic cost to build a new generating unit (LTEMP costs) and the financial outlays that a utility incurs to build a new generating unit (CREDA costs) are fundamentally different. Utility outlays for taxes and insurance are excluded from an economic analysis because

these are transfer payments that are not part of the cost of construction. LTEMP did not include site specific costs that are advocated by CREDA because that level of detail is beyond a typical economic analysis for an EIS. It would be prohibitively time consuming and expensive to determine all possible sites for power plant replacement and all of the costs associated with those sites, and that level of analysis has never been performed for similar EIS documents on the Colorado River. EIA costs are based on typical values that we adjusted for broad regional construction costs considerations such as material and labor. In response to utility cooperator comments on the DEIS, an additional analysis was added to Appendix K looking at a different mix of powerplant replacement technologies which could result in a higher estimate of capacity replacement costs.

6.4.3 Exceedance Level

Summary Comment: There are concerns about exceedance level assumptions used to estimate firm Glen Canyon Dam Powerplant capacity.

Response: An analysis of Western's current marketing commitments shows that the assumption of 90% exceedance level used in the LTEMP EIS is consistent with their marketing planning assumptions. A 90% exceedance level means that there is up to a 10% risk of those commitments not being met in a given year. To address these concerns about future marketing commitment levels, a sensitivity study was performed on 50%, 90%, and 99% exceedance levels. Results are shown in Appendix K.1.10.4 and summarized in Chapter 4.13. These results generally conclude that lost Glen Canyon Dam powerplant capacity under all alternatives except for Alternative B have the highest capacity loss at the 50% exceedance level that progressively decreases through the 99% exceedance level (see Figure K.1-32 in Appendix K). We therefore performed an economic cost sensitivity analysis on these two levels to quantify reasonable cost "bookends."

6.4.4 Ancillary Service Assumptions

Summary Comment: There are concerns about ancillary service assumptions.

Response: Cooperators were concerned that using a lower ancillary service requirement could significantly affect Glen Canyon Dam dispatch, firm capacity levels, and economic evaluations. A simplified sensitivity analysis was therefore performed to gain a general appreciation for the impact of ancillary service assumptions on model outcomes. The analysis was performed on Alternatives A, D, and F under two disparate ancillary service market assumptions. Results should that difference in the combined net present value of capacity and energy was 0.14% or less. Under all cases, this small economic difference was primarily due to the existence of significant levels of "unused" Glen Canyon Dam Powerplant capacity which could be used to fulfill ancillary service obligations. This analysis is documented in Appendix K.1.10.8.

6.4.5 Modeling Assumptions

Summary Comment: There were questions about the modeling assumptions regarding locational marginal prices (LMP) responses to changes operations at Glen Canyon Dam and the Western Electricity Coordinating Council study (WECCi-leaks study).

Response: Text has been edited for clarity and both figures and reference to the WECCi Leaks study have been removed as it was not used as part of the LTEMP analysis.

6.4.6 Small Customer Representation

Summary Comment: The representation of small customers is unrealistic and flawed. Small customers are more limited in their choices of suppliers due to transmission and resources and do not have the financial resources or the load to build new facilities to replace capacity and energy losses.

Response: The representation of small customers is neither unrealistic nor flawed. For the power systems analysis (both expansion and dispatch modeling), we aggregated the small customers together for precisely the reasons outlined in the comment; namely, that small customers could not build their own facilities and are dependent upon other suppliers and power purchase agreements.

6.4.7 Small Customer Loads and Load Growth

Summary Comment: The representation of small customer loads and load growth rates are incorrect.

Response: Small customer load assumptions and simplifications are fully explained and disclosed. Because hourly generation levels were not readily available from publically available sources, we used normalized load profiles from other entities as approximations. Normalized load profiles express loads in terms of a fraction of the peak load such that the peak load is set equal to 1.000 and all other loads are less than 1.000 (i.e., hourly load/peak load). These load shapes were scaled to match estimated historical total load based on information that was collected for the retail rate 40 payer analyses. For example, the UAMPS normalized load profile was used to represent small customers in the west. It was selected because most of the 44 UAMPS members are small municipal systems that serve small to medium cities and towns that have attributes which are similar to many of WAPA's small customers. We judged that this modeling approach produces a reasonable approximation of aggregate small customer loads. In addition, errors occur equally under all alternatives and therefore probably have minimal effects on the comparative results.

6.4.8 System Expansion Plan

Summary Comment: Assumptions regarding a cooperative SLCA/IP system-wide expansion plan are overly simplistic and results in an underestimate of power impacts.

Response: Text revisions have been made for clarification. Power impacts have not been underestimated because this level of modeling and simplification is consistent with and improves upon previous EISs conducted for Glen Canyon Dam, such as the 2007 interim guidelines. Due to the complex nature of the grid, all power systems models with scopes that cover a large geographical area over a multiple year time span, such as the one conducted in support of LTEMP, need to make simplifying assumptions in order for the problem to be tractable. For LTEMP we tailored models and methods to meet study objectives; that are to rank alternatives in terms of economic costs and to gain an appreciation for relative costs among alternatives. As detailed in Appendix K, we performed sensitivity analyses on several key modeling assumptions to learn about the effect of these assumptions on model results and to obtain a reasonable estimate of potential outcomes. We also applied methods and models, such as AURORA, that were more detailed than those used for previous EIS's conducted on power facilities in the Colorado River Basin. We observed that the ranking are very robust changing little as a function of modeling assumptions. We also observed the GTMax-lite model that strips away many of the modeling complexities embedded within AURORA lead to very similar alternative rankings. Thus, we made assumptions and implications at the level appropriate for this type of analysis and have fully disclosed those assumptions in the EIS. We also discussed the possible implications of this simplification of model results. The document also includes several examples of joint powerplant/unit ownerships that currently exist in the study region. The power analysis methods, assumptions and results have been peer reviewed by three external experts and the peer review results are available on the LTEMP website.

6.4.9 Transmission Constraints

Summary Comment: Transmission system constraints on power exchanges in the region should have been included in the analysis.

Response: Detailed transmission system constraints on power exchanges in the region were not explicitly modeled because it would have significantly increased the size and complexity of the problem and it was not expected to have a significant impact on comparative results among alternatives. It is also consistent with previous EISs conducted for Glen Canyon Dam that also did not explicitly represent the transmission system. We did however include on- and off-peak costs on AURORA modeled energy flows (i.e., power transactions) among customers based on average historical transmission rates. These costs tend to dampen bulk power transactions among energy trading entities. The end result was that AURORA estimated generation levels are very similar to historical levels by both fuel type and at the utility level. We have disclosed methodologies, assumptions, limitations and results which were peer reviewed. It is noted in the EIS that the WAPA contract rate of delivery (CROD) will be identical under all alternatives. If feasible, customers can utilize the CROD to schedule the delivery of both WAPA energy and other energy transactions up to the contractual limit.

6.4.10 Renewable Portfolio Standards

Summary Comment: SLCA/IP customers such as SRP are not required to comply with State Renewable Portfolio Standards (RPS).

Response: We acknowledge that RPSs are not required of all LTF customers. SRP and Tri-State do have an internal program to set a target for building significant amounts of renewable or sustainable resources.

6.4.11 Costs of HFEs

Summary Comment: Costs to conduct experiments such as HFEs are underestimated because trading partners would take advantage of Western's inflexible situation during experiments.

Response: We acknowledge that the prices that WAPA is offered from its trading partners during HFEs sometime depart from overall market prices. This has financial implications for WAPA. The power systems economic analysis does not consider these financial transactions because there are no system-level economic impacts. The savings gained by entities that purchase at below market prices are exactly offset by financial losses for entities that sell below market price. The net economic impact is therefore zero.

6.4.12 Costs of Experiments

Summary Comment: The costs to conduct experiments are too low and experiments such as low summer flow would have a devastating impact on power.

Response: The analysis shows that a low summer flow experiment would not significantly, if at all, change annual hydropower production during low summer flow years. There would be an economic impact however with a decrease in NPV between $13.93 million and $21.01 million. Low summer flows are projected to occur infrequently; under the preferred alternative, low summer flow would be expected to be tested once in the second 10 years of the LTEMP period.

6.4.13 Impacts of Macroinvertebrate Production Flows on Hydropower

Summary Comment: Macroinvertebrate production flows may cause serious negative impacts on power and should be conducted in a way that is least damaging to hydropower.

Response: After the DEIS was published, hydropower assumptions and the modeling of macroinvertebrate production flows were revised based on input from WAPA, the results of which show a positive benefit to hydropower capacity. Revised results are consistent with analyses conducted by WAPA regarding a positive net benefit to power.

6.4.14 Effects at Hoover Dam and Glen Canyon Dam

Summary Comment: Concerns were raised about potential perceptions regarding changes in higher Lake Mead elevations and Hoover powerplant "benefits" offsetting Glen Canyon Dam economic impacts.

Response: To address these concerns the description of Hoover Dam impacts were substantially revised. The FEIS no longer refers to changes in the NPV of Hoover as a "benefit" or as "offsetting" alternative costs at Glen Canyon. We also indicate that the economics of Hoover and Glen Canyon are not directly comparable because the analyses used different levels of modeling details. Instead we indicate that the Hoover analysis was performed primarily to disclose the general direction and relative magnitudes of Hoover impacts.

6.5 RETAIL RATE ANALYSIS

6.5.1 Consideration of Wholesale Rate Input

Summary Comment: Retail electric rates were computed without accounting for wholesale rate charged by Western

Response: Wholesale rates were not used because: (1) the wholesale rate study was completed after the retail rate analysis; (2) through directly using data from the power systems model the direct connection between power system costs and rate impacts could be observed and the process was transparent; (3) the capital cost of constructing new capacity incurred by utility systems (such as Tri-state) was directly estimated rather than assuming Western would carry the burden of replacing the capacity. In addition, modeling was peer reviewed by three independent reviewers as well by GCMRC.

6.6 WHOLESALE RATE ANALYSIS

6.6.1 Assumptions

Summary Comment: Concerns regarding the bookends marketing assumptions selected for the wholesale rate analysis

Response: Wholesale rate bookends were chosen because they were thought to represent a reasonable range for the marketing of SLCA/IP power in the post-2024 period and illustrate that the effect of the SLCA/IP rates from the LTEMP EIS alternatives are, in part, driven by sales of AHP energy and capacity.

6.7 EDITORIAL COMMENTS

Numerous substantive editorial comments were submitted on hydropower sections in the DEIS including Sections 3.13, 4.13, and Appendix K. Where appropriate, the text of the EIS was modified to address the specific comments.

7 NATURAL PROCESSES

7.1 NATURALLY PATTERNED FLOW AND RUN-OF-THE-RIVER FLOW ALTERNATIVES

Summary Comment: One commenter suggested that the LTEMP should improve habitats by attempting to recreate the shape of the historic hydrograph by generally increasing water levels until June followed by a gradual ramp down to a lower level between September and February, with a possible late summer spike to simulate late-summer monsoons. The daily fluctuations with dramatic step-ups and step-downs in flow that now occur almost never occurred before the dam was in place.

Response: "Naturally patterned flow" and "Run-of-the-river" alternatives were considered but dismissed in the draft EIS (see Sections 2.3.2, 2.3.11).

7.2 REMOVE NATURAL PROCESSES FROM THE EIS

Summary Comment: One commenter wanted natural processes deleted from the EIS.

Response: No text change made. The natural processes goal was based on several of the Desired Future Conditions (see Appendix A of the EIS) and on NPS management policy.

7.3 NATURAL RESOURCE PERFORMANCE GOAL

7.3.1 Quantitative Performance Metric

Summary Comment: Several commenters stated that a quantitative performance goal should have been established for natural processes, possibly comparing alternative flows with pre-dam flows.

Response: The best available science and models were used in this EIS. There was not adequate information to develop a quantitative performance metric for pre-dam versus post-dam conditions in a consistent manner to facilitate comparison across alternatives for natural processes.

7.3.2 Goal to Restore Is Not Achievable

Summary Comment: A few commenters wanted the following sentence deleted: "For the LTEMP, the analogous natural processes resource goal is to 'restore, to the extent practicable, ecological patterns and processes within their range of natural variability, including the natural abundance, diversity, and genetic and ecological integrity of the plant and animal species native to those ecosystems'." It is not possible to operate Glen Canyon Dam in a manner that could

fully restore natural processes and their drivers to those that occurred under unregulated conditions

Response: No text change made. The natural processes goal was based on several of the desired future conditions (see Appendix A of the EIS) and on NPS management policy. The EIS recognizes that management of dam operations and any subsequent effects on natural processes may not act to fully restore natural resources in the system. Rather, the EIS compares alternatives with regard to how alternative-specific temperature, flow, and sediment conditions may affect processes that depend on these conditions, and possible subsequent responses in natural resources, including not only maintenance of native biota in their current conditions, but also enhance or improve habitats and thus benefit associated biota.

7.3.3 National Park Service Natural Processes Management Policy and Goals

Summary Comment: One commenter noted that an important objective of management of the Colorado River Ecosystem is the ability to sustain healthy populations of native plants and animals and natural ecological processes. NPS management policies state that (1) "whenever possible, natural processes will be relied upon to maintain native plants and animals and influence natural fluctuations in populations of these species" and (2) "the Service ... will try to maintain all components and processes of naturally evolving park ecosystems, including the natural abundance, diversity, and genetic and ecological integrity of the plant and animal species native to those ecosystems" (NPS 2006b). For the LTEMP, the analogous natural processes resource goal is to "restore, to the extent practicable, ecological patterns and processes within their range of natural variability, including the natural abundance, diversity, and genetic and ecological integrity of the plant and animal species native to those ecosystems." It is not possible to operate Glen Canyon Dam in a manner that could fully restore natural processes and their drivers to those that occurred under unregulated conditions." Since management policies are not dictum; why can they not be changed? The commenter further states that statements such as "rely on natural processes" and "try to maintain" are much different from "restore".

Response: Changing NPS Policy is outside the scope of the EIS. The EIS recognizes that management of dam operations and any subsequent effects on natural processes may not act to fully restore natural resources in the system. Rather, the EIS compares alternatives with regard to how alternative-specific temperature, flow, and sediment conditions may affect processes that depend on these conditions, and possible subsequent responses in natural resources, including not only maintenance of native biota in their current conditions, but also enhance or improve habitats and thus benefit associated biota

7.4 OPPORTUNITY TO EXPAND NON-FLOW MANAGEMENT OPTIONS TO IMPROVE AQUATIC AND RIPARIAN HABITAT

Summary Comment: A commenter noted that Glen Canyon Dam is presently functioning to protect native aquatic and riparian species from upstream and downstream threats. However, the very existence of the Dam is at odds with the National Park Service (NPS) Organic Act and the enabling legislation of Grand Canyon National Park. This means that the management objectives

of the NPS at Grand Canyon do not really include using the Dam to foster aquatic and riparian habitat rehabilitation. Reclamation and the NPS could be doing much more to improve riparian habitat quality, particularly now that much of the non-native tamarisk habitat along the river is declining due to tamarisk leaf beetle introduction. Collaboration of these two agencies in this DEIS and the Record of Decision is an opportunity to greatly expand non-flow management options to improve aquatic and riparian habitat area and quality.

Response: The LTEMP is intended to identify operational and experimental management alternatives specifically for protecting and enhancing aquatic, riparian, and terrestrial habitats and their associated biota, as well as protecting cultural resources and balancing human uses in the system. Alternatives considered in the EIS include flow conditions that may support improvements in riparian and aquatic habitats. The LTEMP also includes non-flow management options, such as mechanical trout removal, that may benefit native aquatic biota in the system. All the action alternatives also include a non-flow vegetation treatment experiment to address riparian vegetation including removal of invasive species and replanting of natives. The agencies have been working together, and expect to continue that collaboration beyond the ROD for protecting and improving natural and cultural resources while providing for cultural, recreational, and commercial uses and activities in the Grand Canyon National Park.

7.5 HFEs SHOULD BE INCLUDED IN THE EVALUATION OF EFFECTS TO NATURAL PROCESSES

Summary Comment: A couple of commenters stated that since HFEs have a direct effect to fisheries, plants, animals, and water quality, they should be considered in the effects on natural processes.

Response: HFEs were considered in the effects on all resources in Chapter 3, as well as on Natural Processes.

8 PROCESS AND POLICY

8.1 INCLUDE THPOs IN CONTACT LIST

Summary Comment: Commenters on this issue requested that THPOs be included in the list of groups to be contacted.

Response: Text has been modified as suggested and THPOs have been added to the list of groups to be contacted.

8.2 TRIBES INVOLVEMENT IN ALTERNATIVES DEVELOPMENT

Summary Comment: A commenter on this issue indicated that Tribes should have been invited to participate in alternative development like the Arizona Game and Fish Department was.

Response: Tribes were invited to be Cooperating Agencies in the LTEMP EIS process – see Section 5.1.3 for the process that was used to inviting and communicating with Tribes. Many meetings were held with Tribes throughout the alternative development process, the modeling development and results, the structured decision analysis, and the draft writing and editing to allow for input and comment. Meetings are still continuing with Tribes on the programmatic agreement and on a non-native fish agreement related to the LTEMP. Several traditionally associated Tribes are part of the AMWG process as well as being cooperators, and so were part of the LTEMP process through many meetings and webinars provided through that process.

8.3 SIERRA CLUB'S SCOPING COMMENTS

Comment Summary: The commenter on this issue requested that Sierra Club's scoping comments be added to the official public record and requested that their comments be addressed in the Final Environmental Impact Statement.

Response: We apologize that the Sierra Club scoping letter was inadvertently left out of the initial scoping report that was made available on the LTEMP website. Thank you for calling this to our attention in your comments on the DEIS and we have now added your scoping letter to that report and made the revised version available on our website. Your letter was reviewed and considered in the process of drafting the LTEMP EIS. Below is a summary of the issues you presented in your scoping letter and how we have addressed them in this EIS process.

1) Introduction – concern regarding declining conditions since the dam has been in place – 95% sediment loss, nutrient base, dissolved oxygen, temperature reduction, changes to flood regime, extirpated species, increasing non-native plant species.

Response: This list of concerns were considered in the preparation of the EIS. Chapter 3 of the EIS describes changes that have occurred in the Colorado River Ecosystem since construction of the dam.

2a) Legal Authorities - hydropower generation should be removed from the need statement.

Response: The purpose and need statement clearly articulates the responsibilities of the Secretary of the Interior under the Grand Canyon Protection Act (GCPA); the goal of which is to preserve, mitigate adverse impact to and improve the values for which Grand Canyon National Park and Glen Canyon National Recreation Area were established, including, but not limited to natural and cultural resources and visitor use. The purpose and need and alternatives evaluated in the EIS take direction from the GCPA and attempt to develop an alternative that meets the requirements of the GCPA and applicable Federal laws, regulations, and policies. In addition to Section 1802(a) of GCPA, the Secretary is required to follow numerous other Federal laws, including the 1956 Colorado River Storage Project Act. Both Section 1 quoted in the letter, and Section 7, direct the Secretary to generate the greatest practicable amount of power at Glen Canyon Dam. This requirement is also found in Section 1802(b) of the GCPA. Therefore, removal of power generation from the purpose and need statement in the EIS would be inconsistent with other parts of the GCPA.

2b) Scientific Framework – Full analysis of downstream resources. GCMRC involvement. Clear experimental framework, thresholds, triggers. Implement recovery of native species, and analyze alternatives that experiment with sediment augmentation, temperature modification and restoration of the natural hydrograph.

Response: The LTEMP EIS provided a full analysis of downstream resources that could be affected by the proposed action and alternatives. GCMRC was involved in the development of alternatives, in developing modeling approaches, in subject matter expert meetings throughout the process, in reviewing and editing the EIS, and in peer review of models and finally in the development of a science plan to guide the implementation of LTEMP once a final preferred alternative and ROD are in place. The reintroduction of extirpated species was outside the scope of the LTEMP as stated in Section 1.5.3. Early in scoping, we did consider some alternative concepts with new infrastructure, but determined that consideration of new infrastructure on the dam such as sediment augmentation and temperature modification were outside of the scope as well as economically infeasible at this time as stated in Section 1.5.3. In early scoping we did evaluate several alternatives that would have resulted in dam releases intended to mimic the natural hydrograph. However, preliminary modeling indicated several of those had unacceptable adverse resource impacts, particularly to sediment. Seasonally Adjusted Steady Flows was the most natural hydrograph in an alternative and was carried all the way through as Alternative G. The preferred alternative does incorporate two types of spring releases (sediment triggered and proactive spring HFEs) which provide peak flows that mimic the natural hydrograph to some degree.

3) Modification of Purpose and Need

Response: Please see the answer to Legal Authorities comment.

4) Impacts to Natural Resources – Sediments and Soils

Response: Sediment conservation was fully considered and analyzed in the LTEMP EIS using the best available science and modeling. See Sections 3.3 and 4.3. All of the action alternatives

included high flows of various types and frequencies. The effect of the flow regimes on natural processes and native species was considered in the analysis based on the best available information.

5) Impacts on Natural Resources – Threatened, Endangered and Sensitive Species

Response: Endangered, threatened and sensitive species were considered in the LTEMP EIS analysis based on the best available science and modeling. See Sections 3.5, 3.7, 4.5, 4.7.

6) Unsuccessful Native Fish Recovery

Response: Temperature and flow effects of the preferred alternative on native fish were evaluated in the LTEMP EIS. The preferred alternative includes a spring high flow, called a proactive spring HFE, which would occur generally at a time that the historical record indicates was when spring flooding in Grand Canyon typically occurred. Though proactive spring HFEs have been designed for sediment conservation purposes, they may provide experimental data through GCMRC monitoring efforts on effects to native fish. Though all of the alternatives are expected to have relatively similar effects on native and endangered fish, the preferred alternative includes several actions to manage nonnative fish and experiments designed to improve aquatic invertebrate populations in order to benefit native fish. The preferred alternative performed slightly better than No Action on several native and endangered fish metrics.

7) Unsuccessful Adaptive Management Program: The unsuccessful "Modified Low Fluctuating Flow Alternative" (MLFF) enacted in the Adaptive Management Program has not achieved the desired results of protecting the Canyon's resources including the beaches, the native fishes, and the cultural sites. New alternatives should be developed by the Grand Canyon Monitoring and Research Center to address scientific hypotheses regarding the best possible alternative for sediment retention (i.e., Wright et al. 2008) and mimicking the natural historic hydrograph.

Response: GCMRC helped in the development of alternatives and a seasonally adjusted steady flow alternative was considered as Alternative G. Several alternatives, including the preferred alternative, performed better than No Action on beach and sandbar building metrics.

8) Cumulative Impacts

Response: Cumulative impacts to vegetation, fish, wildlife and endangered species were analyzed in the LTEMP EIS (see Section 4.17). The EIS incorporates elements of, and will supersede, the HFE Protocol and Non-Native Fish Removal Protocol that have been in place since 2012.

9) Impacts on Natural Resources – Water Quality: Restoration of water quality must be addressed in the EIS taking into account the effects of different release structures and their effects on downstream ecology. The EIS should also consider salinity levels, water temperature, turbidity and suspended sediment, nutrients and dissolved oxygen concentrations. An additional critical factor that must be considered is the impact of drought

on the quality of dam releases. For example, when Lake Powell is lower, water releases are warmer than, and oxygen levels differ from, water released from a fuller lake

Response: Impacts to water quality in the Colorado River and reservoirs were considered in the LTEMP EIS. See Sections 3.2 and 4.2. Climate change was analyzed with respect to hydrological effects in Section 4.2. It should be noted that the LTEMP did not affect levels of Lake Powell and Lake Mead at an annual or great time scale; the scope of the LTEMP includes monthly, daily and hourly releases from Glen Canyon Dam, but not annual volumes from Glen Canyon Dam, so the effects to water quality were considered within this scope.

10) Impacts of Reduced Flows Associated with Climate Change: The LTEMP must specifically create a plan for providing water to the Colorado River in Grand Canyon during extended drought periods.

Response: Climate change was considered within the LTEMP EIS. The 2012 Colorado River Basin Study provided data for the EIS, and the modeling included a set of modeling runs to address climate change concerns. This climate change modeling did not alter the pattern of performance of the alternatives and the preferred alternative still performed well when considered in the context of projections regarding future climate change. The scope of the LTEMP includes monthly and hourly releases from Glen Canyon Dam, but not annual volumes from Glen Canyon Dam, so the scope of the analysis was considered with respect to for monthly and hourly changes.

11) Impacts on Natural Resources – Terrestrial Wildlife

Response: Impacts to terrestrial wildlife were considered in the LTEMP EIS in Section 4.7.

12) Impacts on Natural Resources – Vegetation

Response: Impacts to vegetation were considered in the LTEMP EIS in Section 4.6. There was considerable discussion between joint lead staff and GCMRC about different flows to benefit native vegetation species. We discussed the timing and scouring effects of various water flows that could disadvantage nonnative species. Modeling was performed using the best available vegetation model and GIS mapping information and the preferred alternative performed better than the No Action alternative for maintaining native vegetation condition. However, under all alternatives, vegetation condition is expected to decline over time. Because of this, a feature common to all of the action alternatives analyzed in this EIS is an experimental vegetation treatment project to address nonnative vegetation removal, native vegetation planting and other vegetation issues. This was developed in coordination with GCMRC and after discussions with other partners and Tribes.

13) Commenter Recommendations

Recommendation: Restore essential sediment and nutrients into the main stem of the Colorado River in the Grand Canyon.

Response: Sediment conservation was a resource goal as expressed in Section 1.4. More even monthly volumes and frequent HFEs are components of the preferred alternative to address sediment conservation.

Recommendation: Restore flow regimes to properly transport the sediment and nutrients within Grand Canyon, when and where it belongs. The 1994 Biological Opinion and the EIS referred to these as Seasonally Adjusted Steady Flows (USDOI 1995)

Response: The LTEMP EIS evaluated a seasonally adjusted steady flow option, Alternative G, however it was not identified as the preferred alternative as Alternative D showed a better balance to protect downstream resources.

Recommendation: Restore the seasonally variable water temperature in the main stem of the Colorado River through Grand Canyon. The 1994 Biological Opinion and the EIS referred to this as Selective Withdrawal by means of a Temperature Control Device (USDOI 1995). Look to the Temperature Control Device at Flaming Gorge Dam as a source of information and experimentation to guide planning at Glen Canyon Dam. Answer the question of "whether the potential benefits to the endangered fish of operating a TCD and warming the water outweigh the potential adverse effects from potential increases in nonnative predators, parasites and diseases, or other unintended, systemic interactions in the downstream environment." (USDOI USBOR 2007) It is entirely possible – even probable -- that native fish will perform better in the temperature environment in which they adapted (i.e., Clarkson and Childs 2000).

Response: Flow options for affecting temperature were considered as part of the LTEMP and the preferred alternative includes an experimental option for low summer flows. Temperature control devices were outside the scope of this project.

Recommendation: Implement a restoration and recovery program for the Colorado River corridor in Grand Canyon that includes the recovery of all species known to be native to Grand Canyon prior to the operation of Glen Canyon Dam.

Response: The reintroduction of extirpated species was outside the scope of this EIS and is discussed in Section 1.5.3. LTEMP EIS alternatives include experiments that are intended to improve conditions for ESA-listed species and other special status species. The LTEMP EIS team used the best available science and peer-reviewed modeling to determine the potential effects of these alternatives on these species. DOI has worked closely with FWS throughout the 5-year EIS process to ensure that the appropriate experiments, dam operations, and non-flow actions were identified as conservation measures. Formal consultation with FWS has resulted in a Biological Assessment and Biological Opinion on the effects of the proposed action on listed species and designated critical habitat, as presented in Appendix O of the EIS.

The original notice of intent to prepare the LTEMP EIS identified the need to determine whether to establish a recovery implementation program for endangered fish species below Glen Canyon Dam. The LTEMP team found that identifying the need to determine whether to establish a recovery implementation program (RIP) for endangered fish species below Glen Canyon Dam did not meet the purpose and need for the action.

Recommendation: Implement a non-native eradication program to minimize alien species in the Grand Canyon river corridor with a priority on those that prey on, compete with, or otherwise impair the health of native plants and animals. Non-native fish retention should not be a priority in designing new flow regimes.

Response: The LTEMP EIS included and evaluated a number of tools for address non-native fish and non-native vegetation. Some Tribes, particularly Zuni and Hopi, have concerns regarding non-native fish removal methods, so the preferred alternative contains some constraints and mitigation measures to address those concerns.

Recommendation: Complete the Little Colorado River Management Plan as recommended by the 1994 Biological Opinion (USDOI 1995).

Response: Development of this plan is considered outside the scope of the LTEMP EIS.

Recommendation: Address the dysfunction of the Adaptive Management Program. The AMP should be replaced by an open source and independent body of research and advisory scientists, where the monitoring and research data are consistently and thoroughly peer-reviewed prior to providing any recommendation to the Secretary of Interior. The Grand Canyon Research and Monitoring Center should have a significant role in creating the LTEMP, including choosing testable hypotheses, designing best-case flow scenarios to retain sediments and native species in Glen and Grand Canyons, and crafting monitoring regimes.

Response: We assume the commenter is referring to the Adaptive Management Work Group (AMWG) when they refer to the AMP. The GCMRC was involved throughout the LTEMP process and assisted as subject matter experts in with the modeling, analysis, experimental design and assisted with peer review of aspects of the LTEMP. The AMWG is a FACA committee established through the GCPA and exists to provide input to the Secretary of the Interior. Changes to the organization of the committee should be directed to the Secretary. Changes to the structure and focus of the AMWG are outside the scope of this EIS.

Recommendation: Assess how the river could be managed with shrinking reservoirs and emphasize water conservation in long-term dam and reservoir management plans. A study by the National Research Council has indicated that long-term drought is the likely outcome of climate change in the Southwest (NRC 2007). The Bureau should consider at what point river management – specifically, water and power needs – would be better served by maximizing water storage in Lake Mead rather than dividing it between Mead and Powell reservoirs. In fact, an article released just this week raises tensions about keeping Lake Mead full see http://www.climatecentral.org/blogs/dry-weather-is-drawing-down-lake-mead/, accessed 1/31/12). The Bureau should assess the comparative loss of water from bank storage and evaporation between these two maintaining both reservoirs, maintaining only Lake Mead, and an alternative where Lake Powell is kept low to reduce "losses" to infiltration and evaporation.

Response: The LTEMP EIS evaluated a range of annual hydrologic inflow scenarios. It also evaluated a range of monthly, daily, and hourly releases from the Glen Canyon Dam while complying with the LROC as currently implemented through the 2007 Interim Guidelines. The "Fill Lake Mead First" alternative was dismissed as it was outside the scope of the LTEMP. We

also addressed the impacts of climate change in the EIS, which could result in "shrinking reservoirs" in the future.

Recommendation: An alternative that examines what would be required to generate a flow magnitude equal to the pre-dam annual or bi-annual average peak flow, and/or a flow that exceeds the current annual average flow by the same proportion as a pre-dam peak exceeded pre-dam average annual flow, should be included, so that such a flow could be planned when water is available.

Response: Flows greater than 45,000 cfs were considered but dismissed as part of this process for a number of reasons including operational and safety concerns.

Recommendation: If beach sizes continue to shrink, recreational capacity should be adjusted downward to prevent exacerbating beach erosion, damaging cultural sites, and damaging vegetation.

Response: The preferred alternative is expected to increase beach and sandbar size. Visitation is a separate process and not an issue within the scope of the LTEMP EIS. Visitation is set currently through the 2006 Grand Canyon Colorado River Management Plan.

Recommendation: Specific trigger points to guide management decisions must be outlined in the plan. If the dam is truly to be adaptively managed, then the LTEMP must identify detectable thresholds that, if reached, will cause a change in operations to be executed.

Response: The adaptive management process and triggers are adequately addressed in this NEPA document. Section 4.1 and Appendices C and K of the LTEMP DEIS have detailed information on the extensive modeling that was performed with a variety of long term strategies and referring to uncertainties explicitly. The long term strategies were variations of the alternatives that turned various experiments "off" or "on" to model different combinations and frequencies of experiments under a variety of hydrologic inflow conditions. This extensive modeling was coupled with extensive literature review and subject matter expert input to provide thorough analysis. This is sufficient for a NEPA analysis. Additional details of experiments and monitoring will be developed through the AMP annual work plans. Greater specificity regarding triggers for HFE implementation and humpback chub actions have been added to the EIS (Appendices O and P).

Recommendation: A healthy Colorado River in Glen and Grand Canyons must be the top priority of all alternatives proposed in the LTEMP, in order to meet the requirements of the GCPA. There is no evidence that Glen Canyon Dam can be operated to restore species and beaches to their pre-dam condition. This plan should be devised as a last, best effort to restore the National Park Service lands downstream of Glen Canyon Dam. Planners should think holistically about what is required to achieve restoration goals, and create alternatives that aim for success. The cost of these alternatives may be high, but will represent the full cost of Glen Canyon Dam to the American public. We are subsidizing the services provided by Glen Canyon Dam by giving away parts of the Colorado River ecosystem for free, and we deserve to know what it will cost to replace all of it.

Response: The GCPA is central to the purpose and need for this project.

Recommendation: Consider the non-use economic value of the Colorado River to the power and water market area when conducting economic analyses.

Response: A non-use economic study was completed as part of the LTEMP EIS process, however it was completed after the release of DEIS. The results were very comparable to the previous Welsh 1995 study. The results of the new study have been incorporated in the FEIS in Section 4.14.

Recommendation: This is an Experimental and Management Plan. Experimentation must be a component of all alternatives. That is, clearly defined hypotheses, ample monitoring and data analyses, and timely reporting need to be included in every alternative.

Response: Experimentation is included in the LTEMP EIS. Triggers for sediment experiments are clearly articulated. For several fish experiments triggers were developed and defined through the consultation process with FWS with information provided from GCMRC and other experts and cooperators. GCMRC also developed a science plan and will be intimately involved in the implementation of LTEMP experiments through the triennial budget process and on-going monitoring, evaluation and reporting.

Recommendation: The Grand Canyon Monitoring and Research Center should be involved in the development of dam operations alternatives and analyzing the pros and cons of different flow regimes. They should provide significant input into developing testable hypotheses, monitoring regimes, and determining thresholds that will trigger operational changes.

Response: GCMRC was involved throughout the LTEMP EIS process.

Recommendation: Glen Canyon Dam is now approximately 50 years old, and its right spillways have never been tested. We have now experienced climate fluctuations that have come very close to testing both the highest capacity and the lowest capacity of the dam for controlling water flow into the Lower Colorado River. There needs to be a plan for dam failure, either by overtopping or by extremely low lake levels. The safety of the dam, spillways, and adjacent sandstone walls should be examined in this analysis.

Response: Dam safety is a priority of the Bureau of Reclamation and is evaluated comprehensively through Reclamation's Dam Safety program on an -ongoing basis. These on-going evaluations are wholly independent of LTEMP and beyond the scope of this NEPA analysis.

8.4 INVOLVEMENT OF COOPERATING AGENCIES AND SME TEAMS

Summary Comment: Commenters on this issue expressed concern regarding a lack of involvement by Cooperating Agencies on SME teams or in the analysis process, or requested more involvement in ongoing and future research and management of CRE resources.

Response: For the LTEMP EIS process there was a high level of involvement and interaction between the joint lead agencies, the Tribes, the cooperators and the stakeholders of the Adaptive Management Working Group (AMWG). There were also several opportunities for public input above and beyond what is required by NEPA. For over four years regular monthly calls were held with Tribes and cooperators, totaling over 50 meetings. Western Area Power Administration (WAPA) was involved in many additional meetings for alternative development and hydropower subject matter expert questions. Well over 150 meetings were held between the joint lead agencies, Tribes and stakeholders during the course of the development of the draft EIS. All cooperators, Tribes and AMWG stakeholders were provided the opportunity to comment on the purpose and need, objectives, resource goals, modeling metrics, modeling methods, and preliminary modeling results. All cooperators and Tribes were afforded review and comment on a preliminary draft of the EIS as well as the public draft EIS. The joint leads also held additional meetings with Tribes, held many consultation meetings with Tribal councils and provided Tribes the opportunity to submit text to fully reflect their perspectives on all resources within the EIS. Implementation details of experiments and monitoring tailored to the specific resource conditions of the year will be developed through the AMP and GCMRC annual work plans with communication and consultation with a number of partners and stakeholders.

8.5 LTEMP EFFECTS ON RESERVOIR OPERATIONS

Summary Comment: A commenter on this issue requested assurance that management actions and experiments proposed in the DEIS will not operate to modify determinations made under the Interim Shortage Guidelines for both Lake Powell and Lake Mead or to trigger a mid-year review of reservoir operations that would otherwise not occur.

Response: The scope of the LTEMP EIS was to evaluate a range of alternatives with different monthly, daily, and hourly releases from the Glen Canyon Dam. All alternatives are consistent with the LROC as currently implemented through the 2007 Interim Guidelines for annual release volumes. See Sections 3.2 and 4.2 for additional detail.

8.6 LIST RELEVANT LAWS AND MANAGEMENT DOCUMENTS

Summary Comment: A commenter on this issue stated that it is unclear as to how the extensive list of laws identified in the DEIS is specifically relevant to the proposed actions. The FEIS would benefit from identifying only those laws and management documents that are directly related and pertinent to the LTEMP process, or explaining why additional laws are included.

Response: Minor changes have been made. The text was revised to focus on the most relevant laws. There is a statement that these lists are not exhaustive.

8.7 APPLICATION OF STRUCTURED DECISION ANALYSIS (SDA)

Summary Comment: Some commenters questioned and did not support the use of SDA to help determine operations at Glen Canyon Dam, did not participate in the voluntary SDA process for

LTEMP, and rejected any reliance on SDA as the basis for operating Glen Canyon Dam to implement the LTEMP for the next 20 years. Some commenters stated that the DEIS relies on a flawed SDA and SDA should not be included in the DEIS as a basis for selecting a Preferred Alternative.

A commenter believed that the SDA overly relied on modelling outputs to claim objectivity and transparency when actual results depended heavily on the assumptions made in creating the models, inputs selected for running the models, and the manner in which the modeling analyses were made and results reported. The commenter believed that the DEIS relied on modeling outputs to justify a scientific and objective result without acknowledging the significant subjectivity that goes into creating and running the models in the first place.

A commenter believed that the DEIS is legally deficient because it relies on an inadequate and incomplete analysis of hydropower developed for the SDA process.

A commenter stated that the DEIS is Legally Inadequate because it Relies on Flawed Structured Decision Analysis. Specific to the hydropower Performance Metric, because of the varying degrees to which swings and weights are established for the various performance metrics, the hydropower metric is automatically given less weight than other metrics. The swing weighting is set up in such a way that sediment is weighted far more importantly than hydropower.

Response: In an effort to provide multiple opportunities for interested stakeholders to provide input in the LTEMP process, the National Park Service (NPS) and the Bureau of Reclamation (BOR) decided to incorporate facilitated structured decision analysis (SDA) into the LTEMP EIS process. The use of SDA in the LTEMP process was not required by NEPA, nor did it replace the NEPA impact analysis. Participation in the SDA process was a voluntary opportunity for stakeholder input. Text was modified to note that not all stakeholders were in support of the process. See Sections 1.7, 2.1 and Appendix C which explain that SDA one of the many tools utilized in this EIS. Text was revised to clarify the scope and authority of resource goals. As stated in Section 1.7, "While structured decision analysis informed the analysis of the joint leads, it was not the only method by which a preferred alternative was identified. The identification of a preferred alternative was based on the full DEIS analysis and considerations relating to qualitative and quantitative evaluations of impacts. Public comment, socioeconomic considerations, AMWG stakeholder input, and other factors were all considered in this decision." All models have limitations and this EIS includes disclosure of those limitations, as well assumptions. The models and the SDA analysis have also been peer-reviewed.

Section 4.1 and Appendices C and K of the LTEMP DEIS have detailed information on the extensive modeling that was performed with a variety of long term strategies. The long term strategies were variations of the alternatives that turned various experiments off or on to model different combinations and frequencies of experiments under a variety of hydrologic inflow conditions. This extensive modeling was coupled with extensive literature review and subject matter expert input to provide thorough analysis. This is sufficient for a NEPA analysis. EPA gave this document an LO-1 rating, the highest possible.

The swing weighting results were not used to quantitatively evaluate the impacts to hydropower in Chapter 4. Any analysis of swing weighting was independently used in Appendix C and was not the only criteria used for identifying a preferred alternative.

8.8 DOI DISCLAIMER

Summary Comment: A commenter recommended that the FEIS and ROD include appropriate disclaimer language to allow the various interested stakeholders to refrain from disputing or contesting general legal characterizations in the DEIS.

Response: DOI will consider the proposed disclaimer language for inclusion for the ROD.

8.9 DOI RESPONSE TO COMMENTS

Summary Comment: A number of commenters requested acknowledgement and response to their comments, that their comments be incorporated into the EIS, that revisions be shown as tracked changes. Commenters stated that they reserve the right to supplement their comments, and requested that their comment letter, material cited, and DOI response be incorporated into the LTEMP administrative record.

Response: Comments were solicited, collected, and incorporated into the FEIS in accordance with CEQ NEPA regulations and DOI policy and guidance.

8.10 COMMENT PERIOD DEADLINE

Summary Comment: A number of commenters stated that DOI had made several statements as to when comments needed to be mailed and received, causing confusion.

Response: All comments uploaded to the NPS PEPC site or received at Argonne with a postmark of May 9, 2016 were considered. The Federal Register notice states: “Reclamation and the NPS will accept‘ comments that are received or postmarked by May 9, 2016.”

8.11 LANGUAGE REGARDING LROC

Summary Comment: A commenter stated that the LTEMP EIS should not include subjective language regarding implementation of LROC or Interim Guidelines.

Response: Nothing in this document affects future decisions regarding the LROC. We have reviewed the text and modified as appropriate to make that clear.

8.12 DESCRIPTION OF HFE PROTOCOL AND NONNATIVE FISH CONTROL PROTOCOL FOR THE PREFERRED ALTERNATIVE

Summary Comment: Commenters suggested that the specific protocols for implementation of HFEs and nonnative fish control under the preferred alternative should be specified in the EIS rather than simply referring to the existing protocols.

Response: Protocols to be followed for implementation of HFEs and nonnative fish control are presented in the EIS in Section 2.2.4.6, Appendix O (Biological Assessment), and Appendix P (HFE protocol for the preferred alternative). Appendix O includes an attachment that describes the triggers to be applied to various experimental aquatic resource actions and the basis of those triggers.

8.13 CONSERVATION MEASURES TO BE APPLIED UNDER ALTERNATIVE D

Summary Comment: One commenter suggested that the conservation measures to be applied under Alternative D should be identified and described.

Response: Conservation measures to be applied under Alternative D are described in Section 2.2.4.6 and Appendix O (Biological Assessment) of the EIS.

9 RECREATION

9.1 NOTE ECONOMIC BENEFITS OF THE RECREATION INDUSTRY

Summary Comment: Commenters stressed the importance of accounting for the benefits of river recreation to the local economy and enumerated the various direct and indirect economic activities associated with recreation, including rafting trip fares paid by visitors, franchise fees paid by rafting companies, support of rafting services, outfitters and businesses in the area, and spending on car rentals, hotel stays and restaurants. One commenter suggested that trout fishing may not be as important as it is perceived to be.

Response: These issues were all considered in the recreation economics sections of the LTEMP EIS; see Section 4.14 and Appendix L of the EIS. The EIS analysis fully considered the direct and indirect economic effects of recreation use in the project area.

9.2 RECREATION RESOURCE GOALS INCOMPLETE

Summary Comment: Commenters expressed that recreation in the Grand Canyon has been understudied in general as compared to other resources and thus that recreation resource goals and impacts on recreation are not sufficiently articulated in the LTEMP EIS.

Response: Recreation is one of the aspects of the Grand Canyon Protection Act which is an inherent part of the purpose and need for the LTEMP EIS and Section 1.4 includes goals and objectives for recreation. Although there are a limited number of recreation studies, the LTEMP team utilized best available studies for this EIS and utilized modeling where appropriate to address many aspects of recreation. See Section 4.10.

9.3 ADOPT THE GOALS AND OBJECTIVES OF THE AZGFD FISHERIES MANAGEMENT PLAN

Summary Comment: Commenters requested that the goals and objectives of the Arizona Game and Fish Department be incorporated into the LTEMP EIS and that the Arizona Game and Fish Department Fisheries Management Plan- Colorado River-Lees Ferry (Rogers 2015) be cited along with the Park Service's Comprehensive Fisheries Management Plan in the discussion of the recreational fishery.

Response: The AZGFD management plan and NPS's Comprehensive Fisheries Management Plan are independent of the LTEMP EIS. Because of differences in aspects of the two plans, at this time, the joint leads cannot include the objectives of the AZGFD plan or reference this plan in its current form. See also response to comment summary 3.9.

9.4 ADOPTION OF MLFF FLOWS CORRESPONDED WITH DEGRADATION OF THE LEES FERRY FISHERY DROP IN VISITATIONS

Summary Comment: A commenter observed that angler satisfaction and use was very high in the 1970s and 1980s, but declined following the advent of MLFF and the implementation of HFEs.

Response: DOI has not identified any studies that attribute the reduction in angler use days or satisfaction to the advent of MLFF or the implementation of HFEs. No change to the EIS was made in response to this comment.

10 TRIBAL RESOURCES[1]

10.1 OPPOSITION TO MECHANICAL REMOVAL OF TROUT AND TROUT MANAGEMENT FLOWS

Summary Comment: Comments in this category generally oppose mechanical removal or trout management flows due to the adverse effects these actions would have on the cultural values ascribed to the Canyons and Rivers by the Hopi, Zuni and other Tribes. Of particular note are the adverse psychological and sociological effects to the larger Zuni community during mechanical removal and trout management flow actions, the taking of life without justification, and the seemingly opposing management objectives for trout. Additional comments support the Tribal perspective on these matters.

Response: DOI considers mechanical removal as an important tool for minimizing risk to downstream endangered fish from trout regardless of the cause of trout population increases or migration. DOI acknowledges the potential negative effects from all alternatives (and common to all actions) that include the taking of life in the Canyon through direct removal and/or trout management flows. We recognize the Hopi and Zuni perspective on mechanical removal and trout management flows and are committed to working with Tribal leadership on ways to address the ongoing concerns and ensure appropriate mitigation within the river corridor. Under the LTEMP EIS preferred alternative TMFs would only be used when triggered by situations where high numbers of young of the year are predicted. In years when TMFs or mechanical removal may be appropriate, the joint-leads would discuss the trout conditions of the year with AZGFD, GCMRC, and concerned Tribes prior to implementing to develop appropriate options to lessen the potential negative impacts from the proposed actions. In response to specific Zuni comments regarding Zuni perspectives on the adverse effects to their community, we have retained language in 4.9.3 and added language to a number of sections, most specifically in Section 4.9.1.3.

10.2 LACK OF TRIBAL REPRESENTATION IN DEVELOPMENT OF EIS

Summary Comment: Comments in the category generally question the representation of Tribes in the development of the EIS including whether or not Tribal members were part of the SME teams, how many Tribes were contacted in regards to the LTEMP EIS, and how many and what types of Tribal consultation meetings were held.

Response: NPS and Reclamation are committed to working with Tribal communities in order to better understand their concerns in regard to the LTEMP process. Initially, 43 Tribes, bands, and organizations were formally invited to enter into government-to-government consultation on the LTEMP EIS. Five chose to participate as Cooperating Agencies. Cooperating Agencies were invited to monthly conference calls to review progress and reach agreement on major issues

[1] Comments and responses related to Tribal concerns are also presented in Section 11, Socioeconomics and Environmental Justice.

during the preparation of the LTEMP DEIS. In addition, a number of face-to-face meetings as well as webinars and conference calls were held. Detailed information on the consultation process can be found in Chapter 5 and Appendix N. Under most resource sections there are also Tribal perspectives section where the concerns of Tribes are explained in their own words.

10.3 METRIC SHOULD NOT BE USED TO ANALYZE IMPACTS TO CULTURAL AND TRIBAL RESOURCES

Summary Comment: Comments under this category suggest that metrics used to analyze the impacts to cultural and Tribal resources were unwarranted. Specifically, comments suggested that there is little data to support the wind-blown sediment hypothesis and Sand Load Index in relation to availability of sediment for wind deposition and that Time Off-River is not a viable metric to evaluate visitor impacts to archaeological sites.

Response: We have used the GCDAMP Desired Future Conditions (DFCs) as a basis and as a guide for the resource goals and performance criteria. The Cooperating Agencies, Tribes and AMWG stakeholders were given several opportunities to comment on these for the LTEMP EIS and a number of changes were made based on those comments. We also sent the AMWG members and Cooperating Agencies a draft document of the resource goals and objectives on March 27, 2013 that further illustrated how the DFCs were used in developing each resource goal and objective.

The metric values for the Sand Load Index represent the potential for sand to be transported to cultural sites rather than the actual transport that would occur or the level of protection that transport may provide to cultural sites. The EIS acknowledges that the extent to which wind-deposited sediment can stabilize and protect archaeological sites is limited by the local geomorphology and vegetation. The text in Section 4.8.2 and Appendix H has been updated to reflect the most recently published studies regarding wind-blown sediment.

Tribes regularly monitor the condition of culturally important sites and resources within the Canyons. Many Tribes have noted intentional and unintentional damage to sites from visitors, including trailing, trampling, removal of vegetation, disturbance of artifacts, vandalism, and disruption of the sacred context through inappropriate behavior (See Sections 3.9 and 4.9). The time-of-river metric was included to respond this concern. The results showed that there was very little difference among the alternatives for time-off-river.

10.4 CULTURAL LANDSCAPES AND TRADITIONAL CULTURAL PROPERTIES NOT THOROUGHLY DISCUSSED

Summary Comment: Comments in this category suggest that Traditional Cultural Properties, have not been thoroughly analyzed and that the larger cultural landscape of the LTEMP study area, including the Grand Canyon as a Historic National Landmark was not acknowledged.

Response: The LTEMP EIS references forthcoming National Register of Historic Places nominations for the Hopi, Zuni, Navajo, and Hualapai TCPs in Section 3.9. The designation of

the Grand Canyon as a Historic National Landmark is outside the scope of this EIS; however, DOI will continue dialog with the Hualapai and other Tribes throughout the PA process and within the AMWG regarding the importance of cultural resources.

10.5 TRIBAL LANDS AND RESOURCES ON TRIBAL LANDS NOT TAKEN INTO CONSIDERATION

Summary Comment: The comment under this category suggests that the LTEMP EIS did not identify cultural resources on Hualapai and Navajo lands in the Introduction.

Response: The description of lands in this section uses terms based on geography of the canyons rather than on land ownership. Therefore, we feel the wording is appropriate as is; however, we did add text to reflect the perspective of various Tribal cultures regarding the interconnected nature of the cultural landscape.

10.6 IMPACTS TO HUALAPAI TOURISM OPERATIONS NOT THOROUGHLY ANALYZED

Summary Comment: Comments in this category were specifically from the Hualapai Tribe and indicated a concern with the lack of identification of potential impacts to Hualapai Tourism operations near Quartermaster Canyon as well as other Hualapai tourism operations.

Response: Potential impacts to Hualapai tourisms operations near Quartermaster Canyon and other Hualapai operations were consider in Sections 4.10. Based on the analysis conducted for the EIS, sedimentation near the Quartermaster Canyon would not vary significantly among the alternatives. The sedimentation this far down is primarily driven by other factors including the reservoir level at Lake Mead and annual release volumes which are outside the scope of the LTEMP EIS. Additional text was added regarding the details of Hualapai tourism operations in Sections 3.10 and 4.10 of the EIS. Text has been added under each alternative to clarify the impacts to Hualapai tourism operations.

10.7 TRIBAL PERSPECTIVES ON COMPONENTS OF THE COLORADO RIVER ECOSYSTEM

Summary Comment: Several commenters provided comments or text to add to Chapters 3 and 4 that expresses Tribal perspectives on components of the Colorado River Ecosystem such as fish, vegetation, and wildlife. The Zuni expressed concern related to the effects of management actions downstream of Glen Canyon Dam, specifically those directed towards fish, on the well-being of Tribal members.

Response**:** In most cases, the information provided by Tribes was incorporated as provided with only minor editorial modification as needed. Changes were made in Chapters 1, 2, 3, and 4.

10.8 EDITORIAL COMMENTS

Numerous substantive editorial comments were submitted by the Tribes on sections in the DEIS, including portions of Chapters 1, 2, 3, and 4, related to Tribal resources and concerns. Many of these comments were related to descriptions of resources or lands important to the Tribes, Tribal perspectives and views of specific resources in the Canyons or the Canyons as a whole and proper representation of Tribal views on aspects of the alternatives, especially actions that could affect aquatic ecology, vegetation, or wildlife within the Colorado River Ecosystem. In most cases, substantive editorial suggestions provided by Tribes were incorporated as provided with only minor editorial modification as needed.

11 SEDIMENT

11.1 CONCERN OVER EROSION OF SANDBARS AND BEACHES FOLLOWING HIGH FLOWS (I.E., HFEs)

Summary Comment: Commenters expressed concern that, while HFEs may provide benefits to certain beaches, they also create a net loss of sand and erosion to others.

Response: In Sections 3.3 and 4.3 there is discussion of the complexity of beach and sandbar response to HFEs. The geomorphology and other factors dictate that different HFEs build some beaches, but erode others and this is clearly stated but the average results are also considered and the modeling focuses on the average results. Based on the modeling and the extensive literature on sediment in the Grand Canyon, the preferred alternative is expected to perform well for sandbar and beach building and for many other downstream resources to comply with the GCPA. If there were unacceptable adverse impacts caused by HFEs, there is a process defined in the EIS through which HFEs would be suspended

11.2 SPRING HFES—UNCERTAINTY AND CONCERN OVER IMPACTS; MORE TESTING IS NEEDED

Summary Comment: Commenters emphasized that the uncertainties related to spring HFEs, resource trade-offs, and timing. They also noted that spring HFEs need to be experimentally tested and evaluated before adoption becomes an accepted management practice, but the current language surrounding the conduct of spring HFEs (as described in the Glen Canyon Dam High Flow Experiment Protocol Environmental Assessment) severely limits the potential for experimental testing of HFEs during the springtime period.

Response: DOI acknowledge that there are uncertainties regarding the potential impacts of spring HFEs and has reviewed the parameters under which springtime HFE's are conducted and the way in which the accounting periods are applied. Under the preferred alternative, there would be 4-7 spring HFEs on average over the 20 year period, which allows for testing and monitoring of impacts. Under the preferred alternative, spring HFE's are triggered based upon sediment triggers. GCMRC was consulted on the potential to modify the accounting periods and the scientists most familiar with the protocol did not believe it warranted a change in accounting periods.

11.3 EQUALIZATION FLOWS—CONCERN OVER INCREASED EROSION AND HIGHER RATE OF SEDIMENT TRANSPORT

Summary Comment: Commenters noted that equalization flows transport an enormous amount of sediment out of the system. As a result, they should be studied carefully and an effort should be made to change management practices to a proactive approach in order to minimize and mitigate the negative effects of equalization flows.

Response: The scope of this EIS does not include modification of annual volumes. Therefore alternatives that change equalization flows and other annual volumes were not included in this EIS. However, the EIS includes the full range of potential future releases, including equalization flows, to ensure a robust analysis of impacts to the alternatives. The alternatives analyzed in the LTEMP EIS looked at all practical approaches to conserving sediment via changes to monthly, daily, and hourly releases from the Glen Canyon Dam. Recognizing the science of sediment transport and flow, the range of alternatives include experimental proactive spring HFEs to mobilize and deposit or "park" sediment higher on the beaches in anticipation of annual releases greater than 10 maf. Further experimentation or approaches that may be devised in the future could be brought forward through the adaptive management program or GCDAMP triennial budget process and may or may not require additional NEPA compliance.

11.4 SEDIMENT SHOULD BE CONSIDERED A "SECONDARY" RESOURCE

Summary Comment: Commenters expressed concern that the characterization of sediment as the primary objective of the LTEMP EIS appears to be inconsistent with the AMWG-approved and Secretary-recognized identification of sediment as a "secondary" resource to be used to support other DFC resources (i.e., subset of the larger Colorado Ecosystem DFC).

Response: We have used the GCDAMP Desired Future Conditions (DFCs) as a basis and as a guide for the resource goals and performance criteria. The Cooperating Agencies, Tribes and AMWG stakeholders were given several opportunities to comment on these for the LTEMP EIS and we made a number of changes based on those comments. We also sent the AMWG members and Cooperating Agencies a draft document of the resource goals and objectives on March 27, 2013 that further illustrated how the DFCs were used in developing each resource goal and objective. The resource goals and objectives are based on the DFCs and consistent with them but relate more directly to the purpose and need of the LTEMP EIS. Recognizing the science of sediment transport and flow, several alternatives included proactive spring HFEs to mobilize and deposit sediment in anticipation of annual releases greater than 10 maf. Sediment conservation was a resource goal as expressed in Section 1.4.

11.5 CONCERN OVER SEDIMENT ACCUMULATION IN LAKE POWELL AND BEHIND THE DAM

Summary Comment: Commenters expressed concern related to the long-term accumulation of sediment into Lake Powell and its displacement of water storage, effect on flood control capacities, and potential impairment of downstream water delivery. Some commenters also requested a new and comprehensive sediment survey of Lake Powell, including a sediment removal plan.

Response: Long-term of accumulation of sediment into Lake Powell is an uncontrollable function of hydrology above Lake Powell and is also outside the scope of this EIS. The alternatives being considered do not affect the inflow of sediment into Lake Powell.

12 SOCIOECONOMICS AND ENVIRONMENTAL JUSTICE

12.1 REGIONAL ECONOMIC IMPACTS ASSOCIATED WITH BOATING VISITOR EXPENDITURES

Summary Comment: Economic impacts associated with boating visitor expenditures on lodging, food and supplies, equipment sales and rentals, fuel, guide and license fees, etc. form an important part of the local and regional economy.

Response: The economic impacts associated with boating visitor expenditures are assessed in Section 4.14.2.3 of the EIS. The issues listed were considered in this analysis.

12.2 REGIONAL ECONOMIC IMPACTS ASSOCIATED WITH ANGLER VISITOR EXPENDITURES, IN PARTICULAR IMPACTS OF HFEs

Summary Comment: Economic impacts associated with angler visitor expenditures on lodging, food and supplies, equipment sales and rentals, fuel and guide and license fees, etc. form an important part of the local and regional economy.

Response: The economic impacts associated with visitor expenditures related to fishing are assessed in Section 4.14.2.3 of the EIS. The effects of HFEs were considered as well as the issues listed.

12.3 USE VALUES ASSOCIATED WITH ANGLING AND BOATING TRIPS

Summary Comment: Economic impacts associated with angler visitor expenditures on lodging, food and supplies, equipment sales and rentals, fuel and guide and license fees, etc., during HFEs would form an important part of the local and regional economy.

Response: Under current NPS regulations the number of angling boat trips would not change under any of the alternatives given the excess demand for boating permits, with no consequent impact on license revenues, or on employment and income in the region. In addition, access restrictions during HFE events under any given alternative may mean a slight decline in angler visits, slightly reducing license revenues, and employment and income in the region. These impacts are discussed in Section 4.14.2.3 of the EIS.

12.4 NON-USE VALUES ASSOCIATED WITH FISHING RESOURCES

Summary Comment: In addition to the economic impacts, use values associated with angling and boating trips, and non-use values associated with fishing resources are a significant part of the economic value of river resources.

Response: Use values associated with angling in the Upper Grand Canyon, and non-use values associated with fishing resources are assessed in Section 4.14.2.2 of the EIS.

12.5 ECONOMIC IMPACTS ON TRIBES

Summary Comment: Economic impacts of each alternative in individual Tribes should be considered in the EIS

Response: The economic impacts to Tribes were considered in the EIS in the recreation (4.10), Tribal Resources (4.9) and socioeconomics (4.14) sections. There were limitations based on the available data regarding hydropower impacts that precluded separating out impacts further by individual Tribe. The geographic location of minority and low-income populations in an 11-county region is described in Section 3.14.1.5 of the EIS. The environmental justice analysis described in Section 4.14.2.5 includes economic impacts on Tribal groups in the 11-county region as a whole. The impact of HFEs on Tribes is addressed in Section 4.14.2.4 of the EIS.

12.6 IMPACT ON WATER PROVISION

Summary Comment: Impacts of each alternative on water provision should be considered in the EIS.

Response: The scope of the LTEMP EIS was to evaluate a range of alternatives with different monthly, daily, and hourly releases from the Glen Canyon Dam. All alternatives are consistent with the LROC as currently implemented through the 2007 Interim Guidelines for annual release volumes. See Sections 3.2 and 4.2 for additional detail. Because the LTEMP EIS does not affect annual volumes, it will not affect water delivery, allocation or provision. Under the LTEMP variations of the reservoir elevations within the year are small and temporary and based on modeling would not affect potential water diversions from Lake Powell or Lake Mead.

12.7 REGIONAL ELECTRIC POWER ECONOMIC IMPACTS

Summary Comment: Regional economic impact of changes in retail rates and electric power capacity expansion on minority and low-income populations should be considered.

Response: The geographic location of minority and low-income populations in an 11-county region is described in Section 3.14.1.5 of the EIS. The environmental justice analysis described in Section 4.14.2.5 includes economic impacts on Tribal groups in the 11-county region as a whole. The impact of HFEs on Tribes is addressed in Section 4.14.2.4 of the EIS.

12.8 ECONOMIC IMPACTS OF ACTIVITIES OF CONFLUENCE PARTNERS OUT OF SCOPE OF EIS

Summary Comment: Economic impacts of the activities of Confluence Partners (the construction of a tram, walkway, restaurant and amphitheater) should be considered in the EIS.

Response: A full and comprehensive analysis of the impacts potential economic development activities by Confluence Partners was outside the scope of the EIS, however effects of the Grand

Canyon Escalade project based on available project information were considered within the cumulative impacts section (4.17).

12.9 DEPTH OF LITERATURE REVIEW ON USE VALUATION IN APPENDIX I

Comment Summary: The literature review on use valuation in provided in Appendix I does not provide a comprehensive overview of all the relevant literature on use values.

Response: The Appendix referred to (Socioeconomic Technical Information and Analysis) is now Appendix L. This appendix does not summarize use value literature, it provides a summary of the benefit transfer methods and models used to estimate recreation use values in the EIS. References were added in Chapter 3 (Section 3.14) and in appendix L to the Loomis 2014 study, which was a literature review to evaluate the potential for a passive use value for hydropower. More information on the background literature, data, and assumptions in applying the benefits transfer method to the analysis undertaken for the EIS can be found in Reclamation (2014).

12.10 MECHANICAL REMOVAL AND TROUT MANAGEMENT FLOWS

Summary Comment: The killing of fish through mechanical removal and trout management flows are objectionable to the Zuni sensibilities.

Response: Section 4.14.2.5 of the EIS recognizes that the Zuni have established a lasting familial relationship with aquatic life in the Colorado River, and that the taking of life through the mechanical removal of trout or TMFs is considered to be and adverse impact and an offensive, to the Zuni. Based on input and consultations with the Pueblo of Zuni, text has been included considering mitigations such as beneficial use of fish that are removed and Reclamation consulted with the FWS under Section 7 to make some adjustments to the preferred alternative. Based on those adjustments and 'tiers' that were added in the biological assessment (see Appendix O), mechanical removal is now a second 'tier' action, as other actions would be tried first as a 'first tier'. This may reduce the frequency of mechanical removal. Differences in the frequency of the mechanical removal of trout between alternatives are also addressed in this section of the EIS. Consultations continue with Tribes on potential mitigations through an agreement in process regarding non-native fish management.

13 WATER

13.1 CONSIDERATION OF CLIMATE CHANGE EFFECTS RELATED TO WATER SUPPLY REDUCTIONS, EVAPORATION, AND OPERATIONAL LEVELS OF LAKE POWELL

Summary Comment: Commenters emphasized the importance and requested the consideration of climate change effects (e.g., increased temperatures, droughts, etc.) related to water supply reductions, evaporation, seepage, and operational levels of Lake Powell.

Response: This EIS used 21 reconstructed historical hydrological traces that were reweighted based on the 112 traces to represent the best current understanding of what might happen because of climate change. Based on this analysis, the weights on the hydrological traces had a small effect on the aggregate performance but did not change the rankings of alternatives. This result suggests the relative performance of the alternatives would be consistent regardless of the uncertainty of the effects of climate change.

The Basin Study (Reclamation 2012) was peer reviewed and is the best available science regarding climate change projections in the Colorado River Study. The hydrological traces generated for the Basin Study were utilized as described in Section 4.16.1.2 and Appendix C. See also response to comment summary 2.14.

13.2 CONSIDERATION OF CLIMATE CHANGE IMPACTS ON WATER AVAILABILITY, INCREASED DEMAND, AND GREATER DEPLETION

Summary Comment: Commenters emphasized the importance and requested the consideration of climate change impacts (e.g., increased temperatures, droughts, etc.) on water availability, increased water demand (both diversion and consumptive), and greater depletion.

Response: Water depletion assumptions used for the LTEMP EIS represent the best available and documented data provided by and agreed to by the Basin States for use in CRSS modeling.

13.3 INFLUENCE OF TRIBUTARIES AND LAKE POWELL ON MAIN STEM AND LAKE MEAD SALINITY LEVELS

Summary Comment: Commenters inquired about the comparative salinity values and resulting influence of tributaries and Lake Powell on main stem and Lake Mead salinity levels.

Response: As addressed in the EIS in Sections 3.2 and 4.2, some tributaries, such as the Little Colorado River, are significant sources of salinity for the mainstem Colorado River. But, this is diluted as it enters the mainstem and moves downstream. There are also a number of smaller spring-fed tributaries that originate within the Grand Canyon reach, which tend to have very different physicochemical properties than the mainstem; however, their mean flows are so low that their contribution to water quality during base flow is not significant. For Lake Powell, broader patterns are described in the EIS; but, focus was placed on the forebay, since this is the

water that is released downstream. The salinity module of the CRSS RiverWare™ model was used to analyze changes in salinity concentration for Colorado River reaches from Lake Powell to Imperial Dam, which is located downstream of Hoover Dam and Lake Mead. The Salinity Control Act sets numerical criteria for salinity concentrations on the Colorado River. Results and analysis indicate that, regardless of alternative or operating conditions, salinity would not increase over time or exceed control criteria.

13.4 EDITORIAL COMMENTS

Numerous substantive editorial comments were submitted on sections in the DEIS related to water resources, including Sections 3.2, 4.2, and Appendix D. Most of these editorial comments focused on the specific wording of how Glen Canyon Dam would be operated to comply with existing laws and regulations related to water delivery, collectively known as the Law of the River. Where appropriate, the text of the EIS was modified to address the specific comments.

14 WILDLIFE

14.1 AVERTING THE RESPONSIBILITY TO PROTECT NATIVE SPECIES

Summary Comment: A commenter stated that DOI is averting its responsibility to protect native species because all of the alternatives would result in a decrease in native plant community cover. Special status wildlife species will also be impacted (i.e., every alternative causes losses of habitat for the Kanab ambersnail and every alternative threatens to negatively affect at least one other special status wildlife species). Also, all alternatives will cause wetland loss that will affect the northern leopard frog and Yuma clapper rail. Instead of attempting to create an alternative that prevents continued habitat loss, DOI is just attempting to slow the degree of loss. DOI is averting its legal responsibilities to protect endangered species and Grand Canyon National Park, instead of seeking real solutions.

Response: The purpose and need is consistent with the requirements of the Grand Canyon Protection Act and NPS Organic Act because it focuses on protection and preservation of park resources. Alternatives must meet those basic requirements. All alternatives perform similarly when evaluating effects to wildlife species, showing little difference among the alternatives (Tables 4.7-1 and 4.7-2), although the preferred alternative (Alternative D) shows a benefit to wildlife in general compared to the no action alternative (Alternative A), and Alternative D performed the best for vegetation condition overall and resulted in the least wetland loss. The potential benefits of the non-flow vegetation treatment experiment could not be modeled, but were addressed qualitatively in the EIS and would help to further improve vegetation condition. Alternative D was identified as the preferred alternative because it provided the best balance for protecting, mitigating and improve downstream resources.

14.2 HFE IMPACTS ON KANAB AMBERSNAIL

Summary Comment: Commenters stated that HFEs, including extended duration HFEs, could negatively impact the population of the Kanab ambersnail, a Grand Canyon endangered species. Recovery time of the ambersnail population and habitat scoured by HFEs can take 2.5 years and yet this effect was apparently not considered important to the development of Alternative D.

Response: Endangered and threatened species were considered in the LTEMP EIS analysis based on the best available science and modeling, while the FWS has been consulted throughout the preparation of the EIS. The purpose and need of LTEMP activities are consistent with the requirements of the Grand Canyon Protection Act and NPS Organic Act because they focus on the protection and preservation of park resources. Impacts to the Kanab ambersnail are addressed in Section 4.7.2.5, 4.7.3, and the recovery time of 2.5 years was stated in those sections and considered. Additional information is included in Appendix O (biological assessment) of the Final EIS. It should also be noted that new genetic information on the Kanab ambersnail indicates that it is no longer considered a distinct species and the FWS is considering a delisting process for this species.

14.3 OPERATE GLEN CANYON DAM IN A WAY THAT PROTECTS ALL WILDLIFE (INCLUDING LISTED SPECIES)

Summary Comment: A few commenters wanted the life and safety of all wildlife to be considered. They want the Glen Canyon Dam to be operated in a way that preserves wildlife. Wildlife, including listed species, need to be considered when making decisions on the future of the Grand Canyon. The purpose and need of the LTEMP should be to reverse past damage and prevent future damage to the species of Glen and Grand Canyons.

Response: Impacts on wildlife, including special status species, were considered in the LTEMP EIS in Section 4.7. The purpose and need of LTEMP activities are consistent with the requirements of the Grand Canyon Protection Act and NPS Organic Act because they focus on the protection and preservation of park resources. All alternatives must meet those basic requirements.

15 COMMENTERS, AFFILIATION, AND LOCATION WHERE RESPONSES TO COMMENTS ARE FOUND

An index presenting a list of individuals who submitted comments, their affiliated organizations (when provided), and the sections in this appendix where responses to issues raised in their comments is presented in Table Q-3. All individuals who provided a first or last name in their comment submittal to NPS's PEPC database or whose names were otherwise provided on comment letters submitted by other means are included. An affiliation was listed for an individual if it was clear from their submittal that the commenter was representing the organization and was not simply a member of the organization and commenting as an individual. The right-hand column presents the sections in this appendix where responses to substantive issues raised in commenter's letters are located.
