The Priority Without Tribal Shortage Alternative Distribution Model simulates a distribution of water which fully fills all tribal entitlements, distributing shortage among non-tribal entitlements in accordance with elements of the existing priority system. This Alternative Distribution Model reflects a modeling commitment to stakeholders to display a possible distribution of water during shortage that does not short tribal entitlements or allocations; it is not an interpretation of law, contracts, or a legal position.

For each level of modeled shortage, the Priority Without Tribal Shortage Alternative Distribution Model calculates a percentage reduction to the Lower Division States and applies the same percentage reduction to Mexico's 1,500,000 acre-feet per year allotment.

The Excel workbook contains formulas extending into deep shortage levels as a modeling exercise relating to potential capacity constraints on Lake Mead releases, and as a basis for comparison with other distributions of shortage. This deeper shortage level modeling does not represent an effect of the Federal action(s) described in this EIS, and this modeling is for informational purposes only.

C.7.1 Entitlements Which are Not Shorted in the Priority Without Tribal Shortage Alternative Distribution Model

For modeling purposes, the entitlements/allocations in **Table C-30** below have been removed from the priorities in which they are situate pursuant to contracts or other documents, and the sizes of those priority pools are adjusted accordingly. The priority of these entitlements is identified in the Excel workbook and the table below for the purpose of cross-reference, but the fulfillment of these entitlements in the Alternative Distribution Model is no longer dictated by priority; the model does not attempt to emulate shortage deep enough to affect them. Note that CAP allocations are shown for modeling purposes as mainstream consumptive use equivalents, with 5 percent for CAP system loss added to the contract volume. All other entitlements are shown as calculated for the Priority Shortage Allocation Model.

Table C-30
Entitlements and Allocations Not Shorted Under Priority Without Tribal Shortage Alternative Distribution Model

State	Priority	Entitlement Holder, Contractor, or Subcontractor	Consumptive Use or Equivalent Entitlement (af)*
Arizona	CAP NIA-B	White Mountain Apache Tribe	24,971.10
Arizona	CAP NIA-A	Gila River Indian Community	126,630.00
Arizona	CAP NIA-A	Tohono O'odham - Schuk Toak & San Xavier	29,610.00
Arizona	CAP NIA-A	Hualapai Tribe**	4,200.00
Arizona	CAP M&I	San Carlos Apache Tribe	19,052.25

State	Priority	Entitlement Holder, Contractor, or Subcontractor	Consumptive Use or Equivalent Entitlement (af)*
Arizona	CAP Indian	Gila River Indian Community	200,760.00
Arizona	CAP Indian	Tohono O'odham Nation (ST & SX)	39,690.00
Arizona	CAP Indian	White Mountain Apache Tribe	1,278.90
Arizona	CAP Indian	Ak-Chin Indian Community	61,215.00
Arizona	CAP Indian	Fort McDowell Yavapai Nation	19,144.65
Arizona	CAP Indian	Pascua Yaqui Tribe	525.00
Arizona	CAP Indian	San Carlos Apache Tribe	13,335.00
Arizona	CAP Indian	Salt River Pima-Maricopa Indian Community	13,965.00
Arizona	CAP Indian	Tohono O'odham Nation Sif Oidak District	8,400.00
Arizona	CAP Indian	Tonto Apache Tribe	134.40
Arizona	CAP Indian	Yavapai Apache Nation	1,260.00
Arizona	P4(i)	Cocopah Indian Reservation	1,357.42
Arizona	P4(i)	Hopi Tribe	3,037.38
Arizona	P4(i)	Water Reserved by the Secretary for a Navajo-Hopi Settlement	3,500.00
Arizona	P4(i)	Unallocated 4th Priority Mainstream Water	10,230.00
Arizona	P3	Ak-Chin Indian Community	50,000.00
Arizona	PPR	Cocopah Indian Reservation	5,146.27
Arizona	PPR	United States (Cocopah Indian Tribe)	763.80
Arizona	PPR	Fort Mojave Indian Reservation	40,805.64
Arizona	PPR	Fort Mojave Indian Reservation	15,103.26
Arizona	PPR	Fort Yuma Indian Reservation	4,000.50
Arizona	PPR	Colorado River Indian Reservation	27,032.72
Arizona	PPR	Colorado River Indian Reservation	131,048.32
Arizona	PPR	Colorado River Indian Reservation	186,368.00
-	-	**Subtotal**	**1,042,564.61**
California	PPR	Chemehuevi Indian Reservation	6,123.60
California	PPR	Fort Mojave Indian Reservation	9,028.80
California	PPR	Fort Yuma Indian Reservation	36,524.16
California	PPR	Colorado River Indian Reservation	3,398.80
California	PPR	Colorado River Indian Reservation	23,339.78
California	PPR	Colorado River Indian Reservation	6,232.10
-	-	**Subtotal**	**84,647.24**
Nevada	P1 (PPR)	Fort Mojave Indian Reservation	8,397.78
-	-	**Subtotal**	**8,397.78**
-	-	**Total**	**1,135,609.63**

*CAP allocations are shown as mainstream consumptive use equivalents, with 5 percent for CAP system loss added to the Contract volume.

** May at some time be diverted from the Colorado River above Lake Mead.

C.7.2 Present Perfected Rights Assumptions for the Priority Without Tribal Shortage Alternative Distribution Model

The entitlements in **Table C-31** below were removed from the PPR priority system emulated in this Alternative Distribution Model. Otherwise, PPRs are modeled as described for the Priority Shortage Allocation Model; the relative priorities of non-tribal PPRs based on Paragraph (5) of the Appendix to the Consolidated Decree in *Arizona v. California*, 547 U.S. 150 (2006), was not revisited in light of the tribal PPRs no longer being modeled as part of the PPR priority system.

Table C-31
PPRs Not Shorted Under Priority Without Tribal Shortage Alternative Distribution Model

Entitlement Holders	CU Equivalent (af)*	Diversion (af)	PPR No.	Date	Type of Use
Cocopah Indian Reservation	5,146	7,681	1	1917	Tribal
United States (Cocopah Indian Tribe)	764	1,140	8	1915	Tribal
Chemehuevi Indian Reservation	6,124	11,340	22	1907	Tribal
Fort Mojave Indian Reservation	40,806	75,566	3	1890	Tribal
Fort Mojave Indian Reservation	15,103	27,969	3	1890	Tribal
Fort Mojave Indian Reservation	9,029	16,720	25	1890	Tribal
Fort Mojave Indian Reservation	8,398	12,534	81	1890	Tribal
Fort Yuma Indian Reservation	36,524	71,616	23	1884	Tribal
Fort Yuma Indian Reservation	4,001	6,350	3a	1884	Tribal
Colorado River Indian Reservation	3,399	5,860	24	1876	Tribal
Colorado River Indian Reservation	27,033	51,986	2	1874	Tribal
Colorado River Indian Reservation	23,340	40,241	24	1874	Tribal
Colorado River Indian Reservation	131,048	252,016	2	1873	Tribal
Colorado River Indian Reservation	6,232	10,745	24	1873	Tribal
Colorado River Indian Reservation	186,368	358,400	2	1865	Tribal

*Calculated consumptive use equivalents. Historical Decree Accounting data were used to estimate average CU/Diversion ratios as part of development of the CRSS hydrologic modeling dataset for this EIS. For purposes of modeling, these values are assumed to be generally representative of return flow conditions for the specified users, and match CRSS inputs. Those ratios were used to estimate the consumptive use equivalent of diversion entitlements. In CA, miscellaneous PPRs were assumed to have a CU/Div ratio of .64. For IID, consumptive use was assumed to equal diversion since the CU/diversion ratio based on average historical efficiency was 0.996. In AZ, with limited supporting data about miscellaneous PPRs, they were assumed to be fully consumptive. Where an entitlement was quantified on the basis of CU by the Consolidated Decree, those values are used.

Table C-32 on the following page summarizes the non-tribal PPRs remaining in each state, which informs the distribution of water among the Lower Division States as described in the next section.

Table C-32
Summary of Non-Tribal PPRs Remaining in Each State in the Priority Without Tribal Shortage Alternative Distribution Model

State Summary	CU Equivalent Entitlement (af)	Diversion Entitlement (af)
Arizona Total	187,542.80	296,863.00
California Total	2,716,678.90	2,863,051.00
Nevada Total	300.00	500.00
Total	**2,904,521.70**	**3,160,414.00**

C.7.3 Distribution Among States for the Priority Without Tribal Shortage Alternative Distribution Model

The distribution of water among the Lower Division States in this Alternative Distribution Model is similar to the Priority Shortage Allocation Model except as described below.

Generally, state apportionments in excess of PPRs and tribal entitlements are set as co-equal, except that Arizona bears California's share of shortage until the remaining (non-tribal) Arizona Fourth Priority is exhausted.

C.7.3.1 Stage 1, 2, and 3 Shortage Assumptions

In developing the Stage 1 and Stage 2 percentages for the sharing of shortage among the Lower Division States in this Alternative Distribution Model, the consumptive use (or equivalent) of non-tribal PPR entitlements and tribal entitlements were removed from the apportionment volumes in each ratio, as detailed below.

In Stage 1 of this Alternative Distribution Model, shortages are imposed only upon Arizona and Nevada, continuing until the deliveries to non-tribal post-1968 (P4) water entitlement holders in Arizona (including CAP subcontractors) are reduced to zero. Based on modeled full use by P1-3 entitlements in Arizona, and no shortage to Tribes as assumed in this Alternative Distribution Model, approximately 821,834 afy of shortage to Arizona (or 1,978,166 afy of water available to Arizona) exhausts the P4 supply. Stage 1 shortage ends at that point.

The Stage 1 shortage sharing percentages for the Priority Without Tribal Shortage Alternative Distribution Model are computed as follows:

- Nevada bears a reduction of about 8 percent of the total Lower Division States shortage volume, computed as a ratio of Nevada's apportionment less non-tribal PPR and tribal consumptive use (or equivalent) entitlements within Nevada over the sum of the apportionments of the Lower Division States less all non-tribal PPR and tribal consumptive use (or equivalent) entitlements
    - (300 kaf – 300 af - 8,398 af) / (7.5 maf – 1,135,610 af – 2,904,522 af) = 8.42 percent
- Arizona bears the remainder of the total Lower Division States shortage volume (91.58 percent)

The Stage 2 distribution of water among the Lower Division States in this Alternative Distribution Model begins at the end of Stage 1 and ends at the volume of total shortage where reductions to non-tribal PPRs are necessary; at that point, water available to each state equals the consumptive use (or equivalent) of non-tribal PPR entitlements and tribal entitlements within the state.

Stage 2 shortage is the amount of additional shortage above the Stage 1 shortage volume, and the additional shortage is distributed according to the Stage 2 ratios.

The Stage 2 shortage sharing percentages are computed as follows, with the non-tribal PPR and tribal entitlement volumes the same as in the Stage 1 ratios.

- Nevada bears about 8 percent of the Stage 2 shortage in addition to its Stage 1 shortage, computed as a ratio of Nevada's apportionment less non-tribal PPRs and tribal entitlements in Nevada less the amount of shortage applied to Nevada under Stage 1, over the sum of the apportionments of the Lower Division States less total non-tribal PPRs and tribal entitlements less the total amount shorted to users under Stage 1
    - (0.3 maf – NV non-tribal PPRs – NV tribal entitlements - NV Stage 1 shortage) / (7.5 maf – total non-tribal PPRs – total tribal entitlements - total Stage 1 shortage) or
        - (300,000 – 300 - 8,398 – 75,555) / (7,500,000 – 2,904,522 – 1,135,610 – 897,389) = 8.42 percent
- Arizona bears about 29 percent of the Stage 2 shortage in addition to its Stage 1 shortage, computed as a ratio of Arizona's apportionment less non-tribal PPRs and tribal entitlements in Arizona less the amount of shortage applied to Arizona under Stage 1, over the sum of the apportionments of the Lower Division States less total non-tribal PPRs and tribal entitlements less the total amount shorted to users under Stage 1
    - (2.8 maf – AZ non-tribal PPRs – AZ tribal entitlements - AZ Stage 1 shortage) / (7.5 maf – total non-tribal PPRs – total tribal entitlements - total Stage 1 shortage) or
        - (2,800,000 – 187,543 – 1,042,565 – 821,834) / (7,500,000 – 2,716,679 – 1,135,610 – 897,389) = 29.19 percent
- California bears about 62 percent of the Stage 2 shortage, computed as a ratio of California's apportionment less non-tribal PPRs and tribal entitlements in California, over the sum of the apportionments of the Lower Division States less total non-tribal PPRs and tribal entitlements less the total amount shorted to users under Stage 1
    - (4.4 maf – CA non-tribal PPRs – CA tribal entitlements) / (7.5 maf – total non-tribal PPRs – total tribal entitlements - total Stage 1 shortage) or
        - (4,400,000 – 2,716,679 – 84,647) / (7,500,000 - 2,716,679 – 1,135,610 – 897,389) = 62.39 percent

The distribution of water among non-tribal PPRs is characterized as Stage 3, where water available to each state is an aggregation of the non-tribal PPR volumes within the state that could be filled at a given level of shortage, and tribal entitlements within the states.

Table C-33 below summarizes the distribution of shortage and available water to the Lower Division States under the Priority Without Tribal Shortage Alternative Distribution Model. Total shortage volumes include an assumed component for Mexico, as described in the sections that follow, and will not sum across rows.

Table C-33
Summary of Shortage Volumes and Available Water by Lower Division State Under the Priority Without Tribal Shortage Alternative Distribution Model (af)

Total Lower Basin Shortage Volumes	Arizona Shortage Volume	Arizona Available Water	California Shortage Volume	California Available Water	Nevada Shortage Volume	Nevada Available Water
0	0	2,800,000	0	4,400,000	0	300,000

C.7.4 Distribution Within States for the Priority Without Tribal Shortage Alternative Distribution Model

C.7.4.1 Introduction

The distribution of water within the Lower Division States in this Alternative Distribution Model is consistent with the Priority Shortage Allocation Model except as described below. The differences arise from a need to adjust the priority system so that it functions without the tribal entitlements that are modeled as fully satisfied.

C.7.4.2 General State Assumptions

General state assumptions are as described in the Priority Shortage Allocation Model.

C.7.4.3 Nevada Assumptions

In this Alternative Distribution Model, the Nevada priority system was adjusted to reflect 300 afy of non-tribal PPR entitlements, and 8,398 afy of tribal entitlements, limiting the shortage that could be applied to Nevada to 291,602 afy. This does not represent a functional change to the distribution of water within Nevada in comparison to the Priority Shortage Allocation Model, as the single tribal entitlement was also the highest-priority PPR in the state.

C.7.4.4 California Assumptions

In this Alternative Distribution Model, the California priority system was adjusted to reflect 2,716,679 afy of non-tribal PPR entitlements, and 84,647 afy of tribal entitlements, limiting the shortage that could be applied to California to 4,315,353 afy. This represents a very limited change to the distribution of water within California in comparison to the Priority Shortage Allocation Model, as tribal entitlements in California are all PPRs and mostly senior to the non-tribal PPRs in the state.

C.7.4.5 Arizona Assumptions

In this Alternative Distribution Model, the Arizona priority system was adjusted to reflect 187,543 afy of non-tribal PPR entitlements, and 1,042,565 afy of tribal entitlements, limiting the shortage that could be applied to Arizona to 1,757,435 afy. This represents a significant change to the distribution of water within Arizona in comparison to the Priority Shortage Allocation Model, as tribal entitlements in Arizona are part of every priority pool in the state, but with limited effect on tribal PPRs which are already mostly senior to the non-tribal PPRs in the state.

C.7.4.5.1 Arizona Priority Two and Three Assumptions

In this Alternative Distribution Model, the Ak-Chin Indian Community's Priority Three entitlement was removed from its position among the "Various Entitlements" as described for the Priority Shortage Allocation Model, changing the ratios for the distribution of water among those entitlements, and changing the size of Priorities Two and Three in total from 798,059 afy to 748,059 afy. This results in a given volume of shortage to Priorities Two and Three being shared across a smaller pool of users.

C.7.4.5.2 Arizona Priority Four Assumptions

The most significant differences in this Alternative Distribution Model in comparison to the Priority Shortage Allocation Model result from adjustments to Priority Four assumptions. The Arizona Fourth Priority shortage sharing procedure was revised to be consistent with other assumptions for this Alternative Distribution Model. It subtracts: 1) tribal entitlements not shorted, 2) non-tribal PPR entitlements, 3) non-tribal Priority Two and Three entitlements, and 4) the Arizona shortage volume (all on a consumptive use basis) from Arizona's Colorado River water apportionment to derive the fourth priority supply on a consumptive use basis.

The P4(i) available supply is calculated as 11 percent[27] of the fourth priority supply on a consumptive use basis, not to exceed the total of the consumptive use equivalents of entitlements in the P4(i) pool (90,833 afy as modeled). The remainder of the fourth priority supply is available for diversion as fourth priority water by the CAP to fulfill CAP subcontracts.

The calculation of Available CAP Supply is adjusted so that system loss associated with the Fourth Priority is given as 5 percent of the subcontract volumes remaining in the intra-CAP priority system, which are filled by the Available CAP Supply.

P4(i) (Mainstream) Framework and Assumptions

In this Alternative Distribution Model, the following modeled entitlements were removed from the P4(i) pool: Cocopah Indian Reservation, Hopi Tribe, Water Reserved by the Secretary for a Navajo-Hopi Settlement, and Unallocated 4th Priority Mainstream Water. This changes the size of the pool on a diversion basis from 164,652 afy to 144,618 afy, thereby changing the ratios for the distribution of water among those entitlements and resulting in a given volume of shortage to P4(i) being shared across a smaller pool of users.

CAP Framework and Assumptions

This Alternative Distribution Model differs from the Priority Shortage Allocation Model in the constituents of the CAP NIA-B, NIA-A, M&I, and Indian Priorities. The differences are so significant as to render the existing intra-CAP priority system inoperable; one possible approach is reflected in the model so as to complete the modeling exercise, but is not a legal position or proposal.

Eleven modeled entitlements were removed from the CAP Indian Priority pool, leaving a single Indian Priority entitlement of 500 afy (out of 343,079 afy) currently held by a non-tribal entity. One modeled entitlement of 18,145 afy (San Carlos Apache Tribe) was removed from the CAP M&I Priority pool (out of 638,823 afy). Contractual provisions for the distribution of Available CAP Supply between the Indian and M&I Priority pools do not function under these assumptions; accordingly, in recognition of the co-equal nature of the Indian and M&I Priority pools, they were consolidated into a simulated single CAP first priority in this Alternative Distribution Model, totaling 621,178 afy. Water available to this consolidated pool (the first 621,178 afy of Available

[27] Calculated as 90,833 afy divided by 844,745 afy, the ratio of the adjusted P4(i) contracting pool to the sum of the adjusted P4(i) and P4(ii) contracting pools.

CAP Supply) is distributed among the subcontractors in proportion to their subcontract volumes relative to the total.

NIA Priority supply is calculated as the remaining Available CAP Supply above the 621,178 afy necessary to fill the consolidated Indian and M&I first priority. White Mountain Apache Tribe's entitlement was removed from the NIA-B pool, and the following three entitlements were removed from the NIA-A pool: Gila River Indian Community, Tohono O'odham - Schuk Toak & San Xavier, and Hualapai Tribe. NIA Priority supply is used to fill the remaining NIA-A subcontracts first, then fills the NIA-B subcontracts if supply allows, each in proportion to the subcontract volumes relative to the adjusted totals.

CAP system loss associated with the tribal entitlements removed from the CAP priority pools is included in relevant calculations as 5 percent added to the contract volume.

C.7.5 Priority Without Tribal Shortage Alternative Distribution Model Results

The tables in this section present the results of the Priority Without Tribal Shortage Alternative Distribution Model over a range of total shortages to the Lower Basin including Mexico.

Table C-34, the Regional Summary, summarizes the shortage attributed to each priority within the Lower Division States and reflects shortage attributed to Mexico.

Table C-35, the Tribal Summary, presents the shortage impacts on tribes.

Table C-36, the Irrigation Summary, presents the shortage impacts on irrigators.

Table C-37, the Domestic Summary, presents the shortage impacts on domestic users

Table C-34

[1]Agricultural and Other CAP Excess contracts do not confer a Colorado River water entitlement and cannot be exercised under any of the scenarios modeled here

[2]These estimated shortages to priorities within the CAP reflect the effect of CAP system loss, and do not total to CAP shortage at the point of diversion.

Disclaimer: These modeling results for the Priority (w/o Tribal Shortage) Alternative Distribution Model should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Volumes of total shortage include a portion modeled as attributed to Mexico, but that portion is not itemized in summary sheets.

[1]Denotes full or substantial use in tribal agricultural operations, which may or may not be impacted according to the terms of related agreements.
[2]Likely to include domestic, irrigation, and tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands).

Disclaimer: These modeling results for the Priority (w/o Tribal Shortage) Alternative Distribution Model should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: This analysis attributes shortage to the base allocation or entitlement according to its priority, representing an opportunity cost. The ultimate impacts, both financial and in terms of the lost productive value of water, are diverse according to their varied uses and compensation structures under a large body of exchanges, leases, and other Federal and non-Federal arrangements and commitments. The modeled distribution of shortage to the base allocation reflects how shortage affects the ability for allocations to be exercised, and water users will face decisions in administering agreements during a Shortage Condition; actual water orders received each year will affect shortage impacts.
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.

[1]Combined irrigation and domestic entitlement where domestic use is contractually subordinated to irrigation.
[2]Combined irrigation and domestic entitlement where priority of domestic and irrigation uses may be subject to an annual determination that varies based on the water supply conditions.
[3]This user also holds a PPR entitlement.

Disclaimer: These modeling results for the Priority (w/o Tribal Shortage) Alternative Distribution Model should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero.
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.

[1]This user also holds a PPR entitlement.

Disclaimer: These modeling results for the Priority (w/o Tribal Shortage) Alternative Distribution Model should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero.
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.

C.8 Pro Rata Alternative Distribution Model

The Pro Rata Alternative Distribution Model represents a distribution of shortages outside the priority system. It simulates shortages and distributes water on a proportional basis (i.e., at the same percentage reduction from each user's entitlement) across all lower Colorado River and CAP water users. This Alternative Distribution Model reflects a modeling commitment to stakeholders to display the results of this distribution of water; it is not an interpretation of law, contracts, or a legal position.

The Excel workbook contains formulas extending into deep shortage levels as a modeling exercise relating to potential capacity constraints on Lake Mead releases, and as a basis for comparison with other distributions of shortage. This deeper shortage level modeling does not represent an effect of the Federal action(s) described in this EIS, and this modeling is for informational purposes only.

C.8.1 Distribution Among Water Users

In contrast to the Shortage Allocation Models, which distribute water among the Lower Division States according to a specified state-level distribution, the Pro Rata Alternative Distribution Model distributes water across all lower Colorado River and CAP water users based on their entitlement, without regard to state lines.

Entitlements, as modeled for the Priority Shortage Allocation Model, form the baseline against which shortages are assessed for each water user. Each entitlement's percentage share of the total shortage is calculated as the ratio of the entitlement to the sum of all entitlements, including 1.5 mafy for Mexico. The resulting percentages are multiplied by the volume of total shortage to determine the volume of shortage assigned to each entitlement. At a given level of shortage, as a consequence of how that shortage is distributed as described in this paragraph, all entitlements bear the same percentage reduction. The volume of shortage assigned to a water user with entitlements in different priority categories is the sum across multiple line items in the model; designations of priority do not affect the function of this Alternative Distribution Model but are retained to facilitate comparison of the results between models.

PPRs are not recognized in this Alternative Distribution Model as a basin-wide first priority without regard to state lines, and PPRs are included in the distribution of shortages.

In the Pro Rata Alternative Distribution Model, the internal CAP priority system set forth in the CAP Master Repayment Contract and elsewhere is assumed to be inoperable. Instead, individual long-term CAP contracts and subcontracts (rather than the Master CAP Repayment Contract) are modeled as mainstream consumptive use equivalents, with 5 percent for CAP main system loss added to the contract or subcontract volume; all other entitlements are shown as calculated for the Priority Shortage Allocation Model. As a result, this Alternative Distribution Model does not emulate an Arizona P4 shortage sharing formula and does not calculate an Available CAP Supply or a volume of shortage for CAP at the project level. Note that entitlements within the state of Arizona, as modeled in all models, exceed the state's 2.8 maf annual apportionment. In this Alternative Distribution Model, unlike in priority-based modeling, that causes the proportional

shortage to Arizona's apportionment to slightly exceed (within a single percentage point) the proportional shortage to the apportionments and allocation of California, Nevada, and Mexico, respectively, meaning the Lower Division States and Mexico bear shortage not precisely in proportion to their apportionments or allotment.

C.8.2 Pro Rata Alternative Distribution Model Results

The tables in this section present the results of the Pro Rata Alternative Distribution Model over a range of total shortages to the Lower Basin including Mexico.

Table C-38, the Regional Summary, summarizes the shortage attributed to each priority within the Lower Division States and reflects shortage attributed to Mexico.

Table C-39, the Tribal Summary, presents the shortage impacts on tribes.

Table C-40, the Irrigation Summary, presents the shortage impacts on irrigators.

Table C-41, the Domestic Summary, presents the shortage impacts on domestic users.

[1]Agricultural and Other CAP Excess contracts do not confer a Colorado River water entitlement and cannot be exercised under any of the scenarios modeled here.

[2]The CAP priority system is not maintained in the pro rata distribution. CAP contractors and subcontractors are shorted pro rata with non-CAP water users; therefore, there is not an Available CAP Supply calculated for pro rata alternative distribution models, or a shortage volume given for CAP as a whole.

Disclaimer: These modeling results for the pro rata alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).

[1]Denotes full or substantial use in tribal agricultural operations, which may or may not be impacted according to the terms of related agreements.
[2]Likely to include domestic, irrigation, and Tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands)

Disclaimer: These modeling results for the pro rata alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis attributes shortage to the base allocation or entitlement according to its priority, representing an opportunity cost. The ultimate impacts, both financial and in terms of the lost productive value of water, are diverse according to their varied uses and compensation structures under a large body of exchanges, leases, and other Federal and non-Federal arrangements and commitments. The modeled distribution of shortage to the base allocation reflects how shortage affects the ability for allocations to be exercised, and water users will face decisions in administering agreements during a Shortage Condition; actual water orders received each year will affect shortage impacts.
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.

[1]Combined irrigation and domestic entitlement where domestic use is contractually subordinated to irrigation.

[2]Combined irrigation and domestic entitlement where priority of domestic and irrigation uses may be subject to an annual determination that varies based on the water supply conditions.

[3]This user also holds a PPR entitlement.

Disclaimer: These modeling results for the pro rata alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).

Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.

Table C-41

[1]This user also holds a PPR entitlement.

[2]Likely to include domestic, irrigation, and tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands)

Disclaimer: These modeling results for the pro rata alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.

C.9 Lower Basin Pro Rata Alternative Distribution Model

The Lower Basin Pro Rata Alternative Distribution Model represents a distribution of shortages outside the priority system. It simulates shortages and distributes water pro rata, without regard to priority, but within the framework of the Lower Division States proposal submitted on March 6, 2024. This Alternative Distribution Model reflects a modeling commitment to stakeholders to display the results of this distribution of water; it is not an interpretation of law, contracts, or a legal position.

The Excel workbook contains formulas to extend the proposed distribution to deeper shortage levels (pro rata) as a modeling exercise relating to potential capacity constraints on Lake Mead releases, and as a basis for comparison with other distributions of shortage. This deeper shortage level modeling does not represent an effect of the Federal action(s) described in this EIS, and this modeling is for informational purposes only.

C.9.1 Distribution Among States for the Lower Basin Pro Rata Alternative Distribution Model

The Lower Basin Pro Rata Alternative Distribution Model distributes shortages up to 1.5 maf among states based on the specified state reductions modeled and described for the Lower Basin Priority Shortage Allocation Model. Shortages in excess of 1.5 maf are distributed among the Lower Division States and Mexico in proportion to the unreduced remainder of each apportionment, as described below.

- Arizona bears 27.20 percent of the shortage in excess of 1.5 maf, computed as a ratio of Arizona's apportionment less the amount of shortage applied to Arizona under the Static Reduction Zone, over the sum of the apportionments of the Lower Division States and Mexico less the total amount of shortage applied to users under the Static Reduction Zone, or
    - (2.8 maf – 760 kaf) / (9.0 maf – 1.5 maf) = 27.20 percent
- California bears 52.80 percent of the shortage in excess of 1.5 maf, computed as a ratio of California's apportionment less the amount of shortage applied to California under the Static Reduction Zone, over the sum of the apportionments of the Lower Division States and Mexico less the total amount of shortage applied to users under the Static Reduction Zone, or
    - (4.4 maf – 440 kaf) / (9.0 maf – 1.5 maf) = 52.80 percent
- Nevada bears 3.33 percent of the shortage in excess of 1.5 maf, computed as a ratio of Nevada's apportionment less the amount of shortage applied to Nevada under the Static

Reduction Zone, over the sum of the apportionments of the Lower Division States and Mexico less the total amount of shortage applied to users under the Static Reduction Zone, or

  - (300 kaf – 50 kaf) / (9.0 maf – 1.5 maf) = 3.33 percent

- Mexico bears 16.67 percent of the shortage in excess of 1.5 maf, computed as a ratio of Mexico's allotment less the amount of shortage applied to Mexico under the Static Reduction Zone, over the sum of the apportionments of the Lower Division States and Mexico less the total amount of shortage applied to users under the Static Reduction Zone, or

  - (1.5 maf – 250 kaf) / (9.0 maf – 1.5 maf) = 16.67 percent

PPRs are not recognized as a basin-wide first priority without regard to state lines and do not affect the distribution of shortage among states in this Alternative Distribution Model.

Table C-42 below shows a distribution of shortage among the Lower Division States and corresponding volumes of water available to each Lower Division State under the Lower Basin Pro Rata Shortage Allocation Model. Total shortage volumes include an assumed component for Mexico, as described in the sections that follow, and will not sum across rows.

Table C-42
Summary of Shortage Volumes and Available Water by Lower Division State Under the Lower Basin Pro Rata Alternative Distribution Model (af)

C.9.2 Distribution Within States for the Lower Basin Pro Rata Alternative Distribution Model

The Lower Basin Pro Rata Alternative Distribution Model simulates shortages and distributes water on a proportional basis (i.e., at the same percentage reduction from each user's entitlement) within each of the Lower Division States according to the shortage calculated for the state as described in the previous section.

Entitlements, as modeled for the Priority Shortage Allocation Model, form the baseline against which shortages are assessed for each water user. Each entitlement's percentage share of the shortage to each state is calculated as the ratio of the entitlement to the sum of all entitlements within the state. The resulting percentages are multiplied by the volume of shortage to the state to determine the volume of shortage assigned to each entitlement. At a given level of shortage, as a consequence of how that shortage is distributed as described in this paragraph and the previous section, all entitlements within a given state bear the same percentage reduction, but bear a different percentage reduction from entitlements in a different state. The volume of shortage assigned to a water user with entitlements in different priority categories is the sum across multiple line items in the model; designations of priority do not affect the function of this Alternative Distribution Model, but are retained to facilitate comparison of the results between models.

Because PPRs are not recognized in this Alternative Distribution Model as a basin-wide first priority, PPRs are included in the distribution of shortages.

In the Lower Basin Pro Rata Alternative Distribution Model, as in the Pro Rata Alternative Distribution Model, the internal CAP priority system set forth in the CAP Master Repayment Contract and elsewhere is assumed to be inoperable. Instead, individual long-term CAP contracts and subcontracts (rather than the Master CAP Repayment Contract) are modeled as mainstream consumptive use equivalents, with 5 percent for CAP main system loss added to the contract or subcontract volume; all other entitlements are shown as calculated for the Priority Shortage Allocation Model. As a result, this Alternative Distribution Model does not emulate an Arizona P4 shortage sharing formula and does not calculate an Available CAP Supply or a volume of shortage for CAP at the project level. Note that entitlements within the state of Arizona, as modeled in all models, exceed the state's 2.8 maf annual apportionment; in this Alternative Distribution Model, unlike in priority-based modeling, that has a small effect on the distribution of water.

C.9.3 Lower Basin Pro Rata Alternative Distribution Model Results

The tables in this section present the results of the Lower Basin Pro Rata Alternative Distribution Model over a range of total shortages to the Lower Basin including Mexico.

Table C-43, the Regional Summary, summarizes the shortage attributed to each priority within the Lower Division States and reflects shortage attributed to Mexico.

Table C-44, the Tribal Summary, presents the shortage impacts on tribes.

Table C-45, the Irrigation Summary, presents the shortage impacts on irrigators.

Table C-46, the Domestic Summary, presents the shortage impacts on domestic users.

Disclaimer: These modeling results for the Lower Basin Pro Rata should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
[1]Agricultural and Other CAP Excess contracts do not confer a Colorado River water entitlement and cannot be exercised under any of the scenarios modeled here

Disclaimer: These modeling results for the Lower Basin Pro Rata should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis attributes shortage to the base allocation or entitlement according to its priority, representing an opportunity cost. The ultimate impacts, both financial and in terms of the lost productive value of water, are diverse according to their varied uses and compensation structures under a large body of exchanges, leases, and other Federal and non-Federal arrangements and commitments. The modeled distribution of shortage to the base allocation reflects how shortage affects the ability for allocations to be exercised, and water users will face decisions in administering agreements during a Shortage Condition; actual water orders received each year will affect shortage impacts.
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]Denotes full or substantial use in tribal agricultural operations, which may or may not be impacted according to the terms of related agreements.
[2]Likely to include domestic, irrigation, and Tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands)

Table C-45

Disclaimer: These modeling results for the Lower Basin Pro Rata should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]Combined irrigation and domestic entitlement where domestic use is contractually subordinated to irrigation.
[2]Combined irrigation and domestic entitlement where priority of domestic and irrigation uses may be subject to an annual determination that varies based on the water supply conditions.
[3]This user also holds a PPR entitlement.

Table C-46

Disclaimer: These modeling results for the Lower Basin Pro Rata should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]This user also holds a PPR entitlement.
[2]Likely to include domestic, irrigation, and tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands)

C.10 Pro Rata Without Tribal Shortage Alternative Distribution Model

The Pro Rata Without Tribal Shortage Alternative Distribution Model is an adaptation of the Pro Rata Alternative Distribution Model that represents a distribution of shortages to all users except tribes. It simulates shortages and distributes water on a proportional basis (i.e., at the same percentage reduction from each user's entitlement) across all non-tribal lower Colorado River water entitlements, and assumes all tribal entitlements are fully satisfied and are never shorted.

Assumptions for this Alternative Distribution Model are the same as for the Pro Rata Alternative Distribution Model unless described otherwise below. This Alternative Distribution Model reflects a modeling commitment to display a distribution of water during shortage that does not short tribal entitlements/allocations. It is not an interpretation of law, contracts, or a legal position.

The Excel workbook contains formulas extending into deep shortage levels as a modeling exercise relating to potential capacity constraints on Lake Mead releases, and as a basis for comparison with other distributions of shortage. This deeper shortage level modeling does not represent an effect of the Federal action(s) described in this EIS, and this modeling is for informational purposes only.

C.10.1 Entitlements Which are Not Shorted in the Pro Rata Without Tribal Shortage Alternative Distribution Model

For modeling purposes, the tribal entitlements/allocations in the following **Table C-47** have been removed from the distribution of shortage in this Alternative Distribution Model. The priority of these entitlements is only identified in the Excel workbook and the table below for the purpose of cross-reference. Note that CAP allocations are shown as mainstream consumptive use equivalents, with 5 percent for CAP system loss added to the contract volume. All other entitlements are shown as calculated for the Priority Shortage Allocation Model.

Table C-47
Entitlements and Allocations Not Shorted Under this Alternative Shortage Distribution

State	Priority	Entitlement Holder, Contractor, or Subcontractor	Consumptive Use or Equivalent Entitlement (af)*
Arizona	CAP NIA-B	White Mountain Apache Tribe	24,971.10
Arizona	CAP NIA-A	Gila River Indian Community	126,630.00

Arizona	PPR	Colorado River Indian Reservation	27,032.72
Arizona	PPR	Colorado River Indian Reservation	131,048.32
Arizona	PPR	Colorado River Indian Reservation	186,368.00
-	-	**Subtotal**	**1,042,564.61**
California	PPR	Chemehuevi Indian Reservation	6,123.60
California	PPR	Fort Mojave Indian Reservation	9,028.80
California	PPR	Fort Yuma Indian Reservation	36,524.16
California	PPR	Colorado River Indian Reservation	3,398.80
California	PPR	Colorado River Indian Reservation	23,339.78
California	PPR	Colorado River Indian Reservation	6,232.10
-	-	**Subtotal**	**84,647.24**
Nevada	P1 (PPR)	Fort Mojave Indian Reservation	8,397.78
-	-	**Subtotal**	**8,397.78**
-	-	**Total**	**1,135,609.63**

*CAP allocations are shown as mainstream consumptive use equivalents, with 5 percent for CAP system loss added to the Contract volume.

** May at some time be diverted from the Colorado River above Lake Mead.

C.10.2 Distribution Among Water Users

Shortage in this Alternative Distribution Model is distributed among only the remaining non-tribal entitlements after the tribal entitlements described above are set aside and assumed to be fully filled.

Each non-tribal entitlement's percentage share of the total shortage is calculated as the ratio of the non-tribal entitlement to the sum of all non-tribal entitlements, including a proportional component[28] for Mexico. The resulting percentages are multiplied by the volume of total shortage to determine the volume of shortage assigned to each entitlement. At a given level of shortage, as a consequence of how that shortage is distributed as described in this paragraph, all non-tribal entitlements bear the same percentage reduction. The volume of shortage assigned to a water user with entitlements in different priority categories is the sum across multiple line items in the model; designations of priority do not affect the function of this Alternative Distribution Model, but are retained to facilitate comparison of the results between models. Entitlements subject to shortage in this Alternative Distribution Model are summarized in the following **Table C-48**.

Table C-48
Non-Tribal Entitlements Subject to Shortage Under this Alternative Distribution Model

Arizona, California, Nevada, and Mexico Summary	CU Equivalent (afy)
Arizona Total	1,780,346
California Total	4,315,353
Nevada Total	291,602
Mexico Total	1,272,878
Total	**7,660,179**

C.10.3 Pro Rata Without Tribal Shortage Alternative Distribution Model Results

The tables in this section present the results of the Pro Rata Without Tribal Shortage Alternative Distribution Model over a range of total shortages to the Lower Basin including Mexico.

Table C-49, the Regional Summary, summarizes the shortage attributed to each priority within the Lower Division States and reflects shortage attributed to Mexico.

Table C-50, the Tribal Summary, presents the shortage impacts on tribes.

Table C-51, the Irrigation Summary, presents the shortage impacts on irrigators.

Table C-52, the Domestic Summary, presents the shortage impacts on domestic users.

[28] A non-shorted component is set aside for Mexico in proportion to the non-shorted Tribal entitlements in the U.S.; in this model, 15.14 percent of 1,500,000 afy, or 227,122 afy.

Table C-49

Disclaimer: These modeling results for the pro rata (w/o Tribal Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
[1]Agricultural and Other CAP Excess contracts do not confer a Colorado River water entitlement and cannot be exercised under any of the scenarios modeled here
[2]The CAP priority system is not maintained in the pro rata distribution. CAP contractors and subcontractors are shorted pro rata with non-CAP water users; therefore, there is not an Available CAP Supply calculated for the pro rata alternative distribution model, or a shortage volume given for CAP as a whole.

Table C-50
Pro Rata Without Tribal Shortage Alternative Distribution Model Tribal Summary

Disclaimer: These modeling results for the pro rata (w/o Tribal Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis attributes shortage to the base allocation or entitlement according to its priority, representing an opportunity cost. The ultimate impacts, both financial and in terms of the lost productive value of water, are diverse according to their varied uses and compensation structures under a large body of exchanges, leases, and other Federal and non-Federal arrangements and commitments. The modeled distribution of shortage to the base allocation reflects how shortage affects the ability for allocations to be exercised, and water users will face decisions in administering agreements during a Shortage Condition; actual water orders received each year will affect shortage impacts.
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]Denotes full or substantial use in tribal agricultural operations, which may or may not be impacted according to the terms of related agreements.
[2]Likely to include domestic, irrigation, and Tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands)

Disclaimer: These modeling results for the pro rata (w/o Tribal Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]Combined irrigation and domestic entitlement where domestic use is contractually subordinated to irrigation.
[2]Combined irrigation and domestic entitlement where priority of domestic and irrigation uses may be subject to an annual determination that varies based on the water supply conditions.
[3]This user also holds a PPR entitlement.

Table C-52
Pro Rata Without Tribal Shortage Alternative Distribution Model Domestic Summary

Disclaimer: These modeling results for the pro rata (w/o Tribal Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]This user also holds a PPR entitlement.
[2]Likely to include domestic, irrigation, and tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands)

C.11 Pro Rata Without Tribal PPR Shortage Alternative Distribution Model

The Pro Rata Without Tribal PPR Shortage Alternative Distribution Model is an adaptation of the Pro Rata Alternative Distribution Model that represents a distribution of shortages to all entitlements except tribal PPRs. It simulates shortages and distributes water on a proportional basis (i.e., at the same percentage reduction from each entitlement) across all lower Colorado River water entitlements that are not tribal PPRs, and assumes all tribal PPR entitlements are fully satisfied and are never shorted. This Alternative Distribution Model reflects a modeling commitment to display a distribution of water during shortage that does not short certain tribal entitlements. It is not an interpretation of law, contracts, or a legal position.

The Excel workbook contains formulas extending into deep shortage levels as a modeling exercise relating to potential capacity constraints on Lake Mead releases, and as a basis for comparison with other distributions of shortage. This deeper shortage level modeling does not represent an effect of the Federal action(s) described in this EIS, and this modeling is for informational purposes only.

C.11.1 Distribution Among Water Users

Assumptions for this Alternative Distribution Model are the same as for the Pro Rata Without Tribal Shortage Alternative Distribution Model except as described below. The entitlements listed in the following **Table C-53** were removed from the distribution of shortage in this Alternative Distribution Model.

Table C-53
PPRs Not Shorted Under this Alternative Distribution Model

Entitlement Holders	CU Equivalent (af)*	Diversion (af)	PPR No.	Date	Type of Use
Cocopah Indian Reservation	5,146	7,681	1	1917	Tribal
United States (Cocopah Indian Tribe)	764	1,140	8	1915	Tribal
Chemehuevi Indian Reservation	6,124	11,340	22	1907	Tribal
Fort Mojave Indian Reservation	40,806	75,566	3	1890	Tribal
Fort Mojave Indian Reservation	15,103	27,969	3	1890	Tribal
Fort Mojave Indian Reservation	9,029	16,720	25	1890	Tribal
Fort Mojave Indian Reservation	8,398	12,534	81	1890	Tribal
Fort Yuma Indian Reservation	36,524	71,616	23	1884	Tribal
Fort Yuma Indian Reservation	4,001	6,350	3a	1884	Tribal
Colorado River Indian Reservation	3,399	5,860	24	1876	Tribal
Colorado River Indian Reservation	27,033	51,986	2	1874	Tribal
Colorado River Indian Reservation	23,340	40,241	24	1874	Tribal

Entitlement Holders	CU Equivalent (af)*	Diversion (af)	PPR No.	Date	Type of Use
Colorado River Indian Reservation	131,048	252,016	2	1873	Tribal
Colorado River Indian Reservation	6,232	10,745	24	1873	Tribal
Colorado River Indian Reservation	186,368	358,400	2	1865	Tribal

*Calculated consumptive use equivalents. Historical Decree Accounting data were used to estimate average CU/Diversion ratios as part of development of the CRSS hydrologic modeling dataset for this EIS. For purposes of modeling, these values are assumed to be generally representative of return flow conditions for the specified users, and match CRSS inputs. Those ratios were used to estimate the consumptive use equivalent of diversion entitlements. In CA, miscellaneous PPRs were assumed to have a CU/Div ratio of .64. For IID, consumptive use was assumed to equal diversion since the CU/diversion ratio based on average historical efficiency was 0.996. In AZ, with limited supporting data about miscellaneous PPRs, they were assumed to be fully consumptive. Where an entitlement was quantified on the basis of CU by the Consolidated Decree, those values are used.

A non-shorted component is set aside for Mexico in proportion to the non-shorted tribal PPR entitlements in the U.S.; in this model, 6.71 percent of 1.5 mafy, or 100,663 afy. Entitlements subject to shortage in this Alternative Distribution Model are summarized in the following **Table C-54**.

Table C-54
Non-Tribal Entitlements Subject to Shortage Under this Alternative Distribution Model

Arizona, California, Nevada, and Mexico Summary	CU Equivalent (afy)
Arizona Total	2,412,642
California Total	4,315,353
Nevada Total	291,602
Mexico Total	1,399,337
Total	**8,418,934**

C.11.2 Pro Rata Without PPR Tribal Shortage Alternative Distribution Model Results

The tables in this section present the results of the Pro Rata Without PPR Tribal Shortage Alternative Distribution Model over a range of total shortages to the Lower Basin including Mexico.

Table C-55, the Regional Summary, summarizes the shortage attributed to each priority within the Lower Division States and reflects shortage attributed to Mexico.

Table C-56, the Tribal Summary, presents the shortage impacts on tribes.

Table C-57, the Irrigation Summary, presents the shortage impacts on irrigators.

Table C-58, the Domestic Summary, presents the shortage impacts on domestic users.

Table C-55

Disclaimer: These modeling results for the pro rata (w/o Tribal PPR Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
[1]Agricultural and Other CAP Excess contracts do not confer a Colorado River water entitlement and cannot be exercised under any of the scenarios modeled here
[2]The CAP priority system is not maintained in the pro rata distribution. CAP contractors and subcontractors are shorted pro rata with non-CAP water users; therefore, there is not an Available CAP Supply calculated for the pro rata alternative distribution model, or a shortage volume given for CAP as a whole.

Disclaimer: These modeling results for the pro rata (w/o Tribal PPR Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis attributes shortage to the base allocation or entitlement according to its priority, representing an opportunity cost. The ultimate impacts, both financial and in terms of the lost productive value of water, are diverse according to their varied uses and compensation structures under a large body of exchanges, leases, and other Federal and non-Federal arrangements and commitments. The modeled distribution of shortage to the base allocation reflects how shortage affects the ability for allocations to be exercised, and water users will face decisions in administering agreements during a Shortage Condition; actual water orders received each year will affect shortage impacts.
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]Denotes full or substantial use in tribal agricultural operations, which may or may not be impacted according to the terms of related agreements.
[2]Likely to include domestic, irrigation, and Tribal elements (including an unquantified entitlement for the Cocopah Reservation's 1985 lands)

Table C-57
Pro Rata Without PPR Tribal Shortage Alternative Distribution Model Irrigation Summary

Disclaimer: These modeling results for the pro rata (w/o Tribal PPR Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]Combined irrigation and domestic entitlement where domestic use is contractually subordinated to irrigation.
[2]Combined irrigation and domestic entitlement where priority of domestic and irrigation uses may be subject to an annual determination that varies based on the water supply conditions.
[3]This user also holds a PPR entitlement.

Table C-58
Pro Rata Without PPR Tribal Shortage Alternative Distribution Model Domestic Summary

Disclaimer: These modeling results for the pro rata (w/o Tribal PPR Shortage) alternative distribution should only be used to compare the relative magnitude of effects reasonably expected to occur under the alternatives evaluated in this EIS. Modeling assumptions should not be taken as agency position with respect to contract or statutory interpretation, and are not intended to limit Secretarial discretion with respect to current or future policy. This model is not a substitute for the annual process of reviewing water orders and determining which can be filled, and cannot replicate the precision required of that process.

Note: Orange highlights indicate the level at which available water for a priority is reduced. Lighter orange indicates smaller reductions, while the darkest orange indicates a priority is reduced to zero (does not occur in this table).
Note: This analysis does not reflect an operational estimate of when water may cease to be physically available to certain users.
[1]This user also holds a PPR entitlement.

EXHIBIT 5.3.4.1

SECRETARY'S SHORTAGE SHARING APPROACH

UNDER THE 1980 CONTRACT

Secretary's Approach for Determining
The Amount of Water Available to the Nation
During a Time of Shortage Under 1980 Contract

If the Available CAP Supply is insufficient to fill all orders for CAP water, the Secretary shall take the following steps, in succession, as necessary to match the available supply with orders for the delivery of CAP water in each of the categories described below:

1. First, miscellaneous uses of CAP water are reduced, pro rata. If, after eliminating all miscellaneous uses of CAP water, there is still insufficient available CAP water to meet outstanding orders for the delivery of CAP water, the Secretary shall take the following measure.

2. Uses of CAP NIA Priority Water are reduced, pro rata. If, after eliminating all uses of CAP NIA Priority Water, there is still insufficient available CAP water to meet outstanding orders for delivery of CAP water, then the Secretary shall take the following measure.

3. Uses of CAP M&I Priority Water in excess of 510,000 acre-feet are reduced, pro rata. If, after eliminating all uses of CAP M&I Priority Water in excess of 510,000 acre-feet, there is still insufficient available CAP water to meet outstanding orders for delivery of CAP water, then the Secretary shall take the following measure.

4. If the preceding reductions do not bring CAP water orders in line with the Available CAP Supply, uses of CAP Indian Priority Water in excess of 291,574 acre-feet are reduced, in accordance with the Secretarial Decision published in the Federal Register on March 24, 1983.

5. If the preceding reductions do not bring CAP water orders in line with the Available CAP Supply, the available CAP water supply will be allocated between users of CAP Indian Priority Water and users of CAP M&I Priority Water on a 36.37518 and 63.62482 percentage basis, respectively.

6. If step 5 is implemented, the amount of water available for the Nation shall be determined by multiplying the amount of CAP Indian Priority Water by the ratio of the amount of water delivered pursuant to the Nation's CAP Water Delivery Contract in the latest non-shortage Year relative to the total quantity of water delivered to all CAP Contracts for Indian Priority Water in that same Year.

Appendix D. Sensitivity Analysis – Effects of Natural Flow Percentage Used for the Supply Driven Alternative

D.1 Introduction

The Supply Driven Alternative (both Lower Basin Priority [LB Priority] and Lower Basin Pro Rata [LB Pro Rata] approaches) described in **Appendix S** of this Final Environmental Impact Statement (EIS) assumes 65 percent of the preceding 3-year Lees Ferry natural flow is released from Lake Powell, with annual releases constrained between 4.7 and 12.0 million acre-feet (maf). This sensitivity analysis explores the impacts of adjusting the assumed natural flow release percentage, specifically comparing 60 percent, 65 percent, and 70 percent, on key hydrologic and water delivery resources.

D.2 Modeling Results

An analysis was performed to test the sensitivity of the hydrologic and water delivery resources to three different natural flow release percentages (60 percent, 65 percent, and 70 percent). The Colorado River Simulation System (CRSS) model was used to simulate operations under the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) with these three different natural flow release percentages, while holding all other modeling assumptions under the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) constant. See **Appendix A**, CRSS Model Documentation, for detailed modeling assumptions.

Figure D-1 compares the response of key variables to different hydrologic conditions for the different scenarios that vary the natural flow release percentages and Lower Basin shortage distribution methods (both LB Priority and LB Pro Rata approaches). Results are presented using conditional boxplots, which separate results based on five flow categories (see **Chapter 3.2.6** for additional details on conditional boxplots). Each boxplot in the figure illustrates the distribution of modeled results, where the bold center line represents the median value, the top and bottom of each box shows the interquartile range which captures the 25th to 75th percentile, the lines extend to the 10th and 90th percentiles, and the outliers are represented as dots beyond these lines. The following sections compare the responses of key variables to different natural flow release percentages by hydrologic conditions.

D.2.1 Water Year Gap Water Volume

In years when Lake Powell cannot meet its required water year release because of low elevation infrastructure constraints (i.e., Lake Powell is less than 3,490 feet), additional water is introduced

into the system to (partially) make up the shortfall. For modeling purposes, this supplemental volume is termed "gap water." Gap water is injected into Lake Powell and released when conditions allow, subject to the same low-elevation release constraints. Any portion not released in a given water year is tracked as carryover and released in subsequent years. The annual amount of gap water is limited to no more than 23 percent[1] of the Upper Basin's modeled depletion for that year, minus any Upper Basin conservation that occurs. Additional detail is provided in **Appendix A**.

Water year gap water volume is shown in the first column of **Figure D-1**. In the Average Flow Category (12.0-14.0 maf), the median and upper quartile gap water volume is zero at the 60 and 65 percent natural flow release percentages. For the 70 percent natural flow release scenario, the median and upper quartile are slightly over 0.1 maf and 0.9 maf, respectively. As the hydrologic conditions become drier, the gap water volume increases across all scenarios. In the Critically Dry Flow Category (4.5-10.0 maf), the median for the 70 percent natural flow release scenario is 0.8 maf but is zero for 60 percent and 65 percent. With higher natural flow release percentages, the gap water volumes increase and are required more frequently, especially in drier flow conditions, since more Lake Powell releases are infrastructure constrained. Results do not vary with Lower Basin shortage distribution method.

D.2.2 Lake Powell and Lake Mead Water Surface Elevations

Lake Powell and Lake Mead end-of-water year (EOWY) elevation by hydrologic condition are shown in the second and third columns of **Figure D-1**, respectively. Across all flow categories, as the natural flow release percentage increases, the elevation of Lake Powell declines due to higher releases, while Lake Mead elevations increase due to higher inflows.

In the Average Flow Category, median Lake Powell EOWY elevation is 3,633 feet, 3,573 feet, and 3,528 feet in the 60 percent, 65 percent, and 70 percent natural flow release scenarios, respectively, and the bottom quartile of the 70 percent extends below 3,500 feet. In the Critically Dry Flow Category, the median elevation of the 65 percent and 70 percent natural flow release scenarios are nearly at or below 3,500 feet, while the median of the 60 percent scenario is at 3,550 feet. The bottom quartile of the 65 percent and 70 percent scenarios are similar at 3,470 and 3,464 feet, respectively, since releases are limited by infrastructure. The results do not vary by Lower Basin shortage distribution method.

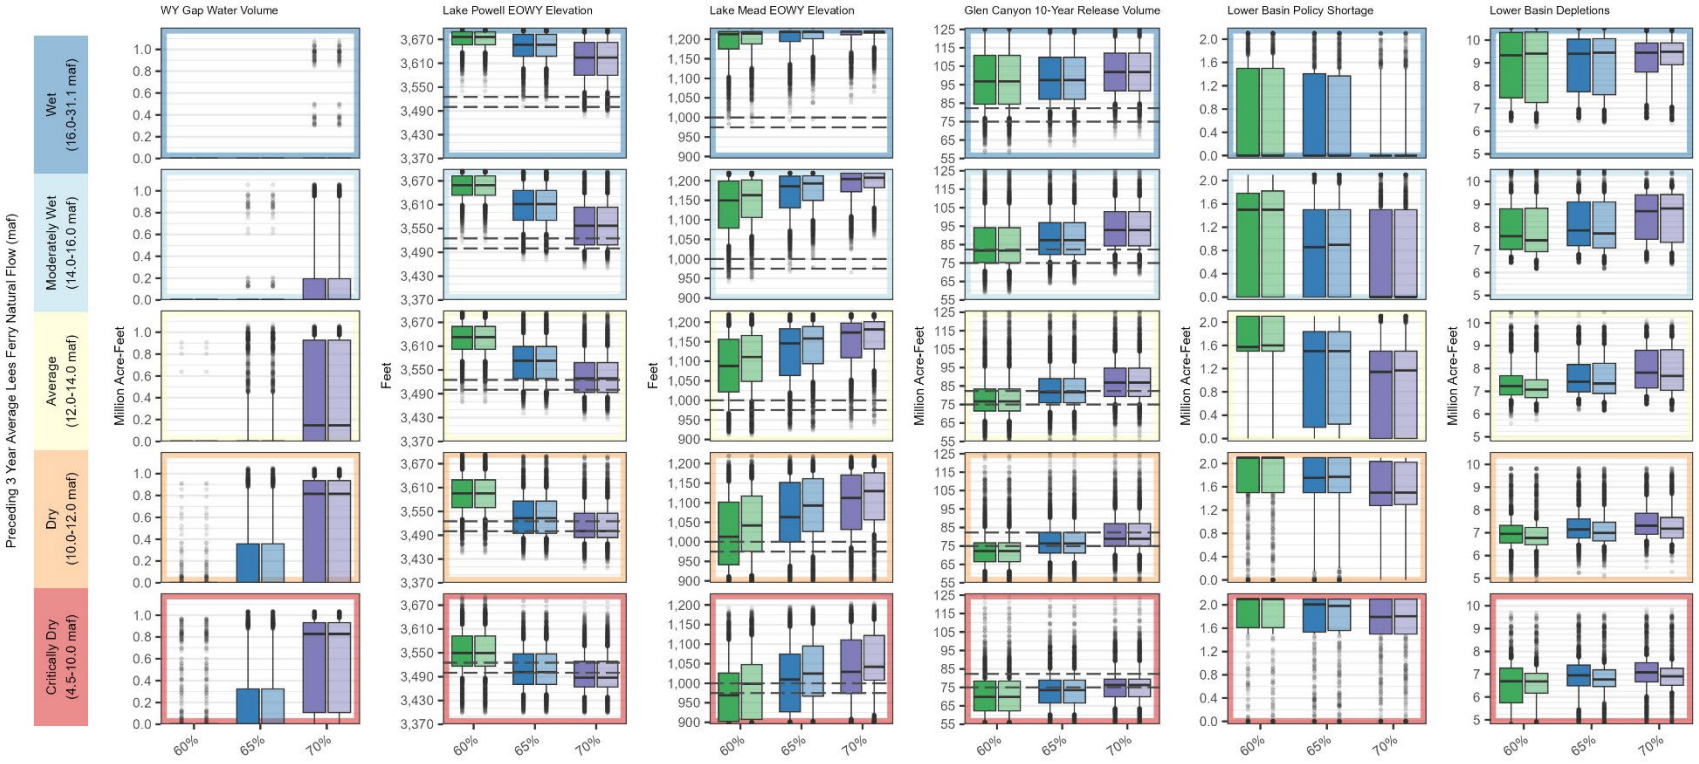
In the Average Flow Category for Lake Mead, the median EOWY elevations are 1,088 feet, 1,146 feet, and 1,173 feet in the 60 percent, 65 percent, and 70 percent scenarios for the LB Priority shortage distribution, and 1,111 feet, 1,158 feet, and 1,181 feet in the 60 percent, 65 percent, and 70 percent scenarios for the LB Pro Rata shortage distribution. The elevation statistics are higher with LB Pro Rata than LB Priority because user-level conservation activity modeling assumptions cause higher volumes of conserved water to be stored in Lake Mead. In the Critically Dry Flow Category, the median elevation of the 60 percent with the LB Priority shortage distribution is below 975 feet, while the 65 and 75 percent scenarios have medians above 1,000 feet. The bottom quartile extends

[1] The 23 percent limit is based on the ratio of the maximum Lower Basin shortage (2.1 maf) to the total Lower Basin apportionment to the United States (U.S.) and the United Mexican States (Mexico) (9.0 maf).

below 1,011 feet in all but the 70 percent scenario, with a median value of 1,025 feet, natural flow release scenario with LB Pro Rata shortage distribution.

D.2.3 Glen Canyon 10-Year Release Volume

Glen Canyon 10-year release volume by hydrologic condition is shown in the fourth column of **Figure D-1**. In the Average Flow Category, the median 10-year releases are 76.7, 81.7 and 86.9 maf in the 60 percent, 65 percent, and 70 percent natural flow release percent scenarios, respectively. The bottom quartile of the 60 percent scenario extends below 75.0 maf and the 65 percent and 70 percent scenario extends below 82.5 maf. In the Critically Dry Flow Category, the median 10-year releases are 69.8, 73.5 and 76.3 maf in the 60 percent, 65 percent, and 70 percent scenarios, with the 60 percent and 65 percent scenario medians below the 75.0 maf volume. All upper quartiles are below the 82.5 maf threshold. The results do not vary by shortage distribution method.



D.2.4 Lower Basin Shortage and Depletion

The Lower Basin shortage and depletion[2] by hydrologic condition are shown in the fifth and sixth columns of **Figure D-1**. The Lower Basin shortage decreases with increasing natural flow release percentage. The shortage distribution approach has only minor impacts on the shortage because the conservation mechanism is operationally neutral and therefore not visible to shortage determination. In the Average Flow Category, the median Lower Basin shortage is 1.6 maf and 1.5 maf in the 60 percent and 65 percent scenarios, respectively, and between 1.1 maf to 1.2 maf for the 70 percent scenarios. The interquartile range (0.6 maf) for the 60 percent scenario is smaller, extending from 1.5 maf to 2.1 maf, compared to the 65 percent and 70 percent scenarios that have interquartile ranges around 1.5 maf. In the Critically Dry Flow Category, the median Lower Basin shortages are all greater than 1.5 maf at 2.1, 2.0, and 1.8 maf in the 60 percent, 65 percent, and 70 percent scenarios, respectively.

As shown in **Figure D-1**, the Lower Basin depletions increase with increasing natural flow release percentage in both shortage distribution methods. The variations in Lower Basin depletions between the LB Pro Rata and LB Priority methods shown in **Figure D-1** is the result of conservation activity modeling in the LB Pro Rata method. Though the Lower Basin shortages are similar between the shortage distribution methods, conservation activity modeling assumptions cause different depletions. In the Average Flow Category, the median depletions are 7.2, 7.4, and 7.8 maf in the 60 percent, 65 percent, and 70 percent scenarios, respectively, for the LB Priority shortage distribution, and 7.1, 7.3, and 7.7 maf in the 60 percent, 65 percent, and 70 percent scenarios, respectively, for the LB Pro Rata shortage distribution. In the Critically Dry Flow Category, the median depletions are 6.7, 6.9 and 7.1 maf in the 60 percent, 65 percent, and 70 percent scenarios, respectively, for the LB Priority shortage distribution, and 6.7, 6.8 and 6.9 maf in the 60 percent, 65 percent, and 70 percent scenarios, respectively, for the LB Pro Rata shortage distribution.

[2] The total Lower Basin policy shortage and Lower Basin depletions include shortages to U.S. Lower Division States and water delivery reductions to Mexico based on the modeling assumptions for the distribution of shortages in the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative. The Bureau of Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico.

Appendix E. DMDU Overview and Approach

E.1 Introduction

Uncertainty is a major challenge for the Post-2026 planning process. In the medium-to- long-term (e.g. 5 to 30 years), future streamflow conditions are the predominant driver of the impacts associated with each alternative (Smith et al. 2022). Future hydrology is expected to be drier (Lukas and Payton 2020, p. 385, 2020; Salehabadi et al. 2022; Wang et al. 2025), but the magnitude and rate of drying is unknown. Not only are future streamflow conditions uncertain, but there is no scientific consensus on how to characterize the uncertainty probabilistically (i.e. the likelihood that a given hydrologic scenario will occur). This is known as deep uncertainty (Lempert et al. 2003; Kwakkel and Haasnoot 2019).

The analytical framework used in this Final Environmental Impact Statement (EIS), called Decision Making under Deep Uncertainty (DMDU), is a non-probabilistic approach that seeks to provide reliable conclusions about robustness – the ability of an alternative to perform acceptably well across a broad range of future conditions (McPhail et al. 2018; Bonham et al. 2024) – and vulnerability – conditions associated with an alternative performing poorly (Bryant and Lempert 2010; Bonham et al. 2025). The Bureau of Reclamation (Reclamation) chose this framework based on the best available science, as explained in Smith et al. 2022.

The purpose of this appendix is to provide an overview of DMDU, document the specific implementation in this Final EIS, and describe the collaborative process that enabled its implementation.

This appendix is structured as follows. **Section E.2**, Background, motivates the need for DMDU and provides an overview of key concepts. **Section E.3**, Methods, describes the specific methods used in this Final EIS. **Section E.4**, Outreach and Collaboration, describes the training and collaborative efforts that were necessary to use DMDU in this Final EIS. **Section E.5** provides a summary of previous sections.

E.2 Background

Uncertainty is often accounted for using probabilistic risk analysis, but risk analysis has several limitations for problems facing deep uncertainty. Risk analysis, in this context, uses a simulation model (such as the Colorado River Simulation System [CRSS]) to evaluate system outcomes over time (such as monthly reservoir elevations) across an ensemble of traces (Wheeler et al. 2022; Reclamation 2024). Then, risk can be evaluated as the percent of traces in which a critical performance threshold is crossed, for example, percent of traces where Lake Powell elevation falls below minimum power pool (3,490 feet).

Each ensemble represents a narrative or a set of assumptions about the future, such as "future hydrology has similar magnitudes to the past 30 years" (Lukas and Payton 2020, p. 346) or "future hydrology will continue to decline at current trends but with increased variability" (Salehabadi et al. 2025). Understanding this assumption is critical because risk percentages can be highly sensitive to the set of traces used. If there is uncertainty about the most appropriate set of assumptions, i.e., deep uncertainty, it is difficult to have confidence in any specific risk percentage, much less determine that it is sufficiently low. If the future proves to be more difficult than the assumed ensemble suggests, risk analysis can lead to a narrow view of what negative impacts are plausible and unintentionally steer decision-makers away from addressing them; if a future is more favorable than was assumed, the analysis can result in decisions that are unnecessarily expensive or austere.

As an alternative to risk-based decision making, DMDU is a well-established branch of decision science that seeks to provide reliable and actionable information about decision alternatives when faced with deep uncertainty (Kasprzyk et al. 2013; Herman et al. 2015; Maier et al. 2016; Marchau et al. 2019; Hadjimichael et al. 2020).

DMDU has three key elements: testing decision alternatives in a broad range of plausible future conditions, robustness analysis, and vulnerability analysis. This section explains these concepts in the context of this Final EIS to provide concrete examples.

1) Each alternative is tested using simulation models in a large ensemble of streamflow traces. This ensemble is statistically designed to include a broad range of conditions, including those outside of the observed record, and the design also minimizes "gaps" in the types of conditions being tested (See **Appendix F**, Approach to Hydrologic Uncertainty). The goal is to maximize the available information about how each alternative performs across a diverse set of traces, rather than predicting the likelihood of an outcome.

2) Alternatives are ranked according to their ability to maintain a specified performance level across a large percentage of traces (robustness). Robustness differs from risk because a) the set of traces being evaluated explores a much broader set of conditions and b) the emphasis is relative comparison of the alternatives (i.e. ranking from most to least robust) rather than a likelihood of success or failure.

3) Vulnerability analysis discovers the conditions in which an alternative is likely to satisfy or fail to meet a given performance level. Here "conditions" refer to the values of statistics describing annual natural flow at Lees Ferry in each streamflow trace. Example streamflow statistics include average annual streamflow during the worst 10-year drought and the driest single year (see **Section E.3**). An example conclusion from vulnerability analysis is that the Basic Coordination Alternative is likely to fall below 3,500 feet if there is a 10-year drought drier than 12.2 maf/year, on average (see **Figure TA 3-8** in **TA 3,** Hydrologic Resources). This is powerful information because it does not depend on any single hydrology ensemble being the "correct" representation of the future (recall, deep uncertainty means there is no consensus on what future hydrology is "correct"). And, when compared to historical extremes, it provides actionable insights. For example, the worst 10-year drought on record averaged 11.8 maf/year (2012-2021). So, unless future conditions are wetter than recent

hydrology, it can reasonably be expected that the Supply Driven Alternative (both Lower Basin Priority and Lower Basin Pro Rata approaches) will result in Lake Powell falling below 3,500 feet.

E.3 Methods

DMDU begins by evaluating each decision alternative in a large set of traces using simulation models. The set of traces used in this study includes 400 hydrologic traces (see **Appendix F**, Approach to Hydrologic Uncertainty). In this Final EIS, each of the 400 hydrologic traces were combined with 3 sets of initial reservoir storage conditions (see **Appendix G**, CRSS Initial Conditions) for a total of 1,200 simulations per alternative per model. Due to recent dry hydrology, however, the high and middle initial conditions are no longer plausible, and this Final EIS considers only the low initial conditions (meaning there are 400 future simulations per alternative per model). Each combination of a hydrologic trace and initial condition is called a future.

Because this Final EIS covers many resources, many models were used, such as CRSS (hydrologic and water deliveries resources), GTMax (electrical power resources), temperature models (water quality and fish resources), smallmouth bass models, and dust emission models (air quality), to name a few (see the technical appendices in **Volume III** for more information). The modeling period covers January 2027 to December 2060. These model runs produce large datasets describing how each alternative performs over time across various streamflow conditions. These datasets are then analyzed in the robustness and vulnerability analyses.

In this Final EIS, robustness is defined as the percent of futures where a performance goal is satisfied (called the satisficing metric in DMDU literature) (McPhail et al. 2018; Bonham et al. 2024). Various other robustness metrics exist, but satisficing was chosen because the performance criteria can be tailored to each resource based on expert input (see **Section E.4**), and because it provides a clear connection to vulnerability analysis. Performance goals are defined using four components: a timeseries, a threshold, a preferred direction, and a frequency. For example, **Figure TA 3-7** in **TA 3,** Hydrologic Resources evaluates the percent of futures in which monthly Lake Powell elevation (the timeseries) stays above (the preferred direction) 3,500 feet (the threshold) in 100 percent of months (the frequency). Robustness is evaluated for each alternative, and the resulting scores are used to rank the alternatives from most to least robust.

Next, vulnerability analysis applies a machine learning algorithm to accomplish two tasks (Bryant and Lempert 2010; Bonham et al. 2025). First, it identifies the streamflow statistic that is the most accurate predictor of whether a given alternative will satisfy or fail to meet a performance criterion. Second, it identifies the specific values of that statistic associated with achieving/failing the criteria. The subsequent paragraphs describe the streamflow statistics, the machine learning algorithm, and the method for evaluating accuracy.

Table E-1 below lists the streamflow statistics included in the vulnerability analysis. Each streamflow statistic is calculated for each of the 400 hydrologic futures. The statistics examine short (1-and 2-year), medium (5- and 10-year), and long-term (20-year) windows because the ability or

inability to satisfy different performance levels can be more strongly associated with different durations than others. Likewise, conditions that describe both dry and wet conditions are included because some resources are prone to failure under dry conditions (e.g., Lake Powell elevation below 3,500 feet) while others are prone to failure under wet conditions (e.g., use of Glen Canyon Dam spillway). In addition to statistics that describe dry and wet conditions, the median of the 2-, 5-, 10-, and 20-year moving average natural flows were also tested to describe "normal" conditions, which proved to be accurate predictors for several analyses important to threatened and endangered fish species (see **Figures TA 8-2** and **8-4** in **TA 8,** Biological Resources- Fish and Other Aquatic Species).

Table E-1
Streamflow statistics tested in vulnerability analysis

Streamflow Statistic	Category
Minimum 1-year natural flow volume	Dry conditions
Average Lees Ferry natural flow during the driest 2-year period	
Average Lees Ferry natural flow during the driest 5-year period	
Average Lees Ferry natural flow during the driest 10-year period	
Average Lees Ferry natural flow during the driest 20-year period	
Maximum 1-year natural flow volume	Wet conditions
Average Lees Ferry natural flow during the wettest 2-year period	
Average Lees Ferry natural flow during the wettest 5-year period	
Average Lees Ferry natural flow during the wettest 10-year period	
Average Lees Ferry natural flow during the wettest 20-year period	
Median of the moving 2-year average Lees Ferry natural flow	Normal Conditions
Median of the moving 5-year average Lees Ferry natural flow	
Median of the moving 10-year average Lees Ferry natural flow	
Median of the moving 20-year average Lees Ferry natural flow	

In this Final EIS, all streamflow statistics in **Table E-1** were considered when determining which is the most accurate predictor.

In this Final EIS, only 10-year statistics (driest 10-year period, wettest 10-year period, and median 10-year period) were considered when selecting the most accurate predictor. Because the Preferred Alternative is a 10-year decision framework, using streamflow statistics based on 10-year averages provides more relevant information than shorter or longer windows. For many resources, a streamflow statistic based on a 10-year average is the most accurate. In some cases, a 10-year statistic resulted in a small decrease in accuracy (e.g. 5-10 percent or less) compared to the best statistic (usually a 20-year statistic), but a small decrease in accuracy was deemed worth the additional relevance to the planned length of the Preferred Alternative decision framework.

The machine learning algorithm used in this analysis is a simplified version of the Patient Rule Induction Method (PRIM; Bryant and Lempert 2010). PRIM identifies values of the streamflow conditions that accurately separate the modeled futures into two categories (those that satisfied and those that failed to meet criteria). Although PRIM can test multiple streamflow statistics simultaneously, it was applied to one statistic at a time to maximize interpretability of the results.

For vulnerability analyses shown in **Volume III,** technical appendices, accuracy was evaluated with a two-step criteria. First, for each streamflow statistic, PRIM was used to identify the value such that at least 90 percent of futures that are predicted to satisfy the performance criteria actually do satisfy it (based on modeling output). Because the goal was to standardize the accuracy of results between alternatives and across resources as much as possible, the value that resulted in an accuracy closest to 90 percent was chosen[1]. This first step defines the value for each streamflow statistic and each alternative. In the second step, the streamflow statistic is selected that, on average across alternatives, has the highest accuracy at predicting a future will fail to meet the performance criteria. In the Draft EIS, all statistics in **Table ES-3** were considered, whereas this Final EIS considered only the driest, wettest, and median 10-year averages. Accuracy at predicting that a future fails the performance criteria generally ranges from 70 to 90 percent, with a limited number of exceptions that are identified with footnotes in their respective technical appendices.

For the 2027-2036 vulnerability analyses reported in **Tables ES-4** and **ES-5** in the Executive Summary, several minor changes were made to better suit a 10-year modeling period. First, because the analysis considered only the first 10 years, the only streamflow statistic evaluated was the average natural flow from 2027-2036. Second, the streamflow value that separates successful and unsuccessful futures was determined such that the value maximizes the average accuracy of predicting successful and unsuccessful futures. This approach resulted in highly accurate predictions of failure (98 percent or greater for all action alternatives)[2] and accurate predictions of success (75 percent or greater for all alternatives).

E.4 Outreach and Collaboration

DMDU is a widely accepted branch of decision science in academic research (Bonham et al 2022; Gold et al. 2022), and it has been applied in several non-academic decision support studies (Dixon and RAND Center for Terrorism Risk Management Policy 2007; Molina-Perez et al. 2019). Reclamation applied DMDU in the 2012 Colorado River Basin Water Supply and Demand Study (Reclamation 2012; Groves et al. 2013) and has funded multiple research-oriented applications investigating annual operations at Lake Powell and Lake Mead (Alexander 2018; Smith et al. 2022; Bonham et al. 2024).

This Final EIS, however, is the first use of DMDU in a decision-making process in the Colorado River Basin where numerous resources are explicitly evaluated. This is a challenge that affords tremendous opportunity for Basin-wide, cross-discipline collaboration. It was necessary for Reclamation to provide education and training so that interested parties (e.g., Basin States, tribes, partner federal agencies, the United Mexican States) could interpret results and incorporate them

[1] To standardize results as much as possible, the values of the streamflow statistics for all 400 futures were tested when evaluating accuracy. In PRIM literature, this implementation would be considered maximally "patient". The patience of the PRIM algorithm, as implemented in existing programming libraries, is controlled by the alpha parameter. To ensure all 400 futures were evaluated in this Final EIS, a custom implementation of PRIM was programmed rather than using existing programming libraries.

[2] Accuracy of predicting failures for the No Action Alternative is lower (68 percent and 86 percent for the Powell and Mead analyses, respectively). Lower accuracy is expected due to reservoir operations in the No Action Alternative being less responsive to hydrologic conditions compared to action alternatives.

into their planning activities. Further, it was necessary for Reclamation to collaborate with subject matter experts to define performance criteria. This section describes three key efforts towards achieving broader familiarity with DMDU in the Basin.

First, Reclamation developed the Integrated Technical Education Workgroup (ITEW) "to ensure that Colorado River partners have a common and accurate understanding of the underlying tools and concepts needed to meaningfully participate in the development of Post-2026 operating alternatives" (Reclamation 2023). The Research and Modeling team gave six educational and training webinars on topics including CRSS, hydrology, DMDU, and reservoir operations from May 2023 to November 2023 (www.usbr.gov/ColoradoRiverBasin/post2026). Participants included tribes, Basin States, municipalities, water and irrigation districts, non-governmental organizations, other federal agencies, researchers, and the United Mexican States.

Second, Reclamation, in partnership with Virga Labs, developed and published the "Colorado River Post-2026 Operations Exploration Tool" (hereafter "web tool"). The web tool is an interactive website (www.crbpost2026dmdu.org), launched in November 2023, that immerses the user in a guided, customizable DMDU analysis with a low barrier to entry. It is loaded with hundreds of operational strategies for Lower Basin reductions and releases from Lake Powell. The user can also create their own strategies using a variety of operational paradigms, which are then modeled in thousands of future scenarios using CRSS and cloud computing. The user defines performance requirements for the resources they are interested in, and the tool calculates robustness and vulnerability.

The web tool has been an important part of building familiarity with DMDU in the Basin. As of March 2026, 879 users have registered to use the web tool and 358 custom operational strategies have been created. It played a major role in shaping the Lower Basin shortage and Lake Powell release operations in the Maximum Operational Flexibility Alternative. Further, the tool supported extensive collaboration between Reclamation, the National Park Service, and the United States Fish and Wildlife Service to define the performance goals that shaped the Lake Powell operations in the Enhanced Coordination Alternative. Given the number of users and consistent use of the web tool for over two years, it is assumed that many others gained valuable knowledge about how to use DMDU to evaluate creative operations in the Basin.

Third, Reclamation, in partnership with AECOM, has led a major collaborative effort with resource experts to define performance thresholds and perform the DMDU analyses presented in this Final EIS. This Final EIS includes over 100 total robustness and vulnerability analyses across 17 different resources. While Reclamation has the subject matter expertise to define the performance requirements for some resource categories (e.g., water deliveries and hydrology), many resources required input from subject matter experts beyond Reclamation. The collaborative process launched in May 2024 and has required three to six meetings per resource. Participants in the collaboration include the cooperating agencies, the United States Geological Survey Grand Canyon Monitoring and Research Center, AECOM, SWCA, Hazen and Sawyer, among others (see List of Preparers, Chapter 6).

E.5 Summary

Due to the long-term planning horizon and deeply uncertain nature of hydrology, DMDU is the preferred analytical framework for the Post-2026 EIS. The main elements of DMDU, as applied in this Final EIS, are a hydrology ensemble that considers a broad range of hydrologic conditions, robustness analysis that ranks operational alternatives, and vulnerability analysis that discovers the streamflow conditions where alternatives satisfy or fail performance criteria. Reclamation has led several efforts leading up to the publication of this Final EIS to build basin-wide familiarity with DMDU, including educational webinars, an interactive web tool, and numerous collaborative meetings with resource experts. The concrete product of these efforts is the analysis contained in the technical appendices in **Volume III** of this Final EIS.

These collaborative efforts have also contributed to critical but difficult to quantify areas. This process has strengthened basin-wide, inter-agency and cross-discipline relationships. It has challenged people to grow in their understanding of the resource models this basin relies on for decision-making. And, it has created quantitative measures of performance for numerous resources where they may not have existed previously. Collectively, these "growing-pains" have paved the way for DMDU as the analytical framework used in this Final EIS, the first such multi-resource, basin-wide, decisional application in the Colorado River Basin.

VIC	Variable Infiltration Capacity

Appendix F. Approach to Hydrologic Uncertainty

F.1 Introduction & Purpose

Future hydrology, the primary driver of how each alternative performs, is deeply uncertain over the medium-to-long-term (Smith et al. 2022). Therefore, alternatives in the Final Environmental Impact Statement (EIS) are evaluated according to how they respond to various hydrologic conditions (streamflow-conditioned analysis), their ability to maintain resource-specific performance goals across a broad range of streamflow conditions (i.e., robustness analysis) and the streamflow conditions in which each alternative is likely to fail those goals (i.e., vulnerability analysis) (McPhail et al. 2018; Bonham et al. 2024; Bonham et al. 2025; see also **Chapter 3.2.6** for information on streamflow-conditioned analysis). This approach, a type of Decision Making under Deep Uncertainty (DMDU; see **Appendix D**, DMDU Overview and Approach) (Marchau et al. 2019), requires a systematically selected set of streamflow traces to use as inputs to the resource modeling.

The modeling in the Final EIS uses 400 streamflow traces selected from a combination of five streamflow ensembles and a statistical subsampling approach. All traces from the Stress Test, Coupled Model Intercomparison Project (CMIP) Phase 5 – Localized Constructed Analogs (CMIP5-LOCA), and Drying with Variability ensembles are included (200 traces), and 200 more traces were subsampled from the Paleo Drought Resampled and CMIP Phase 3 Paleo-Conditioned ensembles using the Kennard Stone algorithm (totaling 400 traces).

The purpose of this appendix is to describe the five streamflow ensembles (**Section F.2**), explain the subsampling approach (**Section F.3**), and discuss the resulting set of 400 traces (**Section F.4**). **Section F.5** provides a summary of previous sections.

F.2 Streamflow Ensembles

F.2.1 Stress Test

The Stress Test ensemble provides continuity with many recent studies (e.g., 2019 Drought Contingency Plan) and routine long-term projections. The ensemble was created by resampling the 1988-2023[1] subset of the historical natural flow record using the index sequential method (Ouarda et al. 1997) and focusing on recent hydrology. This recent period has an 11 percent drier average flow than the full historical record (1906-2023). Use of the Stress Test ensemble is supported by multiple research studies that identified a shifting temperature trend in the Colorado River Basin in the late

[1] 2021-2023 natural flow data are estimates based on the April 2024 24-Month Study (https://www.usbr.gov/lc/region/g4000/NaturalFlow/LFnatFlow1906-2024.2024.4.22.xlsx)

1980s that affected runoff efficiency and resulted in lower average flows for the same amount of precipitation (Woodhouse et al. 2016; McCabe et al. 2017; Udall and Overpeck 2017).

F.2.2 CMIP5-LOCA

The CMIP5-LOCA ensemble uses the best available projections from global climate models that are available at the scale necessary for input to the Colorado River Simulation System (CRSS) model. The ensemble uses Upper Basin flows from a project completed by the Bureau of Reclamation's (Reclamation) Technical Services Center for the Upper and Lower Colorado Regions that relies on data from Vano et al. (2020; Reclamation 2025). These flows were created by running LOCA downscaled climate projections of temperature and precipitation through the Variable Infiltration Capacity (VIC) hydrological model. No secondary streamflow bias correction was applied to the VIC flows. The ensemble includes 64 traces: 32 traces derived from climate projections for representative concentration pathway (RCP) 4.5 and 32 traces from RCP 8.5. Natural flows for Lower Basin sites were determined by applying the k-Nearest Neighbors (kNN; Prairie et al. 2008; Nowak et al. 2010) approach, which selects flows from the historical year whose Lees Ferry flows closely match those of the projected year.

F.2.3 "Drying with Variability"

The "Drying with Variability" ensemble was developed in collaboration with Utah State University. Through a multiyear project that began in 2021, researchers performed in-depth analysis on the ensembles that were available for Reclamation's long-term modeling to identify any gaps in statistical characteristics that could (a) be important for testing the system, and (b) capture aspects of the best available information from different sources (Salehabadi et al. 2022). Analysis showed that none of the available ensembles included a long-term drying trend while maintaining or increasing variability in flow magnitudes.

As part of the project, an ensemble was developed that met these criteria using a statistical approach to combine information from multiple established data sources (Salehabadi et al. 2025). Specifically, the ensemble combines the following information:

- Observed Lees Ferry annual flows from 1931 to 2020 with wet and dry sequencing from the paleo-reconstructed record;
- An extrapolation of the observed temperature trend with an estimate of how runoff efficiency[2] is affected by warmer temperatures;
- Projections from multiple generations of global climate models that indicate that precipitation variability could increase in the future.

Through nonparametric resampling of observed flows and paleo-reconstructed sequencing, application of the long-term declining trend, and a new method for transforming the flow variability while preserving the trend, an ensemble was generated that filled the statistical and narrative gap.

[2] Runoff efficiency is a measure of the amount of streamflow produced for a given amount of precipitation. Runoff efficiency has been shown to decline as temperatures increase due to increased evaporation, drying of soils, and increased evapotranspiration from plants.

To prepare this ensemble for use in CRSS, annual Lees Ferry flows are disaggregated to all 29 natural flow locations using the kNN method (Prairie et al. 2008; Nowak et al. 2010).

The Drying-with-Variability is used as the "reference hydrology" included with every vulnerability analysis in **Volume III**. The reason this ensemble was chosen as the reference hydrology is because it helps the reader interpret the likelihood of undesirable outcomes (e.g., Lake Mead dead pool-related reductions) if the current downward trend continues and/or the frequency and duration of droughts become more severe. Given the significant decline in reservoir storage that has occurred from 2000-2025, long-term planning in the Basin must wrestle with the potential for such a future.

F.2.4 Paleo Drought Resampled (subsampled)

The Paleo Drought Resampled ensemble is a severe drought scenario developed by Salehabadi et al. (2022). The ensemble randomly resamples Lees Ferry flows from the 16th century drought (1576-1600) from Meko et al. (2017) paleo reconstruction to create 100 traces that include unique sequences of flows from this period. The ensemble was subsampled to select 50 traces that fill in patterns missing from the three complete ensembles, as described in the next section. Annual Lees Ferry flows are disaggregated to all 29 natural flow locations using the kNN method (Prairie et al. 2008; Nowak et al. 2010).

F.2.5 CMIP3 Paleo-Conditioned (subsampled)

The CMIP3 Paleo-Conditioned ensemble is developed using two valuable data sources and aligns with a recommendation from Colorado River Basin Climate and Hydrology State of the Science Report (Lukas and Payton 2020). The ensemble was created using the non-parametric conditioning (NPC) method (Prairie et al. 2008) with the Meko et al. (2017) paleo record to define wet-dry sequencing and sampled magnitudes from annual CMIP3 flows. This NPC sampling method was performed on each of the 112 CMIP3 streamflow projections (2024-2060) to create 50 traces for each projection, resulting in 5,600 traces for all 29 natural flow sites. The ensemble was subsampled to select 150 traces that fill gaps in patterns and characteristics, as described in the next section.

F.3 Subsampling Approach

The subsampling was performed using a 3-step procedure and the Kennard Stone algorithm (Kennard and Stone 1969), which, in this application, selects streamflow traces from the Paleo Drought Resampled and CMIP3 Paleo-Conditioned ensembles with statistics not well-represented by traces in the Stress Test, CMIP5-LOCA, or Drying with Variability ensembles.

This section is organized as follows. **Section F.3.1** describes the Kennard Stone algorithm. **Section F.3.2** explains the streamflow statistics used as inputs to Kennard Stone. **Section F.3.3** describes the 3-step sampling procedure.

F.3.1 Subsampling algorithm: Kennard Stone

Given an existing sample of n data points, the Kennard Stone algorithm selects k additional points (for a total of $n + k$ points) from population P such that the k points are maximally different from

the original n and from each other[3]. The algorithm uses an iterative approach; it first identifies k_1 (the first data point to be selected) as the point that maximizes the distance from all n points, where distance is calculated using statistics associated with each point and a selected distance metric. Then, k_2 is selected to maximize the distance from all n points and k_1.This process continues until all k points have been selected (Kennard and Stone 1969; Stevens and Ramirez-Lopez 2020).

In this application, each streamflow trace is a data point. The existing sample of n data points are the traces in the Stress Test, CMIP5-LOCA, and Drying with Variability ensembles (n = 36 traces [Stress Test] + 64 traces [CMIP5-LOCA] + 100 traces [Drying with Variability] = 200 traces). k = 200 so the total number of traces is 400. Mahalanobis distance (Mahalanobis 1936; Brereton 2015) was chosen for the distance metric to account for correlation between streamflow statistics, which are described in the next section.

F.3.2 Streamflow statistics

The streamflow statistics (**Table F-1**) are calculated using 2027-2056 calendar year volumes of natural flow at Lees Ferry, Arizona. The statistics describe dry, wet, and normal flow conditions over various durations (1-, 2-, 5-, 10-, and 20-year windows) to ensure the set of 400 traces cover a broad range of hydrologic conditions. The statistics are calculated for each trace of every ensemble, which are then used in the 3-step application of Kennard Stone described in **Section F.3.3**.

Table F-1
Streamflow statistics used with the Kennard Stone sampling algorithm

Streamflow Statistic	Category
Minimum 1-year natural flow volume	Dry conditions
Average Lees Ferry natural flow during the driest 5-year period	
Average Lees Ferry natural flow during the driest 10-year period	
Average Lees Ferry natural flow during the driest 20-year period	
Maximum 1-year natural flow volume	Wet conditions
Average Lees Ferry natural flow during the wettest 5-year period	
Average Lees Ferry natural flow during the wettest 10-year period	
Average Lees Ferry natural flow during the wettest 20-year period	
Median of the rolling 2-year rolling average natural flow	Normal conditions
Median of the rolling 5-year rolling average natural flow	
Median of the rolling 10-year rolling average natural flow	
Median of the rolling 20-year rolling average natural flow	
2027-2056 Average Lees Ferry natural flow	Long-term average

[3] If n = 0 (i.e., zero data points have been selected to start with), then k_1 and k_2 are selected such that they maximize the pairwise distance between any two points in the population.

F.3.3 3-Step Sampling Approach

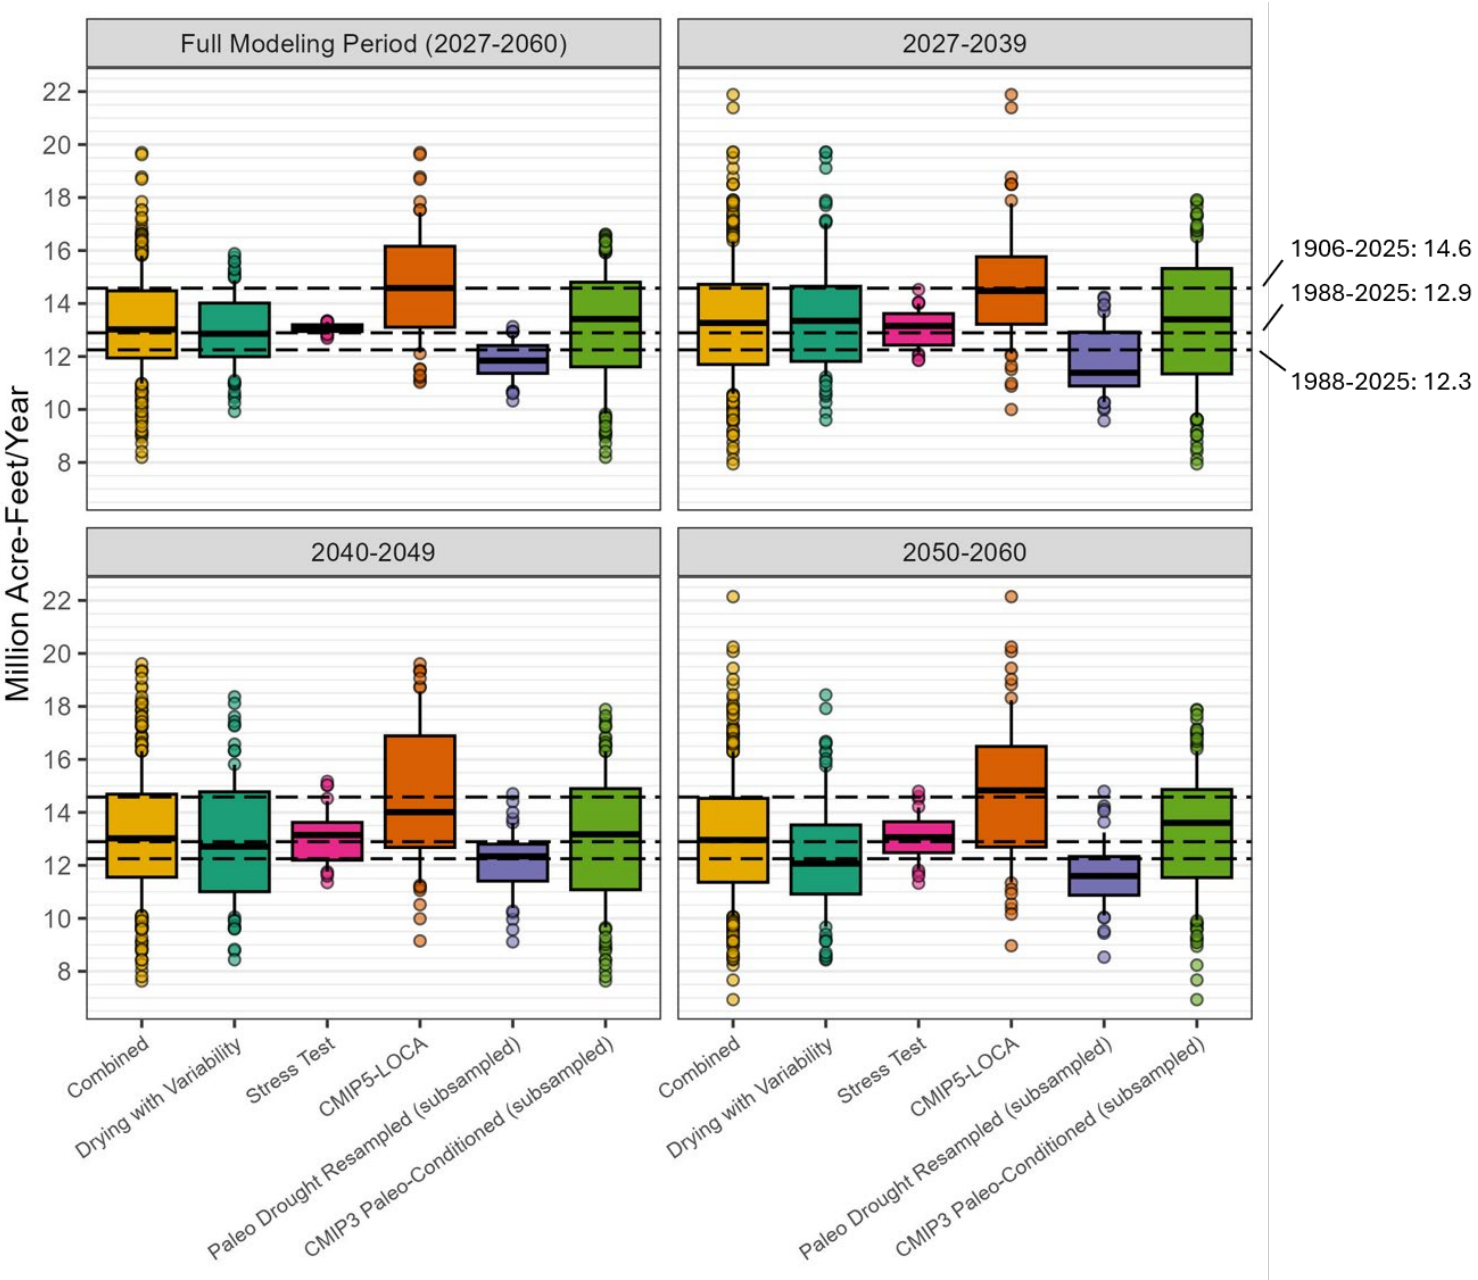
The following 3 steps were used to subsample a total of 200 traces from the Paleo Drought Resampled and CMIP3 Paleo-Conditioned ensembles.

1. Sample 50 traces from the Paleo Drought Resampled ensemble using Kennard Stone. The 50 traces capture the variability present in this ensemble while saving computing time compared to keeping all 100 traces. This brings the total number of traces to 250.

2. Remove very wet traces from CMIP3 Paleo-Conditioned ensemble using filter criteria. This dataset contains a limited number of very wet traces because annual flows originate from the CMIP3 hydrology dataset. The goal was to systematically identify and remove these traces to avoid "shifting" the distribution of the final 400 traces wetter due to dubious high flows. To do so, the CMIP3 Paleo-Conditioned traces were compared to the maximum values for select statistics from the combined Stress Test, Paleo Drought Resampled, and Drying with Variability ensembles. If a given trace was wetter according to any of the selected statistics, then it was removed before step 3. The criteria can be expressed mathematically as:

   - maximum annual flow less than 26.45 million acre-feet (maf) & maximum 2-Year average flow less than 26.11 maf/year & maximum 5-year average flow less than 24.61 maf/year & 2027-2056 average flow less than 16.47 maf/year

   996 traces were removed because they failed one or more of the criteria, leaving 4,604 in traces in the CMIP3 Paleo-Conditioned ensemble before moving to step 3.



3. Sample 150 traces from the pre-filtered CMIP3 Paleo-Conditioned ensemble. This brings the total number of traces to 400.

F.4 Statistics of the 400 Hydrologic Traces

F.4.1 Decadal Average Natural Flow

Figure F-1 shows the distribution of trace average natural flow, grouped by ensemble (x-axis) and by time period (panels). All 400 traces are included in the boxplot labeled "Combined," while the remaining boxplots show traces grouped by ensemble. The time period averages are shown because the correspond to the periods used in the robustness analyses found in **Volume I – Chapter 3** and **Volume III**. For comparison, the dashed lines labelled 14.6, 13.0, and 12.4 show the historical average natural flow in maf from 1906-2025 (full historical record), 1988-2025 (Stress Test period), and 2000-2025 (Millenium Drought), respectively.

Figure F-1
Distribution of average water year natural flow at Lees Ferry, grouped by ensemble (x-axis) and by time period (panels).

Note: The dashed lines labelled 14.6, 12.9, and 12.3 indicate the historical average natural flow in maf from 1906-2025 (full historical record), 1988-2025 (Stress Test period), and 2000-2025 (Millenium Drought), respectively.

The combined set of 400 traces covers the full range of average natural flow present in any individual ensemble while providing a nearly continuous sampling from wet to dry extremes. This is important because this Final EIS evaluates critical performance goals that can fail under dry conditions (e.g. dead pool-related delivery reductions) and wet conditions (e.g. use of the Glen Canyon Dam spillway). Across the Full Modeling Period (2027-2060), average natural flow ranges from about 8.0 to 20.0 maf. Comparing the Combined boxplot to historical averages, about 50 percent of the traces are drier than the 1988-2025 average, over 25 percent of the traces are drier than the 2000-2025 average, and about 10 percent of the traces have an average below 11.0 maf/year. In the subperiods (2027-2039, 2040-2049, and 2050-2060), the 25th, 50th and 75th percentiles are similar to the Full Modeling Period while the tails of the distribution are larger in both the wet and dry direction. This is due to the averages being calculated over 10 to 13 years in the subperiods compared to the 34 years in the Full Modeling Period, which dampens the effect of extremely wet and dry years on the reported averages.

F.4.2 Average Natural Flow in 1 to 20-Year Periods

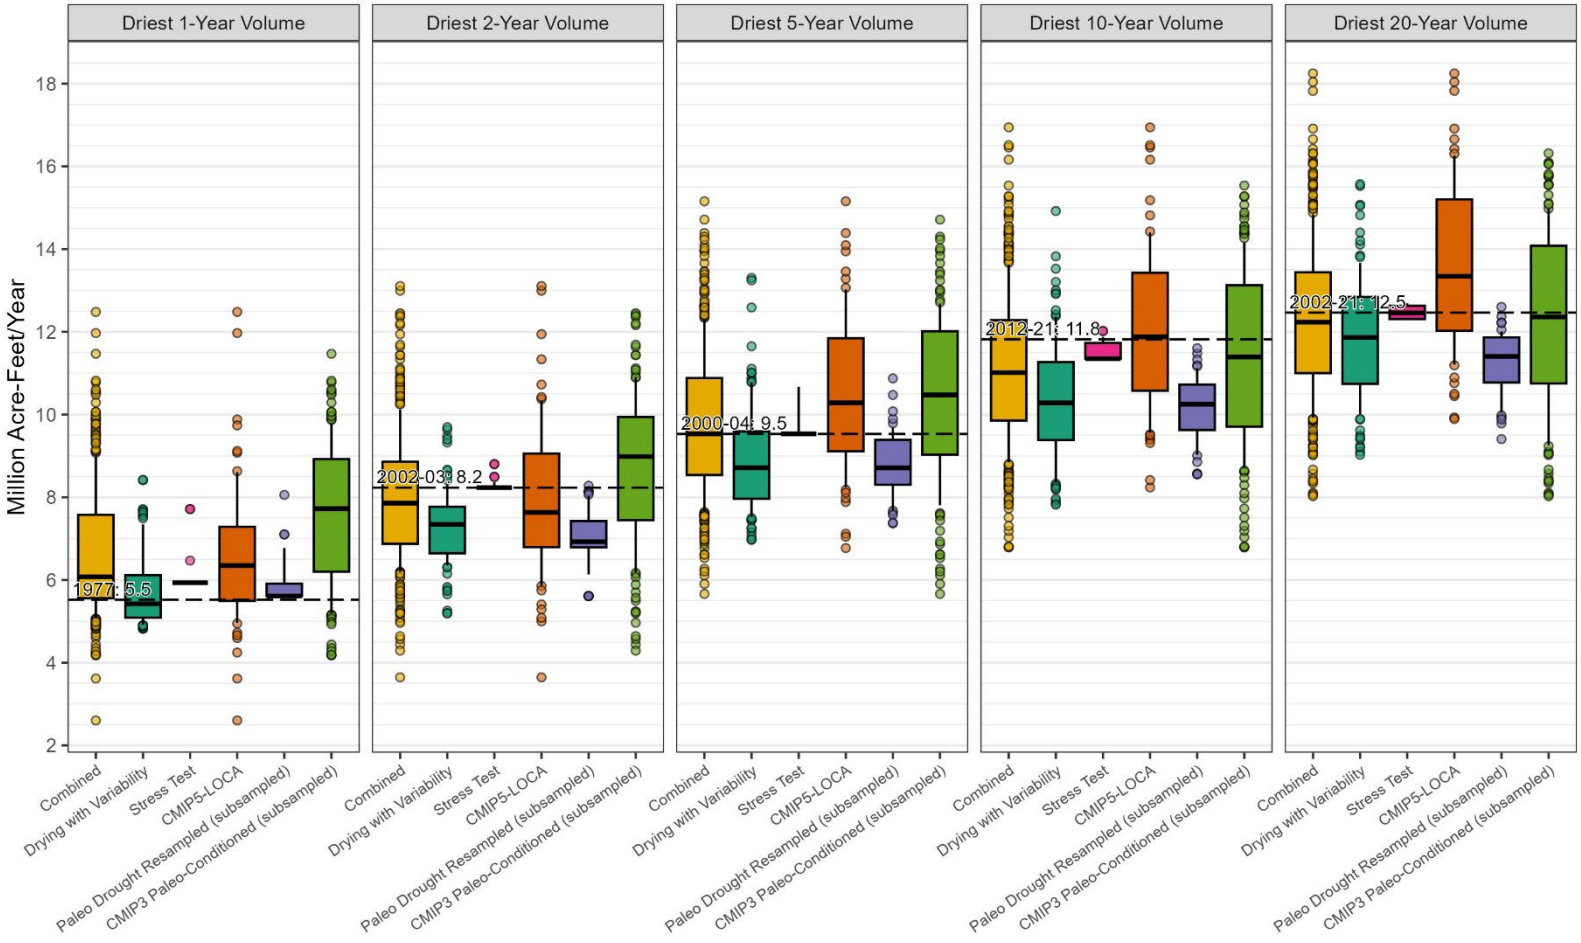


Figure F-2 shows the distribution of the driest 1-, 2-, 5-, 10-, and 20-year average volumes in each trace, grouped by ensemble. The dashed line shows the minimum volumes for each period observed during the historical period (1906-2025). In the Combined ensemble, about 25 percent of traces have a driest 1-year volume less than the historical minimum. For the 2- to 20-year trace averages, 50 percent or more of traces in the Combined ensemble are drier than the historical minimum.

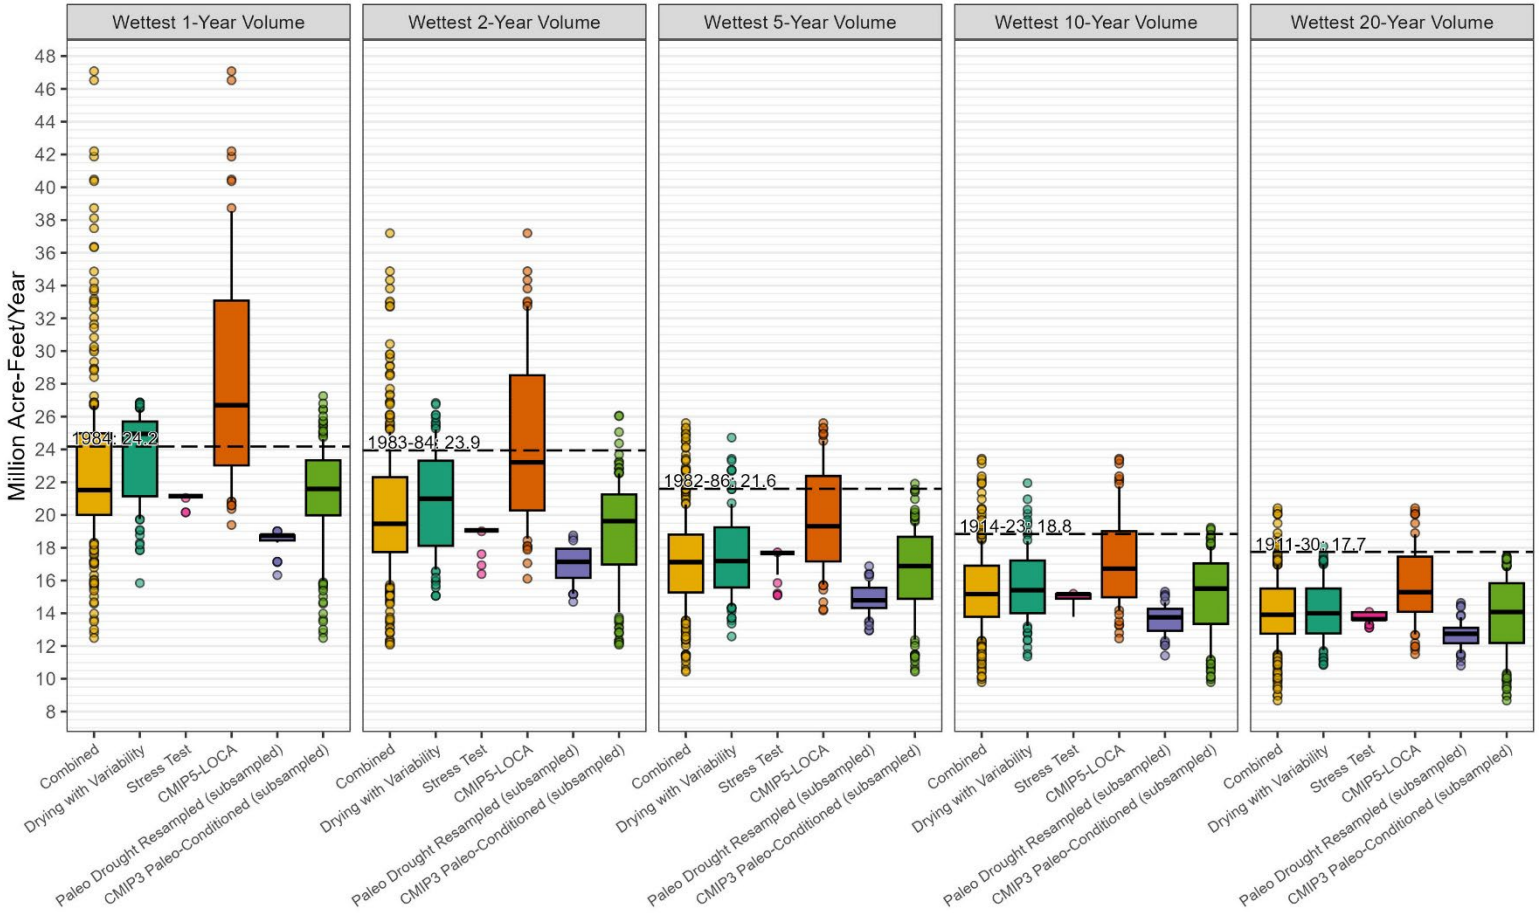
Figure F-3 shows the distribution of the wettest 1-, 2-, 5-, 10-, and 20-year average volumes in each trace, grouped by ensemble. The dashed line shows the maximum volumes for each period observed during the historical period (1906-2025). Across 1-to 20-year trace averages, nearly 75 percent to over 90 percent of traces in the Combined ensemble have values less than the historical maximums.

Considering the wettest 1-year volumes, most traces above the 90th percentile in the Combined ensemble are from the CMIP5-LOCA ensemble. This is also true for the 2- to 20-year volumes, but with some of the very wet traces originating from the Drying with Variability and CMIP3 Paleo-Conditioned ensembles.



The distribution of average natural flow for the Drying with Variability ensemble, which is used as the reference hydrology in the vulnerability analysis figures in **Volume III**, demonstrates a storyline of declining streamflow over time. Over the full modeling horizon, the median average natural flow is 12.9 maf/year (slightly less than the median of the combined ensemble, 13.0 maf/year). In each subsequent subperiod, however, the median average natural flow decreases from 13.4 to 12.7 to 12.1 maf/year.

Figure F-2
Distribution of the driest 1-, 2-, 5-, 10- and 20-Water Year Volumes (columns) in each trace, grouped by ensemble.

Note: Dashed lines show the minimum volumes for each period observed during the historical period (1906-2025).

Figure F-3
Distribution of the wettest 1-, 2-, 5-, 10- and 20-Water Year Volumes (columns) in each trace, grouped by ensemble.

Note: Dashed lines show the maximum volumes for each period observed during the historical period (1906-2025).

F.4.3 Average Natural Flow Statistics Relevant to the Streamflow-Conditioned Performance Analyses

This EIS reports how system status and performance outcomes vary depending on future hydrology, termed streamflow-conditioned analysis. Two versions of streamflow-conditioned analysis were used.

Throughout the Technical Appendices in **Volume III**, streamflow-conditioned boxplots (e.g. **Figure TA 4-1**) shows how the *annual* status of the system (e.g. annual Lower Basin Shortage) changes as a function of *recent, preceding* natural flow conditions. This analysis is described in **Section F.4.3.1**, below.

Figure ES-5 in the Executive Summary shows the results of a streamflow-conditioned tradeoff analysis. This analysis reports important performance metrics (e.g. percent of time Lake Powell elevation is above 3,500 feet, percent of time Lake Mead elevation is above 975 feet) and how performance varies depending on average natural flow *over the next 10-years* (2027-2036, because the Preferred Alternative is a 10-year decision framework). This analysis is described in **Section F.4.3.2**.

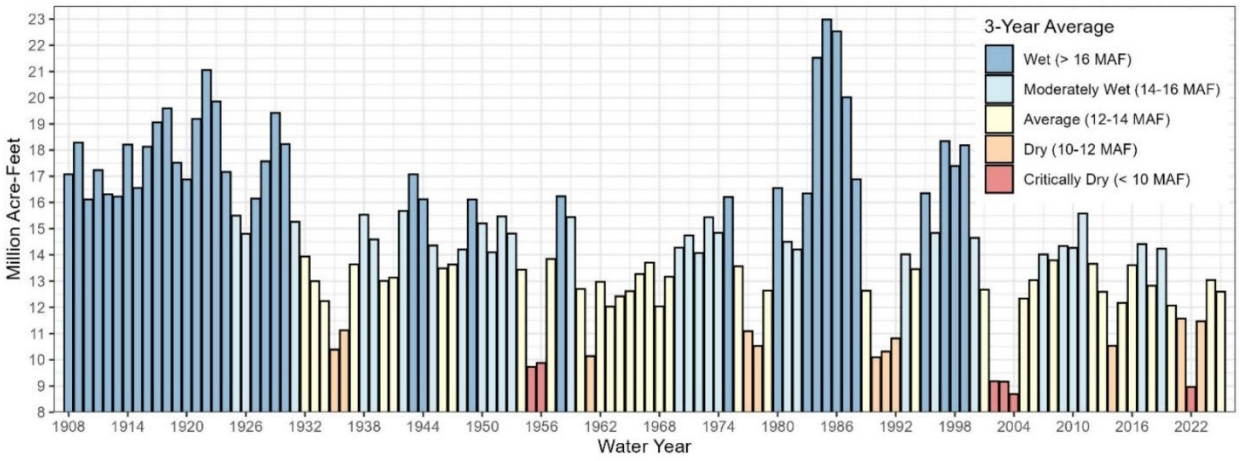
F.4.3.1. Preceding 3-Year Average Flow (Streamflow-Conditioned Boxplots)

The 400 hydrologic traces are the starting point for the streamflow-conditioned boxplot analysis. Each trace is 34 years long, so there are 13,600 years of modeling results (34 years x 400 traces) per alternative. For each year, the average natural flow in the preceding 3 years is calculated. For example, in year 2030 of trace 1, the preceding 3-year average is the average of 2027-2029 in trace 1. For years 2027-2029, the preceding 3 years includes a combination of historical natural flow and natural flow associated with the low initial condition scenario[4]. A 3-year period was chosen (rather than a shorter or longer period) because experimentation demonstrated it is sufficiently long enough to capture the effects of multiple dry or wet years, while remaining short enough to reflect the influence of annual extremes.

Each of the 13,600 years is categorized based on its preceding 3-year average natural flow. The streamflow categories are Wet (greater than 16.0 maf), Moderately Wet (14.0-16.0 maf), Average (12.0-14.0 maf), Dry (10.0-12.0 maf) and Critically Dry (less than 10.0 maf). These streamflow categories were defined based on how they compare to historical conditions and stakeholders' understanding of different historical periods. A comparison of the streamflow groupings to recent historical conditions is provided in **Figure 3-1** and **Table 3-4**. Furthermore, **Figure F-4**, below, shows the 3-year average natural flow for all years in the historical record, colored by the categories used in the streamflow-conditioned boxplot analyses. The figure shows that Wet conditions (3-year average greater than 16.0 maf) were most common prior to 1931 and have not occurred since the 1990s. Since 2000, conditions have been mostly in the Average streamflow category with several years in the Moderately Wet, Dry, and Critically Dry streamflow categories.

[4] In 2027, the preceding 3 years are water years 2024, 2025, and 2026. The water year volume used for 2024 is 11.875 maf, estimated using the unregulated inflow forecast from the August 2024 24-Month Study and a regression equation to convert to natural flow (www.usbr.gov/lc/region/g4000/NaturalFlow/LFnatFlow1906-2024.2024.9.12.xlsx). See the 'documentation' sheet for the regression equation. The natural flow for 2025 and 2026 are estimated from the unregulated inflow from the November 2024 CRMMS low initial condition scenario (see **Appendix G**, CRSS Initial Conditions) and a regression equation to estimate natural flow. The estimated natural flow values are 11.1 maf (2025) and 7.0 maf (2026). The resulting 2024-2026 average is 9.99 maf, meaning that modeling results for 2027 are placed into the Critically Dry streamflow category.

Figure F-4
Historical 3-Year Average Natural Flow Colored by Streamflow Categories used in Streamflow-Conditioned Boxplot Analyses



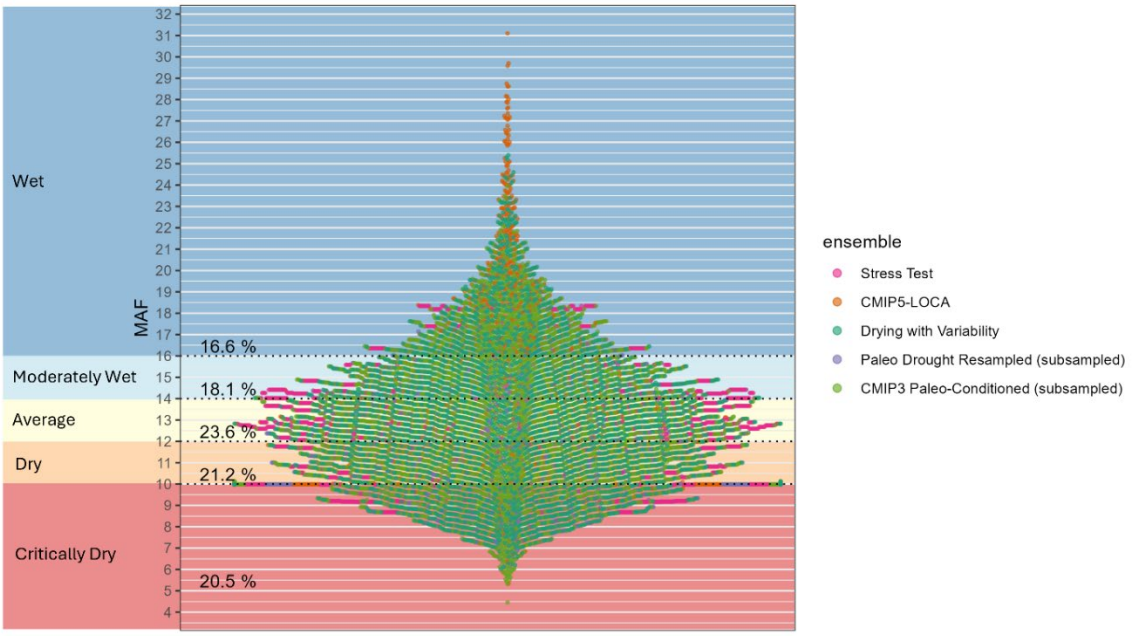


Figure F-5 shows the distribution of preceding 3-year averages across all years in the 400 hydrologic traces used in resource modeling. The streamflow categories are labeled on the left, and the percent of years in each category are reported, with 16.6 percent to 23.6 percent of years falling into each category. The wettest 3-year average is 31.1 maf (occurring in a trace from CMIP5-LOCA), and the driest 3-year average is 4.5 maf (occurring in a trace subsampled from the CMIP3 Paleo-Conditioned ensemble).

Figure F-5
Distribution of Preceding 3-Year Average Natural Flow across All Years in the 400 Hydrology Traces used for Resource Modeling

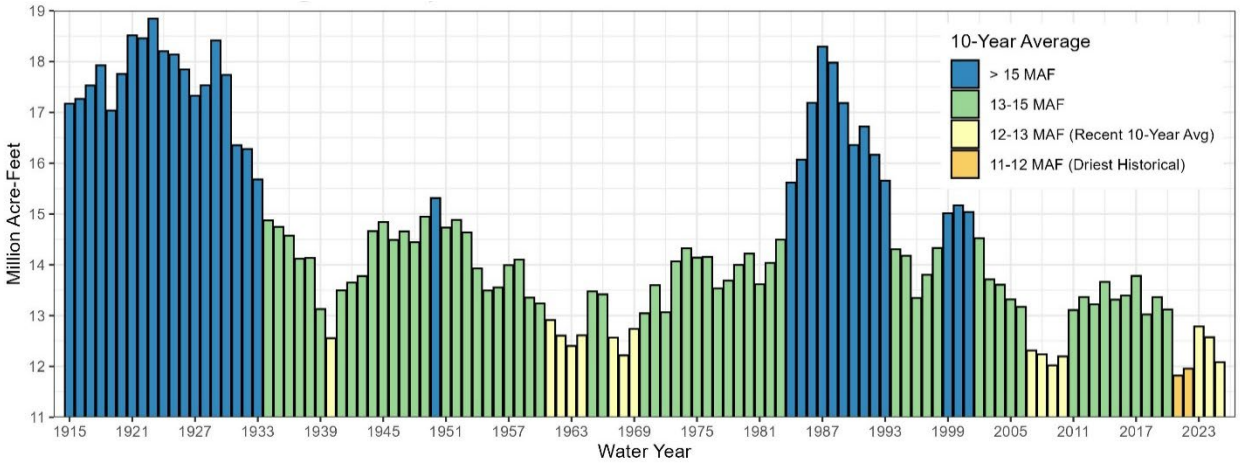
F.4.3.2. 2027-2036 Annual Average (Streamflow-Conditioned Tradeoff Analysis)

For the streamflow-conditioned tradeoff analysis presented in **Figure ES-5**, each streamflow trace (not individual years) is categorized based on the average annual natural flow in water years 2027-2036. The streamflow categories are:

- Recent 10-Year Average: 12.0-13.0 maf (68 traces)
- Driest Historical: 11.0-12.0 maf (55 traces)
- Drier than Historical: 10.0-11.0 maf (32 traces)
- Critically Dry: < 10 maf (31 traces)

Table ES-3 describes how the categories compare to recently observed 10-year averages and the driest observed 10-year average (11.8 maf from 2012-2021). Below, **Figure F-6** shows the 10-year average natural flow for all years in the historical record, colored by the categories used in the streamflow-conditioned tradeoff analysis. The figure shows that averages above 15.0 maf were most common prior to 1934 and have not occurred since 2001. 2021 and 2022 are the only years with 10-year averages below 12.0 maf. 12.0-13.0 maf 10-year averages were observed in 2023, 2024, and 2025.

Figure F-6
Distribution of Preceding 3-Year Average Natural Flow across the 400 Hydrology Traces used for Resource Modeling



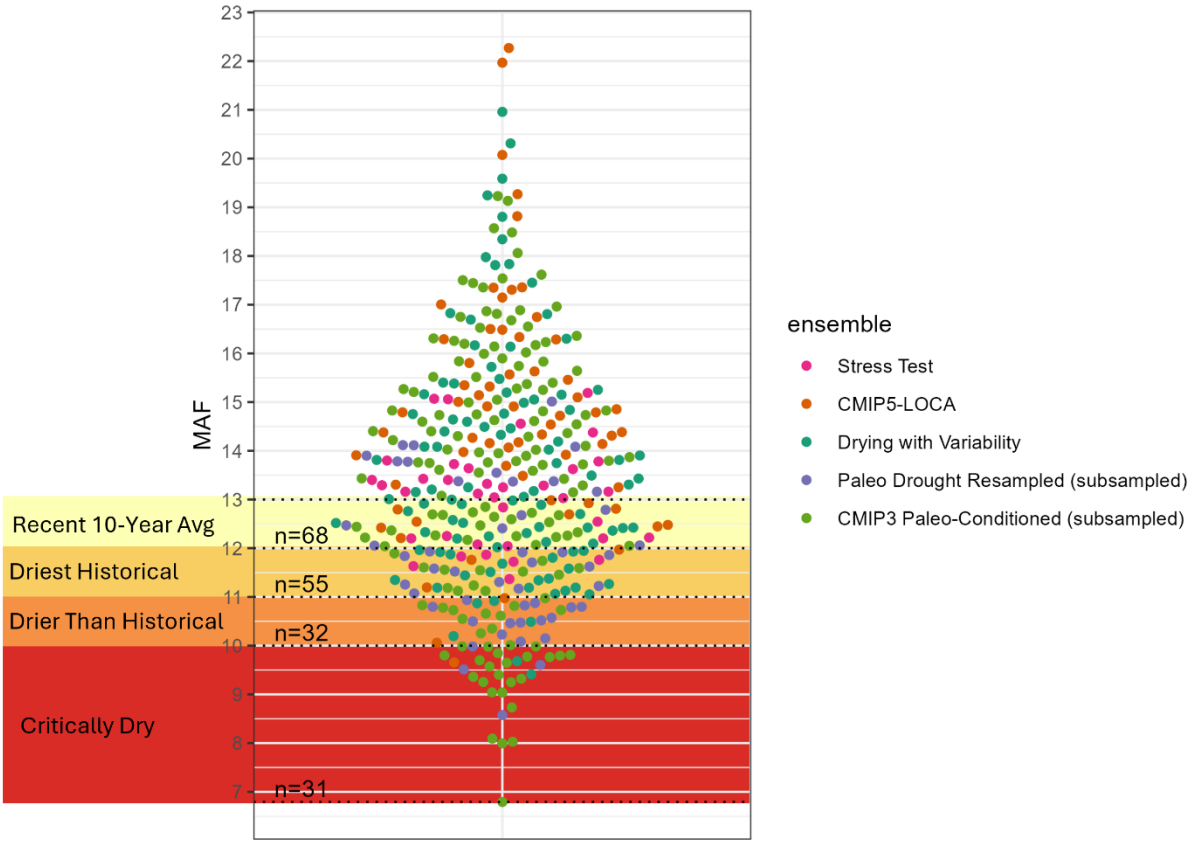


Figure F-7 shows the distribution of the 2027-2036 10-year averages across all 400 hydrologic traces used in resource modeling. The streamflow categories are labeled on the left, and the number of traces in each category are reported, with 31 to 68 traces in each category. Traces wetter than 13.0 maf were excluded from the streamflow-conditioned tradeoff analysis to focus on conditions similar to or drier than recent hydrology; doing so better demonstrates the potential impacts and tradeoffs between alternatives. The driest 2027-2036 average is 6.8 maf, occurring in a trace from the CMIP3 Paleo-Conditioned ensemble.

Figure F-7
Distribution of 2027-2036 Average Natural Flow across the 400 Hydrology Traces used for Resource Modeling

F.5 Summary

Due to the deeply uncertain nature of future hydrology in the Colorado River Basin, DMDU is the analytical framework used in this Final EIS. To reliably evaluate the robustness and vulnerability of the alternatives, it is essential to model them with a systematically selected set of streamflow traces. This Final EIS uses 400 total traces from the following ensembles:

- Stress Test (36 traces)
- CMIP5-LOCA (64 traces)
- Drying with Variability (100 traces)
- Paleo Drought Resampled (subsampled, 50 traces)
- CMIP3 Paleo-Conditioned (subsampled, 150 traces)

All traces from Stress Test, CMIP5-LOCA, and Drying with Variability ensembles were used because they provide continuity with previous analyses and useful storylines about how future

streamflow could decline. Combined, these ensembles span a wide range of plausible streamflow conditions but leave gaps in the types of conditions being evaluated. To fill in the gaps, a subsample of traces was selected from the Paleo Drought Resampled and CMIP3 Paleo-Conditioned ensembles using the Kennard Stone algorithm. The result is a combined set of 400 traces that cover a broad range of plausible conditions with minimal gaps in the types of conditions being tested.

Appendix G. CRSS Initial Conditions

This appendix provides an overview of the three initial conditions used in the Final Environmental Impact Statement (EIS). It also compares these initial conditions to the June 2026 Colorado Basin River Forecasting Center Ensemble Streamflow Prediction (CRMMS-ESP) projected end-of-calendar-year (December 2026) Lake Powell and Lake Mead pool elevations to illustrate how evolving hydrologic conditions informed the selection of the initial condition used in the Final EIS analyses.

G.1 Initial Conditions Used in the Draft Environmental Impact Statement

G.1.1 Initial Reservoir Conditions

For the Final EIS, the Colorado River Simulation System (CRSS) was initialized with three sets of initial conditions to cover a range of possible system conditions on December 31, 2026. Projected system conditions were chosen from Reclamation's official mid-term operations model, the Colorado River Mid-term Modeling System (CRMMS). CRMMS uses an ensemble of monthly unregulated streamflow forecasts developed by the National Weather Service's CRMMS-ESP method.

Specifically, the CRSS modeling for the Final EIS used the November 2024[1] CRMMS-ESP projections of system conditions on December 31, 2026 as the initial conditions for CRSS. Three traces from CRMMS-ESP were selected based on Lake Powell and Lake Mead elevations and correspond to projected Low (Trace 14), Mid (Trace 12), and High (Trace 6) conditions at the end of 2026 (**Table G-1**).

Four reservoirs are not modeled in CRMMS: Strawberry, Starvation, Transmountain Diversion (TMD), and McPhee. Strawberry and Starvation Reservoirs assume a static initial condition. TMD and McPhee use a regression based on previous year's Lake Powell unregulated inflow. For all initial conditions, the December 2026 conditions for TMD and McPhee reservoirs are computed using the Mid initial condition Lake Powell unregulated inflow from CRMMS.

[1] November 2024 CRMMS projections were used as initial conditions because CRSS results for multiple alternatives were finalized in December 2024 and sent to the next stages of resource modeling needed for the Final EIS.

Table G-1
End-of-Month December 2026 Reservoir Conditions Used as Initial Conditions

Reservoir	Low (Trace 14)		Mid (Trace 12)		High (Trace 6)

G.1.2 Preceding Lees Ferry Flows

CRSS and the Decision Making under Deep Uncertainty analysis rely on Lees Ferry natural flow for the period prior to 2026 to support various modeling assumptions and to compute hydrologic statistics. **Table G-2** summarizes Lees Ferry natural flow for water years (WY) 2017–2026. Historical natural flow estimates are available through 2024, with 2021–2024 values considered provisional. Natural flow estimates for 2025 and 2026 vary by initial condition, as they are derived from CRMMS. Since CRMMS operates in unregulated flow space, the unregulated flow is converted to natural flow using the following equation:

$$NF = (0.7311 * \mathrm{U} / 9.60 + 0.2689) * 13.49$$

Where *NF* is the WY Lees Ferry natural flow in million acre-feet (maf); *U* is the WY Lake Powell unregulated inflow in maf; 9.6 is the 1991-2020 average unregulated inflow in maf; 13.49 is the 1991-2020 average Lees Ferry Natural Flow in maf; and 0.7311 and 0.2689 are the slope and intercept of a linear regression between historical WY unregulated and natural flow at Lees Ferry using 1991-2020 data.

[2] The TMD Reservoir is an aggregate representation of Colorado western slope transmountain diversion storage facilities, including Lake Granby, Willow Creek Reservoir, Dillon Reservoir, and Homestake Reservoir.
[3] McPhee elevation in CRSS is the height above dead pool storage.

Table G-2
Lees Ferry Water Year Natural Flow Data

Water Year	Historical Natural Flow (af)	CRMMS-Derived Lees Ferry Flow (af)		
		Low	Mid	High
2017	16,396,512	-	-	-
2018	8,633,462	-	-	-
2019	17,672,049	-	-	-
2020	9,887,593	-	-	-
2021	7,152,000	-	-	-
2022	9,851,000	-	-	-
2023	17,408,000	-	-	-
2024	11,875,000	-	-	-
2025	-	11,130,240	14,021,610	18,805,025
2026	-	6,956,534	10,888,385	12,404,377

In **Chapter 3** and **Volume III** of the Final EIS, conditional boxplots are organized according to the preceding 3-year average Lees Ferry natural flow. Because natural flows in 2025 and 2026 depend on the selected initial condition, the 3-year averages entering 2027 differ across the Low, Mid, and High initial-condition scenarios. Using the values in **Table G-2**, the resulting preceding three-year average flows and the corresponding flow category for each initial condition are shown below:

- Low initial condition: 9,987,258 acre-feet (af) (Critically Dry Flow Category [4.46–10 maf])
- Mid initial condition: 12,261,665 af (Average Flow Category [12–14 maf])
- High initial condition: 14,361,467 af (Moderately Wet Flow Category [14–16 maf])

G.2 Initial Conditions Used in the Final Environmental Impact Statement

The Colorado River system remains under significant hydrologic stress, with both Lake Powell and Lake Mead projected to reach critically low elevations in 2027 unless hydrologic conditions substantially improve. As of June 2026, WY 2026 Lake Powell unregulated inflow is projected to be approximately 3.49 maf (36 percent of average), ranking among the lowest years in the historical record. In light of current conditions, only the Low initial condition was used in the Final EIS (**Section G.1**).

G.2.1 Comparison of the Initial Conditions to the June 2026 CRMMS-ESP Projections

Figure G-1 and **Figure G-2** compare the initial conditions used in the Final EIS to the June 2026 CRMMS-ESP ensemble projections[4] for Lake Powell and Lake Mead pool elevations, respectively. The June 2026 CRMMS-ESP ensemble projects December 2026 Lake Powell pool elevations

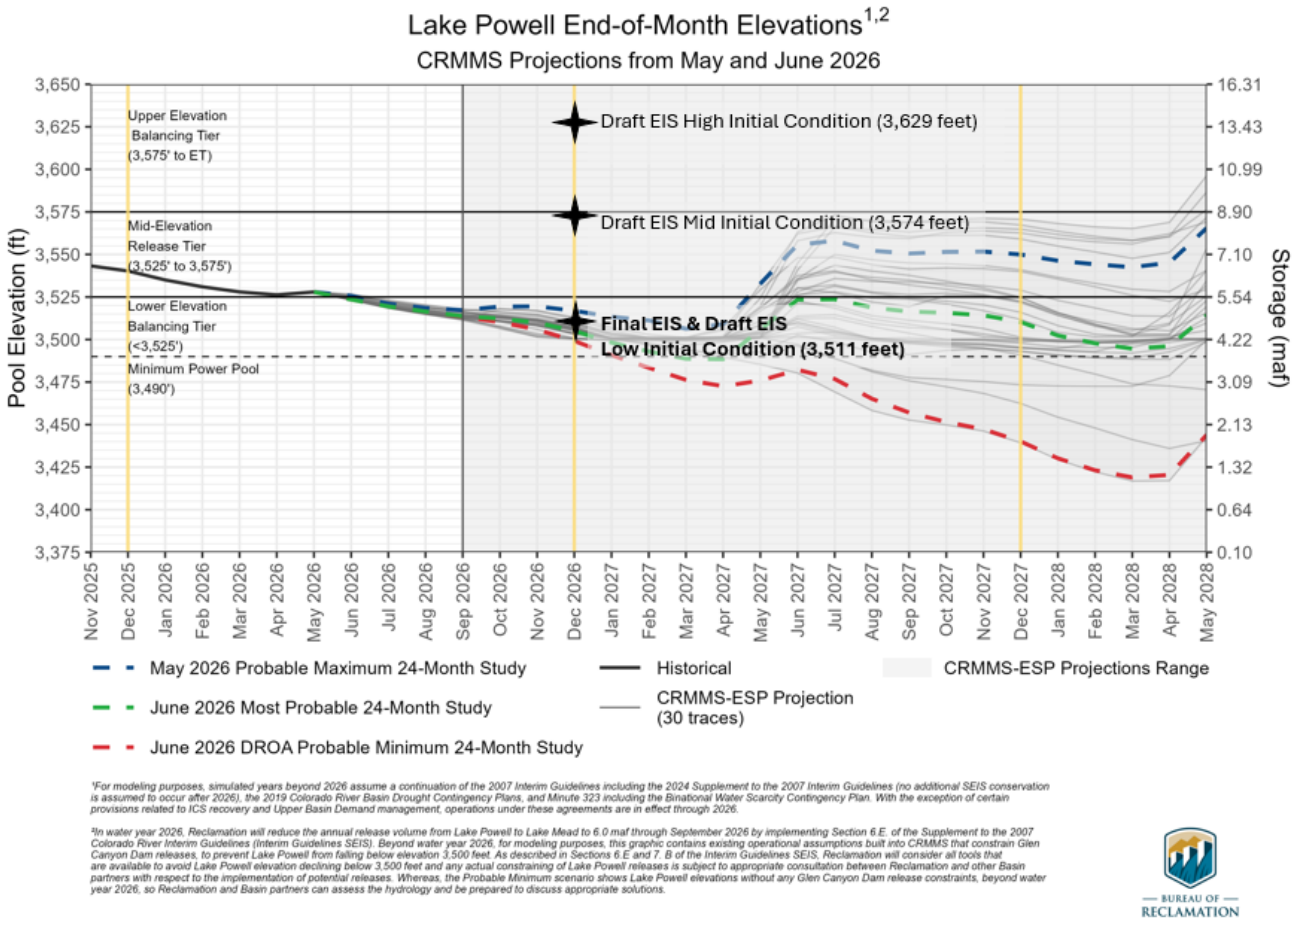
[4] The June 2026 CRMMS-ESP projections are the most recent projections available at the time this EIS was prepared.

ranging from 3,500.01 to 3,513.07 feet. The Low initial condition falls within this projected range, while the Mid and High initial conditions exceed the upper bound of the ensemble by 61.32 and 115.94 feet, respectively.

Similarly, the June 2026 CRMMS-ESP ensemble projects December 2026 Lake Mead pool elevations ranging from 1,031.52 to 1,042.31 feet. The Low initial condition also falls within this projected range, whereas the Mid and High initial conditions exceed the upper bound of the ensemble by 20.98 and 36.30 feet, respectively.

These comparisons demonstrate that the Low initial condition used in the Final EIS is representative of current hydrologic conditions and projected end-of-calendar-year reservoir elevations. Accordingly, the Final EIS only uses the Low initial condition.

Figure G-1
Lake Powell Initial Pool Elevations: Final EIS Assumptions and Current Projections



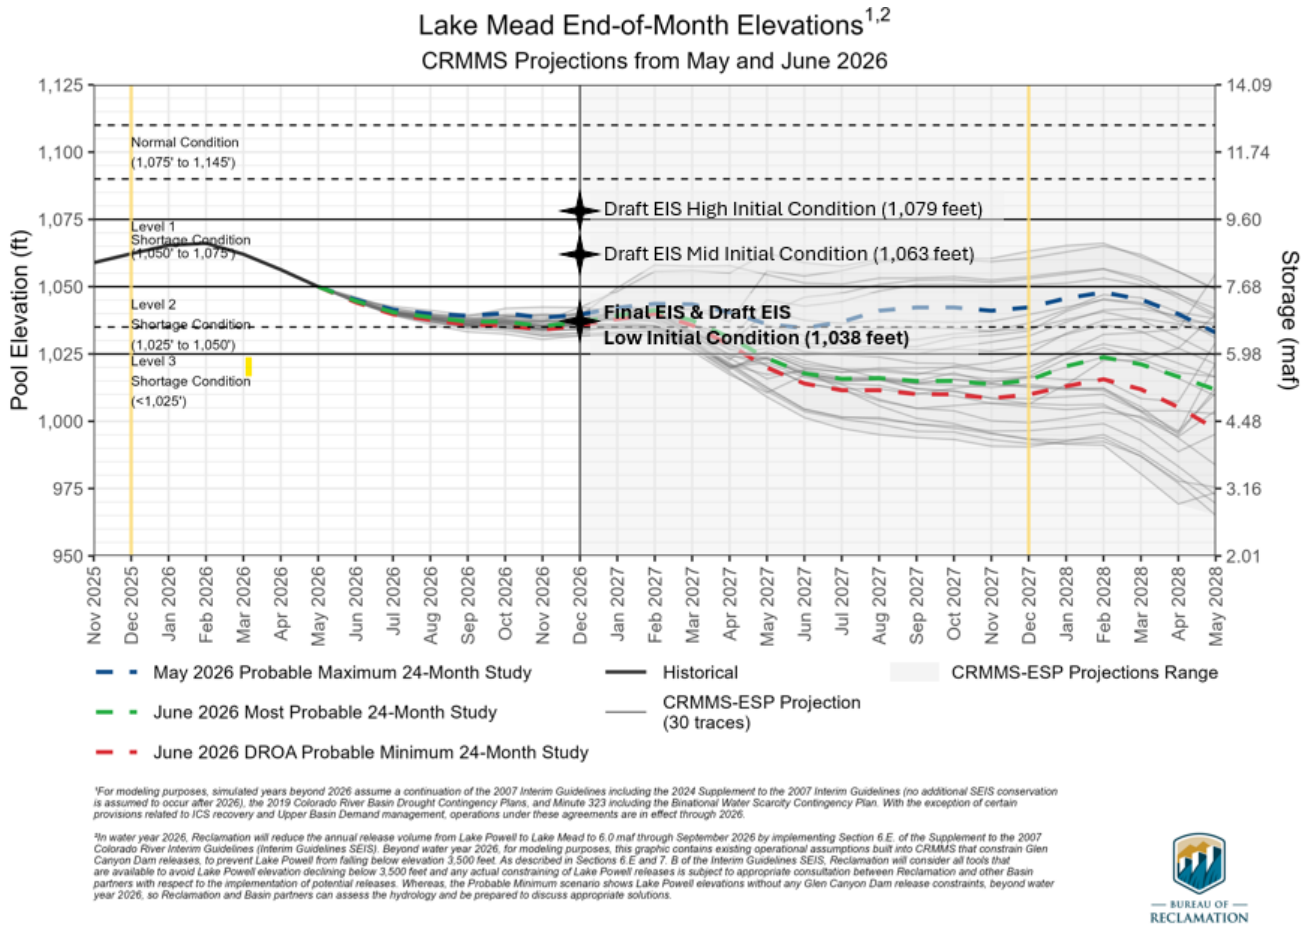


Figure G-2
Lake Mead Initial Pool Elevations: EIS Assumptions and Current Projections

[1]For modeling purposes, simulated years beyond 2026 assume a continuation of the 2007 Interim Guidelines including the 2024 Supplement to the 2007 Interim Guidelines (no additional SEIS conservation is assumed to occur after 2026), the 2019 Colorado River Basin Drought Contingency Plans, and Minute 323 including the Binational Water Scarcity Contingency Plan. With the exception of certain provisions related to ICS recovery and Upper Basin Demand management, operations under these agreements are in effect through 2026.

[2]In water year 2026, Reclamation will reduce the annual release volume from Lake Powell to Lake Mead to 6.0 maf through September 2026 by implementing Section 6.E. of the Supplement to the 2007 Colorado River Interim Guidelines (Interim Guidelines SEIS). Beyond water year 2026, for modeling purposes, this graphic contains existing operational assumptions built into CRMMS that constrain Glen Canyon Dam releases, to prevent Lake Powell from falling below elevation 3,500 feet. As described in Sections 6.E and 7. B of the Interim Guidelines SEIS, Reclamation will consider all tools that are available to avoid Lake Powell elevation declining below 3,500 feet and any actual constraining of Lake Powell releases is subject to appropriate consultation between Reclamation and other Basin partners with respect to the implementation of potential releases. Whereas, the Probable Minimum scenario shows Lake Powell elevations without any Glen Canyon Dam release constraints, beyond water year 2026, so Reclamation and Basin partners can assess the hydrology and be prepared to discuss appropriate solutions.

Appendix H. Sensitivity Analysis – Effects of Demand Schedule Assumptions on Modeled Unused Tribal Water Available for Storage in the Enhanced Coordination Alternative

H.1 Introduction

The Enhanced Coordination Alternative contemplates mechanisms to store Upper Basin unused tribal water in a Lake Powell conservation pool and Lower Basin unused tribal water in the Protection Pool in Lake Mead. The volume of unused tribal water that could be potentially available for storage in each basin is highly dependent on the modeled baseline demands and modeling assumptions developed for each storage mechanism.

This appendix summarizes the baseline demands that the United States (U.S.) Bureau of Reclamation (Reclamation) used to estimate the volumes of unused tribal water available for conservation and storage in each basin, describes the methodology for calculating these volumes, and compares potential accumulation volumes under two demand scenarios. The first scenario is based on baseline demands, which is used in the resource analysis for the Enhanced Coordination Alternative. The second scenario assumes the demands remain near historical (i.e., 2027) levels throughout the simulation period, providing an upper bound on the volume of unused tribal that could be available for storage if future demands do not increase as projected in the baseline scenario.

This appendix is exploratory and for modeling purposes only, is not intended to express any legal positions or conclusions about unused tribal water, and it does not modify any legal authorities applicable to any particular tribe's water resources. Further, nothing in this appendix represents a legal position or interpretation of any of the water rights of any basin tribes, other water users, or the Law of the River including as applicable unused water. Nothing in this appendix shall be construed so as to interpret, diminish or modify the water rights of any tribe or other water users. Reclamation continues to recognize the right of each tribe and of each of the Basin States under existing law to use and develop the water of the Colorado River System.

For purposes of this appendix, unused tribal water is defined as the difference between a quantified[1] entitlement or its depletion equivalent and the associated modeled baseline demand, subject to the following key assumptions:

- The analyzed volumes of unused tribal water are physically and legally available and deliverable for storage in Lake Powell or Lake Mead, as applicable, and can be stored in Lake Powell or Lake Mead consistent with the mechanisms explored in the Enhanced Coordination Alternative.
- In the Lower Basin, the unused tribal water analyzed in this appendix includes mainstream Lower Colorado River water entitlements.
- This appendix does not attempt to define the contours of any trust asset. Please see **Technical Appendix 18**, Indian Trust Assets, for more information on trust assets.
- The analyzed volumes of unused tribal water are derived from the entitlement-holder and do not include any analysis of possible end-user arrangements, if applicable.
- Unused tribal water is water that a tribe does not divert from the mainstream Colorado River or other applicable authorized diversion location in any given year. Unused tribal water does not include return flows or effluent.
- The term unused tribal water is used to describe when a tribe does not fully divert its quantified water entitlement, for any reason; the term does not indicate or imply that any water in the Colorado River System is left unused in any given year, as such water may be used by the other Basin, state(s), or more junior priorities consistent with existing law.
- Rounding may be used for any given entitlement.
- The Colorado River Simulation System (CRSS) requires depletion schedules to function. Tribal water entitlements may be quantified by depletion, diversion, or both, as described in the applicable legal authority. Accordingly, depletion, and/or diversion, entitlement or equivalent volumes are calculated or estimated for CRSS modeling purposes as necessary for model functionality, as described in the sections below.
- The tribal water entitlement is legally quantified, including by settlement, adjudication, or contract, with some caveats for modeling purposes as noted herein. This appendix does not attempt to quantify any currently unquantified tribal water rights.
- This appendix does not address a number of issues that may be related to implementation of any alternative, including but not limited to baseline depletion or consumptive use calculations, forbearance agreements, legal authorities, calculations related to diversion or depletion equivalents, and other operational and accounting details such as verification, water orders, and interaction with shortage distribution scheme(s).

[1] In some instances for modeling purposes, this appendix references an estimate or other data about a tribal water right. Where this occurs, it is not intended to represent a modification, alteration, or interpretation of any legal quantification and law applicable to a tribal water right. Reclamation reserves the right to update any quantifications, estimates, or data applicable to any tribal water rights as needed.

H.2 Overview of Baseline Demand Schedules

H.2.1 Upper Basin Demand Schedules

The Upper Basin CRSS baseline demand schedules were developed using data from the Upper Colorado River Commission's (UCRC) updated 2016 Depletion Demand Schedule.[2] Specifically, the UCRC—in coordination with the Upper Division States—developed decadal projections of water depletion demands by sector at the state level to support long-term planning efforts. These projections represent anticipated water demands under assumed economic and hydrologic conditions. The representation of the Upper Colorado Basin Tribes in the UCRC depletion demand schedule was presented in documentation provided by Reclamation to the Upper Colorado Basin Tribes dated July 13, 2022, that outlines the differences between the 2018 Tribal Water Study[3] demand schedules and the updated 2016 Depletion Demand Schedule. Information on how these projections are integrated into CRSS is provided in **Appendix L**, Upper Division States Depletion Schedules, with the resulting depletion schedules for the Upper Basin Tribes summarized in **Table H-1**. **Table H-1** cites the U.S. Bureau of Reclamation and Ten Tribes Partnership, Colorado River Basin Tribal Water Study (2018) as a source for certain aspects of the tribal water rights discussed herein. This citation is intended to provide an accessible source of information for the reader, and it does not supersede or modify any tribal water rights settlement or other authority. Reclamation reserves the right to update references to tribal water rights authorities in this appendix as needed and appropriate.

Retrieved from http://www.ucrcommission.com/wp-content/uploads/2022/06/UCRC-and-Upper-Division-States-Combined-Resolution-and-Updated-2016-Depletion-Demand-Schedule-June-14-2022-1.pdf.

[3] All disclaimers in the 2018 Tribal Water Study regarding its limitations and assumption are incorporated herein by reference, including that it does not, and shall not, represent a legal position or interpretation of any of the water rights of the Partnership Tribes, by any Basin State, the federal government, or the Upper Colorado River Commission as it relates to the Law of the River. Furthermore, nothing in the Tribal Water Study is intended to, nor shall the Study be construed so as to, interpret, diminish or modify the water rights of any of the Partnership Tribes, any other tribe, any Basin State, the federal government, or the UCRC under federal or state law or administrative rule, regulation or guideline. Reclamation and the Partnership continue to recognize the right of each of the Partnership Tribes and of each of the Basin States under existing law to use and develop the water of the Colorado River System.

[4] The information reflected in the baseline depletion demands schedule relies on information about projected future tribal water demands. The projections were based on information compiled in a Colorado River Basin Ten Tribes Partnership Tribal Water Study (December 2018). As discussed in Chapter 8 of that Study, the technical approach was based on the best science and information available at the time, given limitations related to timeframes and resource constraints, among other things. The Navajo Nation informed Reclamation that it was developing updated projections as part of its water development planning. Reclamation worked with the Navajo Nation as needed to update demand schedules prior to the publication of the Final EIS.

[5] The Post-2026 modeling is based on water rights of the Ute Indian Tribe of the Uintah & Ouray Reservation that have not been ratified by all parties. The Ute Indian Tribe of the Uintah & Ouray Reservation has federally reserved Indian water rights, a portion of which were federally decreed in 1923 and a portion of which have been separately recognized and put to use by the U.S. and the State of Utah, which are not fully resolved. The information presented on these water rights in the Final EIS is for analysis purposes only and does not reflect a legal position or interpretation of the water rights by the U.S.

H.2.2 Lower Division States Depletion Schedules

As part of the Post-2026 Environmental Impact Statement (EIS) process, the Lower Division States CRSS baseline depletion schedules were developed to ensure all water users reach their full entitlement by 2040. In general, the initial 2027 depletion is estimated as the lesser of the historical average maximum use and the user's entitlement. This estimate serves as the starting point for linear interpolation, with annual depletions gradually increasing to the full entitlement by 2040. This methodology is applied to all water users except for Metropolitan Water District, Central Arizona Project, and Southern Nevada Water Authority. For these users, the depletion is estimated by subtracting the total revised depletion schedules of all other users from the State's apportionment. The corresponding diversion is then calculated using historical average efficiency.

The depletion schedules represent the baseline demands, which are further adjusted using CRSS to account for new conservation mechanisms, Intentionally Created Surplus, shortage, surplus, and other alternative specific assumptions. A detailed description of the methodology used to develop

2038	9,029	7,650	4,001	36,524	4,087	2,962
2039	9,029	8,024	4,001	36,524	4,183	3,231
2040-2060	9,029	8,398	4,001	36,524	4,278	3,500
Diversion Entitlement[22]	16,720	12,534	6,350	71,616	4,278	3,500
Depletion Equivalent[23]	9,029	8,398	4,001	36,524	4,278	3,500

[19] This analysis does not include the Hualapai Tribe's Arizona Priority 4 entitlement as it was acquired after the Lower Division States depletion schedules were finalized for this Final EIS.

[20] The Hopi Tribe holds a delivery contract for an Arizona Priority 4 entitlement. This table does not include the Hopi Tribe's Arizona Priority 5 and 6 entitlements. This table is not intended to limit or preclude any future settlement terms associated with the Hopi Tribe's water resources and is not to be construed as a federal legal or policy position.

[21] This column shows the 3,500 acre-feet of Arizona Priority 4 water reserved for a Navajo-Hopi Indian water rights settlement pursuant to paragraph 11.3 of the 2007 Arizona Water Settlement Agreement as a placeholder. This table is not intended to limit or preclude any future settlement terms associated with this water and is not to be construed as a federal legal or policy position.

[22] Unless otherwise noted, see the Consolidated Decree entered by the Supreme Court of the U.S. in *Arizona* v. *California*, 547 U.S. 150 (2006).

[23] CRSS requires depletion schedules; the depletion equivalent is calculated using the diversion entitlement and average historical efficiencies (2008-2022), unless otherwise noted in **Appendix M**, Lower Division States Depletion Schedules.

H.3 Estimated Volume of Unused Tribal Water in the Baseline Demand Schedules

H.3.1 Upper Basin

Table H-3 shows the estimated unused water for the Upper Basin Tribes from 2027-2060.[24] For modeling purposes, unused water is calculated as the difference between each tribe's depletion entitlement (or depletion equivalent) (**Table H-1**) and its corresponding annual baseline depletion demand (**Table H-1**).

In the Enhanced Coordination Alternative, a portion of the total Upper Basin unused volume is assumed to be stored in the Lake Powell conservation pool each year. Additional information on the associated modeling assumptions and portion determination is provided in the following section.

Table H-3
Estimated Unused Water (Depletion) for Upper Basin Tribes (acre-feet)

Year	Jicarilla (NM)	Navajo (NM)	Navajo (UT)	Navajo (AZ UB)	Navajo (Total)	Southern Ute (CO)	Ute Indian (UT)	Ute Mountain Ute (CO)	Total

H.3.2 Lower Division States

Table H-4 shows the estimated unused water for the Lower Division Tribes with mainstream entitlements from 2027-2060. All of the Lower Division Tribes with mainstream entitlements hold diversion entitlements; therefore, for modeling purposes, unused water is calculated as the difference between the depletion equivalent of each tribe's entitlement (**Table H-2**) and its corresponding annual baseline depletion schedule (**Table H-2**).

In the Enhanced Coordination Alternative, a portion of the total unused water volume from the Lower Division Tribes with mainstream entitlements is assumed to be contributed to the Protection Pool each year. These modeling assumptions are detailed in the following section.

Table H-4

H.4 Modeled Volume of Unused Tribal Water Available for Storage

This section compares the modeled volumes of unused tribal water available for storage in Lake Powell and Lake Mead under two assumed demand schedules. As noted, only a portion of the unused tribal water, calculated using the baseline demand schedule and documented in the previous section, is assumed to be available for storage in the Enhanced Coordination Alternative. The assumptions for determining this portion are outlined below, and the resulting volume is compared to the potential volume available for storage if tribal demands remain near historical (i.e., 2027) levels.

H.4.1 Modeled Volume of Unused Tribal Water Available for Storage in Lake Powell

The Enhanced Coordination Alternative includes a Lake Powell conservation pool with a maximum capacity of 2.0 million acre-feet (maf). Both the Upper Division States and Upper Basin Tribes would have equal access to contribute to the conservation pool. In addition to storing Upper Basin conservation in the conservation pool, the Upper Basin Tribes could also store a portion of unused tribal water.

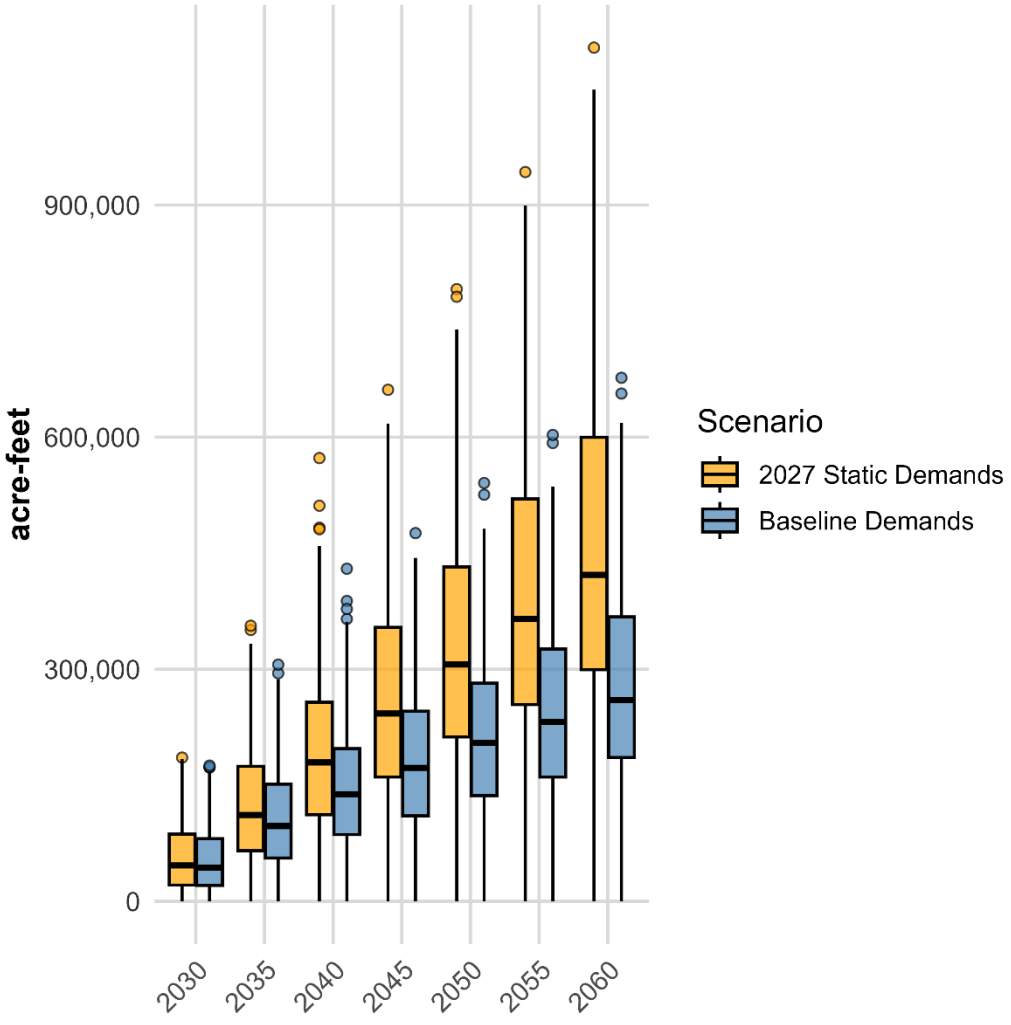
For modeling purposes, 5 to 15 percent of the unused Upper Basin tribal water is assumed to be available for storage in the Lake Powell conservation pool. The specific percentage, which varies with hydrologic conditions, is determined by comparing the modeled water year Lees Ferry natural flow to the 1991–2020 historical average (**Table H-5**). Linear interpolation is used to determine the specific percentage when the modeled (water year) Lees Ferry natural flow falls between 13.49 and 20.24 maf—with contributions increasing proportionally from 5 to 15 percent as natural flow increases across this range. It was assumed that this volume is contributed to the Lake Powell conservation pool without changing the inflow to Lake Powell. This operational modeling assumption implies that at least 5 to 15 percent of the unused Upper Basin tribal water physically reaches Lake Powell; however, the actual volume of unused Upper Basin tribal water that physically reaches Lake Powell is beyond the scope of this analysis.

Table H-5
Upper Basin Tribal Water Available for Storage in the Lake Powell Conservation Pool Relative to Historical Lees Ferry Natural Flow Thresholds

Current Water Year Lees Ferry Natural Flow (maf)	Annual Upper Basin Unused Tribal Contribution (%)
≥ 20.24[25]	15
Between 20.24 and 13.49[26]	5 to 15 (linear interpolation)
= 13.49	5
< 13.49	0

Table H-6 summarizes the potential volume of Upper Basin unused tribal water available for storage in the Lake Powell conservation pool.

Figure H-1 illustrates the potential cumulative contribution based on the baseline demands and the modeled natural flow used in this Final EIS analysis (see **Appendix F**, Approach to Hydrologic Uncertainty), compared to the potential cumulative contribution if the demands remain near historical (i.e., 2027) levels throughout the simulation period. In this latter scenario, the 2027 demands are assumed to remain constant through 2060.



Note, the volumes shown in **Figure H-1** do not represent modeled storage of Upper Basin unused tribal water in the Lake Powell conservation pool. Stored volumes are subject to overall capacity constraints—which also account for other types of conserved water. Furthermore, water is periodically withdrawn according to the modeling assumptions detailed in the **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water.

[25] 150 percent of the historical average Lees Ferry natural flow from 1991-2020.
[26] Historical average Lees Ferry natural flow from 1991-2020.

Table H-6
Potential Volume of Upper Basin Unused Tribal Water Available for Storage in Lake Powell Conservation Pool (acre-feet)

Year	Potential Volume Available for Storage		
	5%	10%	15%

2060	7,000	14,001	21,001

Figure H-1
Potential Cumulative Contribution from Upper Basin Unused Tribal Water

H.4.2 Estimated Modeled Volume of Unused Tribal Water Available for Storage in Lake Mead

The Enhanced Coordination Alternative includes a conservation mechanism referred to as the Protection Pool. In general, the Protection Pool is assumed to be a pool of water in Lake Mead, controlled by Reclamation for Lower Basin-wide benefits, with a maximum capacity of 2.0 maf. It is assumed that water could be acquired through multiple mechanisms, including—but not limited to—both conserved consumptive use and unused Lower Basin tribal water.

For modeling purposes, it is assumed that 10 percent of the unused Lower Basin tribal water can be stored in the Protection Pool. As a result, this water would not be available for diversion and use by lower priority water users. **Figure H-2** shows the resulting maximum potential accumulation of unused tribal water in the Protection Pool given baseline demands, compared with the maximum potential accumulation if the 2027 demands are maintained as static through 2060. The corresponding data is presented in **Table H-7**. Lower priority water users would experience a corresponding reduction in water available for their diversion and use resulting from the volume of unused water storage. Any reductions in water available to lower priority users resulting from increases to baseline demand, however, would be due to tribal water development independent of the Colorado River operations considered herein, and is not an impact of any alternatives.

Figure H-2
Maximum Potential Accumulation of Unused Tribal Water in the Protection Pool

Table H-7
Maximum Accumulation of Unused Tribal Water in the Protection Pool: Assuming 10-Percent Availability for Storage (acre-feet)

Year	Accumulated Volume	
	Baseline Demands[27]	2027 Static Demands

2056	51,871	226,132
2057	51,871	233,670
2058	51,871	241,208
2059	51,871	248,746
2060	51,871	256,283

[27] The CRSS modeling erroneously includes unused tribal water associated with the Hopi Tribe. As such, the volumes here do not match 10 percent of the total in Table H-4 as they should. The maximum magnitude of the discrepancy is 868 acre-feet in 2039-2060.

Note that with the baseline demands, the maximum accumulation volume plateaus in 2040 when all users reach full use of their entitlements; in contrast, the maximum accumulation continues to linearly increase throughout the simulation period if the 2027 demands are maintained.

Additional information on the other types of water that may be stored in the Protection Pool, along with detailed modeling assumptions underlying the creation and use of Protection Pool volumes is provided in **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water.

H.5 Summary

The Enhanced Coordination Alternative contemplates mechanisms to store Upper Basin unused tribal water in a Lake Powell conservation pool and Lower Basin unused tribal water in the Protection Pool in Lake Mead. The volume of unused tribal water available for storage in each basin is highly dependent on the assumed demand schedules and modeling assumptions developed for each storage mechanism. Stored unused tribal water would not be available for diversion and use by lower priority water users, including for some of the existing water uses of Arizona Priority 4 users (including tribes). Because of the sensitivity to these assumptions and the uncertainty associated with future demands, the volume of stored unused tribal water was evaluated using the baseline demand schedules—which generally increase over time—and compared to a scenario assuming continuation of historical demand levels.

This comparison shows that by 2060, approximately 161,933 – 426,714[28] acre-feet of additional unused tribal water could be stored in Lake Powell if Upper Basin tribal demands remain near historical levels compared to the baseline demand scenario, based on an assumed 5 to 15 percent contribution rate. As tribal demands grow over time, the volume of unused tribal water available for storage decreases correspondingly. Similarly, in the Lower Basin, approximately 204,412 acre-feet more unused tribal water could be stored in the Lake Mead Protection Pool if Lower Basin mainstream tribal demands remain near historical levels compared to the projected increases under the baseline demand scenario, based on an assumed 10 percent contribution rate. Both estimates depend on the assumed contribution rates, i.e., the portion of total unused water that can be stored.

[28] This represents the difference between the median and the maximum from **Figure H-1**, reflecting that the modeled Upper Basin volume of unused tribal water available for storage is also dependent on assumed future hydrology.

Appendix H. Sensitivity Analysis – Effects of Demand Schedule Assumptions on Modeled Unused Tribal Water Available for Storage in the Enhanced Coordination Alternative

H.1 Introduction

The Enhanced Coordination Alternative contemplates mechanisms to store Upper Basin unused tribal water in a Lake Powell conservation pool and Lower Basin unused tribal water in the Protection Pool in Lake Mead. The volume of unused tribal water that could be potentially available for storage in each basin is highly dependent on the modeled baseline demands and modeling assumptions developed for each storage mechanism.

This appendix summarizes the baseline demands that the United States (U.S.) Bureau of Reclamation (Reclamation) used to estimate the volumes of unused tribal water available for conservation and storage in each basin, describes the methodology for calculating these volumes, and compares potential accumulation volumes under two demand scenarios. The first scenario is based on baseline demands, which is used in the resource analysis for the Enhanced Coordination Alternative. The second scenario assumes the demands remain near historical (i.e., 2027) levels throughout the simulation period, providing an upper bound on the volume of unused tribal that could be available for storage if future demands do not increase as projected in the baseline scenario.

This appendix is exploratory and for modeling purposes only, is not intended to express any legal positions or conclusions about unused tribal water, and it does not modify any legal authorities applicable to any particular tribe's water resources. Further, nothing in this appendix represents a legal position or interpretation of any of the water rights of any basin tribes, other water users, or the Law of the River including as applicable unused water. Nothing in this appendix shall be construed so as to interpret, diminish or modify the water rights of any tribe or other water users. Reclamation continues to recognize the right of each tribe and of each of the Basin States under existing law to use and develop the water of the Colorado River System.

For purposes of this appendix, unused tribal water is defined as the difference between a quantified[1] entitlement or its depletion equivalent and the associated modeled baseline demand, subject to the following key assumptions:

- The analyzed volumes of unused tribal water are physically and legally available and deliverable for storage in Lake Powell or Lake Mead, as applicable, and can be stored in Lake Powell or Lake Mead consistent with the mechanisms explored in the Enhanced Coordination Alternative.
- In the Lower Basin, the unused tribal water analyzed in this appendix includes mainstream Lower Colorado River water entitlements.
- This appendix does not attempt to define the contours of any trust asset. Please see **Technical Appendix 18**, Indian Trust Assets, for more information on trust assets.
- The analyzed volumes of unused tribal water are derived from the entitlement-holder and do not include any analysis of possible end-user arrangements, if applicable.
- Unused tribal water is water that a tribe does not divert from the mainstream Colorado River or other applicable authorized diversion location in any given year. Unused tribal water does not include return flows or effluent.
- The term unused tribal water is used to describe when a tribe does not fully divert its quantified water entitlement, for any reason; the term does not indicate or imply that any water in the Colorado River System is left unused in any given year, as such water may be used by the other Basin, state(s), or more junior priorities consistent with existing law.
- Rounding may be used for any given entitlement.
- The Colorado River Simulation System (CRSS) requires depletion schedules to function. Tribal water entitlements may be quantified by depletion, diversion, or both, as described in the applicable legal authority. Accordingly, depletion, and/or diversion, entitlement or equivalent volumes are calculated or estimated for CRSS modeling purposes as necessary for model functionality, as described in the sections below.
- The tribal water entitlement is legally quantified, including by settlement, adjudication, or contract, with some caveats for modeling purposes as noted herein. This appendix does not attempt to quantify any currently unquantified tribal water rights.
- This appendix does not address a number of issues that may be related to implementation of any alternative, including but not limited to baseline depletion or consumptive use calculations, forbearance agreements, legal authorities, calculations related to diversion or depletion equivalents, and other operational and accounting details such as verification, water orders, and interaction with shortage distribution scheme(s).

[1] In some instances for modeling purposes, this appendix references an estimate or other data about a tribal water right. Where this occurs, it is not intended to represent a modification, alteration, or interpretation of any legal quantification and law applicable to a tribal water right. Reclamation reserves the right to update any quantifications, estimates, or data applicable to any tribal water rights as needed.

H.2 Overview of Baseline Demand Schedules

H.2.1 Upper Basin Demand Schedules

The Upper Basin CRSS baseline demand schedules were developed using data from the Upper Colorado River Commission's (UCRC) updated 2016 Depletion Demand Schedule.[2] Specifically, the UCRC—in coordination with the Upper Division States—developed decadal projections of water depletion demands by sector at the state level to support long-term planning efforts. These projections represent anticipated water demands under assumed economic and hydrologic conditions. The representation of the Upper Colorado Basin Tribes in the UCRC depletion demand schedule was presented in documentation provided by Reclamation to the Upper Colorado Basin Tribes dated July 13, 2022, that outlines the differences between the 2018 Tribal Water Study[3] demand schedules and the updated 2016 Depletion Demand Schedule. Information on how these projections are integrated into CRSS is provided in **Appendix L**, Upper Division States Depletion Schedules, with the resulting depletion schedules for the Upper Basin Tribes summarized in **Table H-1**. **Table H-1** cites the U.S. Bureau of Reclamation and Ten Tribes Partnership, Colorado River Basin Tribal Water Study (2018) as a source for certain aspects of the tribal water rights discussed herein. This citation is intended to provide an accessible source of information for the reader, and it does not supersede or modify any tribal water rights settlement or other authority. Reclamation reserves the right to update references to tribal water rights authorities in this appendix as needed and appropriate.

Retrieved from http://www.ucrcommission.com/wp-content/uploads/2022/06/UCRC-and-Upper-Division-States-Combined-Resolution-and-Updated-2016-Depletion-Demand-Schedule-June-14-2022-1.pdf.

[3] All disclaimers in the 2018 Tribal Water Study regarding its limitations and assumption are incorporated herein by reference, including that it does not, and shall not, represent a legal position or interpretation of any of the water rights of the Partnership Tribes, by any Basin State, the federal government, or the Upper Colorado River Commission as it relates to the Law of the River. Furthermore, nothing in the Tribal Water Study is intended to, nor shall the Study be construed so as to, interpret, diminish or modify the water rights of any of the Partnership Tribes, any other tribe, any Basin State, the federal government, or the UCRC under federal or state law or administrative rule, regulation or guideline. Reclamation and the Partnership continue to recognize the right of each of the Partnership Tribes and of each of the Basin States under existing law to use and develop the water of the Colorado River System.

[4] The information reflected in the baseline depletion demands schedule relies on information about projected future tribal water demands. The projections were based on information compiled in a Colorado River Basin Ten Tribes Partnership Tribal Water Study (December 2018). As discussed in Chapter 8 of that Study, the technical approach was based on the best science and information available at the time, given limitations related to timeframes and resource constraints, among other things. The Navajo Nation informed Reclamation that it was developing updated projections as part of its water development planning. Reclamation worked with the Navajo Nation as needed to update demand schedules prior to the publication of the Final EIS.

[5] The Post-2026 modeling is based on water rights of the Ute Indian Tribe of the Uintah & Ouray Reservation that have not been ratified by all parties. The Ute Indian Tribe of the Uintah & Ouray Reservation has federally reserved Indian water rights, a portion of which were federally decreed in 1923 and a portion of which have been separately recognized and put to use by the U.S. and the State of Utah, which are not fully resolved. The information presented on these water rights in the Final EIS is for analysis purposes only and does not reflect a legal position or interpretation of the water rights by the U.S.

Year	Jicarilla (NM)	Navajo[4]				Southern Ute (CO)	Ute Indian (UT)[5]	Ute Mtn. Ute (CO)	Upper Basin Total

H.2.2 Lower Division States Depletion Schedules

As part of the Post-2026 Environmental Impact Statement (EIS) process, the Lower Division States CRSS baseline depletion schedules were developed to ensure all water users reach their full entitlement by 2040. In general, the initial 2027 depletion is estimated as the lesser of the historical average maximum use and the user's entitlement. This estimate serves as the starting point for linear interpolation, with annual depletions gradually increasing to the full entitlement by 2040. This methodology is applied to all water users except for Metropolitan Water District, Central Arizona Project, and Southern Nevada Water Authority. For these users, the depletion is estimated by subtracting the total revised depletion schedules of all other users from the State's apportionment. The corresponding diversion is then calculated using historical average efficiency.

The depletion schedules represent the baseline demands, which are further adjusted using CRSS to account for new conservation mechanisms, Intentionally Created Surplus, shortage, surplus, and other alternative specific assumptions. A detailed description of the methodology used to develop

[6] *U.S. Bureau of Reclamation and Ten Tribes Partnership, Colorado River Basin Tribal Water Study* (2018), Table 5.4-A.

Depletion Equivalent[23]	9,029	8,398	4,001	36,524	4,278	3,500

[19] This analysis does not include the Hualapai Tribe's Arizona Priority 4 entitlement as it was acquired after the Lower Division States depletion schedules were finalized for this Final EIS.

[20] The Hopi Tribe holds a delivery contract for an Arizona Priority 4 entitlement. This table does not include the Hopi Tribe's Arizona Priority 5 and 6 entitlements. This table is not intended to limit or preclude any future settlement terms associated with the Hopi Tribe's water resources and is not to be construed as a federal legal or policy position.

[21] This column shows the 3,500 acre-feet of Arizona Priority 4 water reserved for a Navajo-Hopi Indian water rights settlement pursuant to paragraph 11.3 of the 2007 Arizona Water Settlement Agreement as a placeholder. This table is not intended to limit or preclude any future settlement terms associated with this water and is not to be construed as a federal legal or policy position.

[22] Unless otherwise noted, see the Consolidated Decree entered by the Supreme Court of the U.S. in *Arizona* v. *California*, 547 U.S. 150 (2006).

[23] CRSS requires depletion schedules; the depletion equivalent is calculated using the diversion entitlement and average historical efficiencies (2008-2022), unless otherwise noted in **Appendix M**, Lower Division States Depletion Schedules.

H.3 Estimated Volume of Unused Tribal Water in the Baseline Demand Schedules

H.3.1 Upper Basin

Table H-3 shows the estimated unused water for the Upper Basin Tribes from 2027-2060.[24] For modeling purposes, unused water is calculated as the difference between each tribe's depletion entitlement (or depletion equivalent) (**Table H-1**) and its corresponding annual baseline depletion demand (**Table H-1**).

In the Enhanced Coordination Alternative, a portion of the total Upper Basin unused volume is assumed to be stored in the Lake Powell conservation pool each year. Additional information on the associated modeling assumptions and portion determination is provided in the following section.

Table H-3
Estimated Unused Water (Depletion) for Upper Basin Tribes (acre-feet)

Year	Jicarilla (NM)	Navajo (NM)	Navajo (UT)	Navajo (AZ UB)	Navajo (Total)	Southern Ute (CO)	Ute Indian (UT)	Ute Mountain Ute (CO)	Total
2027	3,814	50,069	70,885	9,125	130,079	36,471	74,303	65,056	309,723

H.3.2 Lower Division States

Table H-4 shows the estimated unused water for the Lower Division Tribes with mainstream entitlements from 2027-2060. All of the Lower Division Tribes with mainstream entitlements hold diversion entitlements; therefore, for modeling purposes, unused water is calculated as the difference between the depletion equivalent of each tribe's entitlement (**Table H-2**) and its corresponding annual baseline depletion schedule (**Table H-2**).

In the Enhanced Coordination Alternative, a portion of the total unused water volume from the Lower Division Tribes with mainstream entitlements is assumed to be contributed to the Protection Pool each year. These modeling assumptions are detailed in the following section.

H.4 Modeled Volume of Unused Tribal Water Available for Storage

This section compares the modeled volumes of unused tribal water available for storage in Lake Powell and Lake Mead under two assumed demand schedules. As noted, only a portion of the unused tribal water, calculated using the baseline demand schedule and documented in the previous section, is assumed to be available for storage in the Enhanced Coordination Alternative. The assumptions for determining this portion are outlined below, and the resulting volume is compared to the potential volume available for storage if tribal demands remain near historical (i.e., 2027) levels.

H.4.1 Modeled Volume of Unused Tribal Water Available for Storage in Lake Powell

The Enhanced Coordination Alternative includes a Lake Powell conservation pool with a maximum capacity of 2.0 million acre-feet (maf). Both the Upper Division States and Upper Basin Tribes would have equal access to contribute to the conservation pool. In addition to storing Upper Basin conservation in the conservation pool, the Upper Basin Tribes could also store a portion of unused tribal water.

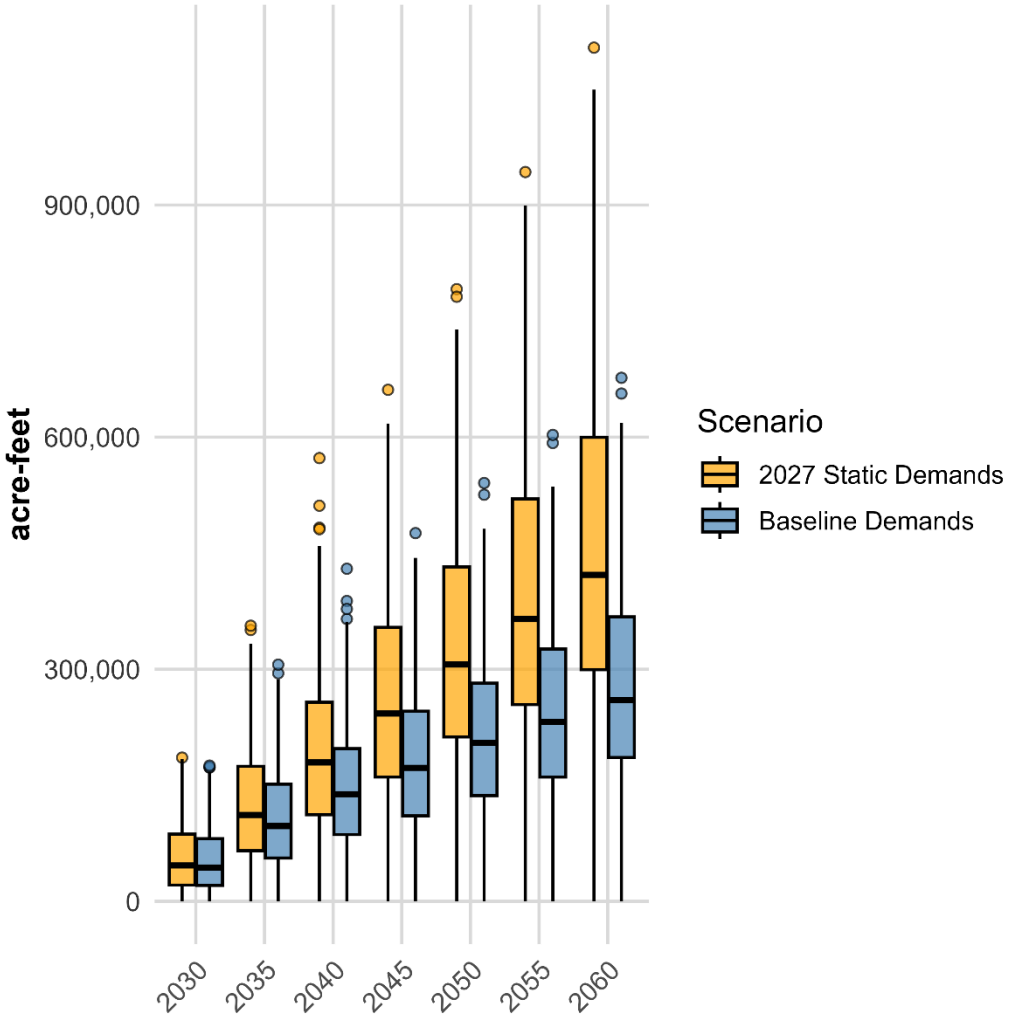
For modeling purposes, 5 to 15 percent of the unused Upper Basin tribal water is assumed to be available for storage in the Lake Powell conservation pool. The specific percentage, which varies with hydrologic conditions, is determined by comparing the modeled water year Lees Ferry natural flow to the 1991–2020 historical average (**Table H-5**). Linear interpolation is used to determine the specific percentage when the modeled (water year) Lees Ferry natural flow falls between 13.49 and 20.24 maf—with contributions increasing proportionally from 5 to 15 percent as natural flow increases across this range. It was assumed that this volume is contributed to the Lake Powell conservation pool without changing the inflow to Lake Powell. This operational modeling assumption implies that at least 5 to 15 percent of the unused Upper Basin tribal water physically reaches Lake Powell; however, the actual volume of unused Upper Basin tribal water that physically reaches Lake Powell is beyond the scope of this analysis.

Table H-5
Upper Basin Tribal Water Available for Storage in the Lake Powell Conservation Pool Relative to Historical Lees Ferry Natural Flow Thresholds

Current Water Year Lees Ferry Natural Flow (maf)	Annual Upper Basin Unused Tribal Contribution (%)
≥ 20.24[25]	15
Between 20.24 and 13.49[26]	5 to 15 (linear interpolation)
= 13.49	5
< 13.49	0

Table H-6 summarizes the potential volume of Upper Basin unused tribal water available for storage in the Lake Powell conservation pool.

Figure H-1 illustrates the potential cumulative contribution based on the baseline demands and the modeled natural flow used in this Final EIS analysis (see **Appendix F**, Approach to Hydrologic Uncertainty), compared to the potential cumulative contribution if the demands remain near historical (i.e., 2027) levels throughout the simulation period. In this latter scenario, the 2027 demands are assumed to remain constant through 2060.



Note, the volumes shown in **Figure H-1** do not represent modeled storage of Upper Basin unused tribal water in the Lake Powell conservation pool. Stored volumes are subject to overall capacity constraints—which also account for other types of conserved water. Furthermore, water is periodically withdrawn according to the modeling assumptions detailed in the **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water.

[25] 150 percent of the historical average Lees Ferry natural flow from 1991-2020.
[26] Historical average Lees Ferry natural flow from 1991-2020.

Table H-6

2060	7,000	14,001	21,001

Figure H-1
Potential Cumulative Contribution from Upper Basin Unused Tribal Water

H.4.2 Estimated Modeled Volume of Unused Tribal Water Available for Storage in Lake Mead

The Enhanced Coordination Alternative includes a conservation mechanism referred to as the Protection Pool. In general, the Protection Pool is assumed to be a pool of water in Lake Mead, controlled by Reclamation for Lower Basin-wide benefits, with a maximum capacity of 2.0 maf. It is assumed that water could be acquired through multiple mechanisms, including—but not limited to—both conserved consumptive use and unused Lower Basin tribal water.

For modeling purposes, it is assumed that 10 percent of the unused Lower Basin tribal water can be stored in the Protection Pool. As a result, this water would not be available for diversion and use by lower priority water users. **Figure H-2** shows the resulting maximum potential accumulation of unused tribal water in the Protection Pool given baseline demands, compared with the maximum potential accumulation if the 2027 demands are maintained as static through 2060. The corresponding data is presented in **Table H-7**. Lower priority water users would experience a corresponding reduction in water available for their diversion and use resulting from the volume of unused water storage. Any reductions in water available to lower priority users resulting from increases to baseline demand, however, would be due to tribal water development independent of the Colorado River operations considered herein, and is not an impact of any alternatives.

Figure H-2
Maximum Potential Accumulation of Unused Tribal Water in the Protection Pool

Table H-7
Maximum Accumulation of Unused Tribal Water in the Protection Pool: Assuming 10-Percent Availability for Storage (acre-feet)

Year	Accumulated Volume	
	Baseline Demands[27]	2027 Static Demands
2027	7,538	7,538

2044	51,871	135,679
2045	51,871	143,217
2046	51,871	150,755
2047	51,871	158,293
2048	51,871	165,830
2049	51,871	173,368
2050	51,871	180,906
2051	51,871	188,444
2052	51,871	195,981
2053	51,871	203,519
2054	51,871	211,057
2055	51,871	218,595
2056	51,871	226,132
2057	51,871	233,670
2058	51,871	241,208
2059	51,871	248,746
2060	51,871	256,283

[27] The CRSS modeling erroneously includes unused tribal water associated with the Hopi Tribe. As such, the volumes here do not match 10 percent of the total in Table H-4 as they should. The maximum magnitude of the discrepancy is 868 acre-feet in 2039-2060.

Note that with the baseline demands, the maximum accumulation volume plateaus in 2040 when all users reach full use of their entitlements; in contrast, the maximum accumulation continues to linearly increase throughout the simulation period if the 2027 demands are maintained.

Additional information on the other types of water that may be stored in the Protection Pool, along with detailed modeling assumptions underlying the creation and use of Protection Pool volumes is provided in **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water.

H.5 Summary

The Enhanced Coordination Alternative contemplates mechanisms to store Upper Basin unused tribal water in a Lake Powell conservation pool and Lower Basin unused tribal water in the Protection Pool in Lake Mead. The volume of unused tribal water available for storage in each basin is highly dependent on the assumed demand schedules and modeling assumptions developed for each storage mechanism. Stored unused tribal water would not be available for diversion and use by lower priority water users, including for some of the existing water uses of Arizona Priority 4 users (including tribes). Because of the sensitivity to these assumptions and the uncertainty associated with future demands, the volume of stored unused tribal water was evaluated using the baseline demand schedules—which generally increase over time—and compared to a scenario assuming continuation of historical demand levels.

This comparison shows that by 2060, approximately 161,933 – 426,714[28] acre-feet of additional unused tribal water could be stored in Lake Powell if Upper Basin tribal demands remain near historical levels compared to the baseline demand scenario, based on an assumed 5 to 15 percent contribution rate. As tribal demands grow over time, the volume of unused tribal water available for storage decreases correspondingly. Similarly, in the Lower Basin, approximately 204,412 acre-feet more unused tribal water could be stored in the Lake Mead Protection Pool if Lower Basin mainstream tribal demands remain near historical levels compared to the projected increases under the baseline demand scenario, based on an assumed 10 percent contribution rate. Both estimates depend on the assumed contribution rates, i.e., the portion of total unused water that can be stored.

[28] This represents the difference between the median and the maximum from **Figure H-1**, reflecting that the modeled Upper Basin volume of unused tribal water available for storage is also dependent on assumed future hydrology.

Appendix I. Sensitivity Analysis – Effects of Alternate Upper Basin Demand Scenarios on Operations at Lake Powell and Lake Mead

I.1 Introduction

Future water depletion demands are required inputs to the Colorado River Simulation System (CRSS) and are one of the key future uncertainties for which assumptions must be developed. This appendix presents a sensitivity analysis that evaluates how future depletion demand assumptions influence modeled system conditions and vulnerabilities. Because of hydrologic and institutional differences between the Upper and Lower Basins, scenarios are treated differently for each basin.

In the Upper Basin, hydrology varies significantly both geographically and from year to year, resulting in shortages when the available supply is insufficient to meet demands. Because water users are subject to this hydrologic variability and the Upper Basin is currently using less than its 7.5 million acre-feet (maf) apportionment, future depletion demand scenarios generally assume depletions will increase over time. In contrast, Lower Basin demands are assumed to equal full apportionment and are met through deliveries from Lake Mead, adjusted for tributary inflows and losses below the reservoir. Shortages in the Lower Basin arise primarily through prescribed delivery reductions under existing operational guidelines and agreements, including shortages and contributions established in the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead and the 2019 Drought Contingency Plan.

Long-term planning studies in the Basin have typically used narrative-based scenarios to project future demands, often assuming increasing Upper Basin demands and fixed apportionments for the Lower Division States and the United Mexican States (Mexico) (7.5 maf and 1.5 maf, respectively), with reductions implemented according to operating policies. Although useful, narrative-based scenarios embed assumptions about the timing and magnitude of future change, making it difficult to isolate the relationships between input assumptions and modeled system vulnerabilities.

The purpose of this sensitivity analysis is to evaluate how alternatives respond to different Upper Basin demand assumptions (differences in Lower Basin demands are already represented through the alternatives' shortage and surplus provisions). To more transparently examine how combinations of supply and demand affect system vulnerability, this appendix evaluates multiple Upper Basin depletion demand scenarios, including several steady-state depletion demand levels. These steady-state scenarios span a broad range of plausible future depletion demands without relying on narrative assumptions about how those depletion demands may evolve over time.

The analysis performed in this appendix is designed to inform a comparison among alternatives in this Final Environmental Impact Statement (EIS) and is not an interpretation or determination of the quantity of water legally available for use in the Upper Basin under the Law of the River and existing legal frameworks.

The Upper Basin depletion demand scenarios evaluated in this sensitivity analysis include:

- Upper Colorado River Commission's updated 2016 Depletion Demand Schedule (2016 UCRC)[1]
- 90 percent 2016 UCRC
- Steady-State 4.5 maf
- Steady-State 5.0 maf
- Steady-State 5.5 maf
- Steady-State 6.0 maf

Section I.2 describes these scenarios in more detail, and **Section I.3** presents a sensitivity analysis comparing the effects of the different depletion demand scenarios on system metrics, robustness, and vulnerability across the alternatives evaluated in this Final EIS.

I.2 Alternative Upper Basin Depletion Demand Scenarios

The 2016 UCRC depletion demand schedule, adopted by the Upper Colorado River Commission on June 14, 2022, is the depletion demand scenario used in the official version of CRSS and the depletion demand scenario used in the Final EIS modeling outside of this sensitivity analysis[2]. This depletion demand schedule is provided by the Upper Division States and the UCRC on a decadal and sector basis; the Bureau of Reclamation (Reclamation) then worked with the states to disaggregate to the spatial (sector by CRSS sub-basin) and temporal (monthly) level necessary for CRSS. The Arizona portion of the Upper Basin demand schedule was developed by Reclamation and is primarily comprised of Navajo Nation uses. The representation of the Upper Colorado Basin Tribes in the UCRC depletion demand schedule was presented in documentation dated July 13, 2022, that outlines the differences between the 2018 Tribal Water Study demand schedules and the

[1] Upper Colorado River Commission (UCRC) & Upper Division States. (2022, June 14). *Combined Resolution and Updated 2016 Depletion Demand Schedule.* Upper Colorado River Commission. Retrieved from http://www.ucrcommission.com/wp-content/uploads/2022/06/UCRC-and-Upper-Division-States-Combined-Resolution-and-Updated-2016-Depletion-Demand-Schedule-June-14-2022-1.pdf.

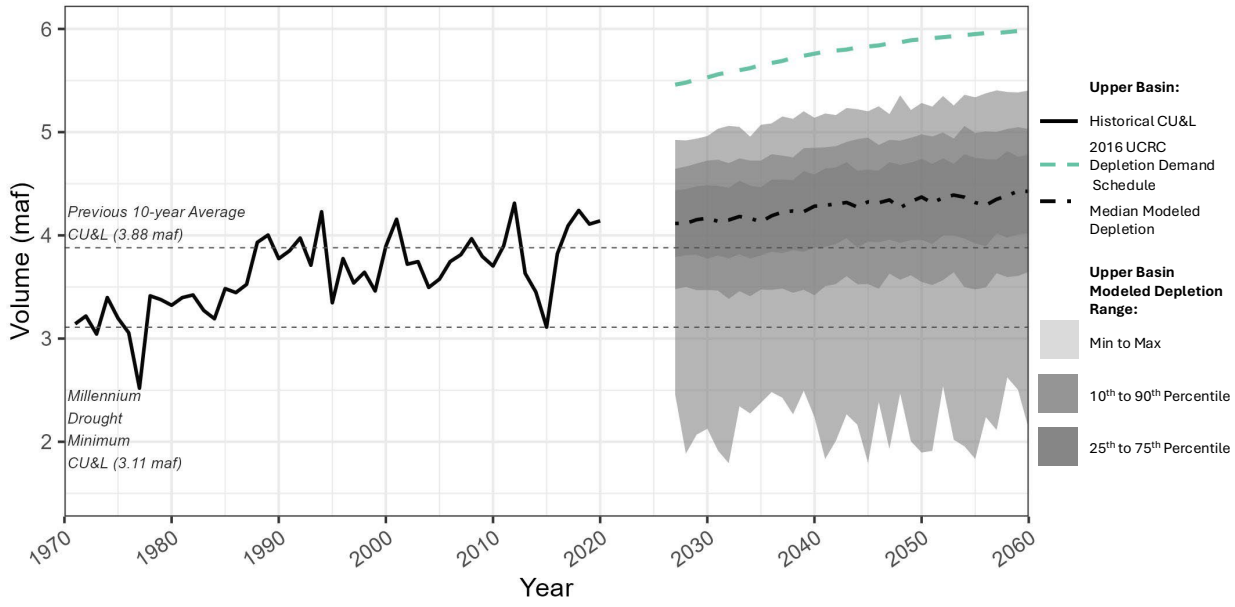
[2] CRSS explicitly models select reservoir evaporation, so the demand schedules used in CRSS do not include reservoir evaporation from Lake Powell, and Flaming Gorge, Blue Mesa, Morrow Point, Navajo, McPhee, Dillon, Granby, Homestake, and Willow Creek Reservoirs.

updated 2016 Depletion Demand Schedule[3,4]. See **Appendix L**, Upper Division States Depletion Schedules, for additional details.

For this sensitivity analysis, five additional Upper Basin depletion demand scenarios were developed using the 2016 UCRC depletion demand schedule as the baseline. The "90 percent 2016 UCRC" scenario was created by multiplying the 2016 UCRC depletion demand schedule by 0.9 for all months. Four additional steady-state depletion demand scenarios span a range of plausible future depletion demands from 4.5 to 6.0 maf in 0.5-maf increments. These steady-state scenarios were created by scaling the 2042 depletion demands from the 2016 UCRC depletion demand schedule so that the total Upper Basin depletion demand equals the target steady-state volume. The year 2042 was selected because it is the midpoint of a 30-year simulation period[5]. Together, these incremental steady-state depletion demand scenarios allows for a more systematic analysis of how combinations of supply and depletion demands affect system vulnerability.

Figure I-1 through **Figure I-6** show the six Upper Basin depletion demand scenarios used in this sensitivity analysis, along with the modeled Upper Basin depletions from the Continued Current Strategies (CCS) Comparative Baseline. For each depletion demand scenario, modeled Upper Basin depletions under the other alternatives would be very similar to those under CCS because all alternatives use the same assumptions for hydrology and modeled operations in reservoirs and reaches above Lake Powell. The only differences in modeled Upper Basin depletions occur when Powell Infrastructure Protection (PIP) releases are made, which differ among alternatives. PIP releases are made from Flaming Gorge, Blue Mesa, or Navajo when Lake Powell reaches low elevations (see **Appendix A**, CRSS Modeling Assumptions, for more details). These figures show how the modeled Upper Basin depletions compare to historical consumptive use and to the depletion demand schedule for a given depletion demand scenario. Because the results would not vary much by alternative, only CCS results are included.

The 2016 UCRC (**Figure I-1**) and 90 percent 2016 UCRC (**Figure I-2**) depletion demand scenarios are the only two scenarios that vary over time. The 2016 UCRC depletion demand scenario begins with a scheduled depletion demand of 5.46 maf in 2027 and increases to a maximum scheduled depletion demand of 5.99 maf in 2060. The 90 percent 2016 UCRC depletion demand schedule is 10 percent lower, with a beginning scheduled depletion demand of 4.91 maf in 2027 and increasing to a maximum scheduled depletion demand of 5.39 maf in 2060. **Appendix L,** Upper Division States Depletion Schedules, provides additional background on the development of the 2016 UCRC



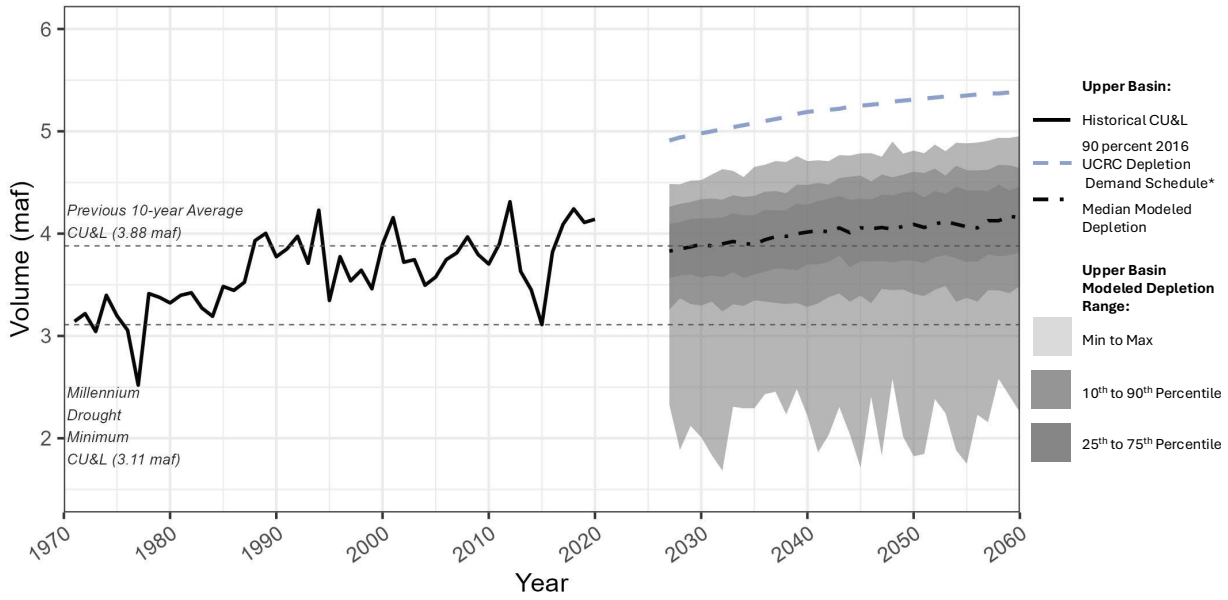
[3] The Post-2026 modeling is based on water rights of the Ute Indian Tribe of the Uintah & Ouray Reservation that have not been ratified by all parties. The Ute Indian Tribe of the Uintah & Ouray Reservation has federally reserved Indian water rights, a portion of which were federally decreed in 1923 and a portion of which have been separately recognized and put to use by the United States and the State of Utah, which are not fully resolved.

[4] The information reflected in the baseline depletion demands schedule relies on information about projected future Tribal water demands. The projections were based on information compiled in a Colorado River Basin Ten Tribes Partnership Tribal Water Study (December 2018). As discussed in Chapter 8 of that Study, the technical approach was based on the best science and information available at the time, given limitations related to timeframes and resource constraints, among other things. The Navajo Nation informed Reclamation that it was developing updated projections as part of its water development planning. Reclamation worked with the Navajo Nation as needed to update demand schedules prior to the publication of the Final EIS.

[5] This was selected before it was known if the Draft EIS would analyze 30 or 34 years and the depletion demand scenarios were not modified between the Draft and Final EIS.

schedule and its integration into CRSS. In general, these schedules represent anticipated water demands under assumed economic and hydrologic conditions, while the CRSS-simulated depletions (modeled Upper Basin depletions) represent modeled consumptive use under simulated hydrologic conditions.

Figure I-1
Annual Upper Basin Historical Consumptive Uses and Losses with 2016 UCRC Future Depletion Demand Schedule and Upper Basin Modeled Depletions, Continued Current Strategies Comparative Baseline



Note: Future depletion demand schedules exclude reservoir evaporation volumes from reservoirs undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation[2]. CRSS simulates consumptive use based on the provided depletion demand scenarios, and the available supply in each year of each simulation. To be comparable to the CRSS input and results, the historical consumptive uses and losses (CU&L) does not include reservoir evaporation undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation but does include remaining Upper Basin reservoirs.

Across all six scenarios, modeled Upper Basin depletions (shown as shaded areas in **Figure I-1** through **Figure I-6**) are lower than the input Upper Basin depletion demand schedule(shown as the colored dashed line in **Figure I-1** through **Figure I-6**), indicating that the CRSS simulations result in some level of modeled shortage in every scenario.

For the steady-state depletion demand scenarios (**Figure I-3** through **Figure I-6**), the median modeled Upper Basin depletions exhibit a slight decreasing trend over the simulation period. This trend reflects the future hydrology ensemble, which also exhibits a slight decreasing trend over time. For more information about the future hydrology used in this analysis, see **Appendix F**, Approach to Hydrologic Uncertainty. Further discussion on the Upper Basin modeled depletions is included below in **Section I.3.1**, Upper Basin Modeled Depletions.

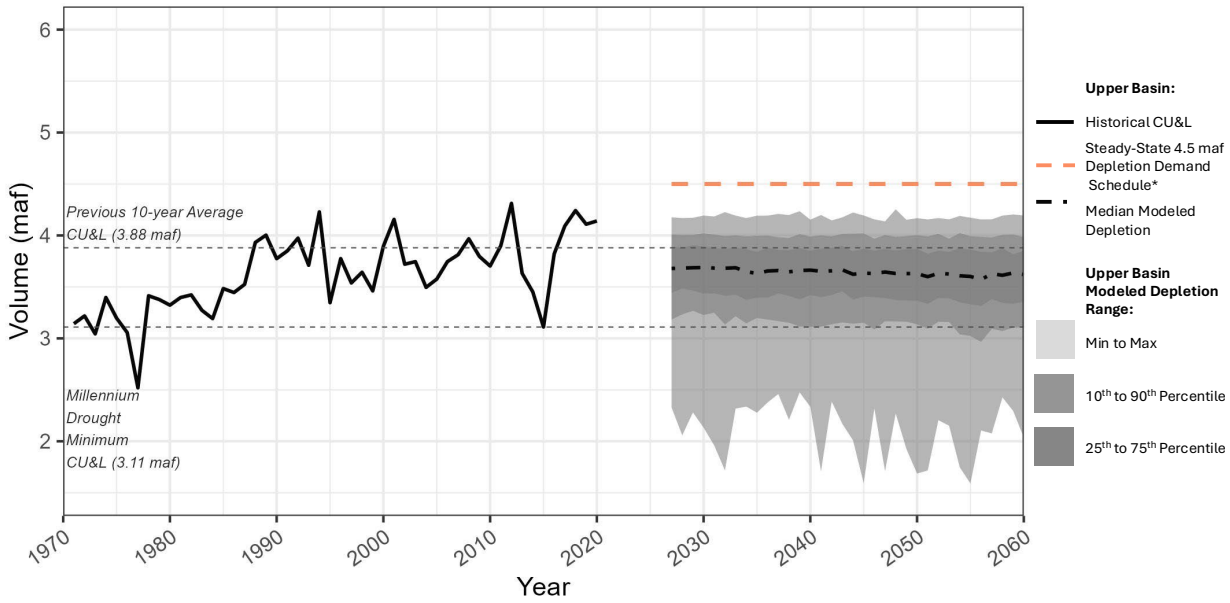


Figure I-2
Annual Upper Basin Historical Consumptive Uses and Losses with 90 percent 2016 UCRC Future Depletion Demand Schedule and Upper Basin Modeled Depletions, Continued Current Strategies Comparative Baseline

* The 90 percent 2016 UCRC depletion demand schedule is one of six depletion demand scenarios used in the sensitivity analysis in this appendix.

Note: Future depletion demand schedules exclude reservoir evaporation volumes from reservoirs undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation[2]. CRSS simulates consumptive use based on the provided depletion demand scenarios, and the available supply in each year of each simulation. To be comparable to the CRSS input and results, the historical CU&L does not include reservoir evaporation undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation but does include remaining Upper Basin reservoirs.

Annual Upper Basin Historical Consumptive Uses and Losses with Steady-State 4.5 maf Future Depletion Demand Schedule and Upper Basin Modeled Depletions, Continued Current Strategies Comparative Baseline

* The Steady-State 4.5 maf depletion demand schedule is one of six depletion demand scenarios used in the sensitivity analysis in this appendix.

Note: Future depletion demand schedules exclude reservoir evaporation volumes from reservoirs undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation[2]. CRSS simulates consumptive use based on the provided depletion demand scenarios, and the available supply in each year of each simulation. To be comparable to the CRSS input and results, the historical CU&L does not include reservoir evaporation undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation but does include remaining Upper Basin reservoirs.

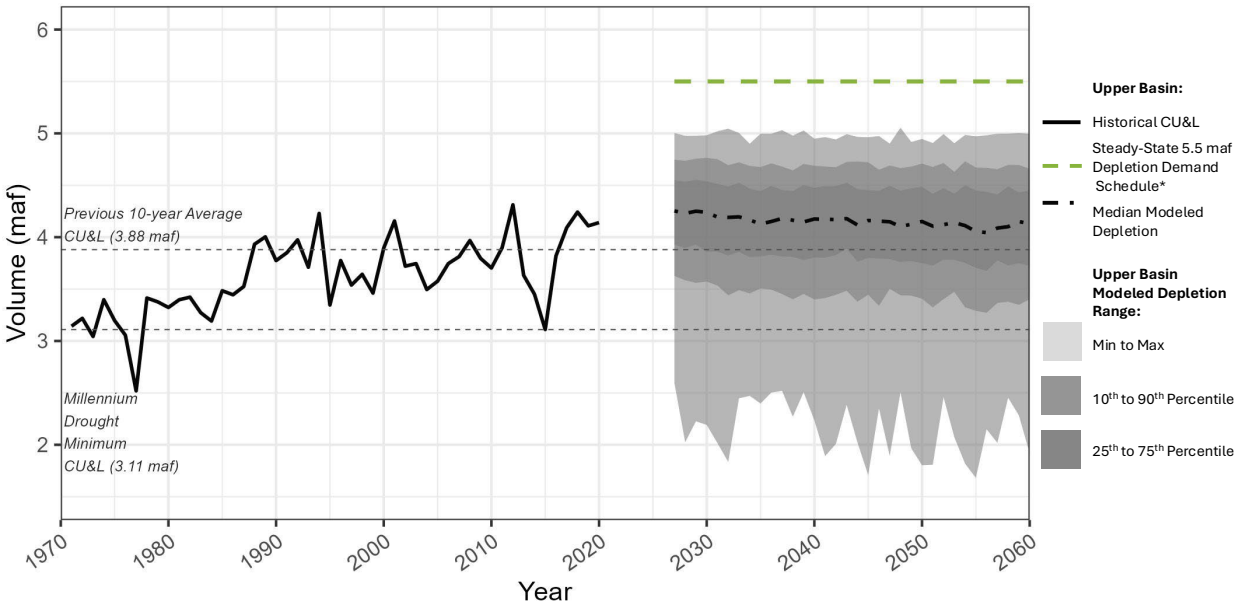

Figure I-4
Annual Upper Basin Historical Consumptive Uses and Losses with Steady-State 5.0 maf Future Depletion Demand Schedule and Upper Basin Modeled Depletions, Continued Current Strategies Comparative Baseline

* The Steady-State 5.0 maf depletion demand schedule is one of six depletion demand scenarios used in the sensitivity analysis in this appendix.

Note: Future depletion demand schedules exclude reservoir evaporation volumes from reservoirs undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation[2]. CRSS simulates consumptive use based on the provided depletion demand scenarios, and the available supply in each year of each simulation. To be comparable to the CRSS input and results, the historical CU&L does not include reservoir evaporation undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation but does include remaining Upper Basin reservoirs.

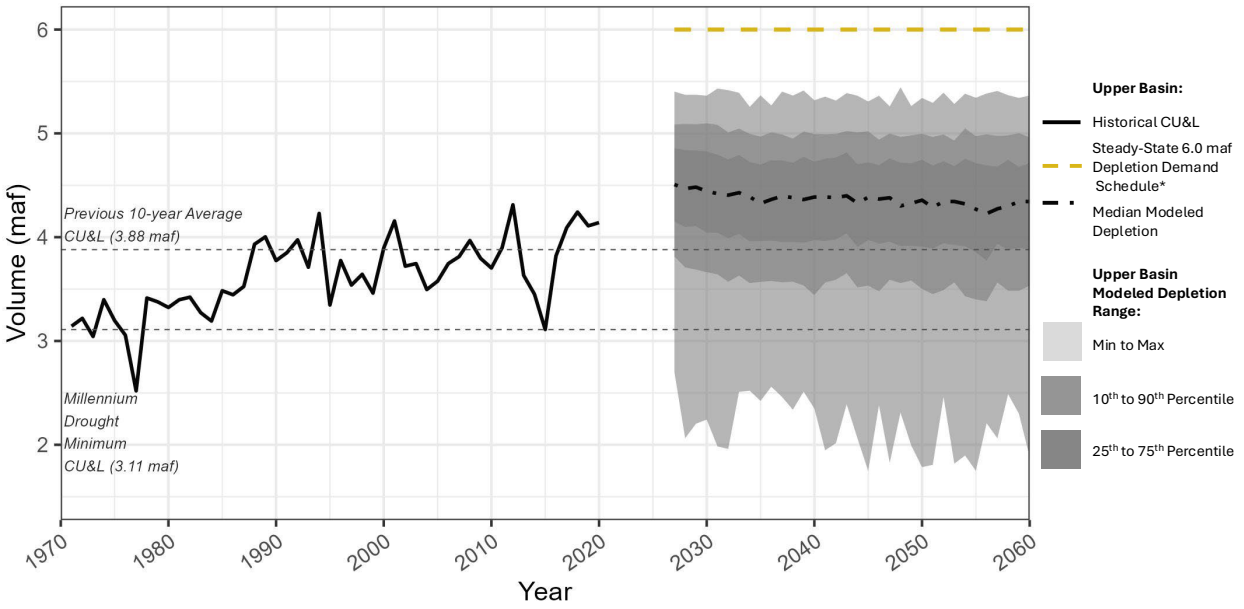

Figure I-5
Annual Upper Basin Historical Consumptive Uses and Losses with Steady-State 5.5 maf Future Depletion Demand Schedule and Upper Basin Modeled Depletions, Continued Current Strategies Comparative Baseline

* The Steady-State 5.5 maf depletion demand schedule is one of six depletion demand scenarios used in the sensitivity analysis in this appendix.

Note: Future depletion demand schedules exclude reservoir evaporation volumes from reservoirs undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation[2]. CRSS simulates consumptive use based on the provided depletion demand scenarios, and the available supply in each year of each simulation. To be comparable to the CRSS input and results, the historical CU&L does not include reservoir evaporation undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation but does include remaining Upper Basin reservoirs.

Figure I-6
Annual Upper Basin Historical Consumptive Uses and Losses with Steady-State 6.0 maf Future Depletion Demand Schedule and Upper Basin Modeled Depletions, Continued Current Strategies Comparative Baseline

* The Steady-State 6.0 maf depletion demand schedule is one of six depletion demand scenarios used in the sensitivity analysis in this appendix.
Note: Future depletion demand schedules exclude reservoir evaporation volumes from reservoirs undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation[2]. CRSS simulates consumptive use based on the provided depletion demand scenarios, and the available supply in each year of each simulation. To be comparable to the CRSS input and results, the historical CU&L does not include reservoir evaporation undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation but does include remaining Upper Basin reservoirs.

I.3 Sensitivity Analysis

For this sensitivity analysis, the six Upper Basin depletion demand scenarios were evaluated in combination with the seven different reservoir operating policies analyzed in this Final EIS:

- No Action Alternative
- Basic Coordination Alternative
- Enhanced Coordination Alternative
- Maximum Operational Flexibility Alternative
- Supply Driven Alternative (Lower Basin [LB Priority] approach)
- Representative Preferred Alternative
- Continued Current Strategies (CCS) Comparative Baseline

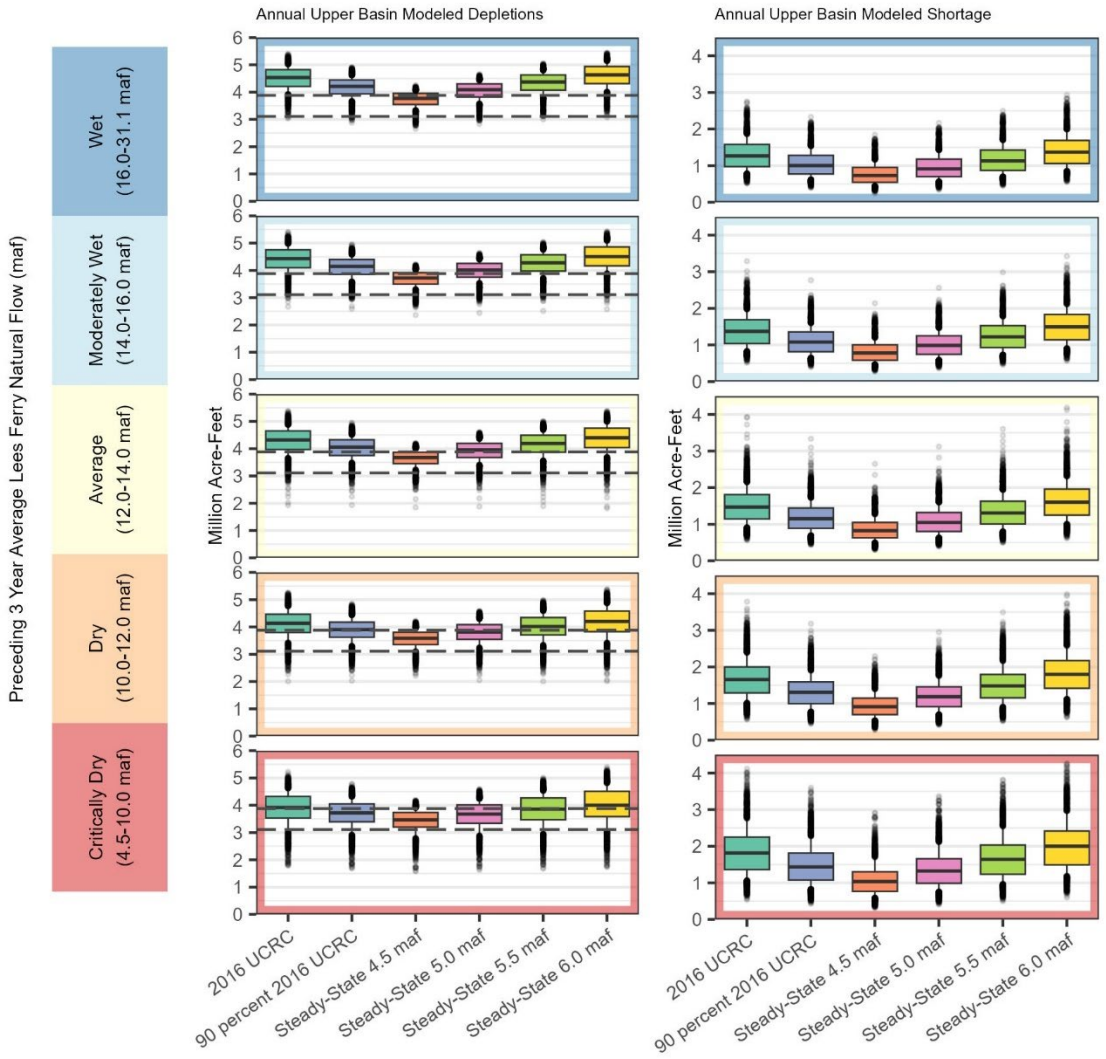
Only the Supply Driven Alternative using the LB Priority shortage distribution approach is used for this sensitivity analysis, as the emphasis is not on how different Lower Division State shortage distributions affect the results.

Each model was run with the same hydrologic ensemble and the initial reservoir conditions used throughout the Final EIS. See **Appendix A**, CRSS Modeling Documentation, for modeling assumptions associated with each alternative, and **Appendix F**, Approach to Hydrologic Uncertainty, and **Appendix G**, Initial Reservoir Conditions, for additional details on hydrology and initial condition assumptions.

The analyses presented in this appendix are based on the Decision Making Under Deep Uncertainty (DMDU) framework used in this Final EIS. DMDU is a non-probabilistic evaluation framework that compares scenarios across a broad range of plausible future conditions and evaluates their performance under varying hydrologic conditions. Additional background and technical information on the DMDU framework are provided in **Appendix E**, DMDU Overview and Approach, and **Chapter 3**, **Section 3.2.6** includes additional details on interpreting the figures and analyses.

The results were analyzed using the following metrics to better understand the impact of the six depletion demand scenarios on "system conditions" under each alternative:

- Upper Basin modeled depletions and modeled shortages
- Lake Powell and Lake Mead pool elevations
- Lee Ferry Compact Point 10-year volume
- Total Lower Basin reductions (shortage plus Lake Mead dead pool-related reductions)



The analysis is organized into four sections. **Section I.3.1** presents Upper Basin modeled depletions and modeled shortages using conditional boxplots. **Section I.3.2** presents Lake Powell and Lake Mead pool elevations, Lee Ferry Compact Point 10-year volume, and total Lower Basin reductions using conditional boxplots. **Sections I.3.3** and **I.3.4** present robustness and vulnerability analyses, respectively, for selected Lake Powell and Lake Mead elevation thresholds.

I.3.1 Upper Basin Modeled Depletions and Modeled Shortages

Figure I-7 shows annual Upper Basin modeled depletions and modeled shortages for the CCS Comparative Baseline across all depletion demand scenarios organized by the preceding three-year average Lees Ferry natural flow. Upper Basin modeled depletions and modeled shortages are only shown for the CCS Comparative Baseline as they do not vary significantly between alternatives, as discussed in **Section I.2**. The bold center line of each box represents the median value. The top and bottom of each box captures the 25th to 75th percentile of the modeled results, respectively. The lines extend to the 10th and 90th percentiles, and the outliers are shown as dots beyond these lines.

Dashed lines on the graph represent the previous 10-year average (3.88 maf) and the millennium drought minimum (3.11 maf) annual Upper Basin consumptive uses and losses, excluding reservoir evaporation for reservoirs with evaporation modeled explicitly in CRSS[2].

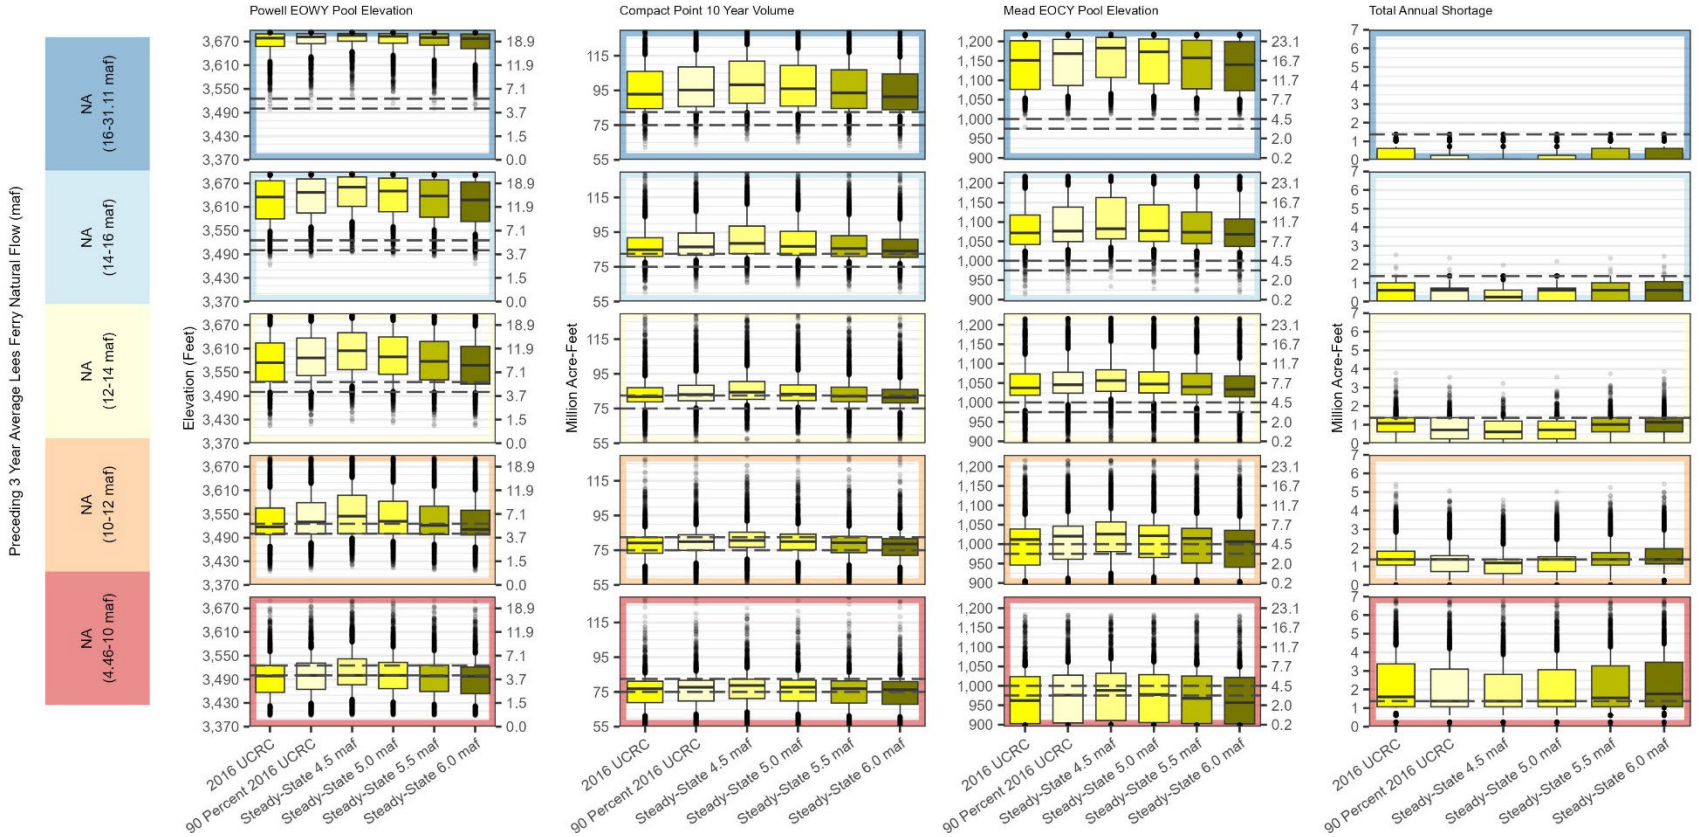
Figure I-7
Projected Annual Upper Basin Modeled Depletions and Shortage Across the 2016 UCRC Depletion Demand Schedule and Five Alternate Upper Basin Depletion Demand Scenarios Simulated Using Continued Current Strategies Comparative Baseline

Note: Future depletion demand schedules exclude reservoir evaporation volumes from reservoirs undistributed by state and other reservoirs where CRSS explicitly models reservoir evaporation[2]. CRSS simulates consumptive use based on the provided depletion demand scenarios, and the available supply in each year of each simulation.

In the Dry Flow Category, the median Upper Basin modeled depletion exceeds the 3.88 maf threshold for all depletion demand scenarios except the Steady State 4.5 maf and Steady State 5.0 maf scenarios. For the Steady State 4.5 maf depletion demand scenario, the 75th percentile is within 77.0 thousand acre-feet (kaf) of the average consumptive use over the last 10 years, while the median is 294.0 kaf less than the historical average consumptive use. For the Steady State 5.0 maf depletion demand scenario, the median is 68.0 kaf less than the historical average consumptive use.

The interquartile range of the Upper Basin modeled depletions increases as the average annual depletion demand increases. In the Dry and Critically Dry Flow Categories, the interquartile ranges differ less between the depletion demand scenarios. In drier conditions, limited water availability constrains depletions, so higher depletion demands do not result in proportionally higher depletions. Across all flow categories, the interquartile ranges remain above the minimum annual Upper Basin consumptive uses and losses (excluding reservoir evaporation) from the millennium drought. The Steady State 4.5 maf depletion demand scenario is the only depletion demand scenario with a 75th percentile below the historical average consumptive use of 3.88 maf; this occurs in the Average, Dry and Critically Dry Flow Categories.

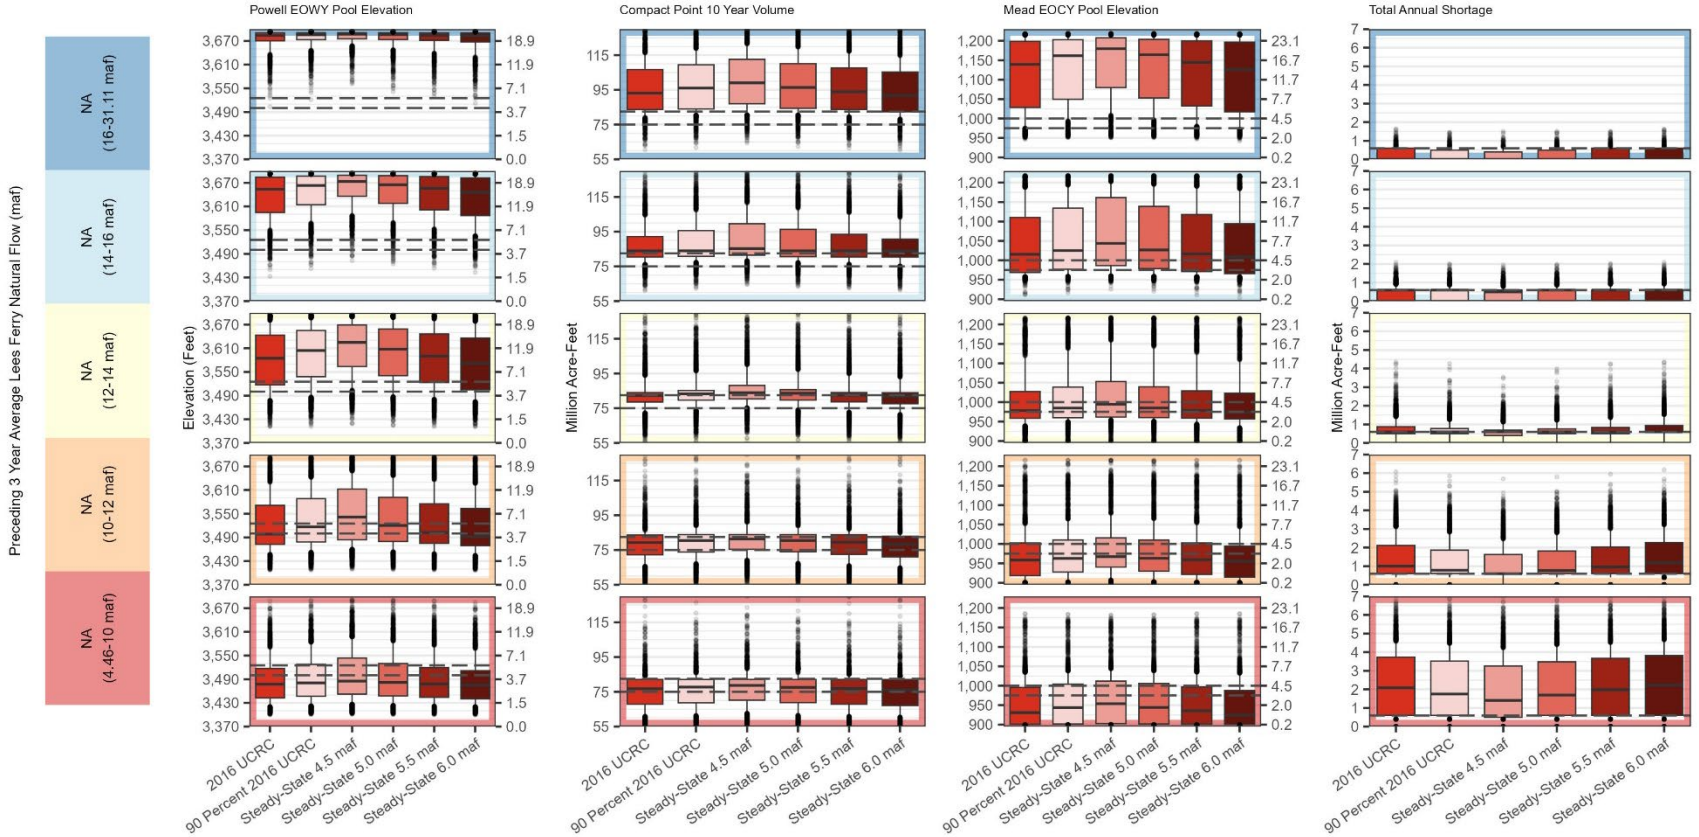
Upper Basin modeled shortages were calculated as the difference between the annual Upper Basin depletion demand scenario and the annual Upper Basin modeled depletions. The annual Upper Basin modeled shortages range between 246.0 kaf and 4.25 maf across all depletion demand scenarios, showing that modeled shortages occurred in every year of the model simulation under all analyzed hydrology sequences. Median Upper Basin modeled shortages typically range between 1.0 maf and 2.0 maf. Only the Steady State 6.0 maf depletion demand scenario reaches 2.0 maf of modeled shortage in the Critically Dry Flow Category. Both the magnitude and the interquartile range of Upper Basin modeled shortages increase under drier hydrologic conditions because a smaller portion of the depletion demand can be met. Similarly, Upper Basin modeled shortages increase as depletion demand schedules increase.



I.3.2 Impact on System Conditions

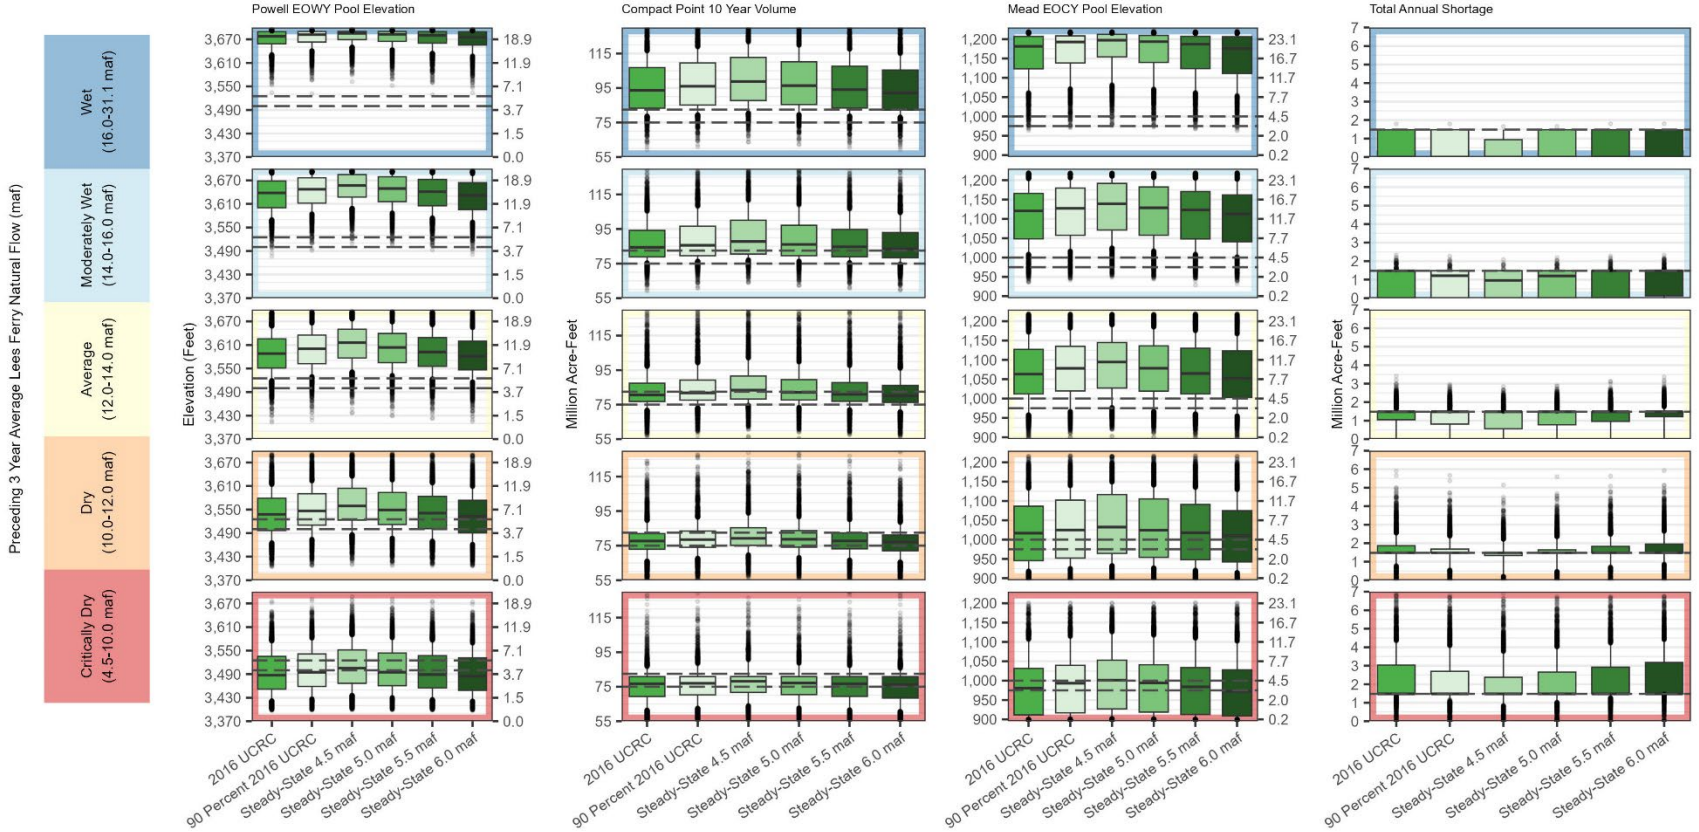
Figure I-8 through **Figure I-14** show Lake Powell end-of-water-year (EOWY) pool elevations, Lee Ferry Compact Point 10-year volumes, Lake Mead end-of-calendar-year (EOCY) pool elevations, and total Lower Basin shortage by flow category across all depletion demand scenarios for the CCS Comparative Baseline and all alternatives.

Dashed lines are included on the boxplots to identify critical elevations and thresholds. At Lake Powell, elevations 3,525 feet and 3,500 feet are included because of their importance to protecting infrastructure, power generation, and the ability to make downstream deliveries. At Lake Mead, elevations 1,000 feet and 975 feet are highlighted for the same reasons. The flow volumes of 82.5 maf and 75.0 maf are included in the Lee Ferry Compact Point 10-year volume. Finally, the Lower Basin total annual shortage (Lower Basin shortage plus dead pool-related reductions) for each alternative includes a dashed line to indicate the maximum shortage for the alternative. Total annual shortage may exceed this value because it includes dead pool-related reductions.



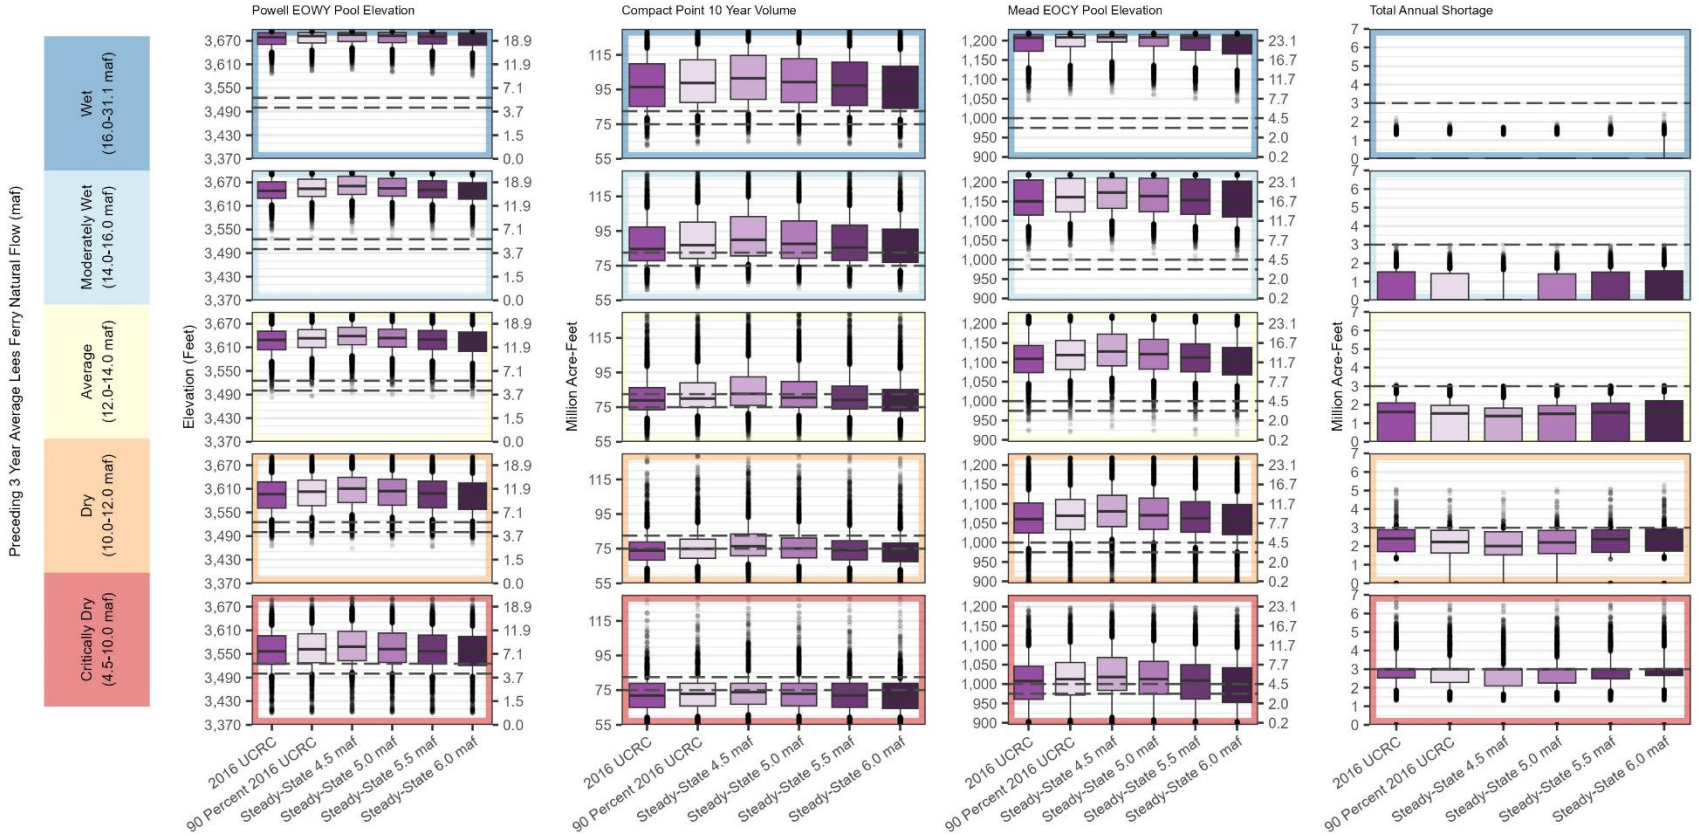
Except for the Supply Driven Alternative (LB Priority Approach), all alternatives and the CCS Comparative Baseline exhibit the same general trend. Compared with higher depletion demand scenarios, lower depletion demand scenarios result in higher Lake Powell elevations, higher Lee Ferry Compact Point 10-year volumes, higher Lake Mead elevations, and lower total Lower Basin shortages. Because higher depletion demand scenarios result in greater modeled Upper Basin depletions (see **Figure I-7**), less water flows into Lake Powell, reducing the volume of water available for release to Lake Mead.

Figure I-8
Lake Powell EOWY Elevation, Lee Ferry Compact Point 10-Year Volumes, Lake Mead EOCY Elevation, and Total Annual Shortage (Lower Basin Shortage and Dead Pool-Related Reductions) for Continued Current Strategies Across the Six Depletion Demand Scenarios



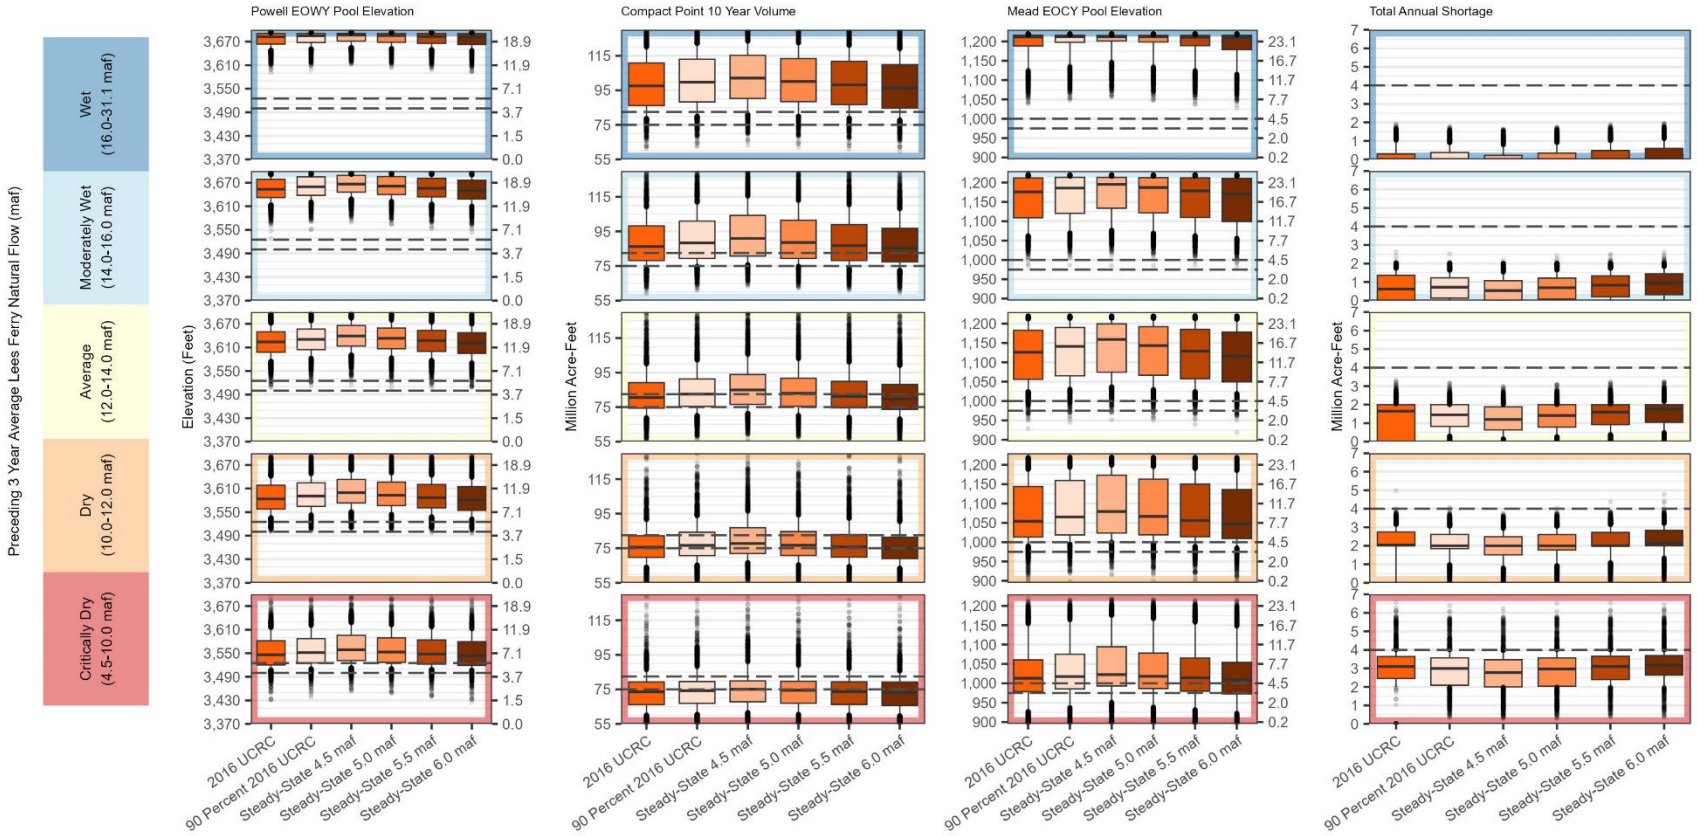
Note: The dashed line in the Total Annual Shortage column indicates a maximum reduction of 1.375 maf in the CCS Comparative Baseline.

Figure I-9
Lake Powell EOWY Elevation, Lee Ferry Compact Point 10-Year Volumes, Lake Mead EOCY Elevation, and Total Annual Shortage (Lower Basin Shortage and Dead Pool-Related Reductions) for the No Action Alternative Across the Six Depletion Demand Scenarios



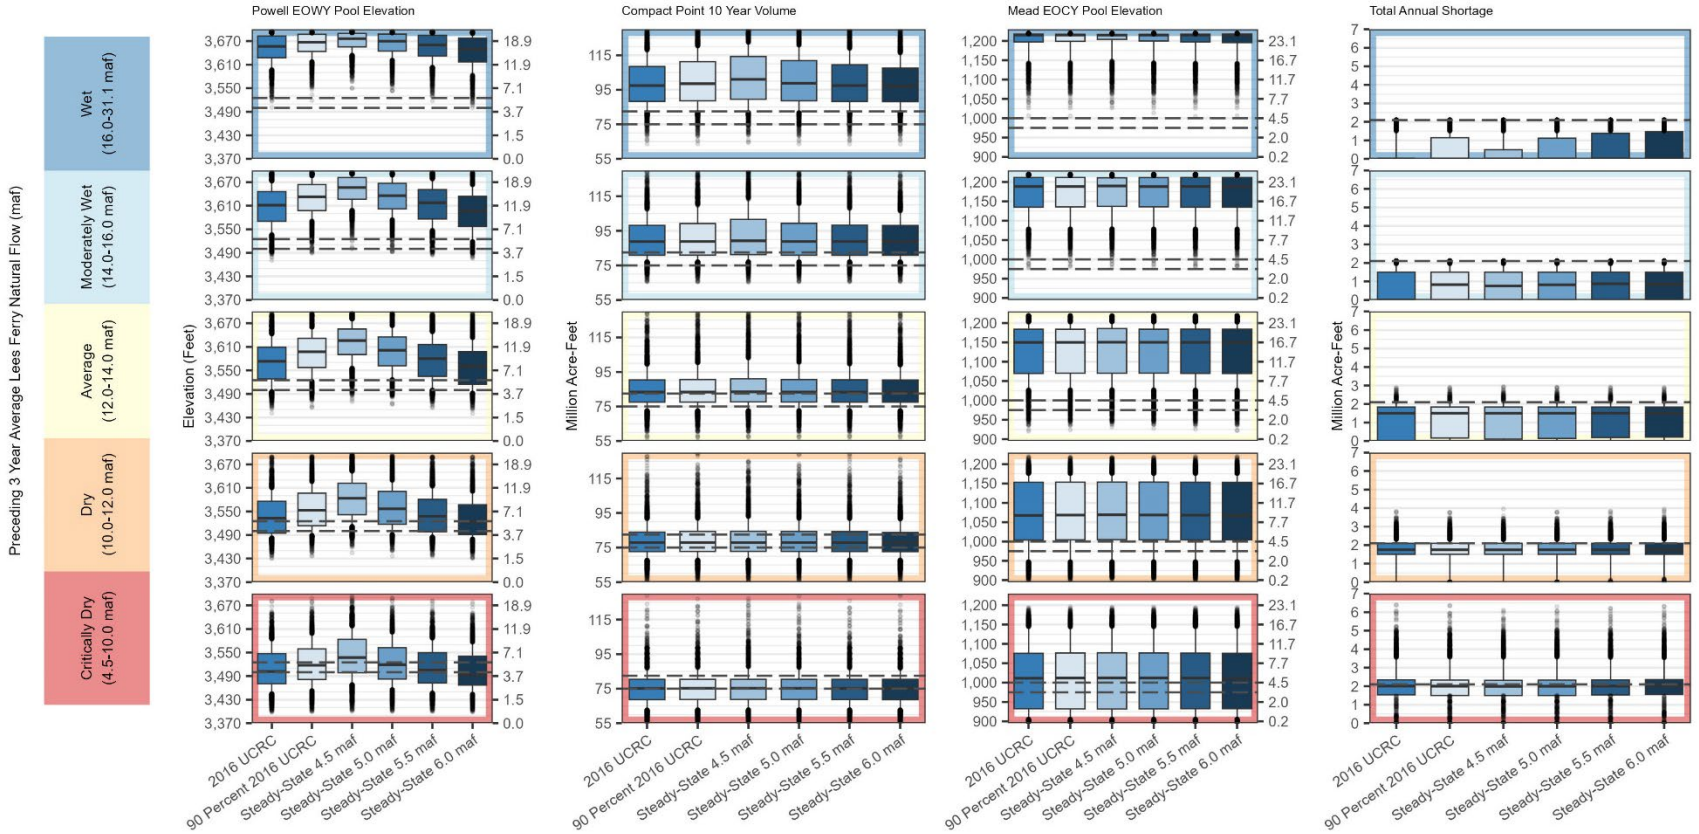
Note: The dashed line in the Total Annual Shortage column indicates a maximum shortage of 0.6 maf in the No Action Alternative.

Figure I-10
Lake Powell EOWY Elevation, Lee Ferry Compact Point 10-Year Volumes, Lake Mead EOCY Elevation, and Total Annual Shortage (Lower Basin Shortage and Dead Pool-Related Reductions) for the Basic Coordination Alternative across the Six Depletion Demand Scenarios



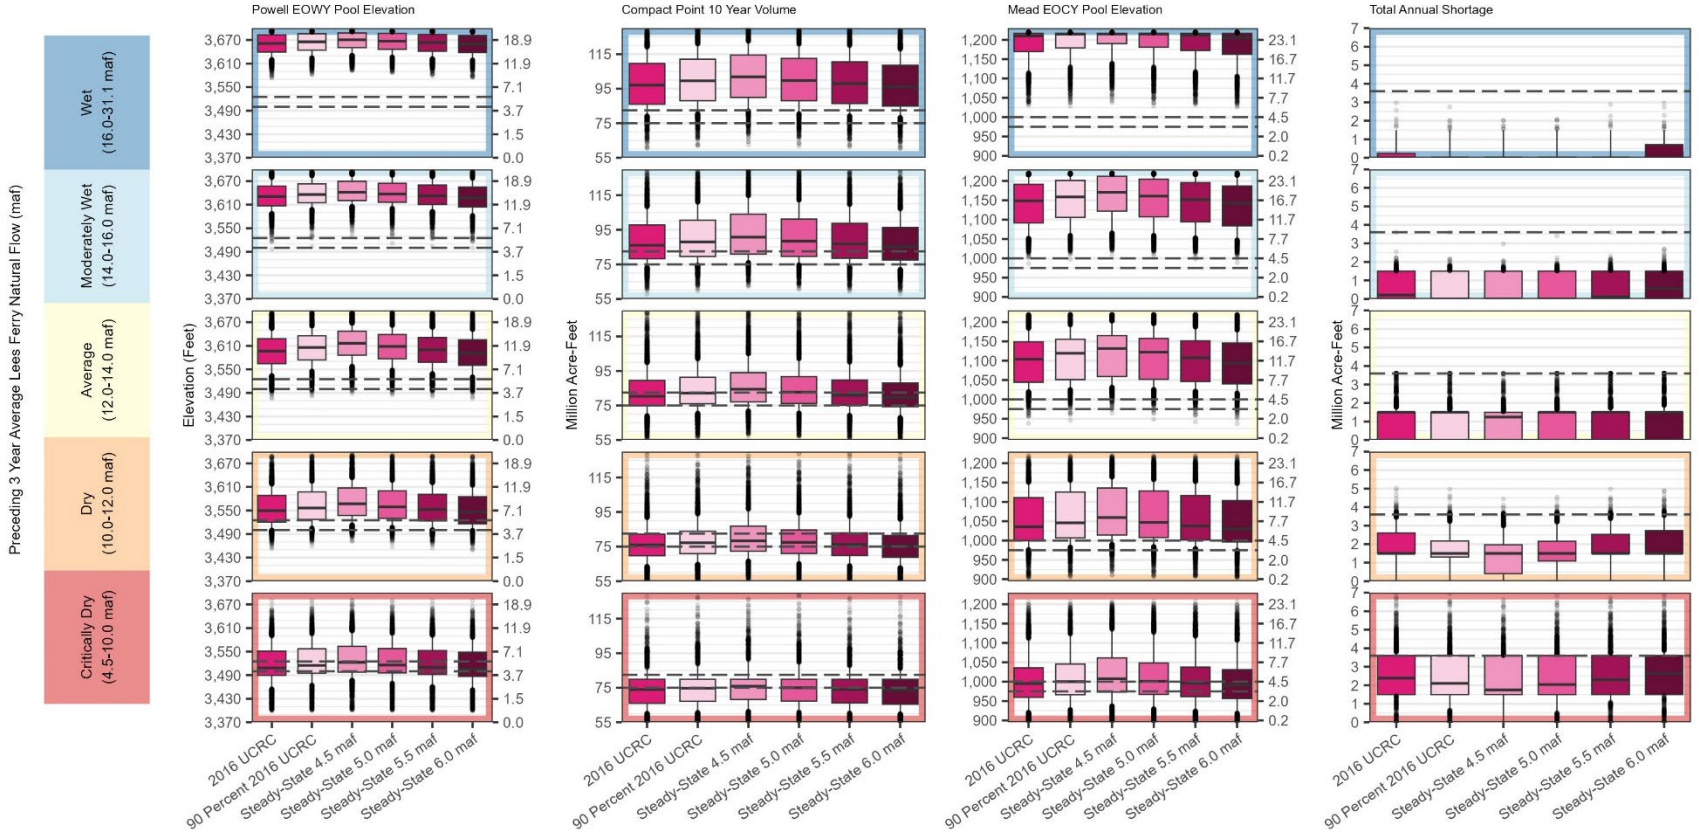
Note: The dashed line in the Total Annual Shortage column indicates a maximum shortage of 1.48 maf in the Basic Coordination Alternative.

Figure I-11
Lake Powell EOWY Elevation, Lee Ferry Compact Point 10-Year Volumes, Lake Mead EOCY Elevation, and Total Annual Shortage (Lower Basin Shortage and Dead Pool-Related Reductions) for the Enhanced Coordination Alternative Across the Six Depletion Demand Scenarios



Note: The dashed line in the Total Annual Shortage column indicates a maximum shortage of 3.0 maf in the Enhanced Coordination Alternative.

Figure I-12
Lake Powell EOWY Elevation, Lee Ferry Compact Point 10-Year Volumes, Lake Mead EOCY Elevation, and Total Annual Shortage (Lower Basin Shortage and Dead Pool-Related Reductions) for the Maximum Operational Flexibility Alternative Across the Six Depletion Demand Scenarios



Note: The dashed line in the Total Annual Shortage column indicates a maximum shortage of 4.0 maf in the Maximum Operational Flexibility Alternative.

Figure I-13
Lake Powell EOWY Elevation, Lee Ferry Compact Point 10-Year Volumes, Lake Mead EOCY Elevation, and Total Annual Shortage (Lower Basin Shortage and Dead Pool-Related Reductions) for the Supply Driven Alternative (LB Priority Approach) Across the Six Demand Scenarios

Note: The dashed line in the Total Annual Shortage column indicates a maximum shortage of 2.1 maf in the Supply Driven Alternative (LB Priority Approach).

Figure I-14
Lake Powell EOWY Elevation, Lee Ferry Compact Point 10-Year Volumes, Lake Mead EOCY Elevation, and Total Annual Shortage (Lower Basin Shortage and Dead Pool-Related Reductions) for the Representative Preferred Alternative Across the Six Demand Scenarios

Note The dashed line in the Total Annual Shortage column indicates a maximum shortage of 3.6 maf in the Representative Preferred Alternative.

For the Supply Driven Alternative (LB Priority approach) (**Figure I-13**), lower steady-state depletion demand scenarios also result in higher Lake Powell elevations. Because Lake Powell releases are based on 65 percent of the preceding 3-year average Lees Ferry natural flow, there are few differences in Lake Mead elevations among the depletion demand scenarios. Under this alternative, Lake Powell releases are determined irrespective of Lake Powell elevation, resulting in similar downstream conditions regardless of the depletion demand scenario. Similarly, there are also few differences in total Lower Basin shortage across the depletion demand scenarios because shortages are based on Lake Mead elevation. Differences in the Compact Point 10-year volumes are observed across depletion demand scenarios, primarily due to infrastructure constraints at high and low Lake Powell elevations. At higher Lake Powell elevations, which occur more frequently in the Moderately Wet and Wet Flow Categories, lower steady-state depletion demand scenarios result in more instances of spill avoidance releases, which increases the Compact Point 10-year volumes.

I.3.3 Robustness

A robustness analysis was used to evaluate each alternative's ability to maintain Lake Powell and Lake Mead above critical elevation thresholds. In this context, robustness is defined as an alternative's ability to achieve a specified level of performance across a broad range of potential future conditions under a given depletion demand scenario.

For this analysis, the specified levels of performance are maintaining Lake Powell above elevation 3,500 feet[6] and Lake Mead above elevation 975 feet[7] during every month of the 34-year simulation period. A modeled future that meets these performance criteria is considered a "successful future." Robustness is expressed as the percentage of the 400 modeled futures that are successful for each alternative–depletion demand scenario combination.

Table I-1 and **Table I-2** compare the robustness of each alternative and depletion demand scenario with respect to maintaining reservoir elevations above 3,500 feet at Lake Powell and 975 feet at Lake Mead, respectively. Of note, the Representative Preferred Alternative results presented in this appendix do not include PIP releases, which would provide additional protection against reaching critical thresholds. In **TA 3**, Hydrologic Resources, **Figures TA 3-7** and **TA 3-12** present the robustness of Lake Powell at elevation 3,500 feet and Lake Mead at elevation 975 feet, respectively, with PIP releases included.

[6] This elevation at Lake Powell provides a 10-foot buffer to protect critical infrastructure, water delivery, and hydropower, which are critically impacted at an elevation of 3,490 feet. See **Section TA 3.2.1**, Issue 1, in **TA 3,** Hydrologic Resources.
[7] This elevation at Lake Mead provides 25-foot buffer from 950 feet - the elevation below which water can only be released through the intake towers, constraining both the volume of water able to be released as well as the ability to generate power.

Table I-1
Robustness of Lake Powell Elevation 3,500 Feet

	Continued Current	No Action	Basic Coordination	Enhanced Coordination	Max Flexibility	Supply Driven (LB Priority)	Representative Preferred
2016 UCRC	18%	4%	13%	74%	86%	18%	28%
90% 2016 UCRC	23%	4%	14%	77%	91%	28%	34%
Steady-State 4.5 maf	25%	4%	16%	79%	94%	45%	40%
Steady-State 5.0 maf	23%	4%	14%	76%	91%	30%	35%
Steady-State 5.5 maf	19%	3%	13%	73%	89%	21%	31%
Steady-State 6.0 maf	17%	3%	11%	70%	86%	15%	26%

Note: Percent of futures in which Lake Powell remains above 3,500 feet in 100 percent of months.

Table I-1 shows that, across all alternatives, the Steady State 4.5 maf scenario resulted in the highest robustness, while the Steady State 6.0 maf scenario resulted in the lowest robustness for maintaining Lake Powell above 3,500 feet. For most alternatives, the different depletion demand scenarios resulted in similar levels of robustness, with differences typically ranging from 1 to 14 percent. The Supply Driven Alternative (LB Priority approach) is the clear outlier. Its robustness varies by 30 percent, ranging from 45 percent of futures for the Steady State 4.5 maf scenario to 15 percent of futures for the Steady State 6.0 maf scenario. Because Lake Powell releases are based on 65 percent of the preceding 3-year average natural flow rather than reservoir elevation, the required release in Supply Driven Alternative (LB Priority approach) is the same regardless of the Lake Powell elevation. As a result, there is a large difference in robustness at Lake Powell across the assumed depletion demand scenarios. The Representative Preferred Alternative exhibits the next largest difference in robustness between the Steady State 4.5 maf and Steady State 6.0 maf scenarios, at 14 percent.

Table I-2 compares the robustness of alternatives with respect to Lake Mead's monthly pool elevation remaining above elevation 975 feet in all months.

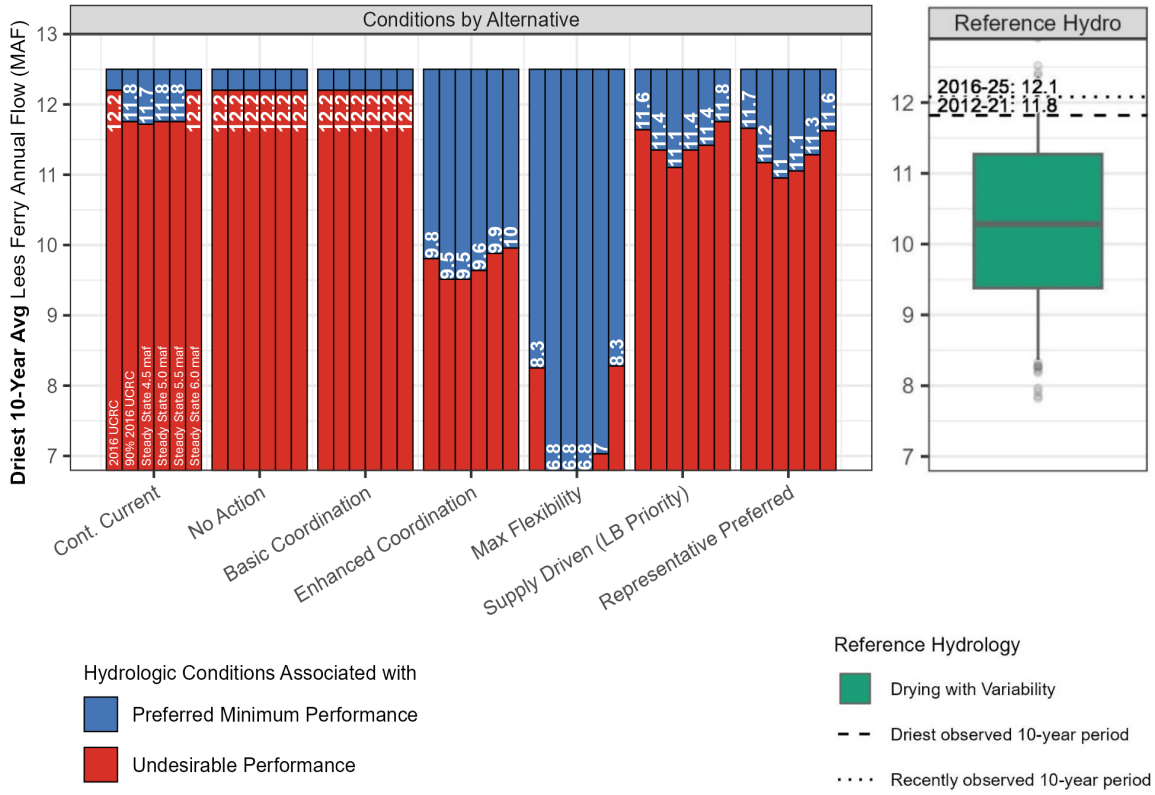
Table I-2
Robustness of Lake Mead Elevation 975 Feet

	Continued Current	No Action	Basic Coordination	Enhanced Coordination	Max Flexibility	Supply Driven (LB Priority)	Representative Preferred
2016 UCRC	38%	21%	50%	65%	70%	61%	50%
90% 2016 UCRC	43%	24%	55%	69%	75%	61%	54%
Steady-State 4.5 maf	48%	25%	58%	72%	79%	61%	61%
Steady-State 5.0 maf	43%	24%	55%	68%	75%	61%	54%
Steady-State 5.5 maf	39%	22%	51%	65%	70%	61%	52%
Steady-State 6.0 maf	35%	18%	46%	61%	68%	60%	49%

Note: Percent of futures in which Lake Mead remains above 975 feet in 100 percent of months.

As at Lake Powell, the Steady State 4.5 maf scenario resulted in the highest robustness, while the Steady State 6.0 maf scenario resulted in the lowest robustness for maintaining Lake Mead above elevation 975 feet. Also consistent with the Lake Powell results, all alternatives except the Supply Driven Alternative (LB Priority approach) exhibited similar levels of robustness across the depletion demand scenarios, with differences typically ranging from 7 to 13 percent. In contrast to Lake Powell results, the Supply Driven Alternative (LB Priority approach) showed no change in robustness at Lake Mead across the depletion demand scenarios. This is because Lake Powell releases are computed as 65 percent of the preceding 3-year average natural flow, producing the same release for a given hydrologic year regardless of the assumed Upper Basin depletion demand scenario.

I.3.4 Vulnerability



A vulnerability analysis was used to identify the hydrologic conditions that tend to result in an undesirable outcome. In this context, vulnerability was defined as an alternative's susceptibility to undesirable performance under a given depletion demand scenario across a broad range of potential future hydrologic conditions.

For this analysis, undesirable performance is defined as Lake Powell falling below elevation 3,500 feet or Lake Mead falling below elevation 975 feet at any time during the 34-year simulation period. Vulnerability complements the robustness analysis by using information from both successful and unsuccessful modeled futures to identify a skillful hydrologic predictor that relates hydrologic conditions to the likelihood a modeled outcome will be successful or unsuccessful under a given alternative and depletion demand scenario. This analysis is useful because it characterizes each alternative-depletion demand scenario combination in terms of the hydrologic conditions that are likely to result in undesirable performance, thereby identifying the conditions under which an alternative is vulnerable.

Figure I-15 shows the flow conditions likely to cause Lake Powell elevations to fall below 3,500 feet for each alternative and depletion demand scenario. This definition of undesirable performance is based on the robustness analysis presented in **Table I-1** above, which defined a future as successful when an alternative maintains elevations above 3,500 feet in every month.

For this vulnerability analysis, the driest 10-year average Lees Ferry annual flow was identified as the streamflow summary statistic most skillful at predicting undesirable performance (see **Appendix E**, DMDU Overview and Approach, **Section E.3** for further information). Vulnerability thresholds for each alternative-depletion demand scenario combination are compared to the observed record and the Drying with Variability Ensemble (shown in the Reference Hydrology panel) using this streamflow summary statistic. For reference, the driest observed 10-year average flow (2012-2021; 11.8 maf) and the most recent 10-year average flow (2016-2025; 12.1 maf) are also shown as dashed and dotted lines, respectively.

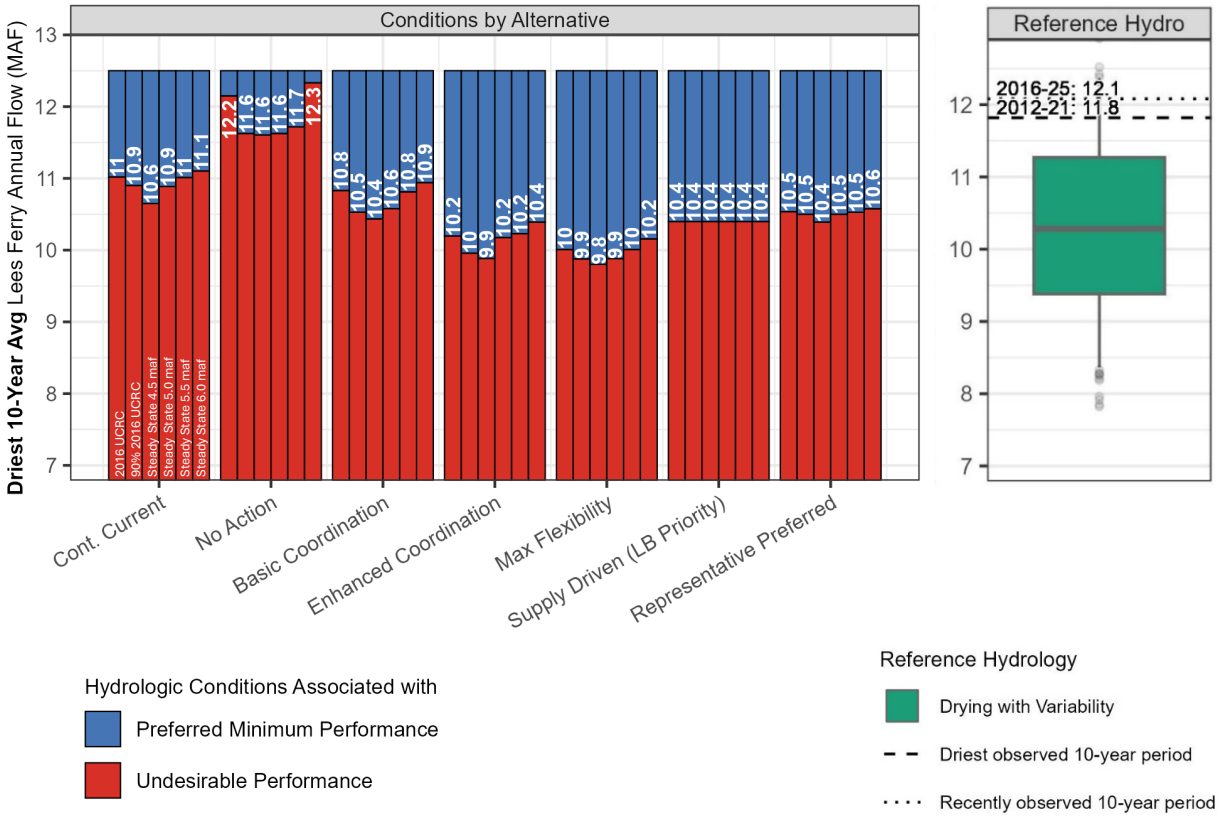
Figure I-15
Conditions that Could Cause Lake Powell Elevation to Fall below 3,500 feet in One or More Months Across All Depletion Demand Scenarios and Alternatives

Across all alternatives, the Steady State 4.5 maf scenario generally has the lowest vulnerability threshold, indicating that the alternatives are less vulnerable under this depletion demand scenario than under the higher depletion demand scenarios. Vulnerability under the 2016 UCRC scenario follows closely behind that of the Steady State 6.0 maf scenario.

The range of vulnerability thresholds across depletion demand scenarios indicates how sensitive each alternative is to the assumed depletion demands. The No Action and Basic Coordination Alternatives show negligible sensitivity, with identical vulnerability thresholds across all depletion demand scenarios. This is consistent with the robustness scores in **Table I-1**, which indicate these alternatives perform poorly regardless of depletion demand scenario.

The CCS Comparative Baseline and Enhanced Coordination Alternative have vulnerability thresholds that vary by 0.5 maf across depletion demand scenarios, while the Supply Driven Alternative (LB Priority approach) and the Representative Preferred Alternative have vulnerability thresholds that vary by 0.7 maf. These small ranges indicate relatively low sensitivity to the depletion demand scenario. For the Maximum Operational Flexibility Alternative, the vulnerability threshold is at or near the bottom of the figure (ranging from 6.8 to 7.0 maf) for the 90 percent 2016 UCRC, Steady State 4.5, 5.0, and 5.5 maf scenarios. Under the 2016 UCRC and Steady State 6.0 maf scenarios, the thresholds are noticeably higher at 8.3 maf. However, this is likely due to the high

robustness scores obtained by the Maximum Operational Flexibility Alternative, which can make it difficult to identify and compare vulnerability thresholds across depletion demand scenarios. In this case, robustness scores are a better indicator of sensitivity, which only vary between 86 percent under the Steady State 6.0 maf scenario to 94 percent under the Steady State 4.5 maf scenario.



Comparing the vulnerability thresholds with the reference hydrology panel indicates that all alternatives except the Enhanced Coordination and Maximum Operational Flexibility Alternatives would be reasonably likely to experience Lake Powell elevations below 3,500 feet over the next 34 years, regardless of the depletion demand scenario. This is because the alternatives are vulnerable to about 75 percent or more of the traces in the Drying with Variability Ensemble, which represents a drier future with conditions like those experienced in recent history. The Enhanced Coordination Alternative may or may not be vulnerable, since it is vulnerable under nearly 50 percent of the traces in the Drying with Variability Ensemble but not vulnerable based on conditions that have occurred historically, regardless of the depletion demand scenarios. The Maximum Operational Flexibility Alternative is reasonably unlikely to experience elevations below 3,500 feet because it is vulnerable under less than 10 percent of the traces in the Drying with Variability Ensemble and not vulnerable under historical conditions, regardless of the depletion demand scenarios.

Figure I-16 shows the flow conditions likely to cause Lake Mead to fall below 975 feet for each alternative-depletion demand scenario combination. This definition of undesirable performance is based on the robustness analysis presented in **Table I-2** above, which defined a future as successful when an alternative maintains elevations above 975 feet in every month.

Like the Lake Powell vulnerability analysis, this vulnerability analysis identified the driest 10-year average Lees Ferry annual flow as the streamflow summary statistic most skillful at predicting undesirable performance.

Similar to the Lake Powell vulnerability analysis, the Steady State 4.5 maf scenario generally has the lowest vulnerability thresholds across depletion demand scenarios, while the Steady State 6.0 maf scenario generally has the highest vulnerability thresholds. The Supply Driven Alternative (LB Priority approach) is not sensitive to the depletion demand scenario, with the same vulnerability threshold across all depletion demand scenarios. The Representative Preferred Alternative is relatively insensitive, with vulnerability thresholds varying by only 0.2 maf. The remaining action alternatives and the CCS Comparative Baseline are also relatively insensitive, with thresholds varying by 0.4 maf for the Maximum Operational Flexibility Alternative and 0.5 maf for both the CCS Comparative Baseline and Enhanced Coordination Alternative. The No Action Alternative is the most sensitive, with vulnerability thresholds varying by 0.7 maf.

Figure I-16
Conditions that Could Cause Lake Mead Elevation to Fall B 975 feet in One or More Months Across All Depletion Demand Scenarios and Alternatives

Comparing the vulnerability thresholds with the Drying with Variability Ensemble indicates that the CCS Comparative Baseline, No Action Alternative, and Basic Coordination Alternative would be reasonably likely to experience elevations below 975 feet over the next 34 years, regardless of the depletion demand scenario. The No Action Alternative is vulnerable under conditions similar to those observed in recent history and in over 75 percent of traces in the Drying with Variability Ensemble. Although the CCS Comparative Baseline and Basic Coordination Alternative are not vulnerable to historical flows, they are vulnerable in 50 to 75 percent of traces in the Drying with Variability Ensemble, regardless of the depletion demand scenario. The remaining alternatives may or may not be vulnerable, as they are vulnerable to about 50 percent of traces in the Drying with Variability Ensemble but not under historical conditions.

I.4 Summary and Conclusions

This sensitivity analysis examined how sensitive the different alternatives are to different Upper Basin depletion demand assumptions. Differences in Lower Basin demands are already represented through the alternatives' different shortage and surplus provisions. Multiple Upper Basin depletion demand scenarios, including steady-state demand levels ranging from 4.5 maf to 6.0 maf, were

evaluated in all hydrologic scenarios for all alternatives and the CCS Comparative Baseline. The Upper Basin modeled depletions and modeled shortages, impact on system conditions, robustness, and vulnerability were compared to evaluate their sensitivity to Upper Basin demand assumptions.

Across nearly all alternatives and performance metrics, lower Upper Basin steady-state depletion demand scenarios (e.g., 4.5 maf) resulted in higher elevations at Lake Powell and Lake Mead, greater 10-year Lee Ferry volumes, and smaller Lower Basin shortages compared to higher steady-state depletion demand scenarios. Consistent with these results, the Steady State 4.5 maf scenario resulted in the highest robustness at maintaining Lake Powell above elevation 3,500 feet and Lake Mead above elevation 975 feet, whereas the Steady State 6.0 maf scenario resulted in the lowest robustness.

The CCS Comparative Baseline, No Action, Basic Coordination, and Enhanced Coordination, Alternatives each showed relatively little variation in robustness and vulnerability across the different Upper Basin depletion demand scenarios. These alternatives consistently showed only minor changes in robustness scores and in the drought severity associated with vulnerability (differences in vulnerability thresholds typically range from 0.0 to 0.5 maf), indicating that their performance is less sensitive to assumed Upper Basin depletion demands than that of the other alternatives.

The Maximum Operational Flexibility Alternative followed similar trends to the CCS Comparative Baseline, No Action, Basic Coordination and Enhanced Coordination Alternatives except when considering the vulnerability at Lake Powell. Like the other alternatives, vulnerability thresholds for the Maximum Operational Flexibility Alternative changed modestly across the lower depletion demand scenarios, but changed sharply at the 6.0 maf depletion demand scenario. However, this sensitivity is likely due to the high robustness scores exhibited by this alternative (86 to 94 percent), which can make it difficult to identify and compare vulnerability thresholds.

The Supply Driven Alternative (LB Priority approach) behaved differently from all others. Because releases from Lake Powell are fixed at 65 percent of the preceding 3-year average natural flow, Lake Powell releases are typically the same for all depletion demand scenarios. As a result, at Lake Powell, robustness exhibited the largest spread of any alternative (a 30 percent range between Steady State 4.5 and 6.0 maf scenarios), and vulnerability thresholds varied by a 0.7 maf range. In contrast, at Lake Mead, both robustness and vulnerability were nearly identical across all depletion demand scenarios, making the Supply Driven Alternative the least sensitive alternative at Lake Mead to Upper Basin depletion demand assumptions.

The Representative Preferred Alternative exhibited a larger range in robustness across the depletion demand scenarios at Lake Powell (a 14 percent range between the Steady State 4.5 and 6.0 maf scenarios), second only to the Supply Driven Alternative (LB Priority approach), indicating a greater degree of sensitivity to the depletion demand scenarios. At Lake Mead, the range of vulnerability thresholds was lower than other alternatives except for the Supply Driven Alternative (LB Priority approach), showing a 0.2 maf difference between the Steady State 4.5 maf and 6.0 maf depletion demand scenarios. However, robustness scored varied from 49 to 61 percent across the depletion demand scenarios, a range similar to the other action alternatives except Supply Driven (LB Priority approach).

For all alternatives, different depletion demand scenarios did not change conclusions when comparing vulnerability thresholds to the Reference Hydrology. For Lake Powell, all alternatives except the Enhanced Coordination and Maximum Operational Flexibility Alternatives are reasonably likely to experience at least one occurrence below elevation 3,500 feet. For Lake Mead, the Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (LB Priority) Alternatives may or may not be vulnerable to elevations below 975 feet because they are vulnerable in about 50 percent of traces in the Drying with Variability ensemble. In contrast, the CCS Comparative Baseline, No Action Alternative, and Basic Coordination Alternative are reasonably likely to experience elevations below 975 feet.

Appendix J. Sensitivity Analysis – Effects of Assumed Parameter Values on 602(a) Storage

J.1 Introduction

The No Action, Basic Coordination, and Representative Preferred Alternatives incorporate storage equalization operations, which include modeling assumptions regarding the 602(a) storage requirement in Lake Powell. Pursuant to the Long-Range Operating Criteria (LROC), annual releases from Lake Powell greater than the minimum objective release occur when Upper Basin storage is greater than the storage required by 602(a) storage, and the storage in Lake Powell is forecast to be greater than the storage in Lake Mead by the end of that water year. Under these conditions, additional releases are made from Lake Powell to equalize the storage in Lake Mead with the storage in Lake Powell by the end of the water year.

The 602(a) storage requirement specifies the amount of storage in Upper Basin reservoirs necessary to assure deliveries to the Lower Basin without impairment to the annual consumptive use in the Upper Basin. If the 602(a) storage requirement is not met, equalization does not occur. The LROC specifies that all relevant factors including historic stream flows, the most critical period of record, the probabilities of water supply, and estimated future depletions be considered when determining the 602(a) storage amount. Calculating the 602(a) storage based on these factors depends on values for several parameters including assumed future Upper Basin water demands, historical natural flow, the magnitude and duration of a critical period flow, and the percent shortage in the Upper Basin during the critical period.

This appendix provides a brief overview of the 602(a) storage requirement and the numerical equation used to calculate the required storage volume. It also provides updated data on Upper Basin water demands and the historical natural flow record, reflecting changes since the 2007 Interim Guidelines. Finally, it analyzes how the 602(a) storage determination varies based on different variables such as ranges of critical period flow, lengths of critical period, and a range of assumed Upper Basin shortage percent during the critical period.

J.2 Description of 602(a) Storage Requirement

Appendix A, CRSS Model Documentation describes the implementation of the 602(a) storage requirement used in this Final EIS. Since 2004, the Interim 602(a) Storage Guideline (69 Fed. Reg. 28945) has been included in the Colorado River Simulation System (CRSS) and relies on parameter values from the 1994 FORTRAN-based CRSS. The algorithm estimates the amount of storage needed in the Upper Basin to ensure that both the minimum objective release and Upper Basin depletions can be met over a future period of n years, assuming inflows during that period match those observed during the most critical historical period.

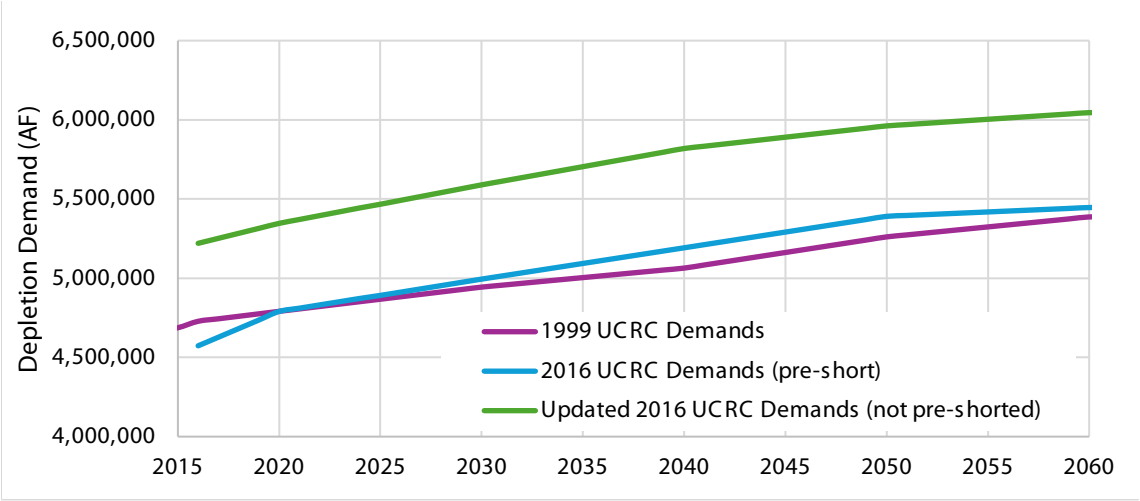
The previously identified critical period for the Colorado River Basin occurred from 1953 to 1964, spanning 12 years. Inflows from this period are used in the 602(a) storage calculation.

At the start of each calendar year, the 602(a) storage requirement is calculated using the following formula (**Table J-1** describes each parameter):

$$602(a) = \{(UBDepletion + UBEvap)* (1 - percentShort/ 100) + minObjRel - criticalPeriodInflow\} * criticalPeriodLength + minPowerPoolStorage$$

Table J-1
Description of Parameters included in the 2007 Interim Guidelines 602(a) Storage Requirement Formula

602(a) Storage Parameters	Definition	Value from 2007 FEIS	Source Data
602(a)	the 602(a) storage requirement		
UBDepletion	the average over the next 12 years of the Upper Basin scheduled depletions	Depends on simulation start year	2007 Interim Guidelines, Appendix C – 1999 Upper Colorado River Commission Depletion Demand Schedule
UBEvap	the average annual evaporation loss in the Upper Basin	560 kaf	Value from CRSS Cyber mainframe
percentShort	the percent shortage applied to Upper Basin depletions during the critical period	0%	Value from CRSS Cyber mainframe
minObjRel	the minimum objective release to the Lower Basin	8.23 maf	1970 Long-range Operating Criteria
criticalPeriodInflow	average annual natural inflow into the Upper Basin during the critical period (1953–1964)	12.18 maf	From WY 1953-1964 Natural Flow dated 6.22.07
criticalPeriodLength	number of years of the critical period (1953-1964)	12	Based on above period
minPowerPoolStorage	the cumulative amount of minimum power pool storage to be preserved in Upper Initial Unit reservoirs	5.179 maf	Value from CRSS Cyber mainframe



To facilitate further exploration of 602(a) storage requirement sensitivity, an extension of the current equalization line in CRSS was based on the same source data (shown above) originally used for 2007 Interim Guidelines equalization line estimation. To better understand the equalization line sensitivity to variations in specific parameters the following parameters were updated to use the latest available version of that parameter, Upper Basin depletion schedule and annual natural flow; or varied across

a range of potential values, critical period inflow and length, and percent shortage, to understand the impact on the computed 602(a) storage.

J.3 Upper Basin Depletion Schedule

The Upper Basin depletion schedule titled the Updated 2016 Upper Colorado River Commission (UCRC) depletion demand schedule, further described in **Appendix L**, Upper Division States Depletion Schedules, replaces the 1999 UCRC depletion demand schedule used during the 2007 Interim Guidelines. The 1999 UCRC schedule pre-shorted depletions because a portion of depletion demands could not be met in the high Upper Basin tributaries that were not represented in the previous version of CRSS. The latest CRSS (version 6) now incorporates methods to apply high tributary shortage directly in CRSS and uses the Updated 2016 UCRC depletion demand schedule. **Figure J-1** compares the Updated 2016 UCRC demands, the 2016 UCRC demands that include pre-shorted values, and the 1999 UCRC demands used in the 2007 Interim Guidelines.

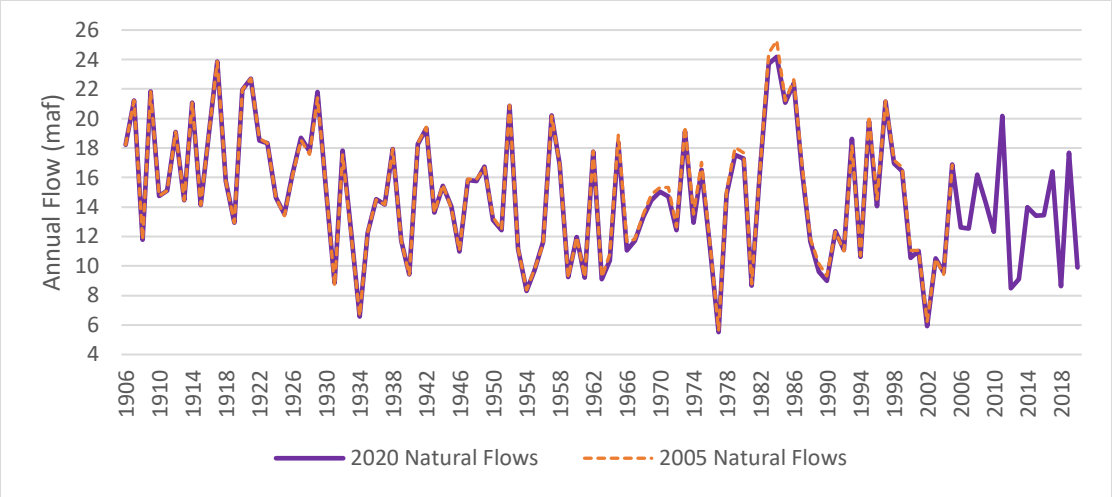


Figure J-1
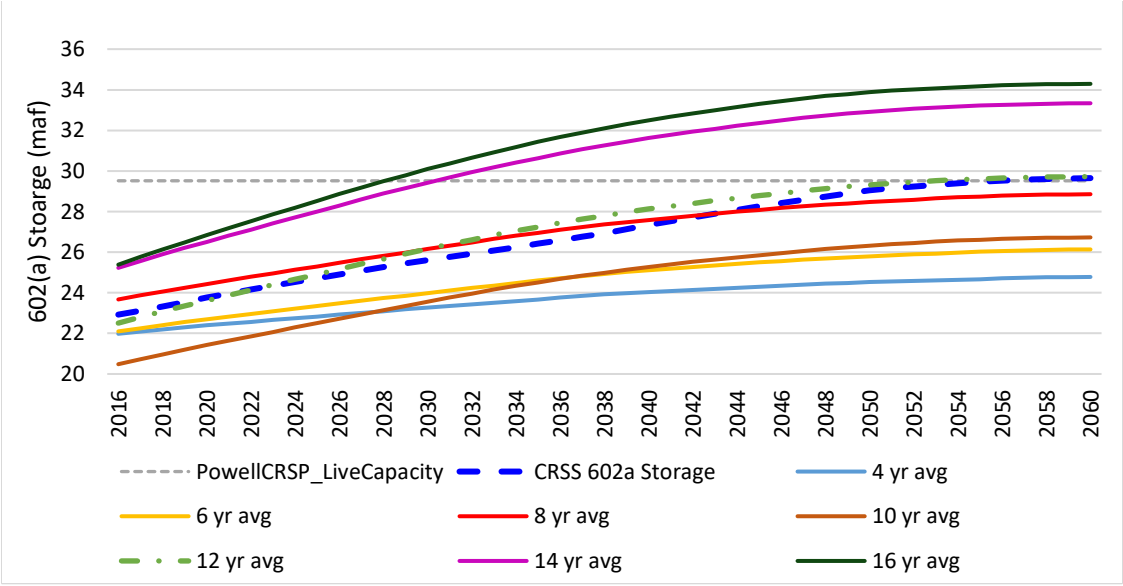
Comparison of UCRC Depletion Demand Schedules (excludes CRSP Evaporation)

J.4 Annual Natural Flow

The latest official natural flow dataset, released December 15, 2022, spans 1906-2020 and replaces the June 22, 2007 natural flow record used during the 2007 Interim Guidelines that spanned 1906-2005. Many incremental changes have been applied since that release, but these only resulted in minor changes (see **Figure J-2**) to the overlapping record.

Figure J-2
WY Colorado River at Lees Ferry Natural Flow Comparison

J.5 Critical Period Inflow and Length



The critical period inflow and length parameters are determined from an analysis of the available natural flow record. Using the 1906-2020 natural flow record the critical period average inflow was computed for different critical period lengths, ranging from four to 20 years (**Table J-2**).[1] The 12-year critical period is still the 1953-1964 period, though the average inflow decreased by 0.05 maf due to the minor, incremental changes that have been applied to the natural flow record since 2005.

Figure J-3 shows the 602(a) storage given critical period lengths of 4, 6, 8, 10, 12, 14, and 16 years based on the 1906-2020 natural flow record and the Updated 2016 UCRC demand schedule with an assumed 10 percent shortage compared to the 602(a) storage requirement computed for the 2007 Interim Guidelines ("CRSS 602[a] Storage" long dashed royal blue line). The 602(a) storage for the 2007 Interim Guidelines used the 1906-2005 natural flow 12-year critical period (1953-1964) inflow of 12.18 maf from the CRSS Cyber mainframe values and the 1999 UCRC pre-shorted demand schedule. Except where otherwise noted, all other parameter values are consistent for all of the computed 602(a) storage requirements in **Figure J-3** and listed in **Table J-1**.

Figure J-3 shows that both the inflow volume and the duration of the critical period have a significant impact on the 602(a) storage requirement. However, it is important to note that the selection of the critical period is not straightforward, and there are no clearly defined or objective criteria available to guide this choice.

[1] The critical period average inflow is the minimum average inflow over a specified critical period length using the updated natural flow record (1906-2020).

Figure J-3
602(a) Storage Values across Various Critical Periods based on Updated Natural Flow and Upper Basin Demands with 10 Percent Shortage

Note: CRSS 602(a) Storage line continues to use the 12-year 1953-1964 period with a 12.18 maf critical period inflow from the original CRSS Cyber mainframe values.

Table J-2
Critical Period Lengths, Inflow, and Years Spanned

Critical Period Length (years)	Critical Period Inflow (maf)	Years in Record- 2020 NF

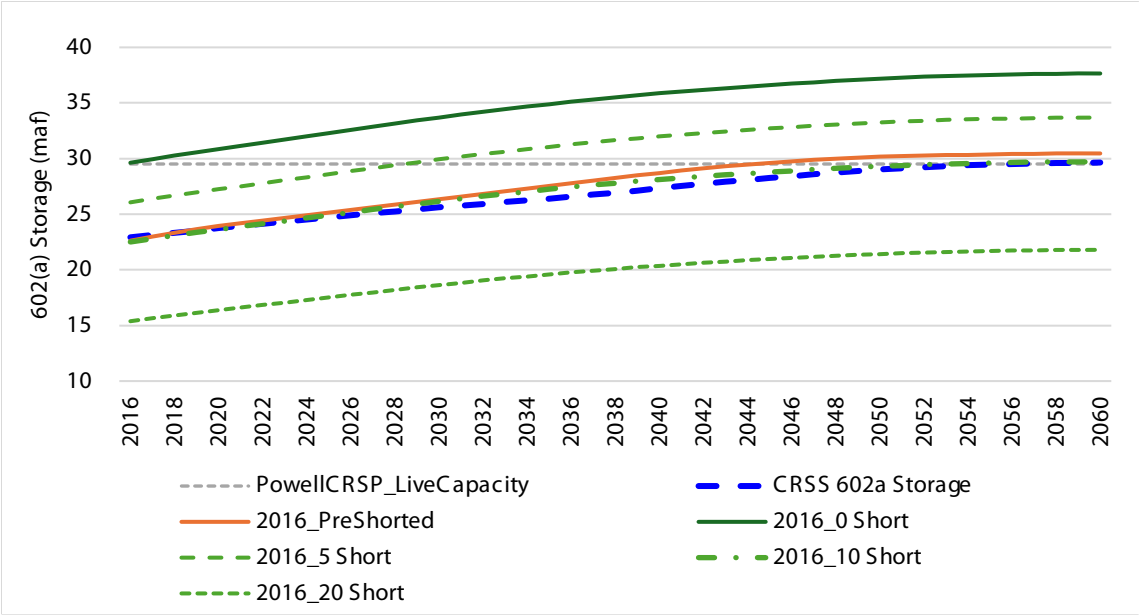
12	12.13	1953-1964



Critical Period Length (years)	Critical Period Inflow (maf)	Years in Record- 2020 NF
13	12.28	2001-2013
14	12.16	2000-2013
15	12.29	2000-2014
16	12.36	2000-2015
17	12.43	2000-2016
18	12.54	2001-2018
19	12.44	2000-2018
20	12.64	1999-2018

J.6 Critical Period Percent Shortage

To isolate the effect of the percent shortage parameter on 602(a) storage the Upper Basin depletion percent shortage varied between 0, 5, 10, and 20 percent. The 12-year critical period calculated from the updated natural flow, highlighted green in **Table J-2**, was held the same.

Figure J-4 compares the 602(a) storage computed using these different percent shortage parameter values and the Updated 2016 UCRC demands to the 602(a) storage computed using 0 percent shortage with the 2016 UCRC pre-shorted demands and the 602(a) storage requirement computed for the 2007 Interim Guidelines ("CRSS 602[a] Storage" long dashed royal blue line).[2] As with the choice of critical period inflow and length the assumed percent shortage during the critical period also exhibits significant impact on the calculated 602(a) storage volume. The Updated 2016 UCRC depletion demand schedule with a 10 percent Upper Basin shortage results in a similar 602(a) storage value to both the 2016 UCRC pre-shorted demand schedule and the 602(a) storage requirement computed for the 2007 Interim Guidelines.

Figure J-4
602(a) Storage Values across Various Upper Basin Depletion Percent Shortages

Note: CRSS 602(a) Storage lines continues to use the 12-year 1953-1964 period with a 12.18 maf critical period inflow from the original CRSS Cyber mainframe values.

J.7 Discussion

The 602(a) storage refers to the quantity of water required to be in storage in the Upper Basin so as to assure future deliveries to the Lower Basin without impairing annual consumptive uses in the Upper Basin. Its calculation depends on several inputs—most notably the assumed future Upper Basin demands, the selected "critical period," and the assumed level of Upper Basin shortage during that period.

Updating these inputs with the most recent information is sensible, but it also highlights how the time period affects the calculation. For example, using the full 1906–2020 natural flow record only

[2] The 602(a) storage for the 2007 Interim Guidelines uses the 1906-2005 natural flow 12-year critical period (1953-1964) inflow of 12.18 maf from the CRSS Cyber mainframe values and the 1999 UCRC pre-shorted demand schedule.

slightly changes the 12-year critical-period average inflow (12.13 maf vs. 12.18 maf using the 1906–2005 record). But the *choice of the critical period itself* has a much larger effect, and there is no objective standard for selecting it. A 12-year period with 12.13 maf average inflow is not necessarily more or less "critical" than a 10-year period averaging 12.02 maf or a 14-year period averaging 12.16 maf, yet each produces a different 602(a) requirement.

Assumptions about future Upper Basin demands introduce similar sensitivities. The 2007 calculation assumed zero Upper Basin shortage during the critical period because it relied on pre-shorted demand schedules. Because the Updated 2016 UCRC demand schedules no longer include pre-shorting, the zero-shortage assumption may no longer be appropriate—and it meaningfully affects the storage requirement.

Overall, this analysis shows that the 602(a) storage requirement varies substantially depending on the choices made for these key parameters. The 602(a) storage used in the 2007 Interim Guidelines generally falls near the middle of the range produced by the different tested assumptions.

Appendix K. Sensitivity Analysis – Effects of Modeling Assumptions with Regard to Future Water Deliveries to Mexico

K.1 Introduction

The proposed federal action includes the adoption of specific interim guidelines for Lower Basin shortages. The interim guidelines would be used by the Secretary to determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River Lower Division States (Arizona, California, and Nevada) (**Section 1.8.2.2**) below 7.5 million acre-feet (maf) (a "Shortage") pursuant to Article II(B)(3) of the Consolidated Decree. The determination of deliveries to Mexico is not a part of the proposed federal action. Any such determination would be made in accordance with the United States (U.S.)-Mexico Treaty on Utilization of Water of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Water Treaty). Nevertheless, modeling assumptions with respect to the distribution of shortages for the Lower Division States include water delivery reductions to Mexico in order to analyze potential impacts on hydrologic and other environmental resources (**Section K.2** and **Appendix A**, CRSS Model Documentation).[1] These modeling assumptions were applied to the No Action Alternative as well as the action alternatives, i.e., the modeling assumptions with regard to the distribution of shortages to the Lower Division States include water delivery reductions to Mexico and are distributed proportionally in all alternatives.[2]

This appendix provides a comparative analysis of the sensitivity of the hydrologic resources to different modeling assumptions with regard to how Mexico would be affected by future water delivery reductions. Two methodologies for computing future water delivery reductions to Mexico, for modeling purposes, are described. The modeling assumptions used to implement the methodologies are also presented.

[1] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the International Boundary and Water Commission (IBWC) in consultation with the Department of State.

[2] The Continued Current Strategies Comparative Baseline includes reductions and contributions for Mexico per Minute 323, which differ from the assumptions used in the No Action Alternative and action alternatives.

K.2 Description of Methodologies

Although many possible methodologies exist that would result in different volumes of potential future water delivery reductions to Mexico, two methodologies were considered in this analysis to assess the sensitivity of the hydrologic resources to a wide range of possible water delivery reductions.[3] Both methodologies are similar and both assume that the water deliveries to Mexico would be reduced in the same proportion as reductions in consumptive uses in the U.S. (shortages). The difference between the methodologies is whether shortages in both the Upper Basin and Lower Basin in the U.S. are considered when applying water delivery reductions to Mexico. Methodology A applies water delivery reductions to Mexico only when shortages to U.S. users in the Lower Basin occur, and water deliveries to Mexico are reduced in the same proportion as the reduction to U.S. users in the Lower Basin. This is the methodology that was used for the resource analyses in Volumes I and III of this Final EIS. Methodology B applies water delivery reductions to Mexico when shortages to U.S. users in either the Upper Basin or Lower Basin or both occur, and water deliveries to Mexico are reduced in the same proportion as the reduction to U.S. users in both the Upper and Lower Basins. These methodologies are described below along with comparisons of the results of the methodologies.

K.2.1 Methodology A

Under Methodology A, water delivery reductions to Mexico are triggered only when deliveries to U.S. users in the Lower Basin are reduced. When triggered, the water deliveries to Mexico are reduced in the same proportion as the reduction to the U.S. users in the Lower Basin. The methodology is as follows:

1) Look-up the total Lower Basin shortage. Under the Representative Preferred Alternative, shortages of specific magnitudes are triggered by specific Lake Mead elevations.
    - Example: for the Representative Preferred Alternative, if Lake Mead elevation is between elevations 1,125 and 1,025 feet, the total Lower Basin shortage is 1.5 maf

2) Compute the water delivery reduction to Mexico by multiplying the total Lower Basin shortage by 16.67 percent. This percentage is computed by taking the ratio of Mexico's allotment to the sum of the Lower Basin U.S. apportionments and Mexico's allotment (1.5 maf/(7.5 maf + 1.5 maf) = 0.1667 or 16.67 percent) and ensures that the water delivery reductions to Mexico are always proportional to the shortages to the U.S. users in the Lower Basin.
    - Example: assuming the total Lower Basin shortage is 1.5 maf, the water delivery reduction to Mexico would be computed as:

        *1.5 maf * 16.67 percent = 0.25 maf*

[3] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

A summary of shortages to U.S. users in the Lower Basin and water delivery reductions to Mexico for four example volumes of total Lower Basin shortage under the Representative Preferred Alternative is provided in **Table K-1** and **Table K-2**, respectively.

Table K-1
Example Shortages to United States Users in the Lower Basin for Methodology A

Lake Mead Effective Elevation (feet)	Total Lower Basin Shortage (maf)	Shortage to United States Lower Basin Users (maf)	Percent Reduction to United States Lower Basin Users	Total U.S. Delivery (maf)
1,135	0.75	0.625	8.3	6.875
1,125 to 1,025	1.50	1.250	16.7	6.250
1,000	2.55	2.125	28.3	5.375
Less than 975	3.60	3.000	40.0	4.500

Table K-2
Example Water Delivery Reductions to Mexico for Methodology A

Lake Mead Effective Elevation (feet)	Total Lower Basin Shortage (maf)	Reduction to Mexico (maf)	Percent Reduction to Mexico	Total Delivery to Mexico (maf)
1,135	0.75	0.125	8.3	1.375
1,125 to 1,025	1.50	0.250	16.7	1.250
1,000	2.55	0.425	28.3	1.075
Less than 975	3.60	0.600	40.0	0.900

Note: Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico.

K.2.2 Methodology B

Under Methodology B, water delivery reductions to Mexico are triggered by shortages to U.S. users in the Upper Basin, in the Lower Basin, or both. When triggered, the water deliveries to Mexico are reduced in the same proportion as the reduction to U.S. users in both the Upper and Lower Basins. The methodology is as follows:

1) Look-up the shortage to be applied to U.S. users in the Lower Basin.
    - Example: for the Representative Preferred Alternative, if Lake Mead elevation is between 1,125 and 1,025 feet, the shortage to U.S. users in the Lower Basin is 1.250 maf (**Table K-1**)

2) Compute the modeled shortage to U.S. users in the Upper Basin. Modeled shortages to U.S. users in the Upper Basin are assumed to occur when the delivery to those users is less than their depletion demand and is calculated as Upper Basin depletion demand minus Upper Basin modeled use (see **Section K.3.1** for more details).
    - Example: in the year 2030, the Upper Basin depletion demand is 5.534 maf and under one hydrologic sequence, The Colorado River Simulation System (CRSS) computed a delivery of 4.427 maf, resulting in a shortage to U.S. users in the Upper Basin of 1.107 maf, in addition to the shortage to U.S. users in the Lower Basin of 1.250 maf[4]

3) Compute the proportional reduction to U.S. users in both the Upper and Lower Basins as the sum of shortages to U.S. users in the Upper and Lower Basin divided by the sum of the Upper Basin scheduled use and the total U.S. Lower Basin apportionments (7.5 maf).
    - Example: the proportional reduction to the U.S. users would be computed as:

$$(1.250\ maf + 1.107\ maf) / (7.5\ maf + 5.534\ maf) = 18.1\ percent$$

4) Compute water delivery reduction to Mexico by applying the same proportional reduction to U.S. users in both the Upper and Lower Basins to Mexico. This is computed by multiplying Mexico's annual Colorado River allotment (1.5 maf) by the proportional reduction to U.S. users in both the Upper and Lower Basins.
    - Example: given the proportional reduction to U.S. users in both the Upper and Lower Basins is 18.1 percent, the water delivery reduction to Mexico would be computed as:

$$1.5\ maf * 18.1\ percent = 0.271\ maf$$

Since Upper Basin depletion demand varies each year (**Appendix L**, Upper Division States Depletion Schedules) and the computed shortages in the Upper Basin vary for each hydrologic sequence, a wide range of possible proportional reductions are simulated by Methodology B (from 4 percent to approximately 53 percent resulting in water delivery reductions to Mexico of approximately 0.065 to 0.791 maf as shown in **Figure K-3**).

Table K-3 shows some examples based on assumed Upper Basin modeled shortage, which fall within the range of actual modeled Upper Basin shortage (see **Section K.3.1**). The examples in **Table K-2** use an Upper Basin depletion demand of 5.835 maf (the average depletion demand over the 2027-2060 modeling period), resulting in the proportional reduction to the U.S. equal to the sum of Upper and Lower Basin U.S. shortages divided by 13.335 maf (7.5 maf plus 5.835 maf).

[4] The computed annual Upper Basin shortage in CRSS is not available until the end of the calendar year. In this example, the 2030 shortage would be used to set the 2031 water delivery reductions to Mexico.

Table K-3
Examples of Shortages to United States Users in the Upper and Lower Basins and Water Delivery Reductions to Mexico for Methodology B

Lake Mead Effective Elevation (feet)	Shortage to Lower Basin (maf)	Example Modeled Upper Basin Shortage (maf)	Total Shortage to United States (maf)	% Reduction to United States*	Reduction to Mexico Delivery (maf)**	% Reduction to Mexico
above 1,145	0.0	0.2	0.2	1.5	0.022	1.5
		1.4	1.4	10.5	0.157	10.5

below 975	3.00	0.2	3.20	24.0	0.360	24.0
		1.4	4.40	33.0	0.495	33.0
		2.5	5.50	41.2	0.619	41.2

* Percent reduction to U.S. based on average depletion demand in the Upper Basin (5.835) and the Lower Basin apportionment (7.5 maf): 5.835 maf + 7.5 maf = 13.335 maf)
** Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico.

K.3 Modeling Results

An analysis was performed to test the sensitivity of the hydrologic resources to these two sets of modeling assumptions (Methodology A and B). The CRSS model was used to simulate water deliveries to Mexico under these two methodologies with all other modeling assumptions held constant. The modeling assumptions under the Representative Preferred Alternative were used for this assessment with one major exception. It was assumed that there was no storage and delivery mechanism in place in order to isolate the effects of each methodology. See **Appendix A**, CRSS Model Documentation, for detailed modeling assumptions. Results are presented using conditional boxplots, which separate results based on five flow categories (see **Section 3.2.6** for additional details on conditional boxplots).

K.3.1 Upper Basin Modeled Shortages

CRSS assumes that shortages in the Upper Basin occur only when there is not sufficient water available within a given reach to meet a user's demand. For purposes of this Final EIS analysis, the total Upper Basin modeled shortage for any year is computed as the total Upper Basin depletion subtracted from the Upper Basin depletion demand for that year. **Figure K-1** provides a conditional boxplot of Upper Basin modeled shortage generated by CRSS over the period 2027 through 2060. The computed shortages to the Upper Basin users are dependent solely upon the hydrologic sequences and are therefore identical under Methodology A and Methodology B.

Figure K-1
Annual Upper Basin modeled shortage

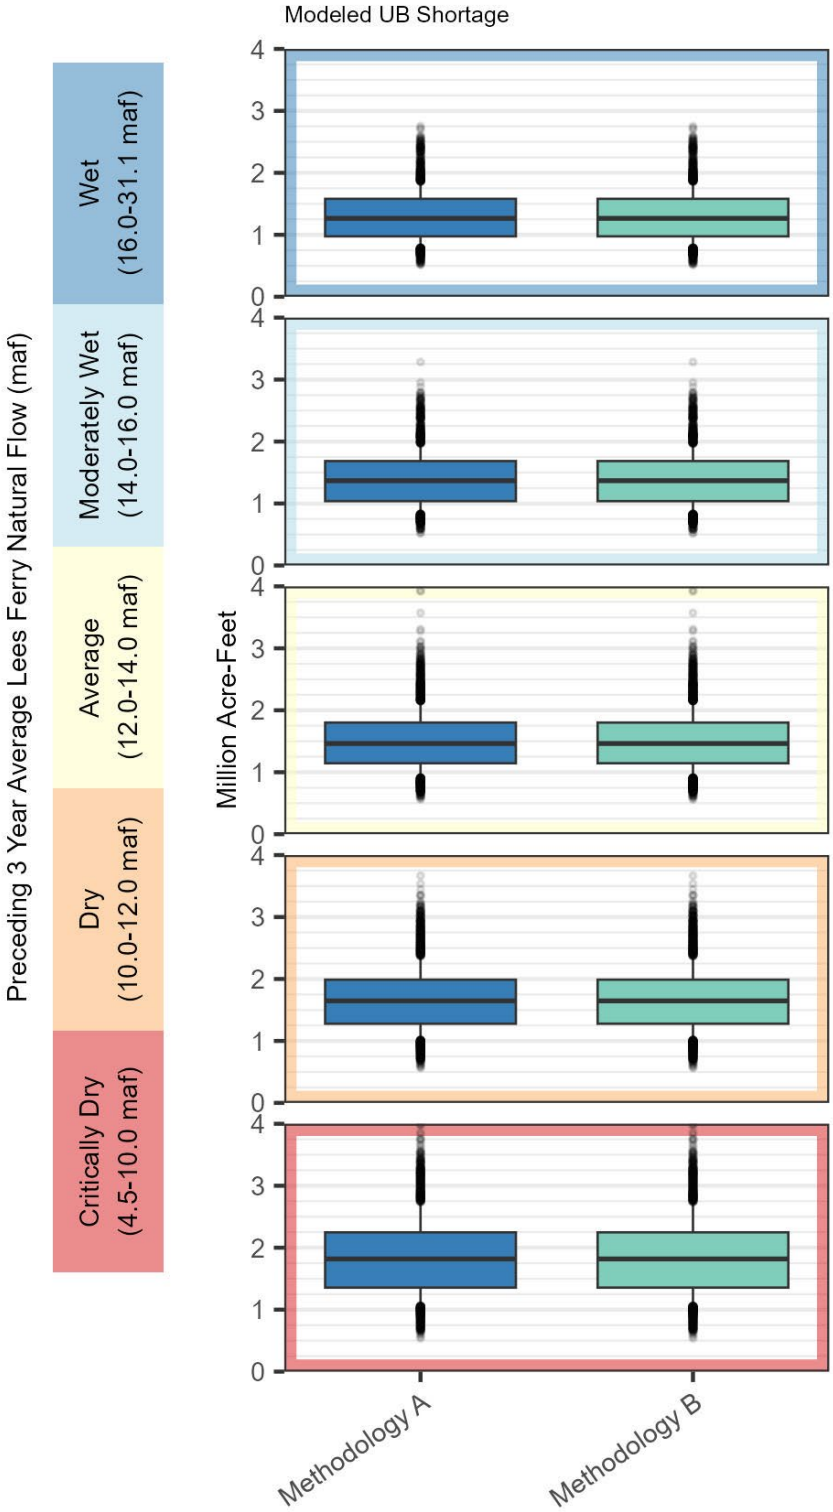

Figure K-1 shows that the Upper Basin modeled shortages range from 0.5 to 4.1 maf, with a modeled shortage occurring in all years. The Upper Basin modeled shortages generally increase in drier flow categories. In the Average Flow Category, the median Upper Basin modeled shortage is 1.5 maf, increasing to 1.6 and 1.8 maf in the Dry and Critically Dry Flow Categories, respectively. As a point of reference, a 1.5 maf Upper Basin modeled shortage represents approximately 26 percent of the average Upper Basin depletion demand during the modeled period.

K.3.2 Lake Powell and Lake Mead Water Surface Elevations

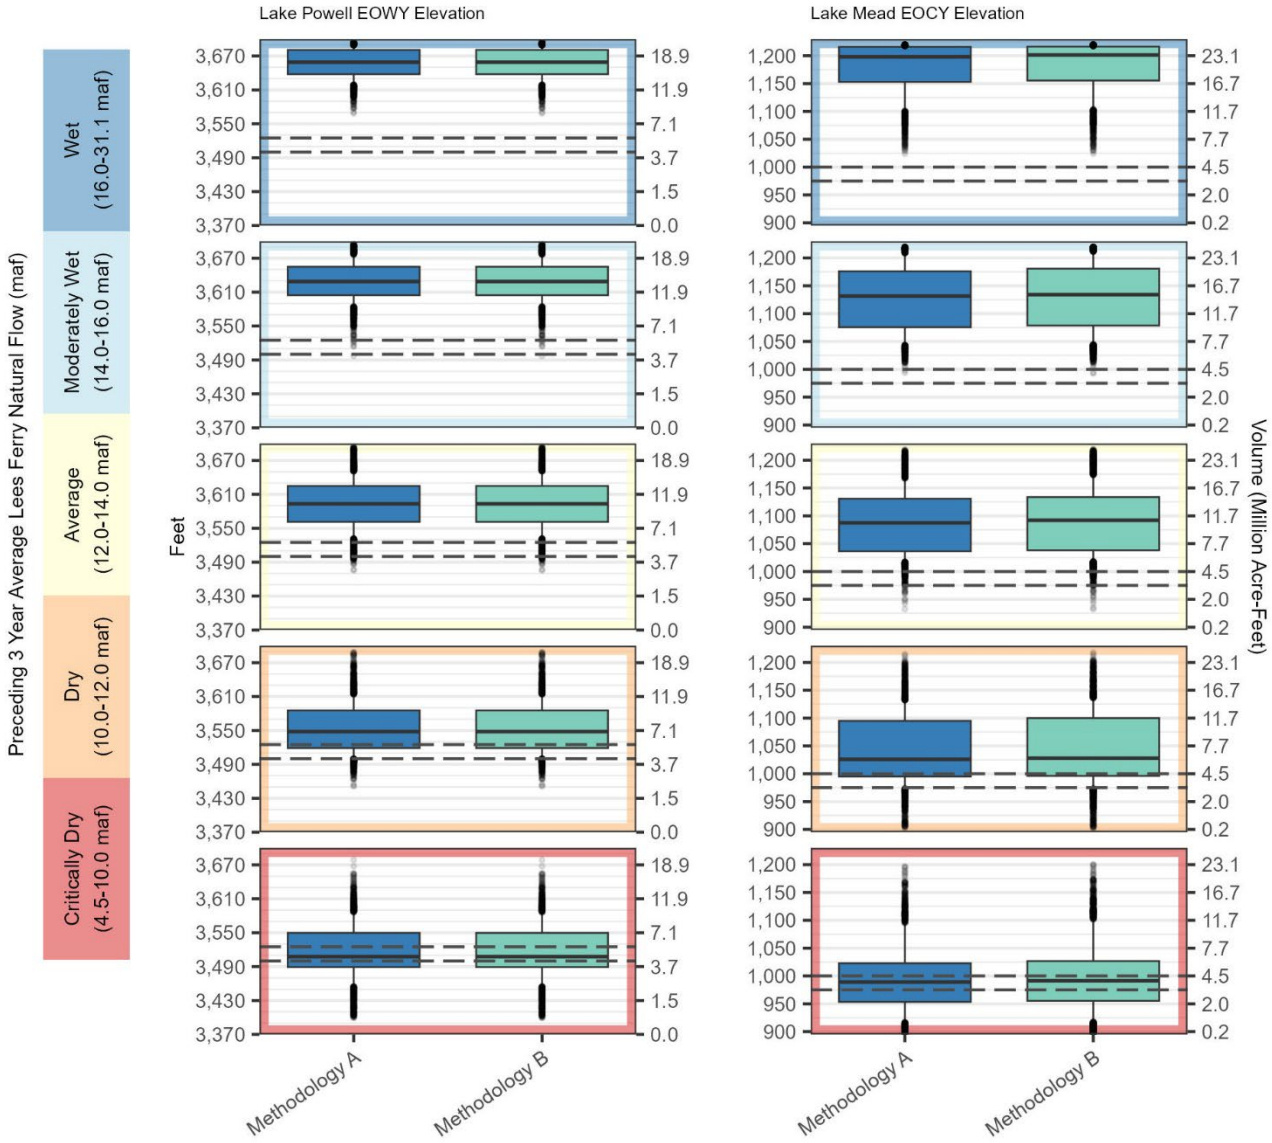
Figure K-2 compares the elevations at Lake Powell and Lake Mead under Methodology A and B. Lake Powell elevations are nearly the same under Methodology A and Methodology B because Lake Powell inflow does not change with different assumptions for water delivery reductions to Mexico. Lake Powell release is generally based only on Lake Powell elevation, except at high elevations where equalization releases consider both Lake Powell and Lake Mead elevation (see **Appendix A**, CRSS Modeling Assumptions for additional details). While there are small differences in Lake Powell elevation between Methodology A and Methodology B in a small number of years at these higher elevations, there are no differences in the statistics shown in the conditional boxplots in **Figure K-2**.

There are small differences in Lake Mead elevations between Methodology A and Methodology B, with the elevations in Methodology B typically higher than those in Methodology A. In the Average Flow Category, the median Lake Mead elevation from Methodology B is approximately 5 feet higher than Methodology A (1,092 and 1,087 feet respectively). In both the Dry and Critically Dry Flow Categories, the median elevation is approximately 2 feet higher in Methodology B than in Methodology A. This is because Methodology B typically results in higher delivery reductions to Mexico than Methodology A (**Section K.3.3**), which results in higher Lake Mead elevations.

K.3.3 Comparison of Water Deliveries to Mexico

As described in **Section 4.2**, water deliveries to Mexico are assumed to be 1.5 maf, except when the model assumes that additional deliveries of up to 0.2 maf have been scheduled or a water delivery reduction has been incurred. Additional deliveries to Mexico of up to 0.2 maf are assumed to occur when Lake Mead is in flood control operations, under 70R Surplus Conditions, or in the assumed "Domestic" Surplus Conditions. A Domestic Surplus (up to 0.5 maf) is assumed to occur when the August 1 Lake Mead effective elevation is at or above 1,165 feet and Flood Control or 70R Surplus is not triggered. When triggered it is assumed that a proportional share (up to 83.35 thousand acre-feet) of the additional water deliveries is provided to Mexico (above 1.5 maf and not more than 1.7 maf total). Reductions in the water deliveries to Mexico are simulated consistent with the modeling assumptions described previously under each methodology. Consequently, simulated water deliveries to Mexico are expected to fluctuate throughout the analysis period (2027 through 2060) reflecting variations in hydrologic conditions under these assumptions.

Figure K-2
End-of-Water Year Lake Powell and End-of Calendar Year Lake Mead elevations



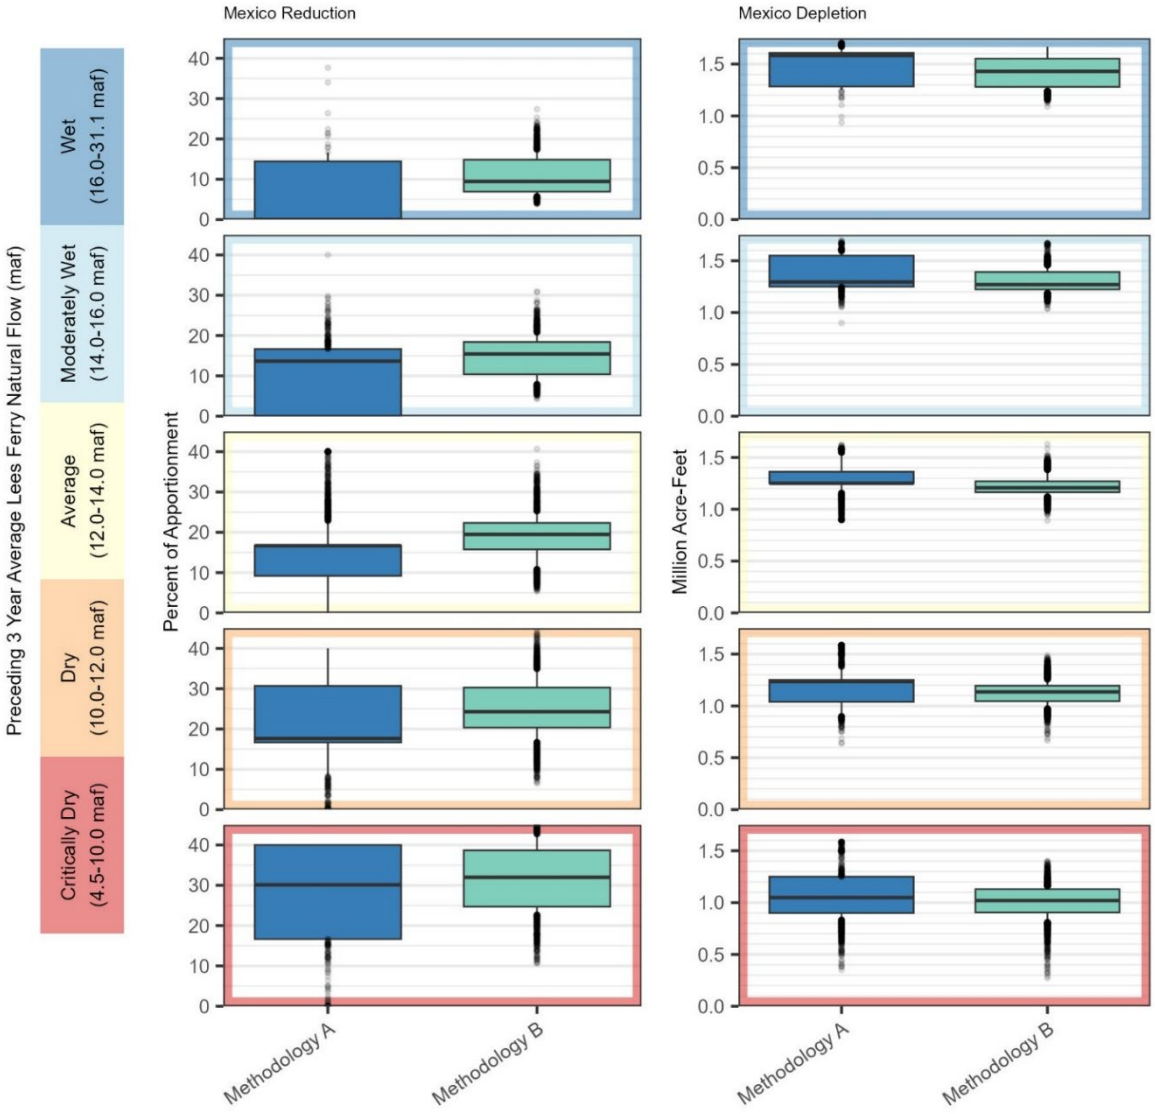


Figure K-3 compares the modeled water delivery reductions to Mexico (volumetrically and as a percent of Mexico's 1.5 maf allotment) and the total annual delivery to Mexico (Mexico depletion) for the two methodologies. Overall, in all flow categories, Methodology B results in higher delivery reductions and lower annual deliveries than Methodology A. **Figure K-3** shows that Methodology A has some years where there are no delivery reductions (e.g., at the 25th percentile in the Moderately Wet Category, and at the 10th percentile in the Average Flow Category), while Methodology B always has some delivery reductions. Additionally, Methodology A results in a maximum delivery reduction of 0.6 maf (or 40.0 percent of allotment), which corresponds to 16.67 percent of the maximum total Lower Basin shortage of 3.6 maf in the Representative Preferred Alternative. The maximum delivery reduction from

Methodology B ranges from 0.411 maf (27.4 percent of allotment) in the Wet Flow Category to 0.791 maf (52.7 percent of allotment) in the Critically Dry Flow Category. **Table K-4** and **Table K-5** report the water delivery reductions to Mexico for all flow categories as a percent of allocation and volumetrically, respectively. The higher overall reductions, higher maximum reductions, and larger range of reductions in Methodology B are because Upper Basin modeled shortages occur frequently and are included in the calculation of the proportional reduction under Methodology B.

Figure K-3
Annual delivery reductions and deliveries to Mexico

Note: The modeled annual delivery reductions and deliveries to Mexico include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Note: The modeled delivery reductions to Mexico include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

The annual delivery to Mexico (**Figure K-3**) shows similar information as the delivery reductions but incorporates years with additional deliveries to Mexico because of Flood Control, 70R, or Domestic Surplus, as previously discussed. Additionally, the annual deliveries incorporate years where the deliveries to Mexico are reduced beyond the specified reductions in Methodology A or B due to dead pool-related reductions (see **Section 3.4.2**, Issue 3 for an explanation of dead pool-related reductions). For example, the minimum annual delivery in the Critically Dry Flow Category in Methodology A is 0.350 maf. With a maximum delivery reduction of 0.60 maf, the minimum delivery due to the specified delivery reductions would be 0.9 maf; the difference between 0.350 maf and 0.9 maf is due to the dead pool-related reductions, which occur when Lake Mead approaches dead pool. Conversely, the maximum annual delivery to Mexico is 1.7 maf and 1.67 maf[5] in the Wet and Moderately Wet Flow Categories for Methodology A and Methodology B, respectively, and reflects the additional deliveries to Mexico above their 1.5 maf allocation. Overall, the annual deliveries to Mexico are lower in Methodology B than in Methodology A, for the same reasons that the reductions are higher, as previously discussed.

K.3.4 Parker Dam Releases

The flows in the river from Parker Dam to Imperial Dam result primarily from the controlled releases from Parker Dam. **Figure K-4** compares the releases from Parker Dam. There are only small differences in the annual releases from Parker Dam between Methodology A and B. In the Average Flow Category, the median Parker Dam release is 6.48 maf in Methodology A and 6.41 maf in Methodology B; in the Dry Flow Category Methodology A is 6.27 maf and Methodology B is 6.21 maf; in the Critically Dry Flow Category Methodology A is 5.91 maf and Methodology B is 5.91 maf. Methodology B produces lower releases in all flow categories across nearly all boxplot statistics, consistent with earlier findings showing greater delivery reductions to Mexico—and therefore lower releases from Parker Dam.

[5] The maximum annual delivery to Mexico is 1.7 maf based on the 1944 Water Treaty. CRSS constrains the available additional delivery volume to Mexico to 200 thousand acre-feet (1.7 maf minus 1.5 maf). It then computes the total delivery to Mexico as 1.5 maf plus additional deliveries minus reductions. Because Methodology B always has a non-zero reduction, the total delivery always results in a number smaller than 1.7 maf. If the CRSS logic was implemented differently, by not constraining the available additional delivery water and instead constraining the total delivery, the total delivery to Mexico under Methodology B could be as high as 1.7 maf. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico.

Attachment A

Verification of Equal Proportional Reductions to United States and Mexico for Methodology A and Methodology B

This page intentionally left blank.

Attachment A. Verification of Equal Proportional Reductions to United States and Mexico for Methodology A and Methodology B

Both Methodology A and Methodology B assume that the water deliveries to Mexico would be reduced in the same proportion as reductions in consumptive uses in the U.S. (shortages). This attachment provides additional information with regard to equal proportional reductions.

Model Verification

In order to verify that the model was accurately computing equal proportional water delivery reductions to Mexico, output from the model was used to compute reductions for both the U.S. and Mexico as a percentage of the appropriate demand.[6] **Table Att. A-1** provides a comparison of these computed values using Methodology A and Methodology B for the U.S. and Mexico. **Table Att. A-1** verifies that under both methodologies, deliveries to Mexico are reduced in the same proportion as deliveries to the U.S.

[6] For Mexico, it is always the reduction divided by 1.5 maf. For the U.S., it is the Lower Basin shortage divided by 7.5 maf for Methodology A, and Lower Basin shortage plus Upper Basin modeled shortage divided by 7.5 maf plus the Upper Basin depletion demand for the year for Methodology B.

Appendix L. Upper Division States Depletion Schedules

L.1 Overview of Methodology for Developing the Baseline Upper Division States Depletion Demand Schedules

The Upper Basin Colorado River Simulation System (CRSS) baseline demand schedules were developed from the Upper Colorado River Commission's (UCRC) updated 2016 Depletion Demand Schedule[1,2]. Specifically, the UCRC—in coordination with the Upper Division States—developed decadal projections of water depletion demands by sector at the state level to support long-term planning efforts. These projections represent anticipated water demands under assumed economic and hydrologic conditions. The Arizona portion of the Upper Colorado River Basin (Upper Basin) demand schedule was developed by the Bureau of Reclamation (Reclamation) and is primarily comprised of Navajo Nation uses. The representation of the Upper Basin Tribes in the UCRC depletion demand schedule was presented in documentation dated July 13, 2022, that outlines the differences between the 2018 Tribal Water Study demand schedules and the updated 2016 Depletion Demand Schedule[3,4].

To integrate the UCRC's decadal projections into CRSS, Reclamation worked with the Upper Division States to disaggregate the state-level demand estimates to CRSS' spatial resolution at an annual timestep. These annual depletion values were further disaggregated to a monthly timestep using sector and subbasin-specific monthly distribution coefficients, which were derived either from data provided by the Upper Division States or from average distributions based on Reclamation's Consumptive Use & Loss reports. Corresponding diversion values were subsequently calculated using the disaggregated depletion estimates and water-user-specific efficiency ratios. State level

[1] Upper Colorado River Commission (UCRC) & Upper Division States. (2022, June 14). *Combined Resolution and Updated 2016 Depletion Demand Schedule*. Upper Colorado River Commission. Retrieved from http://www.ucrcommission.com/wp-content/uploads/2022/06/UCRC-and-Upper-Division-States-Combined-Resolution-and-Updated-2016-Depletion-Demand-Schedule-June-14-2022-1.pdf.

[2] Neither the CRSS baseline demands nor the UCRC 2016 Depletion Demand Schedule include reservoir evaporation undistributed by state from Lake Powell, Flaming Gorge, Blue Mesa, Morrow Point, which averages 520.0 kaf per year.

[3] The Post-2026 modeling is based on water rights of the Ute Indian Tribe of the Uintah & Ouray Reservation that have not been ratified by all parties. The Ute Indian Tribe of the Uintah & Ouray Reservation has federally reserved Indian water rights, a portion of which were federally decreed in 1923 and a portion of which have been separately recognized and put to use by the United States and the State of Utah, which are not fully resolved.

[4] The information reflected in the baseline depletion demands schedule relies on information about projected future Tribal water demands. The projections were based on information compiled in a Colorado River Basin Ten Tribes Partnership Tribal Water Study (December 2018). As discussed in Chapter 8 of that Study, the technical approach was based on the best science and information available at the time, given limitations related to timeframes and resource constraints, among other things. The Navajo Nation informed Reclamation that it was developing updated projections as part of its water development planning. Reclamation worked with the Navajo Nation as needed to update demand schedules prior to the publication of the Final EIS.

reservoir evaporation for reservoirs explicitly represented in CRSS[5], which averages 56.0 thousand acre-feet per year, w removed from the UCRC's decadal projections before loading in CRSS but are included in the table below.

Table L-1 shows the depletion demands for the Upper Basin by state.

2052	47	3,195	705	1,299	757	5,978
2053	47	3,198	706	1,302	758	5,986
2054	47	3,202	707	1,305	760	5,994

[5] Reservoir evaporation distributed by state explicitly represented in CRSS includes Navajo, McPhee, Dillon, Granby, Homestake and Willow Creek reservoirs.

[6] In response to comments received on the Navajo Nation's demands used in the Draft EIS, the values presented in this table reflect updated demands. To fully incorporate the updated demands into the Final EIS analyses, all alternatives and resource models would have had to be re-run, which was not feasible within the given timeline. As such, all modeling and analyses included in this Final EIS still use the demands from the Draft EIS. A sensitivity analysis found that, while the updated demands result in minor changes, they would not significantly affect the relative ranking of alternatives or the conclusions for any resource.

Calendar Year	Arizona[6]	Colorado	New Mexico	Utah	Wyoming	Total Upper Basin

Appendix M. Lower Division States Depletion Schedules

M.1 Introduction

This appendix contains schedules of projected Colorado River system depletions[1] by the Lower Division States (Arizona, California, and Nevada). These schedules were used to model the operation of the Colorado River system under the No Action Alternative, the action alternatives, and the Continued Current Strategies Comparative Baseline. The schedules used to model depletions under Normal Conditions are included in this appendix and are input into the Colorado River Simulation System (CRSS). CRSS then adjusts the schedules to reflect shortage and Surplus Conditions, which vary by alternative and shortage distribution method (**Chapter 2**), as well as assumed conservation activities (**Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

The depletion schedules were developed by the Bureau of Reclamation (Reclamation) with review by the Lower Division States and tribes. This appendix documents the method Reclamation used to develop the depletion schedules and notes where adjustments to this method were made, based on input from the Lower Division States and tribes.

M.2 Methodology for Developing the Baseline Lower Division States Depletion Schedules

The baseline 2027-2060 depletion schedules were developed using a multi-step methodology that incorporates historical water use and efficiency data. First, the average of the three highest annual water use values from 2008–2022 was calculated to estimate each user's potential maximum use. Then, historical efficiency was determined as the ratio of depletion to diversion over the same period. Initial 2027 demands were set as the lesser of this average maximum use or the user's entitlement, with corresponding diversion or depletion values derived using the calculated efficiency. These initial demands are then linearly increased to full entitlement levels by 2040. For the junior water users Metropolitan Water District, Central Arizona Project, and Southern Nevada Water Authority, the depletion schedules are computed by subtracting other users' depletions from the state's apportionment. Several exceptions to this general process are addressed individually based on unique user circumstances.

[1] In this appendix, and in Colorado River Simulation System (CRSS) modeling generally, "depletion" and "consumptive use" are used synonymously and are defined as diversion minus return flow.

A detailed outline of this methodology is provided below. Annual depletion schedules will sum to each Lower Division State's apportionment. Note, if a water user has multiple priorities with the same service area, it is assumed water is diverted first under the senior priority followed by the more junior priorities.

1. **Average Historical Maximum Use**
    - Calculate the average of the three highest annual water use values from 2008-2022 using historical depletion and diversion data from Reclamation's Colorado River Accounting and Water Use Report: Arizona, California, and Nevada reports ("Water Accounting Reports"). This value represents a reasonable estimate of the user's potential maximum use for the upcoming year under existing conditions.
    - If three years of data were not available, the average was calculated using all available data within the specified period.
    - Unless otherwise noted, if a user has multiple water entitlements, the average historical maximum use for the junior water entitlement(s) is calculated as the average of the three highest annual water use values minus the estimated 2027 depletion for the senior water entitlement(s) (from step 3). This approach effectively assumes water has historically been diverted under the senior water entitlement(s) before the junior water entitlement(s).

2. **Average Historical Efficiency**
    - Calculate the historical average efficiency for 2008-2022 using diversion and depletion data from the Water Accounting Reports.

$$\boldsymbol{Efficiency} = \frac{\boldsymbol{Depletion}}{\boldsymbol{Diversion}}$$

    - If complete data for the period is unavailable, use all available data within the specified period.
    - If a water user has no historical diversion data, assume an efficiency of 1 unless additional information is available.
    - Round the resulting average efficiency to two decimal places.

3. **Initial (2027) Demand**
    - Calculate the initial (2027) demand—either depletion or diversion—as the minimum of:
        i. average maximum use (from step 1); or
        ii. the user's entitlement

- If the water user has a consumptive use entitlement, the initial depletion is the minimum of the average maximum historical depletion and the entitlement. The corresponding diversion equivalent is calculated using the historical average efficiency:

$$\boldsymbol{Diversion} = \frac{\boldsymbol{Depletion}}{\boldsymbol{Efficiency}}$$

- If the water user has a diversion entitlement, the initial diversion equals the minimum of the of the average maximum diversion and the diversion entitlement. The corresponding depletion is calculated using the historical average efficiency:

$$\boldsymbol{Depletion} = \boldsymbol{Diversion\ x\ Efficiency}$$

4. **Demand Buildout to Full Entitlement**
    - Use the initial demand estimate (from step 3) and linear interpolation to gradually increase the demand to full entitlement (diversion or depletion) by 2040.

5. **Approach for Junior Water Users**
    - For Metropolitan Water District (California), Central Arizona Project (Arizona), and Southern Nevada Water Authority (Nevada), the depletion is estimated by subtracting the total depletion of all other users from the State's apportionment.
    - The corresponding diversion is calculated using the historical average efficiency.

Disclaimer: Several exceptions apply to the general process, such as water users with both diversion and consumptive use entitlements, users with no history of use, and users with multiple water entitlements. These exceptions are handled on a case-by-case basis and noted on the applicable water users in the following section.

M.3 Lower Division States Depletion Schedules

Table M-1 through **Table M-6i** show the baseline depletion schedules for the modeled Lower Division State mainstream entitlement holders, which are consistent with those reported in Reclamation's Water Accounting Reports. The priorities of the CRSS users in Nevada and California are provided in their respective state tables, while Arizona users are organized into different tables by priority. The priority of each user is used to distribute shortage by priority in multiple alternatives. Note that the CRSS model structure does not include water uses that hold only surplus contracts or uses that would require water above each state's apportionment to satisfy. For surplus modeling assumptions, please see **Appendix A**, CRSS Model Documentation.

Table Number	Depletion Schedule
M-1	Nevada
M-2a through M-2c	California
M-3a through M-3c	Arizona Priority 1
M-4	Arizona Priority 2
M-5a through M-5d	Arizona Priority 3
M-6a through M-6i	Arizona Priority 4

Additionally, for some water users, the CRSS structure aggregates multiple real-world users. In those cases, the assumed priority used in CRSS and in figure labels may not match the priority of all users; the assumed priority is chosen as a modeling simplification. One example of this simplification occurs in the modeling for Nevada Priorities 5 and 6 users, which are included in Priority 8 because the Southern Nevada Water Project services these users. The shortage allocation model provides more detail on the distribution of shortages (**Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation).

NRA – National Recreation Area; P – Priority; PPR – Present Perfected Rights

[1] Southern Nevada water providers depletion schedule for alternatives with mechanism for storage and delivery of conserved water (Enhanced Coordination, Maximum Operational Flexibility, Supply Driven [Lower Basin Priority and Lower Basin Pro Rata approaches] Alternatives) and Continued Current Strategies Comparative Baseline. See **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water, for assumptions on the creation and delivery of conserved water.
[2] Southern Nevada water providers depletion schedule for the No Action and Basic Coordination Alternatives, which do not have a new mechanism for storage and delivery of conserved water.
[3] Water user has both a diversion and depletion entitlement. May include adjustments to applied efficiency.
[4] Present Perfected Right (PPR); highest priority mainstream Colorado River water entitlements that were perfected before June 25, 1929. See Section C.4.1 in Appendix C, Shortage Allocation Model and Alternative Distribution Model Documentation, for more details.
[5] Total State of Nevada water user depletion schedules for alternatives with mechanism for storage and delivery of conserved water (Enhanced Coordination, Maximum Operational Flexibility, Supply Driven [Lower Basin Priority and Lower Basin Pro Rata approaches], Preferred Alternatives) and Continued Current Strategies Comparative Baseline.
[6] Total State of Nevada water user depletion schedules for the No Action and Basic Coordination Alternatives, which do not have a new mechanism for storage and delivery of conserved water.

CVWD – Coachella Valley Water District; MWD – Metropolitan Water District of Southern California; P – Priority; PPR – Present Perfected Rights; QSA – Quantification Settlement Agreement

[1] Water user has both a diversion and depletion entitlement. May include adjustments to applied efficiency.

[2] Adjusted to reflect operational agreements and/or input received from the water user.
[3] In response to comments received on MWD's P4 demands used in the Draft EIS, the values presented in this table reflect updated demands and better match the demand used in the Shortage Allocation Model (**Appendix C** – Shortage Allocation Model and Alternative Distribution Model Documentation). To fully incorporate the updated demands into the Final EIS analyses, all alternatives and resource models would have had to be re-run, which was not feasible within the given timeline. As such, all modeling and analyses included in this Final EIS still use the demands from the Draft EIS. A sensitivity analysis found that, while the updated demands result in minor changes, they would not significantly affect the relative ranking of alternatives or the conclusions for any resource.

IDD – Irrigation and Drainage District

[1] Water user has multiple priorities with distinct service areas. As a result, the average historical maximum use is allocated proportionally. This approach effectively assumes water is not historically diverted under the senior water entitlement(s) before the junior water entitlement(s).

[2] Water user has both a diversion and depletion entitlement. May include adjustments to applied efficiency.

IDD – Irrigation and Drainage District; WUA – Water Users Association

[1] Water user has multiple priorities with distinct service areas. As a result, the average historical maximum use is allocated proportionally. This approach effectively assumes water is not historically diverted under the senior water entitlement(s) before the junior water entitlement(s).

[1] See paragraph 11.3 of the Arizona Water Settlement Agreement, which is also referred to as the "master agreement" in the Arizona Water Settlements Act, Pub. L. 108-451 (Dec. 10. 2004).

[2] Water user has multiple priorities with distinct service areas. As a result, the average historical maximum use is allocated proportionally. This approach effectively assumes water is not historically diverted under the senior water entitlement(s) before the junior water entitlement(s).

Appendix N. International Border Region of the Colorado River[1]

N.1 Introduction

The United States (U.S.) has a delivery obligation to the United Mexican States (Mexico) for waters of the Colorado River pursuant to the February 3, 1944 Water Treaty between the U.S. and Mexico Relating to the Utilization of the Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Water Treaty; U.S. and Mexico 1944). The U.S. Section of the International Boundary and Water Commission (USIBWC) is the U.S. component of a binational organization responsible for administration of the provisions of the 1944 Water Treaty, which includes the Colorado River waters allotted to Mexico. The International Boundary and Water Commission (IBWC) consists of the U.S. Section and the Mexican Section, which have their headquarters in the adjoining cities of El Paso, Texas and Ciudad Juarez, Chihuahua, respectively. Other Colorado River responsibilities identified in the 1944 Water Treaty relate to water delivery, border sanitation, and construction of the Mexican diversion dam (Morelos Dam), stream gaging stations, and flood control levees. The treaty gives the USIBWC, under the foreign policy guidance of the Department of State in the U.S. and the Ministry of Foreign Affairs in Mexico, the authority to settle all differences with respect to the interpretation or application of the treaty, subject to the approval of the two Governments.

The proposed federal action is for the purpose of adopting additional operational guidelines to improve the U.S. Bureau of Reclamation's (Reclamation) annual management and operation of key Colorado River reservoirs for an interim period. The objective of this appendix is to consolidate and summarize analyses related to the International Border Region throughout this Final Environmental Impact Statement (EIS), which are discussed in Technical Appendices titled **TA 3**, Hydrologic Resources, **TA 4**, Water Deliveries, and **TA 6**, Water Quality. Each of the referenced sections utilizes a simulation model to characterize the implications of the baselines and proposed alternatives on the parameters relevant to these resources.[2] To assess the proposed federal action in the EIS, certain modeling assumptions are used to evaluate potential effects on water deliveries to Mexico and on hydrologic and other environmental resources between the Northerly and Southerly International Boundaries (International Border Region). This geographic area is called the

[1] For purposes of this Appendix, the International Border Region is defined as the geographic area between the Northerly International Boundary and the Southerly International Boundary along the Colorado River. This area serves as the international boundary between the U.S. and Mexico.

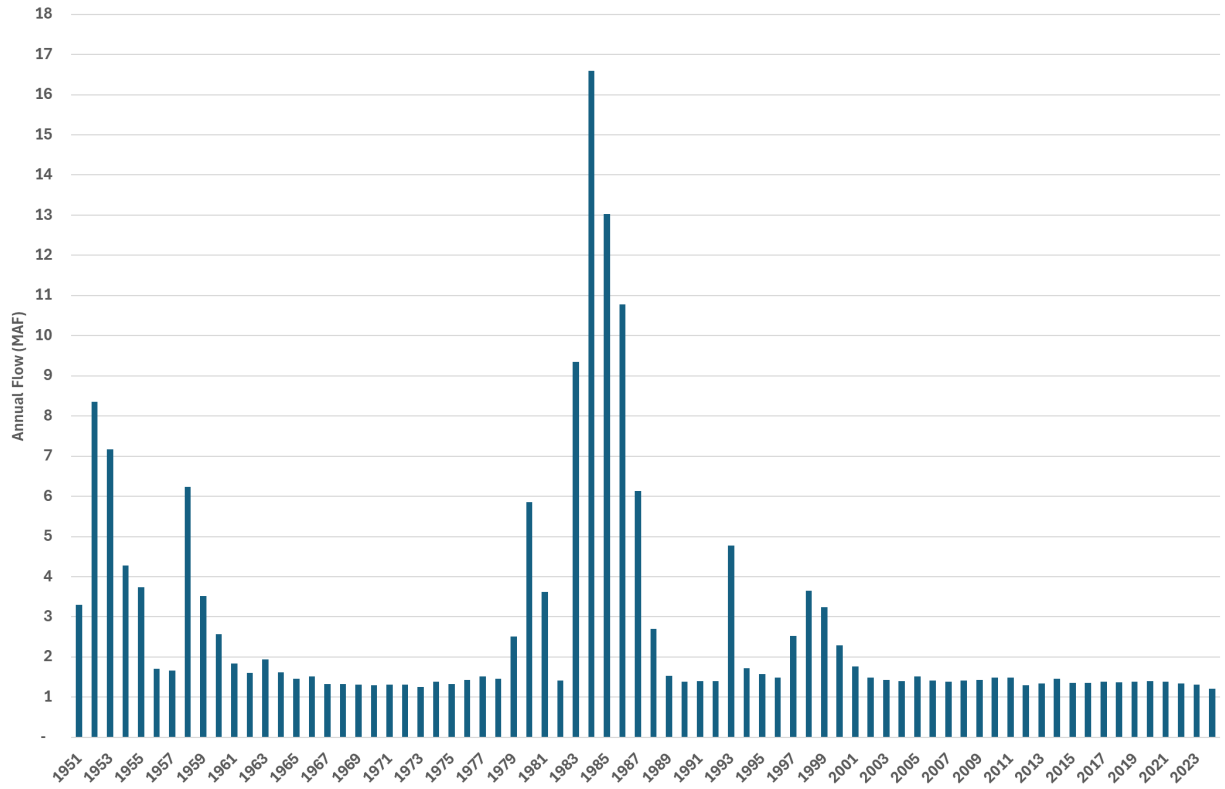
[2] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Limitrophe as the Colorado River is the U.S./Mexico international boundary between those two locations.

N.2 Overview

N.2.1 Affected Environment

The international border region of the Colorado River extends from the Northerly International Boundary (NIB) to the Southerly International Boundary (SIB) where the river channel forms the international boundary between the U.S. (the State of Arizona) on the eastern side of the bank and Mexico (the State of Baja California) on the western side of the bank (**Map N-1**). Approximately 25 miles (40.2 kilometers) upstream of the NIB sits the Imperial Dam, where diversions are made into the Gila Gravity Main Canal and All-American Canal, the latter of which feeds into the Coachella Canal, East Highline Canal, and Central Main Canal before terminating at the western end of the Imperial Valley where it drains into the Westside Main Canal. Some deliveries to Mexico are channeled through the All-American Canal and then diverted either through the Pilot Knob Power Plant or through Siphon Drop and the Yuma Main Canal before returning to the mainstem channel above NIB. Another route is to direct water from Imperial Dam to Laguna Dam before returning to the mainstem channel. Approximately 1.08 miles (1.75 kilometers) downstream of the NIB along the main Colorado River channel is the Morelos Diversion Dam, which diverts water into the Reforma Canal for use in Mexico.



Flows at the NIB reflect releases made from Hoover Dam to meet delivery obligations to Mexico, flood control releases from Hoover Dam, local runoff sources such as irrigation return flows and pumped groundwater discharged into the river channel, unexpected flooding from the Gila River, inadvertent overruns of water deliveries that could not be diverted as intended into the Gila Gravity Main Canal or All-American Canal, and any water released for environmental purposes of the Colorado River Delta region. Under most years, the volume meets or slightly exceeds the delivery obligations to Mexico at NIB, but exceptionally large volumes have occurred in past years primarily due to flood control releases (**Figure N-1**).

The reach between the NIB and SIB is referred to as the Limitrophe. From NIB to the Morelos Dam, approximately 1.36 maf passes annually. Under normal operations, the Morelos Dam diverts the entirety of the remaining Colorado River into the Reforma Canal. Releases or spillway discharges from the Morelos Dam for flood control purposes or environmental restoration have been an infrequent but important source of downstream flows. In recent years, only seepage under and around the dam remains in the natural river channel.

Below Morelos Dam, the Colorado River is characterized by a minimally flowing or dry streambed. Seepage from the dam is joined by agricultural return flows from both the U.S. and Mexico, originating from irrigated fields percolating water into the subsurface alluvium and contributions from three U.S. wasteways (11 Mile Wasteway off levee road and County 11th, 21 Mile Wasteway near Hunters Hole, and a Diversion Channel at SIB near the border at San Luis, Arizona). The Limitrophe is typically considered to be the northernmost reach of the Colorado River Delta and

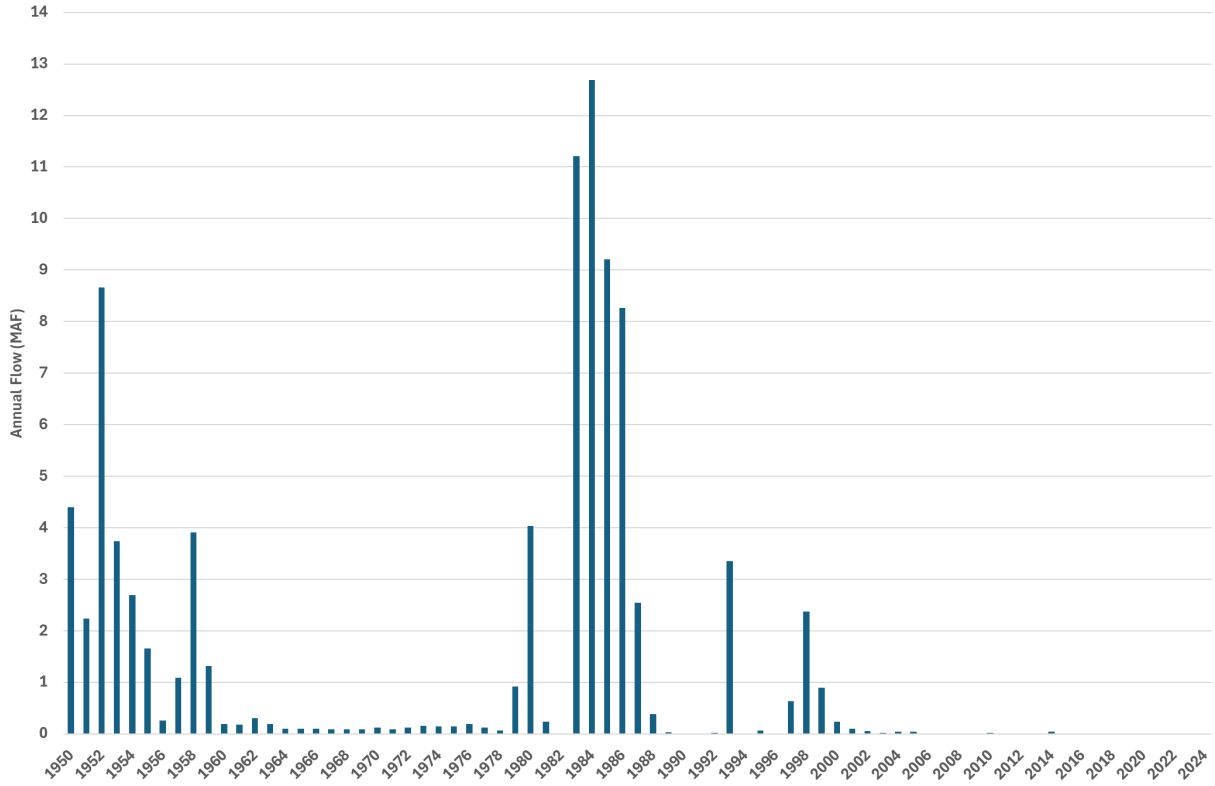
receives less than 3 inches of annual rainfall. Major flows in the Limitrophe have not regularly occurred since the 1980s and to a lesser degree in the 1990s when the reservoirs of Lake Powell Mead and Lake Mead were nearly full and spilling water was required. Notable events occurred from the 1993 Gila River floods and a pilot project that introduced environmental restoration flows (i.e. a "pulse flow") in 2014 under Minute 319 as described below.



Groundwater below the riverbed is recharged from irrigated fields in the Yuma area to the east and from Mexico's irrigation fields and seepage from the Reforma Canal to the west. The depth to groundwater increases from north to south. In the upper reaches, the relatively high-water table allows for perennial flows to exist, while the water table declines significantly towards the SIB (Ramírez-Hernández et al. 2013; Cohen 2013). Low moisture conditions in the root zones make surface vegetation sparse; however, by tapping into pumped groundwater in both countries and delivering water from canal infrastructure in Mexico, several restoration efforts exist along both sides of the riverbanks, such as Gadsden Bend, Miguel Aleman, Janitzio and Hunters Hole. These sites seek to re-establish and maintain vegetation along the riparian corridor in the Limitrophe and enhance habitat conditions for migratory and non-migratory birds and terrestrial species. A study of the composition of avian populations in the Colorado River Delta region demonstrates the high influence of the plant communities and land cover on the variability of bird species, as well as a positive relationship between cover of native riparian trees and shrubs and bird species with an

affinity for riparian forests (Gonzales-Sargas et al. 2024). Two of the five focal reaches of this study are within the Limitrophe.

An extensive study conducted by Cohen (2013) indicated that groundwater conditions had deteriorated over the 57 years prior to their study. While upper reaches showed relatively steadier groundwater elevations, the deterioration was particularly noted in the lower reaches of the Limitrophe where water table elevations dropped around 27 feet between 1960 and 2009. This decline was attributed to several factors, including the decrease of surface flows downstream from Morelos Dam, diminishing groundwater recharge, and increased well pumping along the Arizona-Sonora border. As water tables decline further, resulting in decreasing unmanaged vegetation, the relative value of restoration areas to maintain a riparian habitat increases, such as Gadsden Bend, Miguel Aleman, Janitzio, and Hunters Hole.

Flows reaching the SIB through the Limitrophe have been substantial in past years (**Figure N-2**). Notably in the 1980s, flood control releases from Lake Mead allowed over 12 million acre-feet (maf)/year (14,800 million cubic meters [mcm]/year) to be discharged through the Morelos Dam and down into the Colorado River Delta. In recent decades this flow has been minimal. As a product of Minute 319, an environmental pulse flow of approximately 105,392 acre-feet (af) was released below Morelos Dam in 2014 to mimic a spring flood flow that reached the Sea of Cortez (Pitt et al. 2017).

N.2.2 Previous Binational Coordination

The U.S. and Mexico have a long history of cooperation and coordination with respect to the Colorado River, most notably starting with the 1944 Water Treaty. This treaty guarantees an annual quantity of 1.5 maf (1,850 mcm) to Mexico from the Colorado River under normal conditions, with the potential for up to a total of 1.7 maf (2,100 mcm) during times when surplus waters are available. It also provides for reduced volumes to Mexico under extraordinary drought.

The precise text of the 1944 Water Treaty is as follows:

Article 10(a) of the 1944 Water Treaty states:

> "(a) A guaranteed annual quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) to be delivered in accordance with the provisions of Article 15 of this Treaty"

Further, Article 10(b) of the 1944 Water Treaty states:

> "(b) Any other quantities arriving at the Mexican points of diversion, with the understanding that in any year in which, as determined by the United States Section, there exists a surplus of waters of the Colorado River in excess of the amount necessary to supply uses in the United States and the guaranteed quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) annually to Mexico, the United States undertakes to deliver to Mexico, in the manner set out in Article 15 of this Treaty, additional waters of the Colorado River system to provide a total quantity not to exceed 1,700,000 acre-feet (2,096,931,000 cubic meters) a year. Mexico shall acquire no right beyond that provided by this subparagraph by the use of waters of the Colorado River system, for any purpose whatsoever, in excess of 1,500,000 acre-feet (1,850,234,000 cubic meters) annually."

Additionally, Article 10 of the 1944 Water Treaty states:

> "In the event of extraordinary drought or serious accident to the irrigation system in the United States, thereby making it difficult for the United States to deliver the guaranteed quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) a year, the water allotted to Mexico under subparagraph (a) of this Article will be reduced in the same proportion as consumptive uses in the United States are reduced."

Since the 1944 Water Treaty was signed, a series of implementing agreements, or Minutes, have been agreed upon and signed to facilitate cooperation between the countries. Some of them are of particular relevance to the issues analyzed in this EIS.

Salinity of water is an important concern to users in the Lower Basin including those in the U.S. and Mexico. While some salinity sources naturally exist throughout the Colorado River Basin, agricultural return flows, that are often high in salinity, enter the Colorado River through surface and groundwater pathways. As a result of salinity accumulation, diversions downstream along the Colorado River mainstem are increasingly impacted relative to diversions upstream. Diversions taken by Mexico are often subject to the highest salinity concentrations. This concern over salinity led to Minute 242 of the 1944 Water Treaty.

Resolution 1(a) of Minute 242 explicitly address the salinity concerns of Mexico stating:

> "The United States shall adopt measures to assure that not earlier than January 1, 1974, and no later than July 1, 1974, the approximately 1,360,000 acre-feet (1,677,545,000 cubic meters) delivered to Mexico upstream of Morelos Dam, have an annual average salinity of no more than 115 p.p.m. ± 30 p.p.m. U.S. count (121 p.p.m. ± 30 p.p.m. Mexican count) over the annual average salinity of Colorado River waters which arrive at Imperial Dam, with the understanding that any waters that may be delivered to Mexico under the Treaty of 1944 by means of the All American Canal shall be considered as having been delivered upstream of Morelos Dam for the purpose of computing this salinity."

Today Reclamation meets the obligation of the U.S. to not violate this differential through several different means, including bypassing saline waters through the Main Outlet Drain Extension (MODE) canal around agricultural, municipal, and industrial systems in the U.S. and Mexico and blending water arriving at the NIB through additional upstream releases.

In 2012, the U.S. and Mexico signed Minute 319 to the 1944 Water Treaty, titled *Interim International Cooperative Measures in the Colorado Rier Basin Through 2017 and Extension of Minute 318 Cooperative Measures to Address the Continued Effects of the April 2010 Earthquake in the Mexicali Valley, Baja California.* This Minute established four coordination mechanisms that affected flows in the International Border Region of the Colorado River:

- Based on the framework established in the Record of Decision for Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead (Reclamation 2007a) following the Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead Final EIS (2007 Interim Guidelines; Reclamation 2007b), Mexico agreed to reduced deliveries during times of low reservoir elevation conditions, defined by projected pool elevations of Lake Mead falling below specified thresholds. Three tiers of reductions were defined as "50,000 acre-feet (62 mcm) when the January 1 Lake Mead elevation is projected to be at or below 1,075 feet msl and at or above 1,050 feet msl; 70,000 acre-feet (86 mcm) when the January 1 Lake Mead elevation is projected to be below 1,050 feet msl and at or above 1,025 feet msl; and 125,000 acre-feet (154 mcm) when the January 1 Lake Mead elevation is projected to be below 1,025 feet msl." These low elevation thresholds align with those used to trigger shortages to users in Lower Division States and the volumes of reductions to Mexico were selected generally in proportion to shortage commitments by the Lower Division States in the 2007 Interim Guidelines. Minor adjustments were made to a strict proportionality to accommodate Mexico's preference for lower reductions under less severe conditions and greater reductions under more critical circumstances.
- Water deliveries to Mexico would increase during high elevation reservoir conditions as defined by projected pool elevations of Lake Mead at or above 1,145 feet, at or above 1,170 feet, and at or above 1,200 feet. In each of these cases, increases to annual releases to Mexico of 40.0 kaf (49 mcm), 55.0 kaf (68 mcm), and 80.0 kaf (99 mcm) respectively would be made. Only when flood control releases are required, Mexico would receive an annual increase of up to 200.0 kaf (247 mcm) not to exceed a total of 1.7 maf. The thresholds and

the volumes of flows under high elevation reservoir conditions also mirrored those of Lower Division States.

- Extending an emergency measure put into place as Minute 318 (Adjustment of Delivery Schedules for Water Allotted to Mexico for the Years 2010 Through 2013 as a Result of Infrastructure Damage in Irrigation District 014, Rio Colorado, Caused by the April 2010 Earthquake in the Mexicali Valley, Baja California) that followed an earthquake in April 2010, which damaged Mexico's irrigation infrastructure, Minute 319 established a conservation and storage mechanism, known as Intentionally Created Mexican Allocation, by which Mexico could defer delivery of a portion of their annual allotment of Colorado River water and deliver that water in a future year. This mechanism mirrored a similar program of Intentionally Created Surplus that allows U.S. users in Lower Division States to store water from one year to the next. Both the programs were established with clear rules for depositing and withdrawing water.
- Under the spirit of binational cooperation, a pilot program was initiated to dedicate water to enhance the environmental condition in the Colorado River Delta including its Limitrophe. Water created by conservation measures in Mexico and deferred in the U.S. system provided water for a 105,068 af (129.6 mcm) flow released from Morelos Dam on behalf of the U.S. and Mexican governments. A binational coalition of non-government organizations delivered a proportional amount through Mexico's irrigation canals to targeted restoration areas. Concurrently, this mechanism established the ability for 124,000 af (153 mcm) of water conserved as Intentionally Created Mexican Allocation to be transferred to Lower Division States' Intentionally Created Surplus accounts and used in the U.S..

The term of Minute 319 was 5 years, expiring on December 31, 2017. Prior to its expiration, Minute 323 was signed and entered into force on September 27, 2017, which built on and extended provisions of Minute 319 and added a complementary program to the Lower Basin Drought Contingency Plan until December 31, 2026. Titled the *Extension of Cooperative Measures and Adoption of a Binational Water Scarcity Contingency Plan in the Colorado River Basin*, Minute 323 provided a number of actions as follows:

- Reductions to deliveries to Mexico during low elevation Lake Mead reservoir conditions as specified in Minute 319 were extended.
- Additional deliveries to Mexico during high elevation Lake Mead reservoir conditions as specified in Minute 319 were extended.
- A Binational Water Scarcity Contingency Plan was established that provides for each country to save specified volumes of water at certain low reservoir elevations for recovery at a later date when reservoir conditions improve. Elevation thresholds for Mexico contributions match those developed in the *2019 Colorado River Drought Contingency Plans* (Reclamation 2019), and volumes of savings contributions by Mexico match the percent of additional saved contributions above the required reductions by Lower Division States at each elevation tier.
- A Mexico Water Reserve expands on and incorporates volumes previously stored in the accounts established in Minute 318 and 319, incorporates water retained from any future emergency measures, and provides a mechanism to defer delivery of a portion of Mexico's

annual water allocation through 2026. Delivery and deferral provisions are included in Minute 323.

- Expansion of restored native habitat in the Colorado River Limitrophe and Delta with 210,000 af of water, alongside funding for scientific research and monitoring, and funding for environmental enhancement projects. These elements were provided through equal contributions of the two Federal Governments and a binational coalition of non-governmental organizations, each of which would provide 1/3 of the required funding and water through conservation projects.
- In addition to the 70,000 af of water provided by the U.S. for native habitat enhancement, funding for conservation measures in Mexico would also provide 50,000 acre-feet (62 mcm) of water for the benefit of all users and 109,100 af (135 mcm) of water for use in the U.S.

Concurrent to the implementation of the *Supplement to the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead Record of Decision*, (Reclamation 2024a) following the *Near-term Colorado River Operations Final Supplemental Environmental Statement* (Reclamation 2024b) in March 2024, Minute 330, titled *Expansion of Colorado River Temporary Measures*, was signed between the U.S. and Mexico that requires Mexico to conserve 400.0 kaf between 2023 and 2026, which were in addition to conservation requirements specified in Minute 323. Of this amount, at least 250.0 kaf is water for the Colorado River system, and the remainder is for Mexico's Water Reserve. Any volume in Mexico's Water Reserve shall remain there through December 31, 2026.

N.2.3 Environmental Enhancement Activities

Continuing the binational collaboration initiated in Minute 306 (*Conceptual Framework for United States – Mexico Studies for Future Recommendations Concerning the Riparian and Estuarine Ecology of the Limitrophe Section of the Colorado River and its Associated Delta*), Minute 319 and Minute 323 operationalized environmental cooperation regarding the Colorado River Delta including the shared Limitrophe. Pilot efforts to plan and design water releases through the Limitrophe as well as enhance habitat conditions through re-vegetation have provided in-situ testing of restoration approaches. Over many decades much of the native habitat that was once found in the Limitrophe region is no longer present, or greatly degraded, due to a variety of factors including fire, mechanical removal, and lack of water. In the Limitrophe most of the native habitat now present is in the form of managed restored sites that are irrigated with groundwater or receive water via Mexico's diversion at Morelos Dam. Groundwater dependent sites are not expected to be affected by any changes in the system as the groundwater source and the sites themselves are actively managed independent of surface flows. Sites dependent on diversion infrastructure through Mexico will be affected by site maintenance activities, and the volume of water delivered to these habitat restoration sites will be affected to some extent by the total volume of water delivered to Mexico. The modeled annual deliveries (i.e. depletions) to Mexico include assumptions for reductions in water deliveries to Mexico and deferred deliveries that are available to Mexico for future delivery. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and

implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

The Minute 319 pulse flow of 2014 inundated approximately 4,000 acres (1,600 hectares) of the main channel and adjacent terraces of the Colorado River Delta, achieving connectivity to the Sea of Cortez for the first time since 2001 (Pitt et al. 2017). The pulse flow did not widen the channel or significantly result in geomorphic changes such as scouring sediments beyond 1 meter or bury existing vegetation. However, it did temporarily elevate water tables by as much as 9 meters (30 feet) locally and produced a 17 percent increase in Normalized Difference Vegetation Index (NDVI) or "Greenness" throughout the riparian corridor during the following growing season. This elevated NDVI decreased to pre-pulse levels in most reaches by 2017 and all reaches by 2018 (IBWC 2018; 2022). Although significant amounts of water infiltrated into the dry streambed and only a small amount of water reached the Sea of Cortez, the pulse flow of 2014 helped to reverse a decline in evapotranspiration from 2011 to 2013 (Jarchow et al. 2017a, 2017b).

Following targeted restoration efforts of Minute 323, Nagler et al. (2022) reported positive results measured by Landsat images of two-band Enhanced Vegetation Index (EV12) and evapotranspiration indicators (EVI2 and potential ET (ETo)), while non-restored areas declined notably. Furthermore, bird diversity and abundance of indicator species were 20 percent and 74 percent higher, respectively, in the restoration sites than in unrestored control sites (IBWC 2022). These studies assess conditions across sites throughout the Colorado River Delta, which include sites along the Limitrophe as well as locations outside of the geographic scope of this EIS.

N.2.4 Limits of Analysis

The proposed federal action is for the purpose of adopting additional operational guidelines to improve Reclamation's annual management and operation of key Colorado River reservoirs for an interim period. The scope is limited to evaluating potential impacts of the various alternatives within the U.S. and the Limitrophe reach shared with Mexico. The impacts within Mexico, including reaches downstream of the Limitrophe, are outside of the scope of this EIS. However, to assess the potential effects of the proposed federal action in this EIS, certain model assumptions are used that would potentially affect estimated water deliveries and flows into Mexico. Such modeling assumptions are used regarding the volume of water deliveries to Mexico as well as potential water releases for the Limitrophe as specified by the alternatives being considered.

Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

N.3 Methodology

This appendix compiles and describes a collection of analyses throughout the Environmental Impact Statement that pertain to the International Border Region. This Appendix primarily gathers results

from relevant Technical Appendices including **TA 3**, Hydrologic Resources, **TA 4**, Water Deliveries, and **TA 6**, Water Quality and presents them in a format to show the relative impacts of the proposed alternatives for Mexico, given the assumptions described in **Section N.3.2** and elsewhere. **Chapter 2** and **Appendix S** describes the alternatives that are simulated, **Appendix A**, CRSS Model Documentation, describes the CRSS modeling process and assumptions in detail, and **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, describes the use of the Shortage Allocation Model and Alternative Distribution Models. Refer to those sections for an understanding of the overall modeling processes. Assumptions and terminology used that are unique to the results provided for the International Border Region are described below.

N.3.1 Impact Indicators

Three key areas are considered when evaluating the impacts in the International Border Region. These include the following:

- Impacts on water deliveries and reductions to deliveries to Mexico (equivalent to shortages to Lower Division State users)
- Impacts on salinity/total dissolved solids
- Impacts on hydrologic flows in the Limitrophe

Hydrologic flows in Limitrophe are used as a proxy for environmental conditions in this river reach shared by the U.S. and Mexico.

N.3.2 Assumptions for the International Border Region

N.3.2.1 Colorado River Simulation System (CRSS)

Aspects unique to the international border region, including terminology used, are described in this section. The general assumptions in CRSS are described in **Appendix A**, CRSS Model Documentation.

Deliveries and reductions to Mexico

The relationship between water deliveries and reductions for Mexico is as follows:

Mexico's annual allotment (1.5 maf)	=	Annual water delivery to Mexico	+	Annual water delivery reduction to Mexico

The annual delivery reduction to Mexico can be the result of a policy explicitly specified in an alternative, described hereafter as a *water delivery reduction* for Mexico (as opposed to a shortage as used for Lower Division States) or Lake Mead reaching critically low elevations when the volume of water that can be released from Hoover Dam is insufficient to meet all downstream demands. In this case, modeling assumptions are made to further reduce water deliveries to users in what is termed a dead pool-related reduction. The combination of a water delivery reduction for Mexico and a dead pool-related reduction for Mexico comprises the total water delivery reductions for Mexico.

Total annual water delivery reduction to Mexico	=	Water delivery reduction to Mexico	+	Dead pool-related reduction to Mexico

In all alternatives, both types of water delivery reductions to Mexico occur simultaneously with the equivalent reductions to deliveries to Lower Division States (i.e., shortages). When shortages occur in the Lower Division States, reductions simultaneously occur for Mexico's water deliveries. In all alternatives, except for the Continued Current Strategies (CCS) Comparative Baseline[3], 16.67 percent of any shortage for the entirety of the Lower Basin is applied to Mexico on an annual basis. A comparison of the effects of varied assumptions is provided in **Appendix K**, Sensitivity Analysis – Effects of Modeling Assumptions with Regard to Future Water Deliveries to Mexico.

Lower Basin Shortages (100 percent)	=	Shortages to Lower Division States (83.33 percent)	+	Water Reductions to Mexico (16.67 percent)

There are no guarantees that shortages will be sufficient to keep Lake Mead from approaching dead pool when the water available is insufficient to meet downstream demands, so in this case, dead pool-related reductions are applied to users in Mexico concurrently with users in the Lower Division States. In all alternatives, including the CCS Comparative Baseline, 16.67 percent of any required basin-wide dead pool-related reduction is applied to Mexico as a water delivery reduction on a monthly basis.

Lower Basin dead pool-related reductions (100 percent)	=	Dead pool-related Reductions to Lower Division States (83.33 percent)	+	Dead pool-related Reductions to Mexico (16.67 percent)

The assumption of 16.67 percent of any Lower Basin shortage or dead pool-related reduction being applied to Mexico occurs regardless of the allocation method used among water users within the U.S.. The value of 16.67 percent reflects the fraction of water allocated to Mexico (1.5 maf) relative to the combined allocation for the Lower Division States and allotment to Mexico (9.0 maf).

Salinity Assumptions

CRSS includes salinity tracking capability, which was introduced specifically for the purpose of the International Border Region analyses in this EIS. Using an equation developed by the U.S. Geological Survey (USGS 2018), which can be classified as a hybrid between a mechanistic and statistical model, salinity at Imperial Dam is calculated as a function of Hoover Dam salinity, Parker Dam releases, and diversions by Colorado River Indian Reservation and Palo Verde Irrigation District . Salinity at the NIB is calculated as a function of simulated salinity at Imperial Dam and assumed monthly base flows accruing to the Colorado River between Imperial Dam and the NIB.

[3] The only exception to the consistent approach of applying 16.67 percent of shortages to Mexico is in the CCS Comparative Baseline. In this case reductions to Mexico's water deliveries follow logic derived from Minute 323 including Mexico's contributions to the Binational Water Scarcity Contingency Plan. This provides a point of comparison and is not considered an alternative in this EIS.

While CRSS does simulate flows between Imperial Dam and NIB, historical, average monthly base flows between Imperial Dam and the NIB are specified and used for the sole purpose of estimating salinity at NIB.

The base flows accruing to the river between Imperial Dam and NIB, which are used to estimate the salinity at the NIB, vary for each month but are the same for every year of the analysis. Base flow data includes monthly average volume and salinity estimated using historical data from the period of 2018 through 2022. Base flows include uncontrolled and unmeasured return flows from groundwater, measured irrigation return flows and canal wasteway flows, discharges to the Colorado River from pumped groundwater originating in the South Gila Valley and discharging through the Drainage Pump Outlet Channels, and pumped groundwater from the Yuma Mesa, Yuma Valley, and eastern end of the 242 Well Field, which discharge to the Colorado River by way of the Yuma Mesa Conduit. The salinity at the NIB is calculated via a simple monthly mass balance using the volume of Colorado River water delivered to Mexico by way of Imperial Dam (using the associated Imperial Dam salinity value) plus the base flows and their associated salinity values. The analysis conducted for this EIS does not include simulated operations by Reclamation's Yuma Area Office to ensure compliance with the Minute No. 242 salinity differential (IBWC 1973). A sensitivity analysis was conducted to evaluate how varying the assumed volume of pumped groundwater used to meet Mexico's delivery, within the constraints of CRSS, affects Lake Mead elevations (See **Box 1**). The NIB salinity data provided in this appendix should not be used as projected actual salinity at NIB but instead used to compare alternatives.

Environmental Enhancement Releases

Regarding alternatives that specify releases for habitat enhancement in the Colorado River Delta, water could be provided as discharges into the Limitrophe through or around the Morelos Dam or as additional diversions to Mexico that are strategically discharged back into the Limitrophe or further downstream to support enhancement efforts. For modeling purposes used in this EIS, water dedicated for environmental enhancement is assumed to be diverted by Mexico at the Morelos Dam and reflected as periodic additions to Mexico's diversion and not as flows downstream of the Morelos Dam or flows in the Limitrophe.

N.3.2.2 Shortage Allocation Models and Alternative Distribution Models

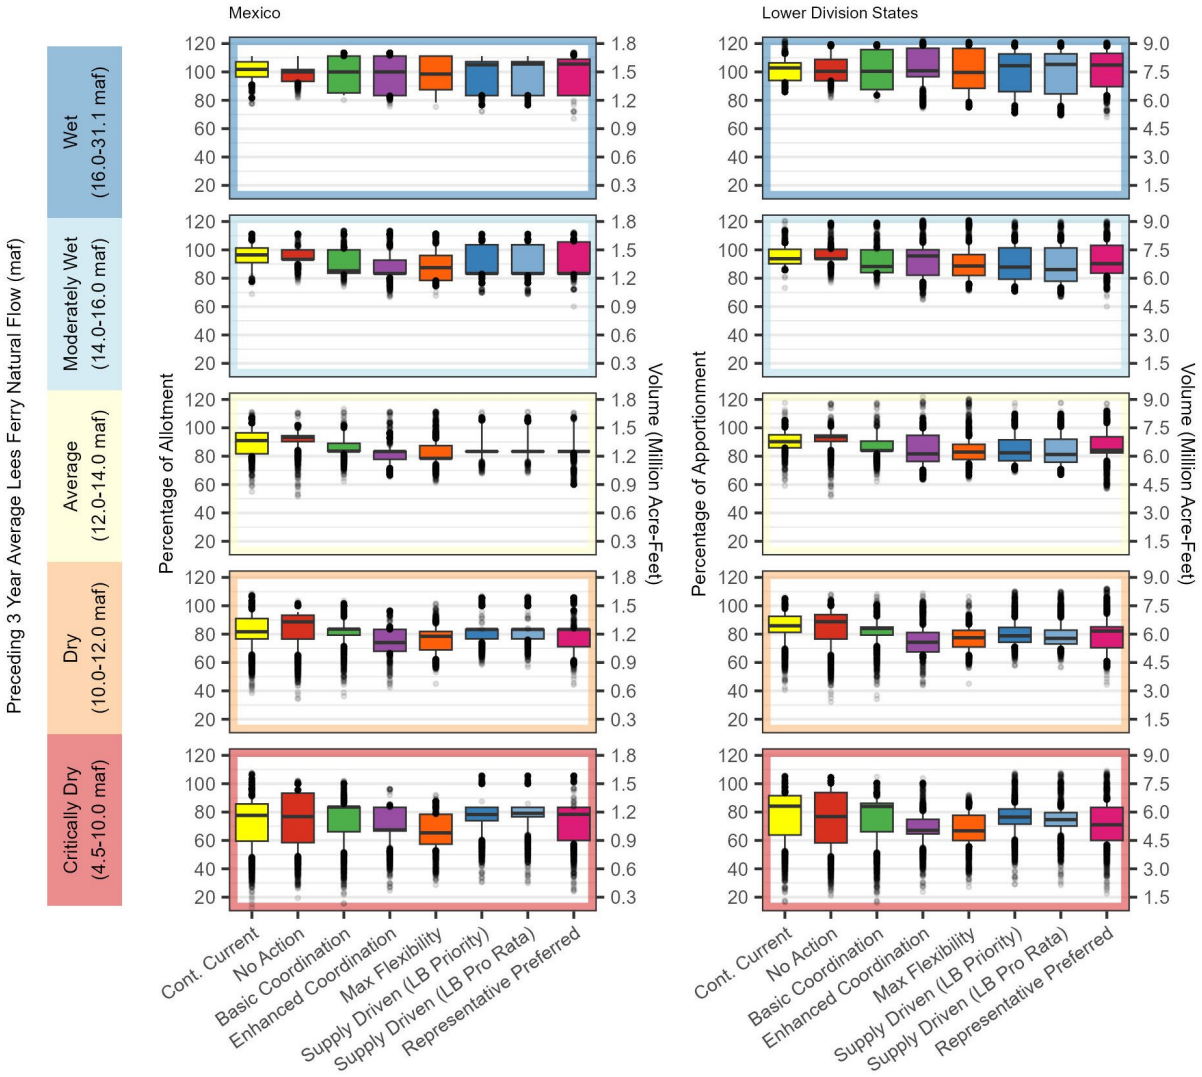
In the spreadsheet models used by Reclamation to represent the allocation of shortages to individual Lower Basin water users, the reduction volumes assigned to Mexico are identical to those in CRSS but use slightly different approaches depending on assumptions of priority vs. pro rata allocation schemes. In priority-based Shortage Allocation Models (SAM) and Alternative Distribution Models (ADM), the basin-wide shortage is separated into shortages to Lower Division States and water delivery reductions to Mexico so that the percent reduction from full allocation or allotment (7.5 maf and 1.5 maf) is identical, which is similar to the process used in CRSS. In the various pro rata ADMs, each user in the Lower Division States is reduced by a proportion of either the basin-wide shortage or state-wide shortages based on the total consumptive use of that user relative to the basin-wide or state-wide uses. In all cases, water delivery reductions allocated to Mexico are then simply the remainder of basin-wide shortages not allocated to the Lower Division States. In all variations of the SAMs and ADMs, the allocation of basin-wide water delivery reductions to Mexico is 16.67 percent, which is identical to the assumption used in CRSS, notwithstanding minor variation

in rounding. Refer to **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, for further information about the SAMs and ADMs.

N.4 Relevant Results

N.4.1 Issue 1: Water Deliveries and Reductions to Mexico

Water Deliveries to Mexico are described in **TA 4**, Water Deliveries, and summarized here. Water deliveries to Mexico are a function of assumed reductions to Mexico and assumptions about the deferral and delivery of conserved water to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.



N.4.1.1 Distributions of annual water deliveries to Mexico and Lower Division States

Figure N-3 presents conditional box plots of water deliveries to Mexico in comparison to deliveries to the combined Lower Division States of California, Arizona and Nevada. These deliveries reflect both the depletions from the river system after shortages (i.e. water delivery reductions) and dead pool-related reductions, which have been subtracted from the total allotments of 1.5 maf for Mexico and 7.5 maf from the Lower Division States. Deliveries (i.e. depletions) also account for modeling assumptions related to voluntary conservation mechanisms. The deliveries are broken out by different hydrologic conditions, categorized by modeled preceding 3-year average Lees Ferry natural flows. The hydrologic analysis is framed using 5 flow categories to help to visualize the different potential states of the system throughout the 34-year period of analysis. The 5 flow categories are: Wet (16-31.11 maf), Moderately Wet (14.0-16.0 maf), Average (12.0-14.0 maf), Dry (10.0-12.0 maf), and Critically Dry (4.46-10.0 maf). Each box plot represents the distribution of modeled outputs, with a horizontal line indicating the median value, the colored box indicating the range of values from the 25th to 75th percentile, the extent of the lines indicating the 10th and 90th percentiles, and circles representing values below the 10th and above the 90th percentiles (See **Chapter 3, Figure 3-2** for a detailed description). The value of the left-hand vertical axes of the figure represents the percent of full allotment (terminology for Mexico) or apportionment (for Lower Division States), therefore in the plot of deliveries for Mexico, 100 percent indicates when Mexico is receiving the annual 1.5 maf of delivery as specified in the 1944 Water Treaty, and in the plot for Lower Division States, 100 percent indicates when these states are receiving 7.5 maf. Scaling the vertical axis by percent allotment or apportionment allows direct comparability between Mexico and the Lower Division States regarding the implications of the alternatives.

To evaluate the relative implications of the alternatives on deliveries to Mexico, an initial focus is on the Average Flow Category (12.0-14.0 maf preceding 3-year average), where the median percent of full allotment ranges from the least impactful No Action Alternative (93.3 percent) to the most impactful Maximum Operational Flexibility Alternative (78.5 percent), with all other alternatives between this narrow range including the Representative Preferred Alternative with 83.3 percent. In the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average), the median percent of

full allotment ranges from the least impactful Basic Coordination Alternative (83.6 percent) to the most impactful Maximum Operational Flexibility Alternative (65.4 percent), with all other alternatives between this expanding range including the Representative Preferred Alternative with a median of 78.4 percent.

Figure N-3
Conditional Box Plots of Calendar Year Water Deliveries to Mexico and Lower Division States

Note: The modeled annual depletions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and deferred deliveries that are available to Mexico for future delivery. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

These values for Mexico are comparable to those of the combined Lower Division States, which in the Average Flow Category (12.0-14.0 maf preceding 3-year average) the median percent of full allocation ranges from the least impactful No Action Alternative (93.8 percent) to the most impactful Supply Driven Alternative (LB Pro Rata approach) (81.2 percent) with the Representative Preferred Alternative with 84.2 percent. Similarly, for the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average) the median percent of full allocation ranges from the least impactful CCS Comparative Baseline (84.2 percent) to the most impactful Maximum Operational Flexibility Alternative (66.8 percent), with the Representative Preferred Alternative providing a median of 71.0 percent of full allocation to Mexico.

Although Mexico's percent of total Lower Basin shortage or dead pool-related reductions is fixed as 16.67 percent among all the alternatives (except for the CCS Comparative Baseline), this does not necessarily equate to identical depletions as a percent of allotment (i.e. apportionment) of reductions between the Lower Division States and Mexico. This is due to varied assumptions on storage mechanism parameters and activity between Mexico and the Lower Division States, and the monthly application of dead pool-related reductions (Note: As seen in a subsequent analyses, annual water delivery reductions (i.e. shortages) are identical as a percent of allotment (or apportionment) for Mexico and the Lower Division States). A comparison of median values of annual depletions under the Average and Critically Dry hydrologic categories is shown in **Table N-1**.

Table N-1
Annual depletions in Mexico and Lower Division States (as a percent of allotment or apportionment) at the median value of years in the average (12.0-14.0 maf preceding 3-year average) and critically dry (4.46-10.0 maf preceding 3-year average) hydrologic categories.

	Average Flow Category (12.0-14.0 maf preceding 3-year average)		Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average)	
	Mexico	Lower Division States	Mexico	Lower Division States
Cont. Current	91.0	90.2	77.7	84.2
No Action	93.3	93.8	76.8	76.8
Basic Coordination	83.6	84.0	83.6	84.0
Enhanced Coordination	83.3	81.6	67.4	67.1
Max Operational Flexibility	78.5	82.9	65.4	66.8
Supply Driven (LB Priority)	83.3	82.4	78.3	76.5
Supply Driven (LB Pro Rata)	83.3	81.2	79.2	74.7
Representative Preferred	83.3	84.2	78.4	71.0

Note: The modeled annual depletions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and deferred deliveries that are available to Mexico for future delivery. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Due to the design of the No Action and Basic Coordination Alternatives having the lowest maximum shortages (0.6 maf and 1.48 maf respectively), these alternatives result in the lowest impact on diversions to Mexico or the Lower Division States, but at the cost of the largest impact on reservoir storage (See **TA 3, Hydrologic Resources, Figure TA 3-18**). The CCS Comparative Baseline has a similarly low maximum shortage (1.38 maf), but these levels of shortage do not begin until Lake Mead is below 1,025 feet. The Maximum Operational Flexibility Alternative has the highest maximum possible shortage (4.0 maf), thus resulting in the highest median impacts on Mexico under these two flow categories of 12.0-14.0 maf and 4.46-10.0 maf preceding 3-year average.

The variability of deliveries during dry conditions is another metric by which to evaluate the alternatives. To do this, the interquartile range (boxed areas representing the range from the 25th to 75th percentiles in **Figure N-3**) is evaluated within the Critically Dry Flow Category (4.46-10 maf). To provide an example calculation for the CCS Comparative Baseline for Mexico in this Hydrologic Category, the 75th percentile (85.7 percent of allotment) minus the 25th percentile (59.5 percent of allotment), results in a 26.2 percent interquartile range (See **TA 4, Water Deliveries, Table TA 4-39** for all percentiles in **Figure N-3**). Three distinct groupings of alternatives are apparent (**Table N-2**). The CCS Comparative Baseline and the No Action Alternative have the widest interquartile ranges (26.2 percent and 34.9 percent respectively for Mexico, and 27.7 percent and 35.5 percent for the Lower Division States). The Basic Coordination, Maximum Operational Flexibility, and Representative Preferred Alternatives all have similar interquartile ranges (between 17.4 percent and 23.3 percent for Mexico and 17.8 percent and 23.3 percent for the Lower Division States). The Supply Driven Alterative has the narrowest interquartile range, with 9.4 percent and 6.7 percent for the Lower Basin Priority (LB Priority) and Lower Pasin Pro Rata (LB Pro Rata) distribution approaches respectively for Mexico, and 10.7 and 9.5 for the Lower Division States. The Enhanced Coordination Alternative spans across the narrowest and mid-range group of alternatives, with 16.7 and 10.3 percent for Mexico and Lower Division States respectively. Several factors affect the sizes of the interquartile ranges. In general, the narrower the variability, the more consistent the releases are to meet demands, which is substantially influenced by the design of the alternatives including the maximum specified shortage, the slope of the shortage operation curve, and the use of conservation and storage mechanisms that help to even out water deliveries. The alternatives with low maximum specified shortages (No Action, Basic Coordination Alternatives, and CCS Comparative Baseline) often lead to dead pool-related reductions, which result in highly variable reductions of use and therefore highly variable annual depletions. Furthermore, these same alternatives have no or minimal storage mechanisms, resulting in less mitigation ability and greater variability of flows near the median. On the other extreme, the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) has the large Lower Basin storage mechanisms, resulting in the small interquartile ranges and low variability around the median. This highlights the benefits of conservation and storage mechanisms to reduce variability in water deliveries. Finally, the Representative Preferred Alternative has a wide interquartile range, despite the specification of a high maximum specified shortage and a large Lower Basin storage mechanism, because of the significant slope of the shortage curve at low reservoir elevations, quicky ranging from 1.5 maf to 3.6 maf between Lake Mead elevations of 1,025 and 975 feet.

Table N-2
Interquartile range of annual depletions (as a range between the 75th and 25th percentile, reported as percent of allotment or apportionment) for Mexico and Lower Division States at the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average).

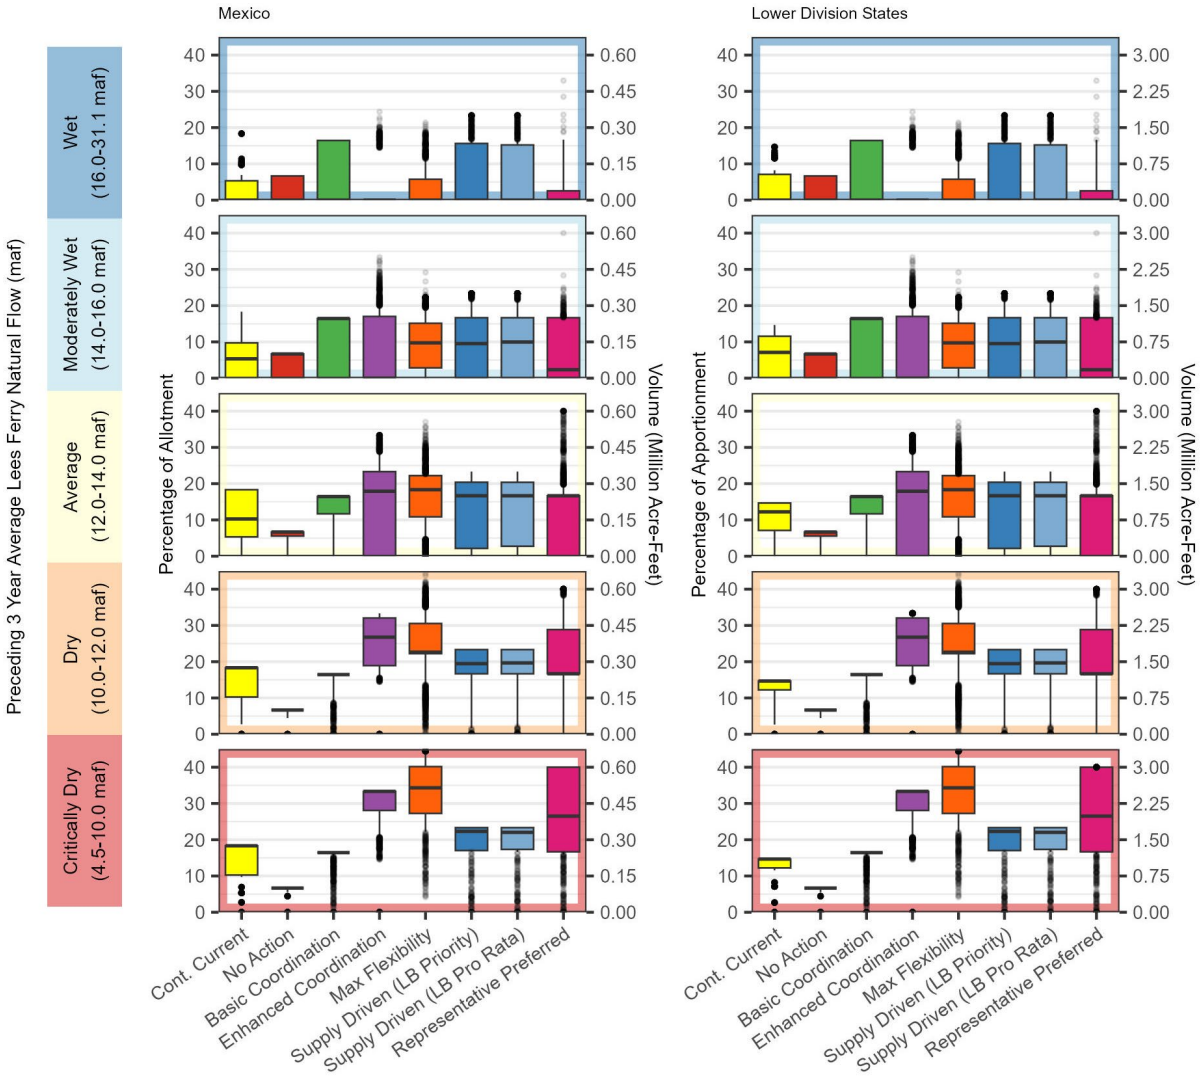
	Interquartile range	
	Mexico	Lower Division States
Cont. Current	26.2	27.7
No Action	34.9	35.5
Basic Coordination	17.4	20.1
Enhanced Coordination	16.7	10.3
Max Operational Flexibility	21.1	17.8
Supply Driven (LB Priority)	9.4	10.7
Supply Driven (LB Pro Rata)	6.7	9.5
Representative Preferred	23.3	23.3

Note: The modeled annual depletions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and deferred deliveries that are available to Mexico for future delivery. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Looking further into the distributions under the Critically Dry Flow Category (4.46-10.0 maf) (**Table N-3),** all alternatives show the possibility of deliveries to Mexico being reduced to extremely low percentages of their 1.5 maf apportionment, ranging from a minimum of 12.7 percent and 15.2 percent of apportionment (corresponding to 0.19 maf and 0.23 maf of total deliveries to Mexico) under the Current Continued Strategies and the Basic Coordination Alternative respectively, to a 30.5 percent of apportionment (0.46 maf) for the Supply Driven Alternative (LB Priority approach). The minimum delivery to Mexico under the Representative Preferred Alternative is 24.1 percent of apportionment (0.36 maf).

Table N-3
Annual depletions in Mexico (as a percent of allotment) at the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average)

	Percentile						
	max	90th	75th	50th	25th	10th	min
Cont. Current	107.1	91.0	85.7	77.7	59.5	48.6	12.7
No Action	101.7	94.4	93.3	76.8	58.4	49.1	19.4
Basic Coordination	101.7	85.2	83.6	83.6	66.1	51.8	15.2
Enhanced Coordination	96.3	83.3	83.3	67.4	66.7	54.9	24.6
Max Operational Flexibility	92.1	78.5	78.5	65.4	57.4	53.2	28.6
Supply Driven (LB Priority)	105.6	83.3	83.3	78.3	73.9	60.5	30.5
Supply Driven (LB Pro Rata)	105.6	83.3	83.3	79.2	76.7	63.9	29.7
Representative Preferred	105.6	83.3	83.3	78.4	60.0	57.9	24.1



Note: The modeled annual depletions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and deferred deliveries that are available to Mexico for future delivery. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

N.4.1.2 Distributions of annual water delivery reductions to Mexico and Lower Division States

Using the same 5 preceding hydrologic flow categories to help to visualize the different potential states of the system throughout the 34-year period of analysis, **Figure N-4** shows the volume of water delivery reductions to Mexico alongside those of the combined Lower Division States. Due to the differences in magnitudes of use and corresponding shortages between Mexico and the Lower Division States, the left-hand axes show the percent of allotment or apportionment to allow comparability, and the right-hand axes show the volumes of water delivery reductions.

The magnitude of water delivery reductions to Mexico reflects the design of the policies as well as the hydrologic conditions but does not reflect any dead pool-related reductions which are significant under alternatives with limited specified Lower Basin shortages. Under the Average Flow Category (12.0-14.0 maf preceding 3-year average), the Maximum Operational Flexibility Alternative results in the largest median reduction value of 18.3 percent of apportionment for Mexico (**Table N-4**). The Enhanced Coordination is similar with a median value of 17.9 percent. The Supply Driven (both LB Priority and LB Pro Rata approaches) and Representative Preferred Alternatives all have median values of 16.7 percent of Mexico's apportionment. In contrast, both baselines reflect low water delivery reductions with the CCS Comparative Baseline resulting in a median of 10.3 percent and the No Action Alternative with a median of 6.7 percent of the apportionment to Mexico, while the Basic Coordination Alternative results in a median reduction of 16.4 percent of the apportionment to Mexico. However, these three alternatives result in more frequent dead pool-related shortages as described in a subsequent analysis.

Figure N-4
Conditional Box Plots of Calendar Year Delivery Reductions to Mexico and Lower Division States

Note: The modeled annual delivery reductions to Mexico include assumptions that are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Table N-4
Water delivery reductions (as percent of allotment or apportionment) for Mexico and Lower Division States at the median value of years in the Average (12.0-14.0 maf preceding 3-year average) and Critically Dry (4.46-10.0 maf preceding 3-year average) Flow Categories.

	Average Flow Category (12.0-14.0 maf preceding 3-year average)		Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average)	
	Mexico	Lower Division States	Mexico	Lower Division States
Cont. Current	10.3%	12.2%	18.3%	14.7%
No Action	6.7%	6.7%	6.7%	6.7%
Basic Coordination	16.4%	16.4%	16.4%	16.4%
Enhanced Coordination	17.9%	17.9%	33.3%	33.3%
Max Operational Flexibility	18.3%	18.3%	34.3%	34.3%
Supply Driven (LB Priority)	16.7%	16.7%	22.3%	22.3%
Supply Driven (LB Pro Rata)	16.7%	16.7%	22.0%	22.0%
Representative Preferred	16.7%	16.7%	26.5%	26.5%

Note: The modeled annual delivery reductions to Mexico include assumptions that are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Under the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average), the largest median water delivery reduction to Mexico occurs using the Maximum Operational Flexibility Alternative with a median of 34.3 percent of the apportionment to Mexico followed by the Enhanced Coordination Alternative with a median of 33.3 percent. The alternative with the lowest median water delivery reduction is the No Action Alternative (6.7 percent); however, as shown below, this low water delivery reduction results in the lowest avoidance of dead pool-related reductions. The Representative Preferred Alternative results in a median water delivery reduction to Mexico of 26.5 percent of their 1.5 maf allotment, or 0.40 maf.

The median water delivery reductions by a percent of apportionment are identical between Mexico and the Lower Division States under all alternatives (**Table N-4**). The one exception is the CCS Comparative Baseline, which is the result of current policies derived from the combination of actions specified in Minute 319 and Minute 323 for Mexico, and the combination of actions specified in the 2007 Interim Guidelines and 2019 Lower Basin Drought Contingency Plan for the Lower Division States.

Figure N-4 also shows the implications of proactive versus delayed water delivery reductions to both the Lower Division States and Mexico. The comparatively wide interquartile range of the Representative Preferred Alternative in the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average) suggests that under these dire conditions, there is little predictability in the required

reductions to water use. The primary difference of this alternative compared to the Enhanced Coordination and Maximum Operational Flexibility, which have similar maximum reduction volumes, is the level of reductions remain at 1.5 maf until Lake Mead falls to 1,025 feet, at which time the required reductions increase rapidly; The other similar alternatives use more gradually increasing reductions, thereby more proactively reducing the range of likely shortages under this Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average). Under the Average Flow Category (12.0-14.0 maf preceding 3-year average), water delivery reductions under the Enhanced Coordination Alternative range widely as the reduction curves span a wide step from no reductions to 1.5 maf of reductions as the combined effective storage of Lake Powell and Lake Mead exceeds 60 percent. In comparison, the Maximum Operational Flexibility Alternative has a linearly increasing reductions throughout the range of the combined seven-reservoir storage conditions, resulting in a comparatively consistent interquartile sizes throughout all preceding hydrologic conditions. In other words, the more continuous the shortage curves are in a policy design, the more uniform one can expect the shortage ranges to be within any hydrologic category, while policies that are designed with steps in shortage volumes result in wider possible variations of shortages once a storage condition nears the threshold of those steps. The upper limits of the interquartile ranges reflect the maximum shortages designed by the policies, but not those that would result from dead pool-related reductions.

All modeled results used to develop the conditional box plots for Mexico in **Figure N-4** are shown in **Table N-5**. The value within each cell represents the percent of Mexico's 1.5 maf allotment that would be subject to a water delivery reduction, and the shading represents instances where the maximum planned water delivery reduction occurs for each alternative. If a modeled scenario reaches the maximum water delivery reduction, then any additional water delivery reductions would occur as dead pool-related reductions and is not reflected in the magnitude of the cell values.

With maximum Lower Basin shortage volumes of 0.6 maf for the No Action Alternative (corresponding to a maximum 0.6 maf x 16.67 percent = 100.0 kaf reduction to Mexico) and 1.48 maf for the Basic Coordination Alternative (corresponding to an assumed maximum 1.48 maf x 16.67 percent = 247 kaf reduction to Mexico), the percent reduction numbers are comparatively low but the maximum reduction levels are reached in over half of the years (50th percentile) even within the Average Flow Category (12.0-14.0 maf). On the other extreme, under the Maximum Operational Flexibility Alternative, the shortage percentages are higher but with a maximum Lower Basin shortage of 4.0 maf (corresponding to an assumed maximum 4.0 maf x 16.67 percent = 100.0 kaf reduction to Mexico) this value is infrequently reached, i.e. only during the Critically Dry Flow Category (4.46-10.0 maf) and in less than 10 percent of traces and years modeled. In the Representative Preferred Alternative with a maximum Lower Basin shortage of 3.6 maf (corresponding to an assumed maximum of 3.6 maf x 16.67 percent = 400.0 kaf reduction to Mexico) this maximum reduction occurs across Dry through Moderately Wet hydrologic conditions (10.0-16.0 maf) but in less than 10 percent of all modeled futures. Only in Critically Dry hydrologic conditions (4.46-10.0 maf) do dead pool-related reductions occur in 25 percent of modeled futures.

Table N-5
Modeled water delivery reductions (as a percent of 1.5 maf allotment) to Mexico within each flow category

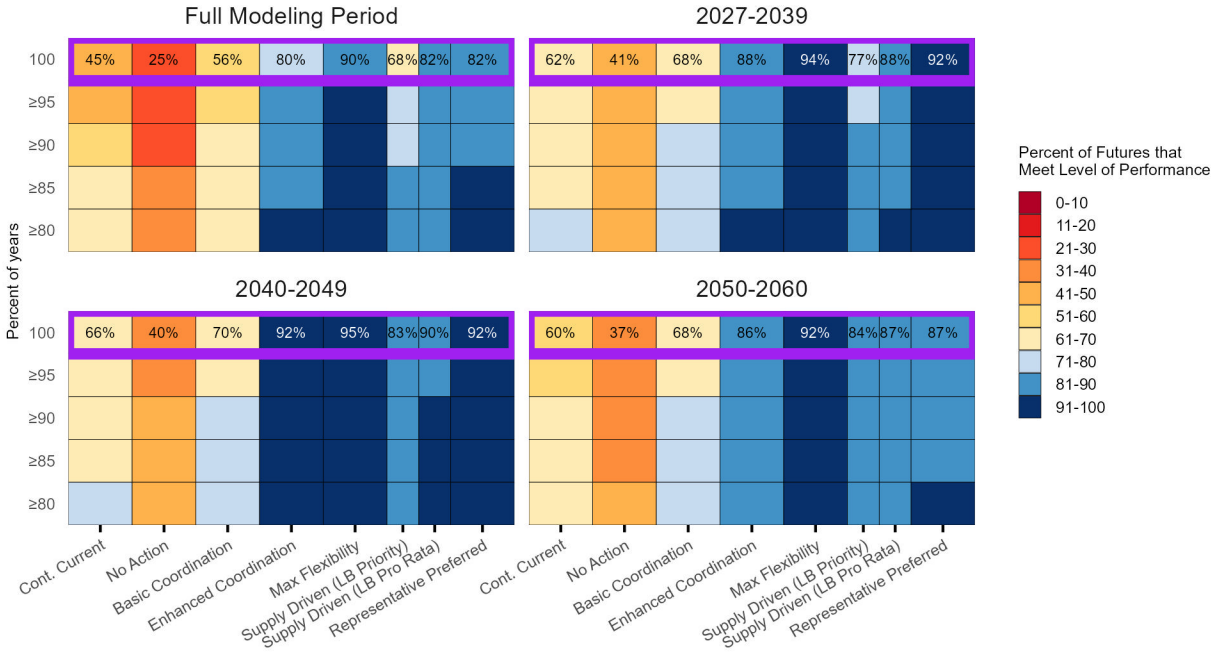
Notes:
- Percentiles indicate the range of distribution with each category and correspond to the box plots in **Figure N-4**. Shading indicates conditions in which the maximum Lower Basin Shortage has been reached, thus the maximum planned water delivery reduction to Mexico has been reached. Numbers with shaded percentages do not include dead pool-related reductions, therefore total reductions to Mexico are likely greater than these percentages to maintain proportionality with total Lower Basin Shortages that do include dead pool-related reductions.
- The modeled annual delivery reductions to Mexico include assumptions that are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.



The cell values in **Table N-5** demonstrate how the magnitude of potential planned water delivery reductions generally increases based on the maximum reduction designed within the alternative, allowing a relative ranking of the alternatives from the lowest reductions in the No Action Alternative and increasing to the Maximum Operational Flexibility Alternative. The No Action Alternative shows the smallest numbers (up to 6.7 percent, corresponding to maximum reduction of 100.0 kaf for Mexico) which occur frequently, while the Maximum Operational Flexibility Alternative shows the largest numbers (up to 44.5 percent, corresponding to maximum reduction of 667.0 kaf for Mexico) but occurs infrequently across all modeled futures. The Representative Preferred Alternative has a maximum percent of Lower Basin water delivery reduction (up to 40.0 percent, corresponding to maximum reduction of 600.0 kaf for Mexico) falling between the Maximum Flexibility Alternative and Enhanced Coordination Alternative.

No Action	<	Basic Coord.	<	Current Cont. Strat.	<	Supply Driven Alternatives	<	Enhanced Coord.	<	Representative Preferred	<	Maximum Flexibility
Lowest Water Delivery Reductions												Highest Water Delivery Reductions

In contrast to the cell values, the extent of shading in **Table N-5** demonstrates the relative susceptibility of each alternative to reach its maximum shortage. If the maximum water delivery reductions are reached and the reservoirs continue to decline due to supply-demand imbalances, Mexico, along with users in the Lower Division States, would be subject to dead pool-related reductions as Lake Mead elevations decline. Only by keeping Lake Mead above dead pool can water releases assuredly be made to Mexico that are only subjected to planned reductions.

To support this finding, **Figure N-5** shows the ability of each alternative (columns) to avoid dead pool-related reductions at Lake Mead in the specified percent of years (rows) using the 400 futures analyzed in CRSS. The highlighted row in this robustness heatmap represents the percentage of futures that an alternative successfully avoids dead pool-related reductions in 100 percent of the years. The top left plot demonstrates the robustness across the 34-year modeled time horizon, while the other plots demonstrate the robustness of avoiding dead pool-related reductions in individual time periods of 2027-2039, 2040-2049, and 2050-2060.

Figure N-5
Lake Mead Dead Pool-Related Reductions Robustness Heatmap
Percent of futures in which dead pool-related reductions are avoided in the percent of years specified in each row

To support comparison among alternatives during the period most relevant to implementation of the Preferred Alternative, the heat maps focus on results from the first modeling period, which includes years 2027–2039. Considering this first modeling period, the Maximum Operational Flexibility Alternative keeps Mexico, along with all Lower Basin water users, from facing dead pool-related reductions in 94 percent of the 400 futures assessed, while the No Action Alternative avoids dead pool-related reductions in only 41 percent of futures. The CCS Comparative Baseline and Basic Coordination Alternative improve performance relative to the No Action Alternative by avoiding dead-pool related reductions in 62 and 68 percent of futures respectively (i.e. robustness scores), while the Supply Driven Alternative (LB Priority approach) reaches a 77 percent robustness score. The Enhanced Coordination Alternative and the Supply Driven Alternative (LB Pro Rata approach) achieve a robustness score near the level of the Maximum Operational Flexibility Alternative with 88 percent of the future hydrologic scenarios avoiding dead pool-related shortages. Finally, the Representative Preferred Alternative avoids dead pool-related reductions in 92 percent of future

hydrologic scenarios, reflecting a high level of protection from any reductions that would occur beyond those specified in this alternative. Given the focus on results on the first modeling period from 2027-2039, and the robustness scores in **Figure N-5**, a ranking of alternatives based on Mexico and Lower Division States' susceptibility to dead pool reductions is as follows.

Max. Flex.	<	Representative Preferred	<	Enhanced Coord.	=	Supply Driven Pro rata	<	Supply Driven Priority	<	Basic Coord.	<	Cont. Current	<	No Action
Lowest suscept-ability to dead pool reductions														Highest suscept-ability to dead pool reductions

The robustness analysis of future time periods in **Figure N-5** indicates somewhat different ranking orders for the Representative Preferred, Enhanced Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives, but the Maximum Operational Flexibility always shows the highest level of robustness to protect against dead pool-related reductions while the No Action Alternative, CCS Comparative Baseline, and Basic Coordination Alternative results in the least robust alternatives with respect to dead pool-related reductions.

N.4.2 Issue 2: Quality of water delivered to Mexico

Water salinity of deliveries to Mexico are described in **TA 6**, Water Quality and summarized here, with a particular emphasis on salinity at Imperial Dam and NIB.

Due to natural and anthropogenic sources, high salinity in the Colorado River is an issue of concern for both the U.S. and Mexico and is actively managed. Minute 242 of the 1944 Water Treaty specifies a maximum annual differential of salinity between water that arrives at the Morelos Dam and that which arrives at the Imperial Dam. As described earlier, Reclamation meets this obligation through several coordinated actions. A portion of the water delivery to Mexico is met using pumped groundwater in the Yuma Area, which also helps to maintain water tables in the Yuma Area. While high-salinity groundwater can be bypassed through the MODE canal to route it around agricultural, municipal, and industrial systems in both the U.S. and Mexico, water bypassed through the MODE is not used to satisfy delivery obligations to Mexico; however, some quantity of pumped groundwater can be discharged into the river channel to help meet delivery obligations to Mexico. To ensure that water delivered at the NIB meets required salinity standards, Reclamation limits the volume of pumped groundwater discharged to the river to comply with the Minute 242 annual salinity differential of 115 ppm (+/- 30 ppm). The remainder of the pumped groundwater is either discharged to the MODE / Bypass Drain (in the case of pumped groundwater from the South Gila Valley) or is not pumped (in the case of water from the 242 Well Field that is delivered north through the 242 Pipeline and Yuma Mesa Conduit). To satisfy delivery obligations with Mexico, any volume that cannot be met from pumped groundwater is met from upstream releases of mainstream Colorado River water.

Relevant to the federal action addressed in this Final EIS is a comparative assessment of the long-term implications of the proposed alternatives on salinity levels at both the Imperial Dam and NIB. The impacts of the alternatives are provided as concentrations at the principal points of diversion at the Imperial Dam and NIB and are not intended to be used to determine salinity differential compliance as specified in Minute 242. To meet the salinity differential, Reclamation actively manages operations through the means described above at a smaller timescale than is required for this Final EIS; however, a sensitivity analysis was conducted to evaluate how varying the assumed volume of pumped groundwater (a key variable in managing deliveries and salinity pursuant to Minute 242) used to meet Mexico's delivery, within CRSS constraints, affects Lake Mead elevations, total Lower Basin shortages, and flows below Parker Dam (See **Box 1**).

Box 1: Sensitivity of Lake Mead to Varying the Assumed Volume of Pumped Groundwater Used to Meet Mexico's Delivery, within the Constraints of CRSS

Background

Reclamation primarily manages salinity levels at the NIB by varying the volume of pumped groundwater discharged to the Colorado River between Imperial Dam and the NIB and delivered to Mexico at the NIB to satisfy 1944 Water Treaty requirements. If pumped groundwater from the South Gila Valley (Drainage Pump Outlet Channels) cannot be delivered to the NIB due to Min 242 salinity limitations, it is discharged into the MODE where it is not charged to the 1944 Water Treaty. Similarly, if pumped groundwater from the 242 Well Field cannot be delivered to the NIB for reasons of salinity compliance, those wells are shut down (only those wells in the eastern portion of the 242 Well Field that discharge to the 242 Pipeline, Yuma Mesa Conduit, and ultimately the NIB). In CRSS, the only explicitly modeled pumped groundwater is assumed to be 25.0 kaf/year and broadly labeled as the 242 Well Field. When discharging pumped groundwater to the river would prohibit the U.S. from meeting the salinity differential of 115 ppm (+/- 30 ppm), the volume of pumped groundwater discharged into the Colorado River is reduced. Under this circumstance, to make up for the reduction of pumped groundwater discharged to the river, and to ensure delivery requirements to Mexico are maintained, upstream releases of mainstream Colorado River water are increased, which have a lower salinity than the pumped groundwater.

Sensitivity Analysis

With respect to salinity management, the highest level of impact on Lake Mead occurs when no additional pumped groundwater is introduced into the Colorado River between Imperial Dam and the NIB. This historically occurs intermittently throughout the year, therefore a conservative assumption with respect to the impacts on Lake Mead and subsequent Lower Basin shortages is to analyze the implications of eliminating the contributions of the 242 Well Field throughout the entire modeled period. Such an analysis indicates the impacts of reducing pumped groundwater by 25.0 kaf/year on Lake Mead.

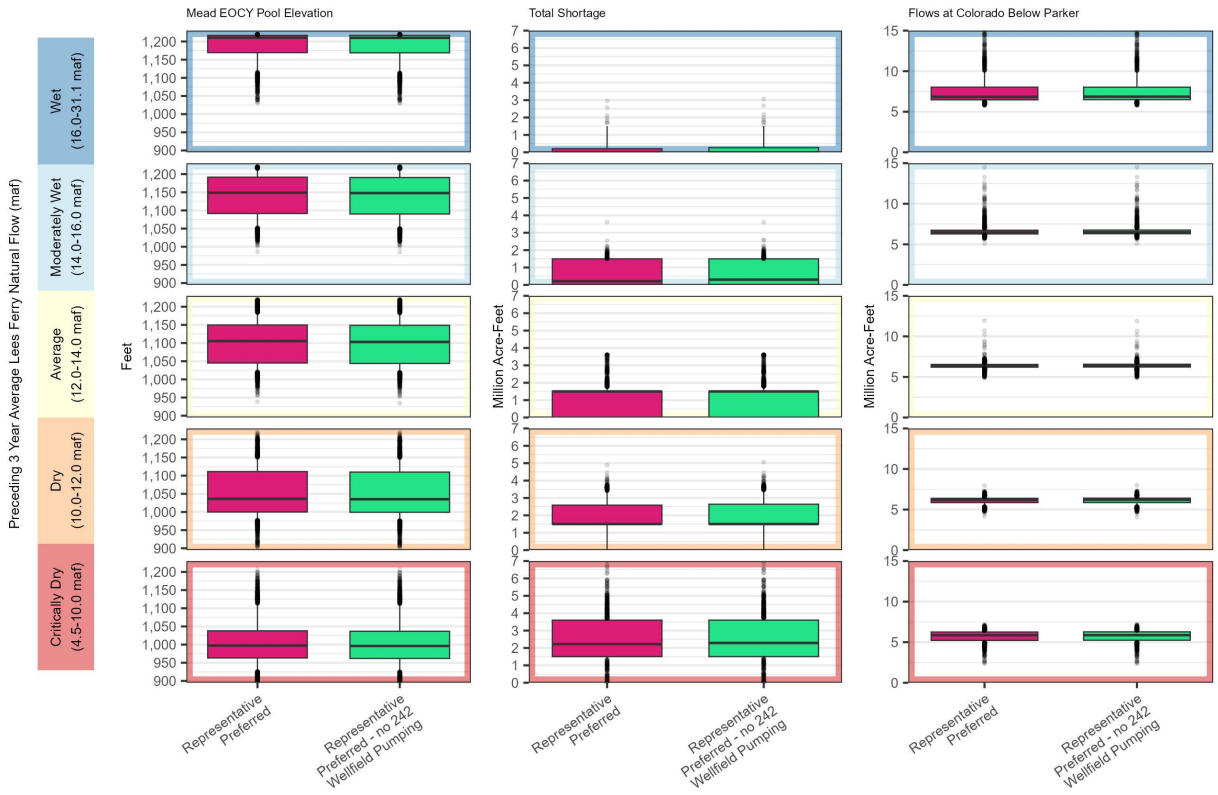
Results

The implications of removing the contributions of pumped groundwater (labeled as the 242 Well Field) in the Representative Preferred Alternative are described here and shown in **Figure N-6**. Considering a year-by-year comparison across all 400 hydrologic futures, an overall average reduction in Lake Mead pool elevation of 0.93 feet occurs, with a median reduction of 0.96 feet.

This results in an increase of annual flows below Parker Dam by a mean (and median) of 25,000 af. As a result, there is a mean increase of 457 af in total Lower Basin shortages across all years and hydrologic futures. In the design of the Representative Preferred Alternative, the majority of modeled results for Lake Mead pool elevations occur where static shortages of zero, 1.5 maf or 3.6 maf result, hence there is no shortage increase whenever Lake Mead elevation falls within ranges from 1,145 to 1,125 feet and 1,025 to 975 feet (see **Chapter 2**, Description of Alternatives, **Figure 2-1**) and these threshold elevations are not crossed by the additional releases to reduce salinity. Considering the 5 categories of preceding 3-year hydrologic flow conditions, the median decrease in Lake Mead pool elevation ranges from 0.48 feet for the Wet hydrologic category (16-31.11 maf preceding 3-year average) to 2.38 feet for the Average hydrologic category (12.0-14.0 maf preceding 3-year average). This corresponds to median increases in annual flows below Parker Dam from 15,000 to 24,000 af respectively. When the preceding 3-year period has been Moderately Wet (14.0-16.0 maf) or Critically Dry (4.46-10.0 maf), Lake Mead is likely to be at elevations that fall along the narrow abrupt shortage changes (1,145 to 1,125 feet and 1,025 to 975 feet), resulting in median shortage increases of 92.0 kaf and 64.0 kaf within those respective categories.

Eliminating the contribution of the 242 Well Field and supplying the equivalent volume of water from Lake Mead releases only marginally improves the salinity at Imperial Dam but notably improves the salinity at the NIB by a mean (and median) of 19 mg/L (milligrams per liter; or ppm) across all years and hydrologic futures (**Figure N-7**). This difference in impact is due to two factors: 1) the relatively small proportional increase of inflows from Lake Mead to Imperial Dam (as a function of total flow at Imperial Dam) compared to the larger proportional increase of Colorado River flows delivered to NIB, as a function of the total NIB delivery, when eliminating the 242 Well Field; and 2) the replacement of higher saline inflows from the 242 Well Field, which only affects salinity at NIB and not Imperial Dam.

Figure N-6
Implications on Lake Mead Elevations, Lower Basin Shortages, and Flows Below Parker Dam when Removing Pumped Groundwater Contributions to Manage Salinity



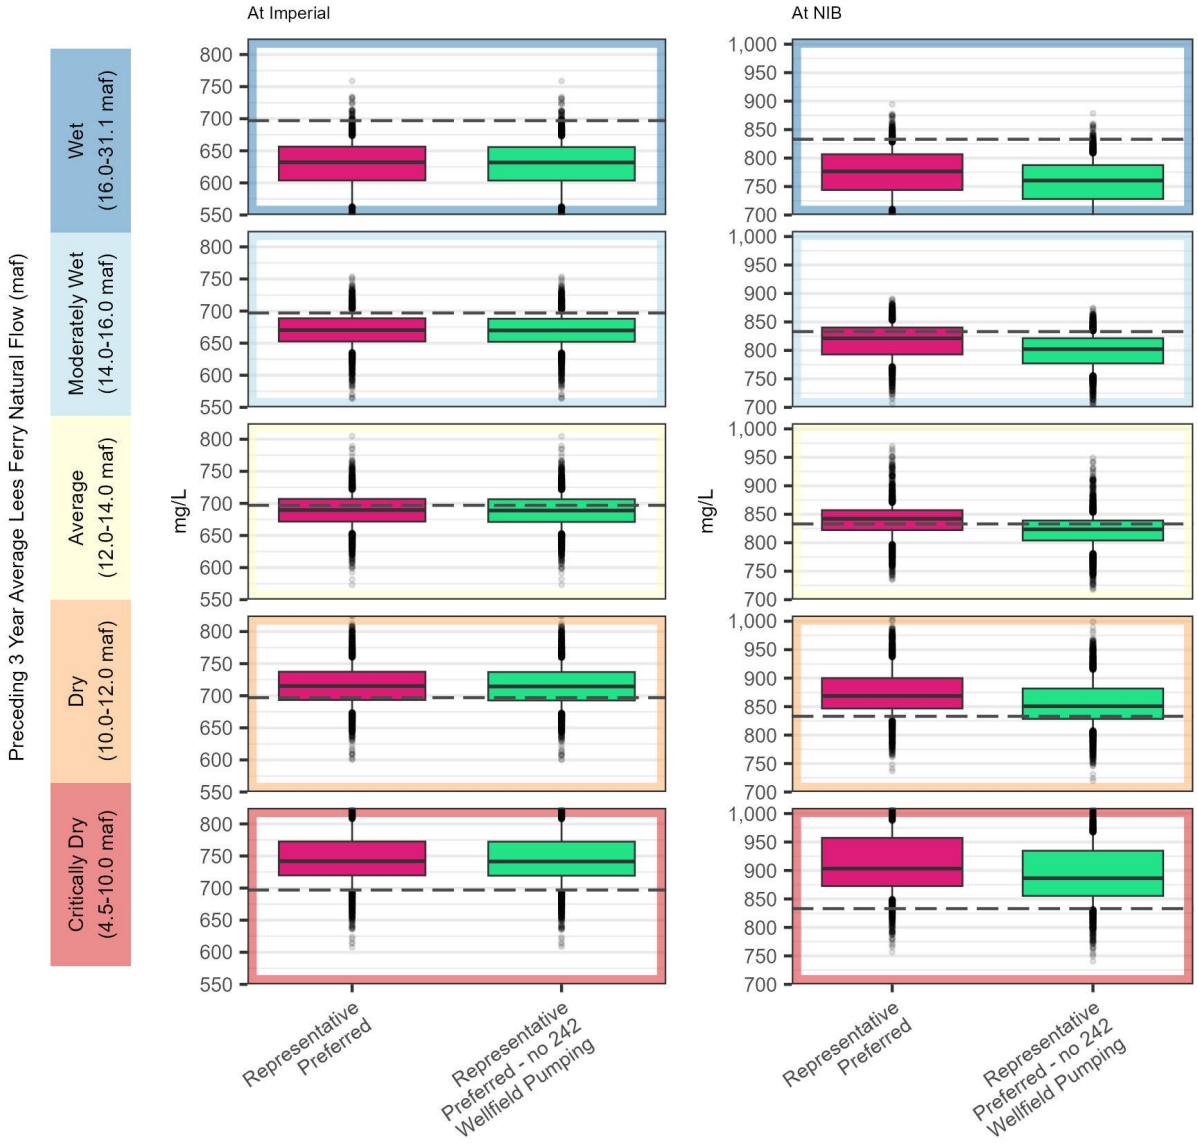


Figure N-7
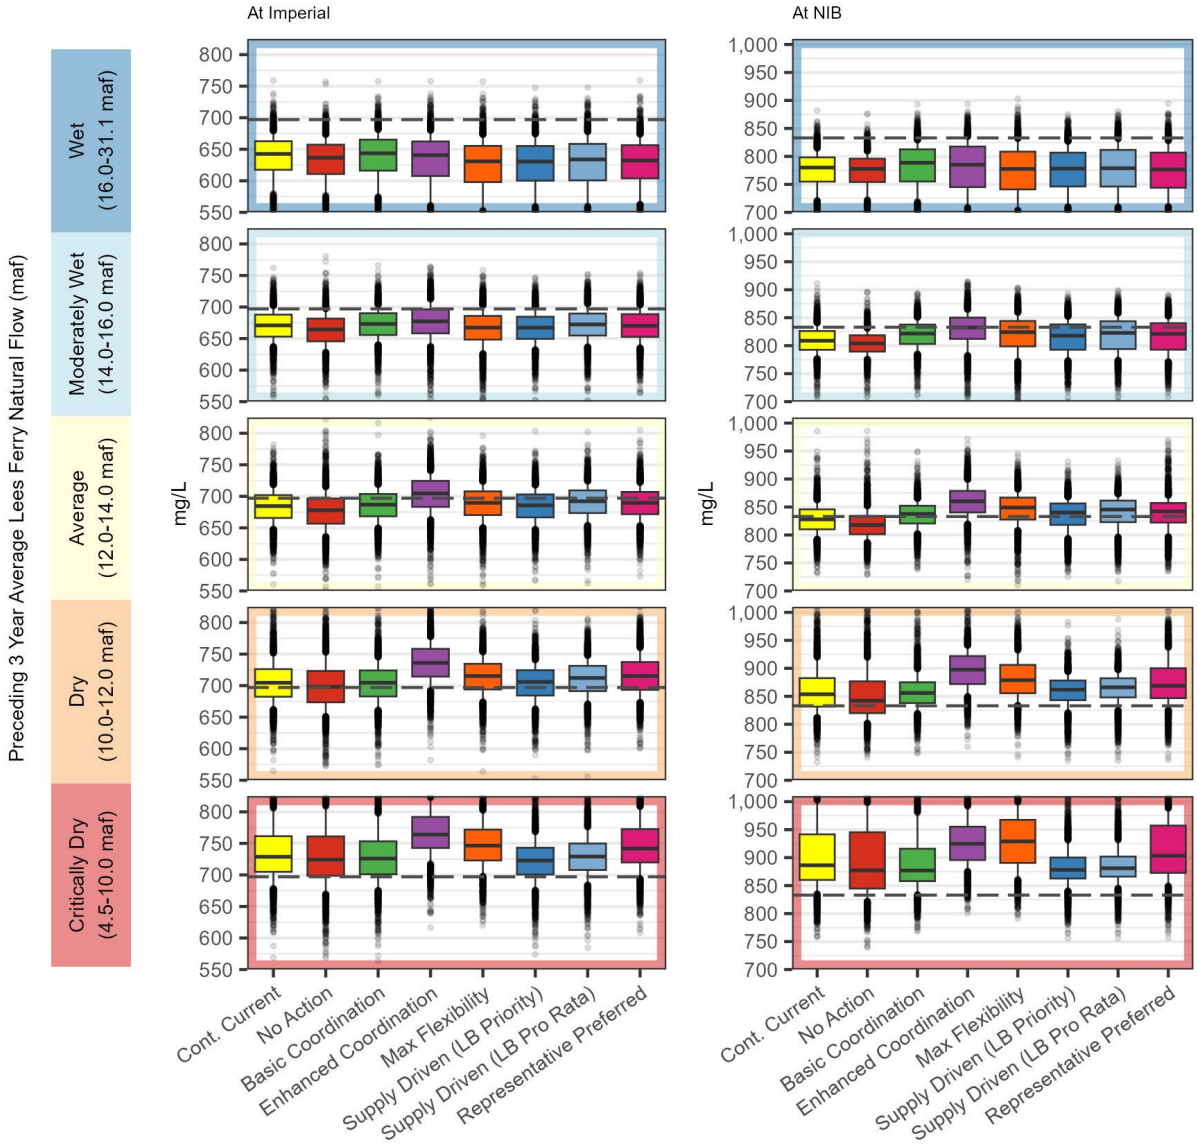
Implications on Annual Flow-Weighted Average Salinity Concentrations when Removing Pumped Groundwater Contributions

N.4.2.1 Salinity ranges at Imperial Dam and NIB



Average annual salinity ranges at Imperial Dam and NIB for the modeled alternatives are shown in **Figure N-8** using the same 5 preceding hydrologic flow categories to help visualize the different relative impacts throughout the 34-year period of analysis. While these graphics suggest similar impacts across the scenarios on an annual flow-weighted average basis, relative differences between the alternatives can be seen and are attributed primarily to the frequency of shortages and secondarily to the shortage distribution method used among water uses along the reaches below Lake Mead. For reference purposes, the flow-weighted average annual salinity from 2012 to 2024 is 697 mg/L at the Imperial Dam and 833 mg/L at NIB, shown as horizontal dotted lines in the conditional box plots. Salinity levels clearly increase under drier conditions compared to wetter conditions, with the interquartile ranges consistently below the reference lines in the Wet Category (16-31.1 maf preceding 3-year average) while the interquartile ranges of the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average) fall above these reference lines.

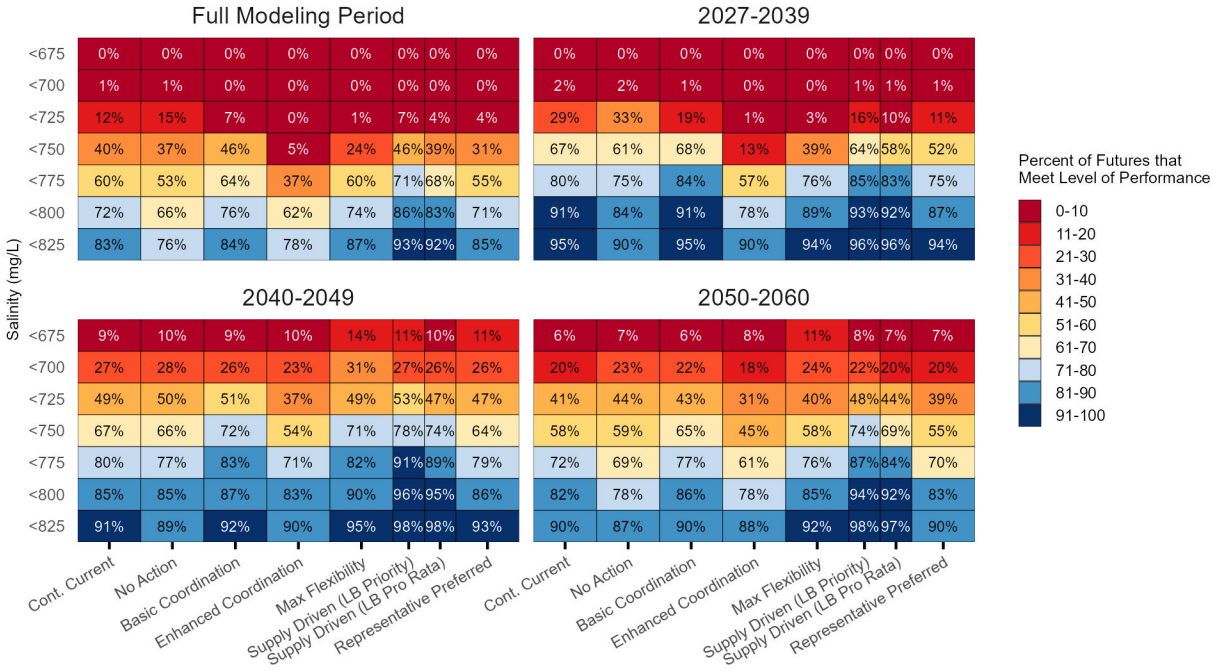
The magnitude of shortages has the effect of reducing releases and retaining more water in Lake Powell and Lake Mead in certain alternatives, so assuming the downstream mass loading of salt follows historical trends, this results in increasing salinity concentrations anywhere downstream of the reservoirs where flows are diminished[4]. At Imperial Dam, results from the Critically Dry Flow Category (4.46-10.0 maf preceding 3-year average) indicate that the highest median salinity values occur in the Enhanced Coordination Alternative, followed by the Maximum Operational Flexibility and Representative Preferred Alternatives, each of which have the highest maximum shortage policies 3.0, 4.0, and 3.6 maf/year respectively (**Figure N-8**). At NIB, the median salinity of the Maximum Operational Flexibility Alternative is slightly higher than the Enhanced Coordination Alternative, with the Representative Preferred Alternative resulting in the third highest salinity. However, the order of these three policies with respect to maximum shortages does not reflect the same order of resulting salinity levels. The second factor affecting salinity levels is the distribution and locations of shortages taken by users in the Lower Division States. Any reduction to water deliveries reduces the flows downstream of Lake Mead; however, shortages applied to users further downstream result in reduced overall flow volumes for longer stretches of the river, including at the point of diversion, as compared to the case when shortages are applied to users higher in the basin. As a conceptual example and strictly for the purpose of understanding this geographical aspect, reductions resulting in shortages to users only on the Central Arizona Project would reduce flows between Lake Mead and Lake Havasu but allow the same volume of water (and salinity dilution resulting from greater lateral inflow salinity concentrations) downstream of Lake Havasu and entering the All-American Canal at Imperial Dam as would occur without any shortages. However, reductions of the same magnitude taken only from the Imperial Irrigation District would result in lower flows from Lake Mead to the Imperial Dam resulting in higher salinity values into the All-American Canal (and less-so at the Morelos Dam) due to salinity sources introduced between Lake Havasu and the Imperial Dam. When considering these spatial relationships of the users alongside the priority system with more junior users upstream (i.e., Central Arizona Project) and more senior users downstream (i.e. Imperial Irrigation District), an alternative with priority distribution would tend to result in lower salinity levels at Imperial Dam while a pro rata distribution would result in

[4] In the case of NIB, operational modifications on a smaller timescale by Reclamation's Yuma Area Office can be made to ensure that the Minute 242 salinity differential is met.

higher salinity levels at Imperial Dam. This result is apparent in the Supply Driven Alternative (LB Pro Rata approach) resulting in higher salinity levels at Imperial Dam compared to the Supply Driven Alternative (LB Priority approach). Even more pronounced is the higher salinity levels at Imperial Dam resulting from the Enhanced Coordination Alternative, which uses a basin-wide pro rata shortage allocation, relative to the Maximum Operational Flexibility and Representative Preferred Alternatives, both of which primarily use priority-based shortage allocations.

Figure N-8
Conditional Box Plots of Annual Flow-Weighted Average Salinity Concentrations at Imperial Dam and at the Northerly International Boundary (NIB). Dashed horizontal lines represent the flow-weighted average annual salinity from 2012 to 2024 (697 mg/L at Imperial Dam and 833 mg/L at NIB)

Differences in salinity levels using priority vs. pro rata alternatives are not apparent at NIB because of two reasons. First, both distribution methods assume that a 16.67 percent water delivery reduction to Mexico is applied from any shortage that occurs and is therefore not subject to the choice of distribution method. In other words, the volume of water that flows past the Imperial Dam and reaches the NIB is the same regardless of the decision of priority vs. pro rata among users in the Lower Division States. Second, salt loading introduced below Imperial Dam only affects salinity levels at Morelos Dam and are not affected by distribution methods upstream in the USA. The lack of effect of distribution method on salinity at NIB reveals that salinity sources between Imperial and NIB dominate the effects of varying salinity concentrations further upstream.



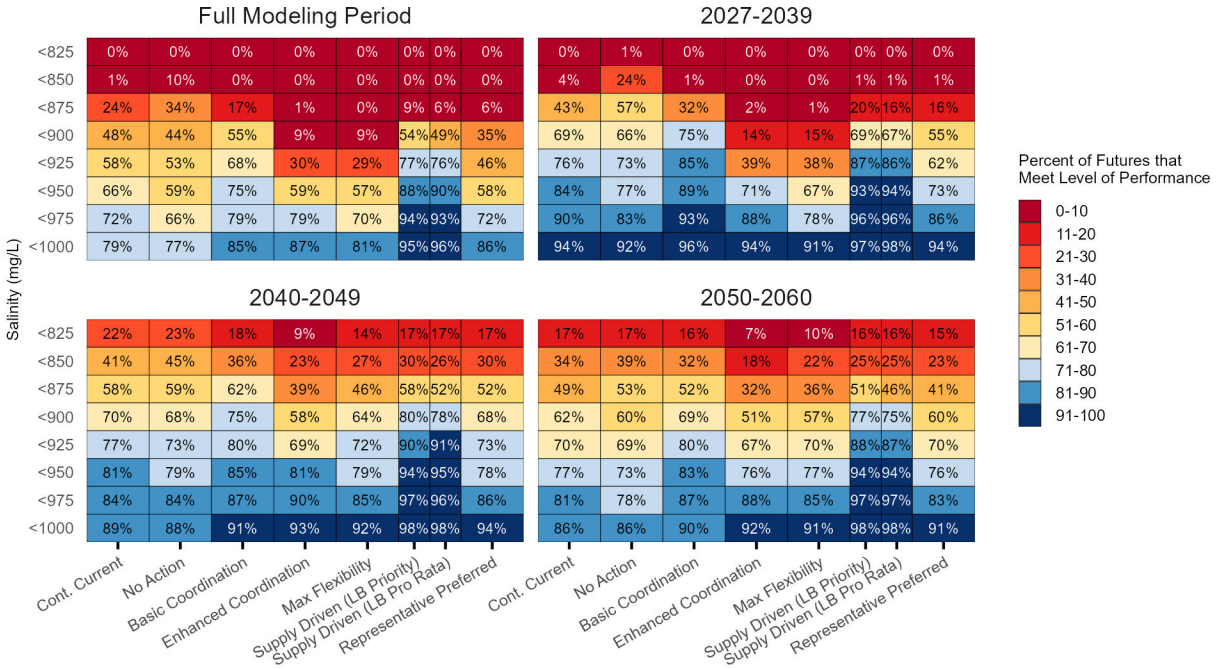
N.4.2.2 Number of traces that average annual salinity at Imperial Dam and NIB exceed tolerances[5]

The differences in policies over various levels of salinity are also shown in **Figure N-9** for Imperial Dam and **Figure N-10** for NIB. These heatmaps demonstrate the percent of futures that meet a level of performance as defined by the maximum salinity levels on the y-axis, with the most difficult criteria to achieve being a lower salinity concentration (top row) and the easiest criteria to achieve being a larger salinity number (bottom row). The heatmaps are provided considering the full modeled period (2027-2060) as well as three incremental periods (2027-2039, 2040-2049, and 2050-2060), allowing an understanding of the ability to stay below thresholds over time. A range of average annual salinity thresholds are provided at each location to accommodate the impacts on different uses.

As described earlier, the flow-weighted average annual salinity at the Imperial Dam from 2012 to 2024 is 697 mg/L. To evaluate alternatives with an approximation of this criterion using **Figure N-9**, one can see that all alternatives, including the Representative Preferred Alternative, are rarely able to maintain salinities below 700 mg/L when considering the- entire modeling time horizon of 2027 to 2060, meaning the salinity exceeds this threshold at some point under almost every alternative during this modeled time range. To support comparison among alternatives during the period most relevant to implementation of the Preferred Alternative, we initially focus on results from the first modeling period, which includes years 2027–2039. During this period, **Figure N-9**, also shows the inability to stay below the salinity threshold of 700 mg/L. This first decade is heavily influenced by the current low reservoir conditions and high likelihood of shortages, resulting in reduced releases from Lake Mead.

[5] The salinity analysis provided by CRSS is on a monthly basis and on a coarse spatial resolution and therefore does not capture the operational options that Reclamation has to manage salinity to meet the differential as described in Minute 242. The value of this analysis is also not in the absolute numbers which are an aggregation of multiple hydrologic scenarios and across time, but instead to compare the alternatives considered in this EIS based on the relative implications for salinity levels at key locations.

Figure N-9
Salinity at Imperial: Robustness
Percent of futures in which the concentration is below the specified value in every year



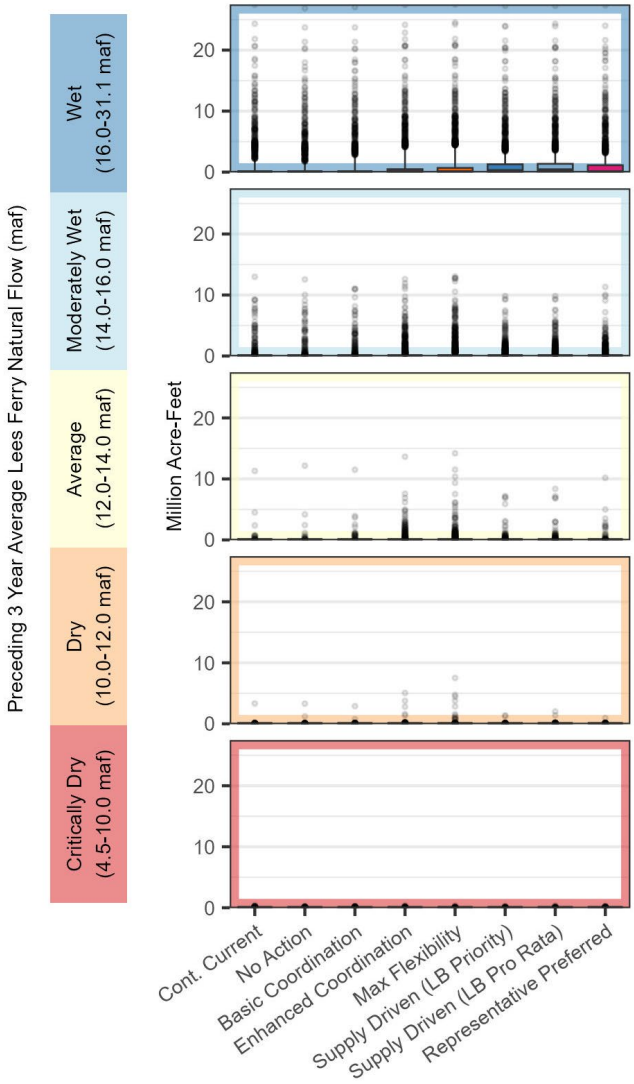
However, when looking at time ranges into the future when initial reservoir conditions are less influential on the results, the No Action Alternative produces results that stay below 700 mg/L in 28 percent of the futures in the 2040-2049 time range, and 23 percent in the 2050-2060 time range. With results quite similar to the No Action Alternative, the Maximum Operational Flexibility Alternative has the highest number of futures that stay below 700 mg/L with 31 percent of futures from 2040-2049 and 24 percent of futures from 2050-2060. The narrow range of percentages among these vastly different alternatives indicates a relative insensitivity of maximum shortages to stay below this particular salinity threshold. The alternative with the least number of futures that stay below 700 mg/L is the Enhanced Coordination Alternative, which uses a basin-wide pro rata shortage distribution method, resulting in 23 percent and 18 percent of futures staying below this threshold over the 2040-2049 and 2050-2060 time ranges respectively. This indicates that the distribution method has a more profound impact on salinity than the overall levels of shortage at the 700 mg/L threshold at Imperial Dam, however this tendency does not hold true across all salinity thresholds with the maximum shortage having an increasing impact under less stringent salinity criteria. The influence of the distribution method is also demonstrated by observing the two approaches of the Supply Driven Alternative and noting the LB Pro Rata approach consistently scores less than the LB Priority approach.

With respect to the Representative Preferred Alternative relative to the No Action Alternative, and particularly during the first decade of the analysis (2027-2039), widening the range of salinity thresholds reveals that a reduction in robustness from 33 percent to 11 can be seen when aiming to

stay below 725 mg/L and from 61 percent to 52 percent when aiming to stay below 750 mg/L. The reductions are significantly less than the changes resulting from the Enhanced Coordination and Maximum Operational Flexibility Alternatives which effectively never stay below these salinity thresholds during this initial decade. **Figure N-10** shows the relative impacts of the modeled alternatives on salinity at NIB. As described earlier, the flow-weighted average annual salinity at the NIB from 2012 to 2024 is 833 mg/L. Although this specific value is not listed among the y-axis of **Figure N-10**, the figure reveals that the ability to avoid salinity levels that exceed this concentration are rare in the first decade of analysis (2027-2039) but increases in subsequent decades (2040-2049 and 2050-2060). Overall, avoiding critical salinity levels is more likely in the No Action Alternative, CCS Comparative Baseline, and Basic Coordination. For example, staying under an 850 mg/L threshold occurs in 24 percent of the futures under the No Action Alternative in 2027-2039, but staying below this threshold is nearly impossible in the Enhanced Coordination, Maximum Operational Flexibility, Supply Driven (both LB Priority and LB Pro Rata approaches), or Representative Preferred Alternatives, indicating a more notable impact of high maximum policy shortages on the salinity at NIB compared to salinity at Imperial Dam. Furthermore, exceeding salinity thresholds at NIB is not significantly affected by the choice of shortage distribution method, which can be seen with the nearly equal percent of futures between the LB Priority and LB Pro Rata approaches of the Supply Driven Alternative. This lack of influence of the distribution method at NIB compared to Imperial Dam is again explained by the dominant role of additional salinity introduced between the two locations.

Figure N-10
Salinity at the NIB: Robustness
Percent of futures in which the concentration is below the specified value in every year

N.4.3 Issue 3: Flows below Morelos Dam



As shown previously in **Figure N-2**, flows in the Limitrophe were historically significant in the 1980s during flood control years; however, in recent years these flows have been limited to water passing Morelos Dam in excess of Mexico's scheduled delivery due to flood control operations at Hoover Dam, releases from Hoover Dam that cannot be used due to local circumstances such as unexpected rainfall, seepage from Morelos Dam, flows from the Gila River, irrigation return flows, groundwater inflow, or water released in 2014 specifically for the purpose of environmental restoration related to Minute 319. **Figure N-11** shows the volumes of water released from Morelos Dam under the different alternatives analyzed and categorized by the same preceding 3-year Lees Ferry natural flows used in previous analyses. The implications of the alternatives for the Limitrophe differ primarily due to changes in the frequency and magnitude of possible future flood control releases. As Lake Powell and Lake Mead are maintained in higher elevations such as in the Maximum Operational Flexibility Alternative, there is an increased likelihood of spills causing such flood control releases from Lake Mead. This difference, however, is only observable in limited ranges of hydrologic conditions from Dry to Moderately Wet preceding 3-year averages.

Most notable, under the Average, Dry, and Critically Dry hydrologic categories (below 14.0 maf preceding 3-year average) flows below Morelos Dam into the Limitrophe occur in less than 10 percent of the hydrologic futures and therefore can be considered infrequent and incidental. Even in the Moderately Wet Flow Category (14.0-16.0 maf preceding 3-year average), flows in the limitrophe occur in the Enhanced Coordination, Maximum Operational Flexibility, and both Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) in just over 10 percent of the modeled futures. In the Wet Flow Category (16.0-31.1 maf preceding 3-year average), the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) results in some flows in the Limitrophe at the median (50 percent of modeled futures), but in the Representative Preferred Alternative, flows occur in only 25 percent of modeled futures.

Although infrequent, in all hydrologic categories except for the Critically Dry Flow Category (4.46-10.0 maf), there is always a possibility of short-duration large volume flows in the Limitrophe. These are the result of exceptionally high flows that could occur in some of the hydrologic futures considered in the modeling analysis.

The modeled flows in **Figure N-11** are exclusively the result of flood control releases. Future water use could also occur due to restoration efforts in the Limitrophe. Although habitat conditions are severely deteriorated from natural conditions, previous restoration efforts have resulted in positive responses in sites such as Hunters Hole in the U.S. and Miguel Aleman in Mexico. These sites are irrigated through pumped groundwater or releases made from Mexico's canal system and not reliant on flows immediately below Morelos Dam. A third site, initiated by the Cocopah Indian Tribe, will add a further 400 acres of native habitat and will be supplied from a conveyance pipe delivering a portion of the Tribe's unused rights from a nearby irrigation canal. In the modeling of alternatives for this EIS, releases made for environmental restoration sites are assumed to be diverted by Mexico at Morelos Dam and re-released into the Colorado River in Mexico after traveling through Mexico's canal infrastructure, therefore, are not reflected in **Figure N-11**. These releases are explicitly and exclusively included in the Maximum Operational Flexibility Alternative.

Figure N-11
Calendar Year Total Annual Flow Volume Released Below Morelos Dam

Implications of the modeled alternatives on riparian vegetation and habitat conditions in the Limitrophe reach are not explicitly modeled for comparison, but one can surmise from the Minute 319 environmental pulse flow in 2014 that increased frequency of flows passing below Morelos Dam resulting from flood control releases from Lake Mead is beneficial for these conditions and reduced likelihood of flood flows and continued groundwater declines will cause further vegetation deterioration in this region. The intermittent nature of future natural flooding events reaching the Limitrophe suggests that the Maximum Operational Flexibility Alternative, which provides for storing of water and periodic releases for habitat restoration, is the only alternative that is likely to have beneficial implications for vegetation and habitat conditions in this region.

Appendix O. Analysis of Lake Powell Infrastructure Protection Releases

O.1 Lake Powell Infrastructure Protection Release Analysis

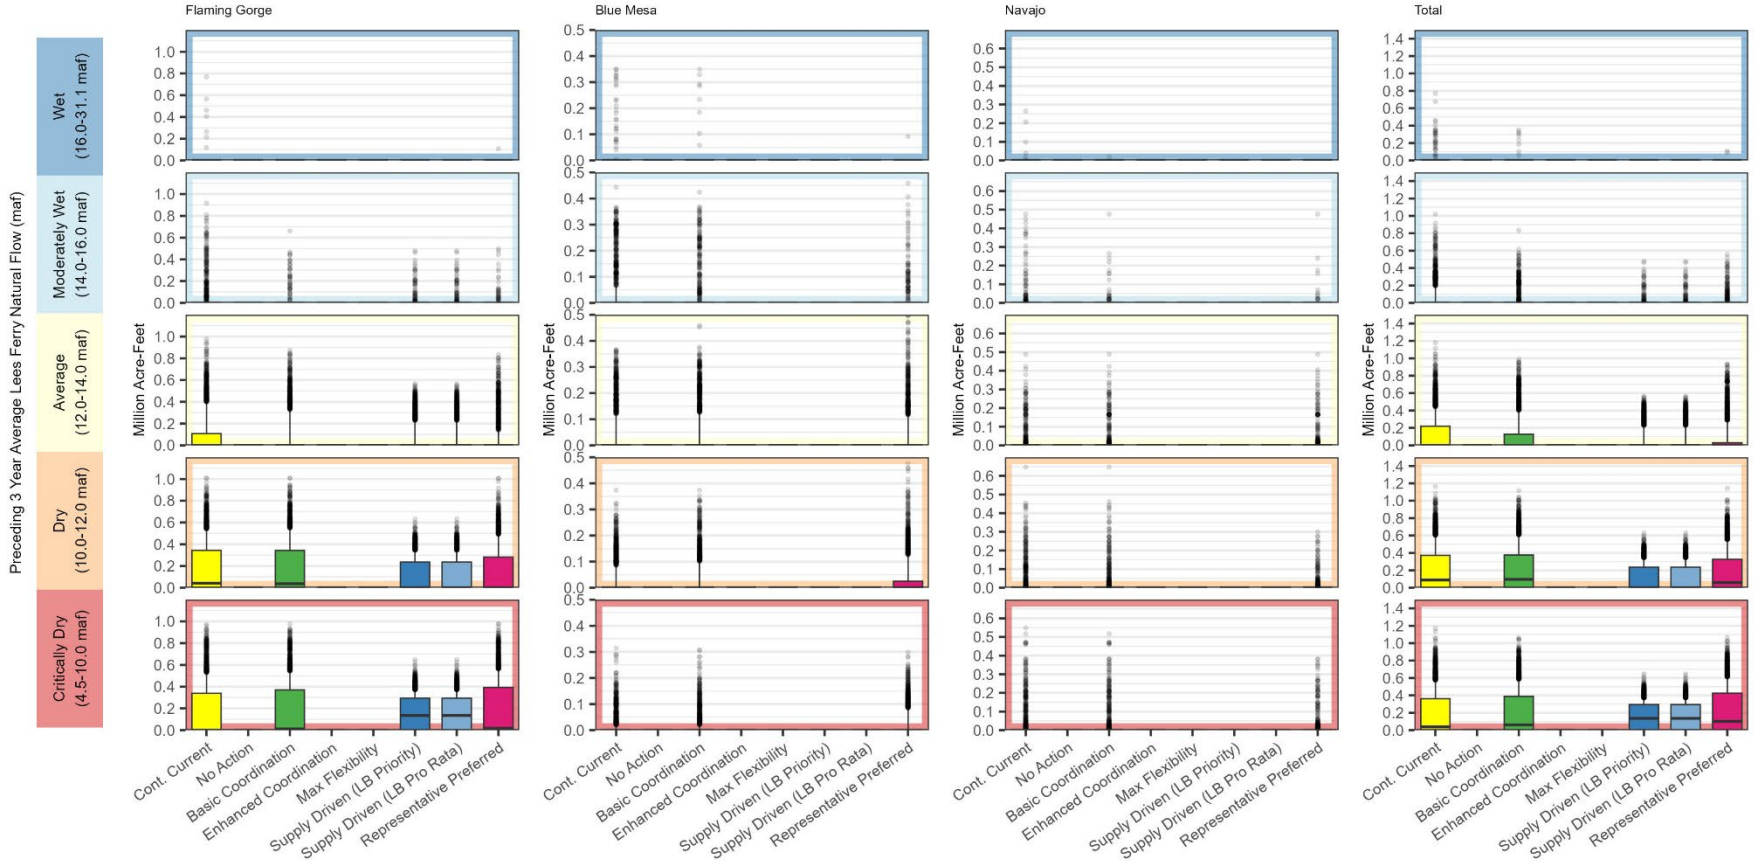
The Final Environmental Impact Statement (EIS) includes alternatives that assume additional releases from the Colorado River Storage Project Upper Initial Units (UIUs; Flaming Gorge, Blue Mesa, and Navajo Reservoirs) to protect infrastructure at Lake Powell. Operations at these units specifically contemplated in the Final EIS alternatives are intended to remain within the scope of the existing Records of Decision. This appendix analyzes these modeled releases – referred to as Powell infrastructure protection (PIP) releases – across alternatives. The PIP release modeling assumptions are simplifications of the actual PIP process, which, like the Drought Response Operations Agreement, involves collaborative decision-making among stakeholder workgroups and includes subjective judgments that cannot be captured in a model. The modeled PIP releases represent a potential range of releases and do not necessarily reflect the views of all stakeholders. Actual releases may be lower, higher, or may not occur. The modeling assumptions regarding operation of the UIUs presented in this Final EIS are not intended to, and do not, limit the Secretary's ability to operate these facilities as necessary to respond to hydrologic conditions in accordance with applicable federal law, including operations for the authorized purposes as stated in the 1956 Colorado River Storage Project Act. These modeling assumptions are intended solely for National Environmental Policy Act analysis and do not reflect a position by Reclamation on operations that might be implemented under a PIP collaborative process.

The Continued Current Strategies (CCS) Comparative Baseline, Basic Coordination Alternative, Supply Driven (both Lower Basin Priority [LB Priority] and Lower Basin Pro Rata [LB Pro Rata] approaches) Alternative, and Representative Preferred Alternative include modeled PIP releases, which are triggered when Lake Powell is projected to decline, or physically declines, below elevation 3,525 feet. The CCS Comparative Baseline and the Basic Coordination and Representative Preferred Alternatives assume additional releases from Flaming Gorge, Blue Mesa, and Navajo Reservoirs, while the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative assumes additional releases only from Flaming Gorge Reservoir. Each UIU's operations are adjusted within their Records of Decision as noted in **Appendix A**, CRSS Model Documentation, **Section A.5.11**. Additionally, PIP releases in the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative are limited to 500 thousand acre-feet (kaf) annually, while the CCS Comparative Baseline, the Basic Coordination and Representative Preferred Alternatives do not have constraints on annual releases. The Lower Colorado River Basin (Lower Basin) shortage distribution method does not impact Upper Colorado River Basin operations for the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative, as the Lake Powell operations are independent from Lower Basin operations. While the results for both Lower Basin shortage distribution methods are

included, the results included in this appendix are identical and will therefore not be differentiated in the discussion. Details on modeling assumptions are in **Appendix A**, CRSS Model Documentation, **Section A.5.11**. The following sections compare the responses of individual and total annual PIP release volumes and frequency under different hydrologic conditions. Results are presented using conditional plots, which separate results based on five flow categories (see **Chapter 3.2.6** for additional details on conditional plots).

O.1.1 PIP Release Volumes

PIP release volumes shown in **Figure O-1** are estimates of the additional annual volumes released from each UIU and the total of all three UIUs. Each reservoir has different operating years and monthly targets that are used to estimate the additional releases. During years when PIP releases are triggered due to Lake Powell's projected or actual pool elevation, the following calculations are used to estimate annual additional release volumes:



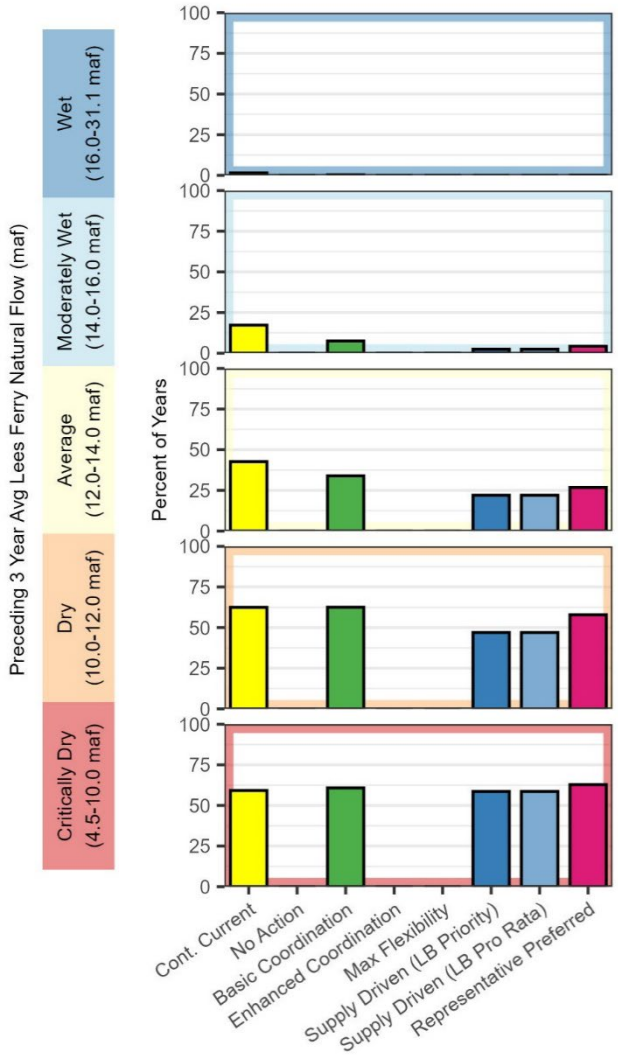
- Flaming Gorge: previous May 1 (April 30 in Colorado River Simulation System) storage minus current May 1 storage
- Blue Mesa: previous December 31 storage minus current December 31 storage
- Navajo: sum of water year additional releases

Even though the UIUs operate on different annual scales, their annual volumes are aggregated to compute a total annual volume of estimated PIP water released, since additional releases from Flaming Gorge and Blue Mesa cannot be determined each month in Colorado River Simulation System.

Figure O-1 shows PIP release volumes across all years (2027-2060) of the simulation. If there is no PIP release in a year, the data remains in the plot as zero. Each boxplot in the figure illustrates the distribution of modeled results, where the bold center line represents the median value, the top and bottom of each box shows the interquartile range, which captures the 25th to 75th percentile, the lines extend to the 10th and 90th percentiles, and the outliers are represented as dots beyond these lines. The No Action, Enhanced Coordination, and Maximum Operational Flexibility Alternatives are zero for all flow categories and all percentiles because PIP releases are not included in those alternatives.

Figure O-1 illustrates that there are limited PIP releases in the Average Flow Category. Volumes released from UIUs are zero at the median. When aggregated to total volumes, the upper quartile of the CCS Comparative Baseline is 220 kaf, the Basic Coordination Alternative is 130 kaf, and the Representative Preferred Alternative is 30 kaf, while the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative remains at zero.

Figure O-1
Response of PIP Release Volumes by Reservoir Across Alternatives



As hydrologic conditions become drier, PIP releases increase in volume. In the Critically Dry Flow Category, median PIP releases are greater than zero in all scenarios that include PIP releases; the total PIP releases are 38 kaf, 61 kaf, 100 kaf, and 136 kaf, for the CCS Comparative Baseline, Basic Coordination Alternative, Representative Preferred Alternative, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative, respectively. Most of the PIP releases come from Flaming Gorge, which has the largest storage of any of the UIUs. For the CCS Comparative Baseline and the Representative Preferred and Basic Coordination Alternatives in the Critically Dry Flow Category, annual total releases can be as large as 1.2 million acre-feet, but 90 percent of the futures release 0.6 million acre-feet or less. The Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative has releases up to 650 kaf, but 90 percent of the releases are 380 kaf or less. Under the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternative, the maximum PIP release at Flaming Gorge is specified to be 500 kaf; however, there are a few instances where Flaming Gorge is modeled to release more than 500 kaf due to monthly operational constraints.

O.1.2 PIP Release Frequency

PIP release frequency across all years (2027-2060) of the simulation by hydrologic condition is shown in **Figure O-2**. Each bar in the figure reports the percent of years with PIP releases in each flow category. The No Action, Enhanced Coordination, and Maximum Operational Flexibility Alternatives are zero for all flow categories because PIP releases are not included in those alternatives. In the Average Flow Category, PIP releases occur more frequently under the CCS Comparative Baseline and the Basic Coordination Alternative at 43 percent and 34 percent of years, respectively, compared to the Representative Preferred and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives at 27 and 22 percent of years, respectively. The frequency of PIP releases is greater in the Dry Flow Category than the Average Flow Category across all scenarios where PIP releases are modeled. In the Critically Dry Flow Category, the percent of years with PIP releases decreases slightly in the Dry Flow Category under the CCS Comparative Baseline (59 versus 62 percent of years) and the Basic Coordination Alternative (61 versus 62 percent of years). Under the Supply Driven (both LB Priority and LB Pro Rata approaches) and Representative Preferred Alternatives, PIP releases are greatest in the Critically Dry Flow Category, occurring in 59 and 63 percent of years, respectively.

Appendix P. Tribal Consultation and Coordination Efforts

For purposes of this National Environmental Policy Act (NEPA) process, the Bureau of Reclamation (Reclamation) is consulting and coordinating with Basin Tribes who have entitlements to or contracts for Colorado River water and those that may be affected by or have interests in the proposed federal action.

P.1 Summary of Tribal Consultation and Coordination

There are many federally recognized tribes with entitlements to or contracts for Colorado River water, or who may be affected by or have interests in the proposed federal action. There are 30 federally recognized tribes within the geographic Colorado River Basin (Basin). Reclamation consults regularly with these tribes regarding Colorado River issues. These tribes are listed in **Table P-1** and shown on **Map P-1**.

Table P-1
Basin Tribes

— BUREAU OF —
RECLAMATION

Map P-1
Tribes and Reservations within the Colorado River Basin

The Ten Tribes Partnership is a coalition of 10 federally recognized tribes with rights and unresolved claims to Colorado River water. The partnership was created in 1992 and has an ongoing consultation relationship with Reclamation. Federally recognized tribes of the Ten Tribes Partnership are listed in **Table P-2**.

Table P-2
Ten Tribes Partnership Tribes

- Chemehuevi Indian Tribe
- Quechan Indian Tribe
- Cocopah Indian Tribe

Of the 22 federally recognized tribes in Arizona, 14 have fully resolved, adjudicated rights, or partially resolved rights to water from the Colorado River. A significant portion of that water is provided through the Central Arizona Project (CAP). Reclamation has a long-standing and ongoing consultation relationship with tribes receiving Colorado River water through the CAP. **Table P-3** lists CAP Tribes.

- Zuni Tribe

P.2 Tribal Consultation Efforts

Reclamation has engaged regularly with the tribes since the publication of the notice of intent (NOI) to prepare the Post-2026 Operational Guidelines and Strategies for Lake Powell and Lake Mead Environmental Impact Statement (EIS) on June 16, 2023. **Table P-5** provides a summary of those tribal consultation and coordination efforts conducted by Reclamation between publication of the NOI and July 1, 2026.

On June 24, 2022, Reclamation published a Federal Register Notice to conduct a public "pre-scoping" effort requesting public input on the process and substantiative elements for post-2026 operations prior to the anticipated initiation of the formal NEPA in 2023. In response to the public comment period that ran through September 1, 2022, Reclamation received 11 letters from individual tribes and two group letters from Basin Tribes.

Reclamation formally commenced post-2026 tribal consultation on June 12, 2023, with a letter to all 30 Basin Tribes announcing the posting of the NOI in the Federal Register and the start of a scoping comment period. In response to this scoping comment period, Reclamation received 16 letters from individual Basin Tribes. The results of the scoping period were compiled in the Scoping

Summary Report and shared with the Basin Tribes. During the scoping period, Reclamation conducted seven individual government-to-government consultations with Basin Tribes and hosted fifteen group tribal meetings across the Basin.

On January 18, 2024, Reclamation sent a consultation letter to the 30 Basin Tribes initiating the alternatives development phase of the process. The goal of the alternatives development phase was to provide a reasonable and broad range of alternatives for managing the Colorado River system and its resources through consultation and collaboration with a broad range of stakeholders. During the alternatives development phase, Reclamation conducted 16 individual government-to-government consultations with Basin Tribes and hosted 64 group tribal meetings across the Basin. In addition, a group of Basin Tribes informed Reclamation's development of the Enhanced Coordination Alternative through participation in meetings throughout 2024 and 2025 to discuss proposed management strategies and review modeling results.

On January 15, 2026, Reclamation sent a letter to the 30 Basin Tribes announcing the publication of the Draft EIS and initiating formal consultation. In connection with the release of the Draft EIS, Reclamation hosted a series of technical meetings with tribes to provide an overview of the document and set up additional consultations. During the Draft EIS public comment period, Reclamation participated in individual government-to-government consultations with 20 of the 30 Basin Tribes and received 23 tribal comment letters. Following the initial Draft EIS consultation, Reclamation continued to meet regularly with tribes during the development of the preferred alternative and Water Year 27/28 Operations plans. Between March 19 and July 1, 2026, Reclamation hosted 10 group tribal technical meetings and 16 government-to-government consultations with the Basin Tribes.

Throughout the Post-2026 NEPA process, Reclamation and the Basin Tribes committed to a robust communication and consultation plan that incorporated tribal priorities and comments into the process. Reclamation and tribes engaged each other through monthly information calls, tribal technical workgroups, and government-to-government consultations to ensure that tribes remained informed on the developing process and provided meaningful contributions to the final NEPA analysis and operations plan. At the conclusion of the NEPA process and signing of the Record of Decision, Reclamation will continue to consult with the Basin Tribes on operational decisions related to the 10-year decision framework.

Table P-5
Summary of Tribal Consultation Efforts

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
6/12/2023	Tribal Letter: Upcoming Notice of Intent to Prepare an EIS for Development of Post-2026 Colorado River Operations	Notification of NOI and scoping comment period	Letter sent to tribal leaders of the 30 Basin Tribes
6/13/2023	Meeting with Gila River Indian Community	Virtual meeting	Gila River Indian Community

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
6/14/2023	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
6/15/2023	Basin Tribal Information Exchange	Monthly meeting	Tribal leaders and representatives for tribes throughout the Basin
6/15/2023	Southern Ute Indian Tribe Visit	Southern Ute invited Upper Colorado Basin leadership to meet with the council to discuss the Colorado River, tribal water infrastructure needs, and tour projects on the reservation.	Southern Ute Indian Tribe
7/20/2023	Basin Tribal Information Exchange	Monthly meeting	Tribal leaders and representatives for tribes throughout the Basin
8/8/2023	Meeting with Gila River Indian Community	Hybrid meeting; in person in Washington, DC	Gila River Indian Community
8/9/2023	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
8/11/2023	Inter-Tribal Council of Arizona	Tribal Leaders' Water Policy Council	Leaders from 21 tribes in Arizona
8/24/2023	Basin Tribal Information Exchange	Monthly meeting	Tribal leaders and representatives for tribes throughout the Basin
8/29/2023	Jicarilla Apache Nation Visit	Jicarilla Apache invited Upper Colorado Basin leadership to meet with the council to discuss the Colorado River and tribal concerns	Jicarilla Apache Nation
8/30/2023	Ute Mountain Ute Tribe Visit	Ute Mountain Ute invited Upper Colorado Basin leadership to meet with the council to discuss the Colorado River, tribal water infrastructure needs, and tour projects on the reservation.	Ute Mountain Ute Tribe
9/5/2023	Southern Ute Indian Tribe	Government-to-government consultation	Southern Ute Indian Tribe
9/19/2023	Federal-Tribes-States Legal/Technical Group Meeting	Provide updates on the Post-2026 process to the legal and technical representatives	Tribal legal and technical representatives for tribes throughout the Basin

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
9/21/2023	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
9/28/2023	Federal-Tribes-States Legal/Technical Group Meeting	Provide updates on the Post-2026 process to the legal and technical representatives	Tribal legal and technical representatives for tribes throughout the Basin
10/3/2023	Federal-Tribes-States Leadership Meeting	Provide updates on the Post-2026 process to the tribal leadership	Tribal leaders for tribes throughout the Basin
10/19/2023	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
10/25/2023	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
11/29/2023	Federal-Tribes-States Leadership Meeting	Provide updates on the Post-2026 process to the tribal leadership	Tribal leaders for tribes throughout the Basin
11/30/2023	Inter-Tribal Council of Arizona	Tribal Leaders' Water Policy Council	Leaders from 21 tribes in Arizona
12/13/2023	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
12/14/2023	Gila River Indian Community	Government-to-government consultation	Tribal leadership, technical/legal staff
1/18/2024	Tribal Letter: Post-2026 Alternatives Development Consultation Request	Government-to-Government consultation request	Letter sent to tribal leaders of the 30 Basin Tribes
1/18/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
2/2/2024	Federal-Tribes-States Leadership Meeting	Provide updates on the Post-2026 process to the tribal leadership	Tribal leaders for tribes throughout the Basin
2/14/2024	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
2/15/2024	Federal-Tribes-States Legal/Technical Meeting	Provide updates on the Post-2026 process to the legal and technical representatives	Tribal legal and technical representatives for tribes throughout the Basin
2/22/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
2/28/2024	Federal-Tribes-States Leadership Meeting	Provide updates on the Post-2026 process to the tribal leadership	Tribal leaders for tribes throughout the Basin
2/29/2024	Ak-Chin Indian Community	Government-to-government consultation	Tribal leadership, technical/legal staff
3/5/2024	Hualapai Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
3/21/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
4/3/2024	Quechan Indian Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
4/10/2024	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
4/18/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
4/23/2024	Jicarilla Apache Nation	Government-to-government consultation	Tribal leadership, technical/legal staff
5/6/2024	Southern Ute Indian Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
5/10/2024	Inter-Tribal Council of Arizona	Tribal Leaders' Water Policy Council	Leaders from 21 tribes in Arizona
5/16/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
6/12/2024	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
6/21/2024	Ute Mountain Ute Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
6/20/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
6/27/2024	Federal-Tribes-States Legal/Technical Meeting	Provide updates on the Post-2026 process to the legal and technical representatives	Tribal legal and technical representatives for tribes throughout the Basin
7/18/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
7/26/2024	Federal-Tribes-States Legal/Technical Meeting	Provide updates on the Post-2026 process to the legal and technical representatives	Tribal legal and technical representatives for tribes throughout the Basin

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
8/8/2024	Federal-Tribes-States Leadership Meeting	Provide updates on the Post-2026 process to the tribal leadership	Tribal leaders for tribes throughout the Basin
8/14/2024	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
8/22/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
9/13/2024	Inter-Tribal Council of Arizona	Tribal Leaders Water Policy Council	Leaders from 21 tribes in Arizona
9/15/2024	Federal-Tribes-States Leadership Meeting	Provide updates on the Post-2026 process to the tribal leadership	Tribal leaders for tribes throughout the Basin
9/17/2024	Federal-Tribes-States Legal/Technical Meeting	Provide updates on the Post-2026 process to the legal and technical representatives	Tribal legal and technical representatives for tribes throughout the Basin
9/19/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
10/7/2024	Ute Indian Tribe of Uintah and Ouray Reservation	Government-to-government consultation	Tribal leadership, technical/legal staff
10/9/2024	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
10/17/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
11/6/2024	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
11/15/2024	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
11/20/2024	Federal-Tribes-States Leadership Meeting	Provide updates on the Post-2026 process to the tribal leadership	Tribal leaders for tribes throughout the Basin
11/21/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
12/5/2024	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
12/12/2024	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
12/19/2024	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
1/10/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
1/23/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
2/5/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
2/11/2025	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
2/14/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
2/20/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
2/27/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
3/19/2025	Colorado River Indian Tribes	Government-to-government consultation	Tribal leadership, technical/legal staff
3/21/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
3/30/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
3/31/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
4/9/2025	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
4/17/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
4/17/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
4/30/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
5/15/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
5/22/2025	Navajo Nation/ Hopi Tribe/ San Juan Southern Paiute Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
5/22/2025	30 Basin Tribes and Department Leadership	Meet Acting Assistant Secretary of Water and Science; Post-2026 updates	Tribal leaders, legal staff for 30 Basin tribes
5/23/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
5/28/2025	Ak-Chin Indian Community	Government-to-government consultation	Tribal leadership, technical/legal staff
5/28/2025	Fort Yuma Quechan Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
6/5/2025	Gila River Indian Community	Government-to-government consultation	Tribal leadership, technical/legal staff
6/5/2025	Colorado River Indian Community	Government-to-government consultation	Tribal leadership, technical/legal staff
6/5/2025	Navajo Nation and the Hopi Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
6/5/2025	Ute Mountain Ute Tribe, Southern Ute Indian Tribe, Jicarilla Apache Tribe, Ute Indian Tribe	Government-to-government consultation	Tribal leadership, technical/legal staff
6/11/2025	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
6/26/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
7/23/2025	Tohono O'odham Nation	Provide updates on Post-2026 process to tribal leadership	Tribal leadership, technical/legal staff
7/24/2025	Tribal Flexible Elements Workgroup	Technical workgroup meeting	Tribal technical representatives
7/24/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
8/13/2025	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
8/28/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
9/18/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
10/16/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
10/22/2025	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
10/24/2025	Inter-Tribal Council of Arizona	Tribal Leaders' Water Policy Council	Leaders from 21 tribes in Arizona
11/14/2025	30 Basin Tribes and Department leadership	Meet Assistant Secretary of Water and Science; update on Post-2026 process; hear comments from tribes	Tribal leadership and technical/legal staff
11/20/2025	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
12/3/2025	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
12/5/2025	P26 Draft EIS Tribal Technical Session #1	A review of Draft EIS Alternatives and the analysis approach for tribal-related resources.	Tribal leaders and representatives for tribes throughout the Basin
12/19/2025	P26 Draft EIS Tribal Technical Session #2	A review of Lower Basin Shortage Distribution Methods, Models, and Comparison of Methods.	Tribal leaders and representatives for tribes throughout the Basin
1/15/2026	Tribal Letter: Draft EIS Consultation	Initiating tribal consultation on the Draft EIS	Letter sent to tribal leaders of the 30 Basin Tribes
1/15/26	Basin Tribal Information Exchange	Monthly Meeting	Tribal leaders and representatives for tribes throughout the Basin
2/2/20206	The Hopi Tribe	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff
2/3/2026	P26 Draft EIS Tribal Technical Session #3	Approach to Post-2026 EIS resource analysis and how to interpret results.	Tribal leaders and representatives for tribes throughout the Basin
2/9/2026	Southern Ute Indian Tribe	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff
2/9/2026	Ute Mountain Ute Tribe	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff

Date	Meeting Title/Subject of Correspondence	Purpose	Tribes Invited
2/10/2026	Jicarilla Apache Nation	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff
2/11/2026	Ten Tribes Partnership Meeting	Bimonthly meeting with member tribes of the Ten Tribes Partnership	The 10 member tribes of the Ten Tribes Partnership
2/11/2026	Yavapai Apache Nation	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff
2/12/2026	The Navajo Nation	P26 Technical Meeting	Tribal technical/legal staff
2/13/2026	Colorado River Indian Tribes	P26 Technical Meeting	Tribal technical/legal staff
2/13/2026	Ute Indian Tribe of Uintah and Ouray Reservation	P26 Technical Meeting	Tribal technical/legal staff
2/13/2026	Fort McDowell Yavapai Nation	P26 Technical Meeting	Tribal technical/legal staff
2/13/2026	Ak-Chin Indian Community	P26 Technical Meeting	Tribal technical/legal staff
2/17/2026	Hualapai Tribe	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff
2/18/2026	Colorado River Indian Tribes	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff
2/18/2026	Fort Yuma Quechan Tribe	P26 Draft EIS Government-to-Government Consultation	Tribal leadership, technical/legal staff

Appendix Q. Federal Register Notices

Four Federal Register notices have been issued to inform the public about the formulation of the interim operational guidelines and the preparation and availability of the Environmental Impact Statement. The full text of the Federal Register notices is provided in this appendix.

Q.1 Request for Input on Development of Post-2026 Colorado River Reservoir Operational Strategies for Lake Powell and Lake Mead Under Historically Low Reservoir Conditions (Federal Register, June 24, 2022; 87 FR 37885)

the individual turbines to the offshore substations, substation interconnector cables linking the substations to each other, offshore export cables, an onshore export cable system, 2 onshore substations, and connections to the existing electrical grid in New Jersey. The WTGs and offshore substations, inter-array cables, and substation interconnector cables would be located on the OCS approximately 13 nautical miles (15 statute miles) southeast of Atlantic City, New Jersey, within the area defined by Renewable Energy Lease OCS–A 0498 (Lease Area). The offshore export cables would be buried below the seabed surface in the OCS and State of New Jersey owned submerged lands. The onshore export cables, substations, and grid connections would be located in Ocean County and Cape May County, New Jersey.

Alternatives: BOEM considered 26 alternatives when preparing the DEIS and carried forward 6 alternatives for further analysis in the DEIS. These six alternatives include five action alternatives and the no action alternative. Twenty alternatives were rejected because they did not meet the purpose and need for the proposed action or did not meet screening criteria, which are presented in DEIS appendix C. The screening criteria included consistency with law and regulations; technical and economic feasibility; environmental impact; and geographic considerations.

Availability of the DEIS: The DEIS, Ocean Wind 1 COP, and associated information are available on BOEM's website at: *https://www.boem.gov/renewable-energy/state-activities/ocean-wind-1*. BOEM has distributed digital copies of the DEIS to all parties listed in DEIS appendix K, which also includes the location of all libraries receiving a copy. If you require a flash drive or paper copy, BOEM will provide one upon request, as long as copies are available. You may request a flash drive or paper copy of the DEIS by calling (703) 787–1520.

Cooperating Agencies: The following nine Federal agencies and State governmental entities participated as cooperating agencies in the preparation of the DEIS: Bureau of Safety and Environmental Enforcement; U.S. Environmental Protection Agency; National Marine Fisheries Service; U.S. Army Corps of Engineers; U.S. Coast Guard; U.S. Fish and Wildlife Service, Department of Defense; New Jersey Department of Environmental Protection; and New York State Department of State. The National Park Service participated as a participating agency.

Information on Submitting Comments: BOEM does not consider anonymous comments. Please include your name and address as part of your comment. BOEM makes all comments, including the names and addresses of respondents, available for public review online and during regular business hours. Individual respondents may request that BOEM withhold their names, addresses, or any other personal identifiable information (PII) included in their comment from the public record; however, BOEM cannot guarantee that it will be able to do so. If you wish your name, address, or other PII to be withheld, you must state your request prominently in a cover letter and explain the harm that you fear from its disclosure such as unwarranted privacy invasion, embarrassment, or injury. All submissions from organizations or businesses and from individuals identifying themselves as representatives or officials of organizations or businesses will be made available for public inspection in their entirety.

Authority: 42 U.S.C. 4231 *et seq.* (NEPA, as amended) and 40 CFR 1506.6.

William Y. Brown,

Chief Environmental Officer, Bureau of Ocean Energy Management.

Request for Input on Development of Post-2026 Colorado River Reservoir Operational Strategies for Lake Powell and Lake Mead Under Historically Low Reservoir Conditions

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice and request for input.

SUMMARY: The Secretary of the Interior has directed the Bureau of Reclamation (Reclamation) to begin work to develop operating strategies for the continued coordinated operation of Lake Powell and Lake Mead. A number of reservoir and water management decisional documents and agreements that govern operation of Colorado River facilities and management of Colorado River water are currently scheduled to expire at the end of 2026. These include the December 2007 Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (2007 Interim Guidelines), among other important management documents, both within the United States, as well as international agreements between the United States and Mexico pursuant to the United States-Mexico Treaty on Utilization of Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Water Treaty).

DATES: Submit written comments on the proposed development of Post-2026 Colorado River Operational Strategies pursuant to this notice on or before September 1, 2022.

Reclamation will host two public webinars to summarize the content and purpose of this **Federal Register** notice. The webinars will take place on Tuesday, July 12, 2022, from 10 a.m. to 11 a.m. (MDT), and on Thursday, July 14, 2022, from 10 a.m. to 11 a.m. (MDT).

ADDRESSES: Send written comments on the proposed development of Post-2026 Colorado River Operational Strategies to *CRB-info@usbr.gov*.

The virtual meeting held on Tuesday, July 12, 2022, may be accessed at *https://teams.microsoft.com/l/meetup-join/19%3ameeting_YTg1ZmVmMDItNzkxMC00YjM2LTg3NmEtNmIwMWI3ZGEyNjJm%40thread.v2/0?context=%7b%22Tid%22%3a%220693b5ba-4b18-4d7b-9341-f32f400a5494%22%2c%22Oid%22%3a%22388b569b-9117-49f0-b6f1-cd12ff0587b0%22%7d;* or call in (audio only) at (719) 733–3211, Phone Conference ID: 100 899 510#.

The virtual meeting held on Thursday, July 14, 2022, may be accessed at *https://teams.microsoft.com/l/meetup-join/19%3ameeting_MWE0YmZhNDItOGQwZC00YmRiLWJiMmItZDM4ZDUwN2JlNzcx%40thread.v2/0?context=%7b%22Tid%22%3a%220693b5ba-4b18-4d7b-9341-f32f400a5494%22%2c%22Oid%22%3a%22e792bef3-e313-4746-82d1-a6064d5ee897%22%7d;* or call in (audio only) at (202) 640–1187, Phone Conference ID: 795 497 392#.

FOR FURTHER INFORMATION CONTACT: Carly Jerla, Senior Water Resources Program Manager, Bureau of Reclamation, at (303) 517–1160; or by email at *cjerla@usbr.gov*. Individuals in the United States who are deaf, deafblind, hard of hearing, or have a speech disability may dial 711 (TTY, TDD, or TeleBraille) to access telecommunications relay services. Individuals outside the United States should use the relay services offered within their country to make international calls to the point-of-contact in the United States.

SUPPLEMENTARY INFORMATION: Through this notice, and prior to formally initiating a National Environmental Policy Act (NEPA) process (or processes) to develop post-2026 operations for Lake Powell and Lake Mead (among other potential actions), Reclamation is requesting input on: (a) processes that can be employed to encourage and facilitate meaningful participation of Colorado River Basin (Basin) partners, stakeholders, and the general public in the anticipated upcoming NEPA process(es); as well as (b) potential substantive elements and strategies for post-2026 operations to consider in the anticipated upcoming NEPA process(es). Reclamation anticipates formally initiating the NEPA process through a Notice of Intent to Prepare an Environmental Impact Statement in the **Federal Register** in early 2023. As noted in more detail below, given current conditions in the Colorado River Basin, Reclamation may utilize multiple NEPA efforts, or other appropriate processes, to address emerging low-reservoir conditions in the Basin.

The Colorado River Basin provides essential water supplies to approximately 40 million people, nearly 5.5 million acres of agricultural lands, and habitat for ecological resources across the Southwestern United States and Northwestern Mexico. The limited water supplies of the Colorado River are declining and the Colorado River Basin is currently experiencing a prolonged period of drought and record-low runoff conditions resulting in historically low reservoir levels at Lake Powell and Lake Mead. The period from 2000 through 2022 is the driest 23-year period in more than a century and one of the driest periods in the last 1,200 years. Absent a change in hydrologic conditions, water use patterns, or both, Colorado River reservoirs will continue to decline to critically low elevations threatening essential water supplies across nine states in the United States and the Republic of Mexico (Mexico). It is foreseeable that without appropriate responsive actions and under a continuation of recent hydrologic trends, major Colorado River reservoirs could continue to decline to ''dead pool''—elevations at which water cannot be regularly released from a reservoir—in coming years. As stated in the 2019 Lower Basin Drought Contingency Plan:

> . . . as a result of actual operating experience subsequent to the adoption of the 2007 Interim Guidelines, as well as emerging scientific information regarding the increasing variability and anticipated decline in Colorado River flow volumes, the Parties recognize and acknowledge that entities that rely on the Colorado River as a water source face increased individual and collective risk of temporary or prolonged interruptions in water supplies, with associated adverse impacts on the society, environment and economy of the southwestern United States.

The current unprecedented drought and low-runoff conditions are anticipated to persist and potentially worsen as a result of a number of factors, including increasing temperatures in the Basin, and other effects of climate change.

As a result of the exceptionally low runoff conditions over the past 3 years (2020, 2021, and 2022), unprecedented drought response operations have been triggered at Lake Powell and Lake Mead consistent with the 2007 Interim Guidelines and agreements adopted pursuant to the 2019 Colorado River Drought Contingency Plan Authorization Act (Pub. L. 116–14) (the 2019 Drought Contingency Plan (DCP) Act). The unprecedented risks facing the Colorado River Basin was the subject of a June 14, 2022 U.S. Senate hearing in which Reclamation Commissioner Camille Touton noted that while no one knows how dry the next few years could be, if recent (2018-present) dry conditions continue, Lake Powell and Lake Mead face extraordinary risks over the next 12–24 months, and that additional actions are needed to protect the reservoirs from rapidly declining to critically-low elevations: reductions totaling millions of acre-feet in reductions of use across the Basin could be needed to stabilize the reservoirs.

Background on Development of the 2007 Interim Guidelines.

Initially spurred by a 5-year period in which Lake Powell and Lake Mead lost nearly half of the combined storage in the reservoirs as a result of an ongoing multi-year drought, decreasing overall system storage, and growing demands for Colorado River water, at the direction of the Secretary of the Interior, Reclamation initiated a NEPA process in 2005 to develop operating guidelines for the coordinated operations of Lake Powell and Lake Mead, along with Lower Basin shortage criteria (and other related actions). See 70 FR 57322 (September 30, 2005). Following completion of the NEPA process (and associated compliance activities), in December 2007 Secretary of the Interior Kempthorne approved the Record of Decision for the 2007 Interim Guidelines. Published at 73 FR 19873 (April 11, 2008). The 2007 Interim Guidelines provided objective operating criteria for the coordinated operations of Lake Powell and Lake Mead and for determining Lower Basin shortage conditions, as well as establishing a program to encourage water conservation actions in the Lower Basin.

Operational Agreements, Operating Experience and Changed Circumstances Since Adoption of the 2007 Interim Guidelines.

Operational Agreements

Since their adoption, the 2007 Interim Guidelines have provided operating criteria for Lake Powell and Lake Mead including provisions designed to provide a greater degree of certainty to water users about timing and volumes of potential water delivery reductions, as well as additional operating flexibility to conserve and enhance water storage in Colorado River system reservoirs. In 2012, the United States and Mexico adopted Minute 319, a binational agreement adopted pursuant to the 1944 Water Treaty. Minute 319 provided interim (2012–2017) operating provisions that implement the provisions of the 1944 Water Treaty, establishing objective criteria for treaty deliveries through a wide range of reservoir conditions, and established mechanisms that provide Mexico with the flexibility to reduce water use and defer delivery of the reduced volumes in subsequent years. Minute 319 also provided U.S. funding to enhance water conservation and riparian habitat in the Colorado River Delta and Limitrophe region.

Notwithstanding the elements of the 2007 Interim Guidelines (and Minute 319), as hydrologic conditions worsened thereby increasing the risk of reservoirs declining to critically-low conditions, in 2013–2014, Reclamation and stakeholders began pursuing additional adaptive management actions. Among other drought response activities, the Upper and Lower Basin DCPs were adopted pursuant to the 2019 DCP Act. A further agreement with Mexico in 2017 (Minute 323) had previously established enhanced water reduction, water conservation, and savings mechanisms pursuant to the 1944 Water Treaty. Both the 2007 Interim Guidelines and the DCPs are anticipated to be in place for an interim period through 2026.[1] Similarly, Minute 323 is anticipated to be in effect through 2026.

[1] Except for the special provisions described in Section XI.G.8. of the 2007 Interim Guidelines, the 2007 Interim Guidelines are anticipated to remain in effect through December 31, 2025 (through preparation of the 2026 Annual Operating Plan). With the exception of certain Intentionally Created Surplus recovery and Upper Basin demand management provisions, operations under the

Continued

2020 Review of Operating Experience

The interim nature of the 2007 Interim Guidelines has provided the opportunity to gain valuable experience in the management of Lake Powell and Lake Mead under the adopted operations, improving the basis for making future operational decisions, both during the interim period and after. Section XI.G.7.D. of the 2007 Interim Guidelines required the documentation of this experience and an evaluation of the effectiveness of the 2007 Interim Guidelines. In fulfillment of this provision, in December 2020, Reclamation published on its website its ''Review of the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead'' (the 2020 7.D. Review).

The purpose of the 2007 Interim Guidelines was determined in the early stages of the NEPA process led by Reclamation to develop the guidelines and consists of 3 components. As stated in Section IV of the 2007 Interim Guidelines, the purpose is to:

- ''improve Reclamation's management of the Colorado River by considering trade-offs between the frequency and magnitude of reductions of water deliveries, and considering the effects on water storage in Lake Powell and Lake Mead, and on water supply, power production, recreation, and other environmental resources;
- provide mainstream United States users of Colorado River water, particularly those in the Lower Division states, a greater degree of predictability with respect to the amount of annual water deliveries in future years, particularly under drought and low reservoir conditions; and
- provide additional mechanisms for the storage and delivery of water supplies in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions.''

The 2020 7.D. Review found that the 2007 Interim Guidelines were largely effective as measured against this stated purpose.

However, with respect to the 4 operational elements of the 2007 Interim Guidelines (Coordinated Operations of Lake Powell and Lake Mead, Lower Basin Surplus Guidelines, Lower Basin Shortage Guidelines, and Storage and Delivery of Conserved Water in the Lower Basin), the 2007 Interim Guidelines failed to provide sufficiently robust operating provisions to address the increasing severity of the drought and low runoff conditions exacerbated by climate change. By 2013–2014, as a result of the worsening drought, a broad consensus within the Basin emerged that additional actions were needed to reduce the risk of Lake Powell and Lake Mead reaching critically low elevations. This led to the adoption of the DCPs and other voluntary adaptive actions.

The 2020 7.D. Review also documented important considerations for enhancing future effectiveness: (1) enhanced flexibilities and transparency for water users; (2) expanded participation in conservation and Basin-wide programs; (3) increased consideration of the linkage that occurs through coordinated reservoir operations, particularly with respect to the uncertainties inherent in model projections used to set operating conditions; and (4) more robust measures to protect reservoir levels.

Reclamation received written input during the 2020 7.D. Review process from a diverse group of partners and stakeholders across the Colorado River Basin. One area of significant comment was with respect to the stakeholder engagement process used to develop the 2007 Interim Guidelines. Multiple commenters expressed that the process was inadequate to meaningfully engage a sufficiently diverse group of stakeholders. Given the increased partner and stakeholder participation in Basin decision-making processes since the adoption of the 2007 Interim Guidelines, the Department of the Interior (Department or Interior) is particularly focused on developing and implementing a process that facilitates and encourages meaningful participation of Basin partners and stakeholders including other Federal agencies, the seven Colorado River Basin States, Native American Tribes, non-governmental organizations (NGOs), academic experts, and the general public. As discussed below, the Department is also committed to identifying processes that can complement the efforts of the International Boundary and Water Commission (IBWC) to develop post-2026 agreements that would succeed current agreements contained in Minute 323.

Changed Circumstances Since Adoption of the 2007 Interim Guidelines

As Reclamation and the Department prepare to initiate a NEPA process for the post-2026 Colorado River Reservoir Operational Strategies for Lake Powell and Lake Mead under historically low reservoir conditions, it is important to succinctly highlight a few areas where circumstances have changed since adoption of the 2007 Interim Guidelines. Reclamation welcomes input on these changed circumstances as well as suggestions on potential strategies that would be appropriate to more successfully address these changed circumstances given the expectation that conditions will continue to change in the Colorado River Basin in the years and decades ahead.

1. With respect to issues involving hydrology, risk facing the Basin, and advances in scientific understandings:

Since 2000, 50 percent of these years have seen less than 11 million acre-feet (maf) of annual natural flow at Lees Ferry and 13 percent have seen less than 8 maf. The 21st century has been 20 percent drier than the 20th century, and the 5-year average has declined by 33 percent in 23 years. Future strategies should consider these conditions and the likelihood of continued declines in supply.

The 2007 Interim Guidelines were developed in response to 5 years of drought and precipitous reservoir declines and were based primarily on the modeling assumption of a stationary climate where future inflows were adequately represented in the observed historical record.

Since 2007, unprecedented drought has changed our understanding of basin hydrology; climate science tells us that the future temperatures in the Colorado River Basin will continue to warm and that we can expect an increased likelihood of experiencing deep, prolonged droughts.

The 2020 7.D. Review found that while the 2007 Interim Guidelines were effective at meeting their overall purpose, the increasing severity of the drought demonstrated that the 2007 Interim Guidelines were insufficiently robust to protect reservoir storage, requiring the adoption of the DCPs and other responsive adaptive actions.

Nevertheless, even the additional actions adopted subsequent to the 2007 Interim Guidelines were demonstrably insufficient to address the ongoing drought and low runoff conditions. With declining reservoir conditions, Reclamation undertook emergency and other drought response actions in both 2021 and 2022 to protect infrastructure and operations at Glen Canyon Dam.

The latest global climate model-derived projections of climate change agree that temperatures will warm, but precipitation and impacts on basin hydrology continue to show a wide range of potential futures and experts cannot say with a high degree of confidence or specificity what is most likely to happen in a nonstationary

Guidelines and the DCPs are in effect through December 31, 2026.

climate (*i.e.,* the question ''what will future runoff be?'' cannot be answered). Hydrologic uncertainty combined with uncertain future growth and water use compound to mean that it is impossible to assign probabilities to any given future and the basin is experiencing conditions of deep uncertainty.

These factors lead Reclamation to observe that in developing post-2026 guidelines in a nonstationary, drying system, a different approach toward addressing risk that employs planning methods that account for deep uncertainty must be taken. Such an approach should enhance the ability to identify robust policies that are better prepared to adapt to changing conditions.

For planning purposes, robust policies are those that withstand a broad range of future conditions and are not based on a single set of assumptions about water supply and demand. With increasing temperatures across the basin, predictions of commensurate decreases in reliable supply, and uncertainty in future demands, Reclamation believes that future policies must be tested across a wide range of potential future conditions, including drought sequences that are longer and more severe than those that have been observed. Absent such an approach, policies are likely to be insufficiently robust, adaptable, and successful.

2. With respect to issues regarding engagement and inclusivity in Colorado River decision-making:

The domestic stakeholder process used to develop the 2007 Interim Guidelines was considered, at the time, to have engaged a wide range of stakeholders and included extensive public involvement. Central to this process was technical outreach and modeling support provided by Reclamation.

In the intervening 15 years, there has been an increasing level of collaboration and communication across the Basin—indicating the necessity of more deeply engaging a broader range of stakeholders during the upcoming process(es). Meaningfully engaging and encouraging the participation of Colorado River Basin Tribes, representatives of Mexico, and NGOs was crucial to the success of the key and essential operational decisions that have come about since the adoption of the 2007 Interim Guidelines.

As we approach the initiation of efforts to develop post-2026 guidelines, Reclamation has identified that it intends to design and implement a stakeholder process that is inclusive, transparent, and encourages meaningful engagement. In order to accomplish this commitment, Reclamation intends to prioritize stakeholder technical education, technical outreach, and timely access to relevant technical information. Reclamation intends to support parties in developing strategies and would welcome input on recommended steps to ensure active participation by a wide range of Basin partners, stakeholders, and the general public. Reclamation will continue to seek to prioritize the development of approaches that have broad-based support.

a. With respect to Colorado River Basin Tribes:

During the preparation of the 2007 Interim Guidelines, the Department conducted extensive engagement with Native American Tribes in the Colorado River Basin (Basin Tribes) regarding the potential adoption of operating guidelines for Lake Powell and Lake Mead and related actions, including the adoption of rules regarding creation, accounting and delivery of Intentionally Created Surplus. See 2007 Final Environmental Impact Statement (FEIS), Appendix I, at *https://www.usbr.gov/lc/region/programs/strategies/FEIS/AppI.pdf.*

Notwithstanding the engagement documented in the 2007 FEIS, during the implementation of the 2007 Interim Guidelines, many Basin Tribes have expressed deeply-held concerns, viewpoints, and objections to the lack of full engagement and consultation, and that any engagement during the development (and implementation) of the 2007 Interim Guidelines was insufficient to address the range of interests, needs, and fundamental rights of the Basin Tribes. These concerns have significantly increased as water supply conditions in the Basin have been increasingly impacted by drought, low runoff, and the effects of climate change.

Interior has undertaken extensive efforts across the Basin to facilitate Indian Water Rights Settlements, enhance Tribal utilization of water rights, engage with Tribal Governments, and facilitate Basin engagement. For example, beginning last year, Reclamation has hosted monthly Tribal Information Exchanges as one mechanism to share timely information on Colorado River Basin conditions, challenges, and opportunities for investment and water conservation programs. While these efforts have continuously increased over time, there are extraordinary and unique challenges facing Basin Tribes.

Basin Tribes have expressed their concerns in direct correspondence to the Secretary of the Interior and have formally requested commitments from Interior for greater inclusion in the NEPA process to develop post-2026 operations, as well as increased engagement and consultation during the implementation of any guidelines developed pursuant to the upcoming NEPA process.

Interior recognizes that each Basin Tribe possesses unique rights (including water rights), unique viewpoints, and concerns with respect to current and projected conditions in the Basin. While it is premature at this time for Interior to make precise decisions about the content of post-2026 operations, the Secretary of the Interior has and is committed to engage and consult with the Basin Tribes in a meaningful and transparent manner during the upcoming NEPA process and to fully consider tribal input and viewpoints through government-to-government consultation, consistent with the Department's Detailed Plan for Improving Interior's Implementation of Executive Order 13175, *Consultation and Coordination with Indian Tribes,* found at *www.doi.gov/priorities/tribal-consultation.* Interior is interested in receiving specific input on the most effective processes that can be employed during the upcoming NEPA process(es) to ensure that these commitments are fully implemented.

b. With respect to engagement with Mexico:

The 2007 Interim Guidelines were adopted under the authority of the Secretary of the Interior. Accordingly, the scope of the 2007 Interim Guidelines was domestic, and no decisions were made regarding operations under the 1944 Water Treaty.

Since 2007 an extraordinary cooperative process has been forged between the two nations with the participation of the Department and Reclamation in support of agreements developed between the United States and Mexico Sections of the IBWC. Since adoption of the 2007 Interim Guidelines, significant international agreements on the Colorado River are memorialized in Minutes 316, 317, 318, 319, and 323.

With Minute 323 scheduled to expire at the same time as the 2007 Interim Guidelines and the 2019 DCP, the United States and Mexico have expressed a policy goal of developing a successor to Minute 323 on a parallel timeline as the domestic development of post-2026 operational approaches. This policy goal is intended to ensure that Colorado River reservoirs continue to be managed in a manner that ensures an

appropriate degree of operational alignment.

While not determining in any way what processes the IBWC may choose to utilize, the Department would welcome input on how the Interior-led domestic planning processes could be implemented in a coordinated and complementary fashion to those of the IBWC.

3. With respect to the current and emerging operational challenges and potential for significant disruptions to Colorado River water supplies under continued low-runoff conditions:

While previous actions, especially the DCP, were intended to preserve Reclamation's ability to undertake post-2026 planning with a stable system and avoid crisis planning, very dry hydrology since the adoption of the DCP has resulted in Lake Powell and Lake Mead nearing critically low elevations.

Should the conditions continue or worsen, we recognize that in addition to post-2026 planning under the anticipated NEPA process(es), Reclamation may likely need to also prioritize implementation of near-term actions to stabilize the decline in reservoir storage and prevent system collapse. Reclamation has not yet determined what additional actions or processes may be required to address these near-term operational risks. It is anticipated that near-term response actions and development of post-2026 operations will need to proceed on parallel timelines.

- *Process:* Reclamation seeks specific input on suggested mechanisms for the anticipated NEPA process(es) to ensure that a wide range of Basin partners, stakeholders, and the general public can meaningfully engage and participate in the development of post-2026 operational strategies.
- *Substantive elements of post-2026 operations:* Reclamation seeks input on potential substantive elements and strategies that should be considered for post-2026 operations and considered in the anticipated upcoming NEPA process(es).

With respect to both these areas where Reclamation is seeking input through this **Federal Register** notice, Reclamation is particularly interested in receiving specific recommendations that can be considered and potentially integrated as the initiation of the NEPA process is being developed.

Reclamation notes that it intends to formally initiate the NEPA process for development of post-2026 operations through a Notice of Intent to Prepare an Environmental Impact Statement in the **Federal Register** in early 2023. Any input received as part of this **Federal Register** notice request for input will be fully considered by Reclamation but formal scoping comments will be solicited following initiation of the anticipated NEPA process. Decisions by entities whether or not to submit input regarding this **Federal Register** notice shall not limit or prejudice in any manner comments such entities may choose to submit during the formal scoping period following a formal Notice of Intent to initiate preparation of an Environmental Impact Statement (anticipated in early 2023).

Public Disclosure of Comments

Before including your address, phone number, email address, or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

Tanya Trujillo,

Assistant Secretary for Water and Science.

BILLING CODE 4332–90–P

INTERNATIONAL TRADE COMMISSION

Notice of Receipt of Complaint; Solicitation of Comments Relating to the Public Interest

AGENCY: U.S. International Trade Commission.

ACTION: Notice.

SUMMARY: Notice is hereby given that the U.S. International Trade Commission has received a complaint entitled *Certain Mobile Electronic Devices, DN 3625;* the Commission is soliciting comments on any public interest issues raised by the complaint or complainant's filing pursuant to the Commission's Rules of Practice and Procedure.

FOR FURTHER INFORMATION CONTACT: Lisa R. Barton, Secretary to the Commission, U.S. International Trade Commission, 500 E Street SW, Washington, DC 20436, telephone (202) 205–2000. The public version of the complaint can be accessed on the Commission's Electronic Document Information System (EDIS) at *https://edis.usitc.gov.* For help accessing EDIS, please email *EDIS3Help@usitc.gov.*

General information concerning the Commission may also be obtained by accessing its internet server at United States International Trade Commission (USITC) at *https://www.usitc.gov.* The public record for this investigation may be viewed on the Commission's Electronic Document Information System (EDIS) at *https://edis.usitc.gov.* Hearing-impaired persons are advised that information on this matter can be obtained by contacting the Commission's TDD terminal on (202) 205–1810.

SUPPLEMENTARY INFORMATION: The Commission has received a complaint and a submission pursuant to § 210.8(b) of the Commission's Rules of Practice and Procedure filed on behalf of Maxell, Ltd. on June 16, 2022. The complaint alleges violations of section 337 of the Tariff Act of 1930 (19 U.S.C. 1337) in the importation into the United States, the sale for importation, and the sale within the United States after importation of certain mobile electronic devices. The complainant names as respondents: Lenovo Group Ltd. of China; Lenovo (United States) Inc. of Morrisville, NC; and Motorola Mobility LLC of Libertyville, IL. The complainant requests that the Commission issue a limited exclusion order, cease and desist orders, and impose a bond upon respondents alleged infringing articles during the 60-day Presidential review period pursuant to 19 U.S.C. 1337(j).

Proposed respondent, other interested parties, and members of the public are invited to file comments on any public interest issues raised by the complaint or § 210.8(b) filing. Comments should address whether issuance of the relief specifically requested by the complainant in this investigation would affect the public health and welfare in the United States, competitive conditions in the United States economy, the production of like or directly competitive articles in the United States, or United States consumers.

In particular, the Commission is interested in comments that:

(i) explain how the articles potentially subject to the requested remedial orders are used in the United States;

(ii) identify any public health, safety, or welfare concerns in the United States relating to the requested remedial orders;

(iii) identify like or directly competitive articles that complainant, its licensees, or third parties make in the United States which could replace the subject articles if they were to be excluded;

(iv) indicate whether complainant, complainant's licensees, and/or third party suppliers have the capacity to

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

[RR03040000, 23XR0680A1, RX187860005004001]

Notice of Intent To Prepare an Environmental Impact Statement and Notice To Solicit Comments and Hold Public Scoping Meetings on the Development of Post-2026 Operational Guidelines and Strategies for Lake Powell and Lake Mead

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice and request for comments.

SUMMARY: The Secretary of the Interior (Secretary) has directed the Bureau of Reclamation (Reclamation) to develop post-2026 Colorado River reservoir operational guidelines and strategies for Lake Powell and Lake Mead (referred to as "post-2026 operations"). Several important reservoir and water management decisional documents and agreements that govern operation of Colorado River facilities and management of Colorado River water are currently scheduled to expire at the end of 2026. Through this **Federal Register** notice, Reclamation is formally initiating the process to prepare an environmental impact statement (EIS) for the development of post-2026 operations.

DATES: This **Federal Register** notice initiates the public scoping process for the EIS. Reclamation requests that the public submit comments concerning the scope of specific operational guidelines, strategies, and any other issues that should be considered on or before August 15, 2023.

Reclamation will host three virtual public meetings/webinars to provide summary information and receive oral comments:

- Monday, July 17, 2023, 1 p.m. to 2 p.m. (MDT)
- Tuesday, July 18, 2023, 10 a.m. to 11 a.m. (MDT)
- Monday, July 24, 2023, 6 p.m. to 7 p.m. (MDT)

ADDRESSES: Please send written comments pursuant to this notice to *crbpost2026@usbr.gov* or Bureau of Reclamation, Attn: Post-2026 (Mail Stop 84–55000), P.O. Box 25007, Denver, CO 80225.

The registration link for the webinar held on Monday, July 17, 2023, is *https://swca.zoom.us/webinar/register/WN_-_hvFoMcRJ-l98k4n7-GvQ,* or the dial in option (audio only) is (602) 753–0140 or (720) 928–9299; Webinar ID: 918 5524 0606.

The registration link for the webinar held on Tuesday, July 18, 2023, is *https://swca.zoom.us/webinar/register/WN_sbSwzBJhQ66Z-E65TGXX1g,* or the dial in option (audio only) is (602) 753–0140 or (720) 928–9299; Webinar ID: 963 7946 3234.

The registration link for the webinar held on Monday, July 24, 2023, is *https://swca.zoom.us/webinar/register/WN_r0ozNRpmRu-hmEpYxe0-Qg,* or the dial in option (audio only) is (602) 753–0140 or (720) 928–9299; Webinar ID: 949 1587 3150.

FOR FURTHER INFORMATION CONTACT: Amanda Erath, Colorado River Post-2026 Program Coordinator, Bureau of Reclamation, at (303) 445–2766, or by email at *crbpost2026@usbr.gov*. Please also visit the project website at *https://www.usbr.gov/ColoradoRiverBasin/Post2026Ops.html*. Individuals in the United States who are deaf, deafblind, hard of hearing, or have a speech disability may dial 711 (TTY, TDD, or TeleBraille) to access telecommunications relay services. Individuals outside the United States should use the relay services offered within their country to make international calls to the point-of-contact in the United States.

SUPPLEMENTARY INFORMATION: This document provides notice that Reclamation intends to prepare an EIS for post-2026 operations and conduct public scoping. Reclamation is issuing this **Federal Register** notice pursuant to the National Environmental Policy Act of 1969, as amended (NEPA), 42 U.S.C. 4321 *et seq.;* the Council on Environmental Quality's regulations for implementing NEPA, 43 CFR parts 1500 through 1508; and the Department of the Interior (Department or Interior) NEPA regulations, 43 CFR part 46.

Background

The Colorado River Basin has been in a prolonged period of drought and low-runoff conditions, and despite current projections of 2023 runoff being well above average, the period from 2000 through 2023 is currently estimated as the second driest period in more than a century and one of the driest periods in the last 1,200 years. From 2000 to 2004, Lake Powell and Lake Mead lost nearly half of their combined storage. The onset of this period of acute drought spurred the development of the 2007 Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (2007 Interim Guidelines). Over the past 15 years since the adoption of the 2007 Interim Guidelines, as drought and low-runoff conditions continued, additional responsive actions were needed to complement the 2007 Interim Guidelines (*e.g.,* 2019 Colorado River Basin Drought Contingency Plan (DCP)). At the end of 2026, a number of reservoir and water management decisional documents and agreements that govern the operation of Colorado River facilities and management of the Colorado River are scheduled to expire. These include the 2007 Interim Guidelines, the DCP, and other important management documents within the United States, as well as Minute 323 between the United States and Mexico pursuant to the United States-Mexico Treaty on Utilization of Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Water Treaty).

Since 2021, the Department has undertaken several actions to protect critical infrastructure in response to declining reservoir elevations and the deepening of drought conditions from 2020 to 2022. As the summer of 2022 ended with near record low elevations in Lake Powell and Lake Mead, the Department recognized that, absent a change in hydrologic conditions, water use patterns, or both, Colorado River reservoirs would continue to decline to critically low elevations before the 2007 Interim Guidelines expired. In order to modify guidelines for the operation of Glen Canyon and Hoover Dam for the remainder of the interim period (through 2026) to address these historic drought and low runoff conditions in the Basin, the Department initiated a NEPA process on November 17, 2022, to prepare a Supplemental Environmental Impact Statement (SEIS) for Near-term Colorado River Operations. The draft SEIS was released for public review on April 14, 2023. In light of the Lower Basin states' consensus-based system conservation proposal submitted on May 22, 2023, the Department temporarily withdrew the draft SEIS so

that it can fully analyze the effects of the proposal under NEPA. Reclamation intends to publish an updated draft SEIS for public comment with the consensus-based proposal as an action alternative and finalize the SEIS process later this year.

Recognizing the need to begin to develop long-term strategies for Colorado River operations while simultaneously addressing the current drought conditions and preparing for the potential of continuing low runoff and low reservoir conditions, the Department published a **Federal Register** notice on June 24, 2022 (87 FR 37884), related to post-2026 operations. In that **Federal Register** notice, the Department specifically requested public input on procedural approaches to developing the post-2026 operational strategies (process) and potential substantive elements of post-2026 operations. In response, the Department received substantial input from States, Tribes, water districts, non-governmental organizations, and the public. The input received has been summarized in a ''Pre-Scoping Summary Report'' (Available at *https://www.usbr.gov/ColoradoRiverBasin/documents/Post-2026_Pre-Scoping%20Comment%20Summary%20Final_Updated1.30.2023_508.pdf*) and is being considered and integrated into this NEPA process. This NOI follows that important early opportunity for public input, and formally initiates the post-2026 NEPA process.

With respect to the relationship between the ongoing SEIS process and the post-2026 process, the November 2022 **Federal Register** notice was clear that the SEIS: ''does not interfere with, supplant, or supersede that separate post-2026 guidelines development process. Rather, this SEIS will inform and complement the development of post-2026 guidelines.'' The SEIS is focused on limited sections of the 2007 Interim Guidelines to develop the operational tools necessary to address potential extreme drought conditions during the 2024 to 2026 timeframe. In contrast, the post-2026 process will address the subsequent timeframe and revisit all sections of the 2007 Interim Guidelines and other operating agreements that expire in 2026 (*e.g.*, the DCP). The appropriate scope of post-2026 operations will be determined after conclusion of the public scoping process.

The June 2022 **Federal Register** notice for pre-scoping for post-2026 operations anticipated ''that near-term response actions and development of post-2026 operations will need to proceed on parallel timelines.'' The SEIS and post-2026 processes are now underway and proceeding simultaneously as predicted. Every effort will be made to provide clear and timely information regarding the milestones for public engagement in the post-2026 process to minimize the stakeholder and public burden of tracking and engaging in both efforts.

Purpose of This Notice of Intent

To assure the continued stability of the Colorado River system into the future, Reclamation announces its intent to prepare an EIS for post-2026 operations and is now soliciting public comments on the scope of specific operational guidelines, strategies, and any other related issues that should be considered in the upcoming EIS.

Reclamation invites all interested members of the public, including the seven Colorado River Basin States, Tribes, water and power contractors, representatives of the agricultural industry, municipal water providers, environmental organizations, representatives of the recreation industry, representatives of academic and scientific communities and other organizations and agencies to provide oral and written comments. Reclamation anticipates publishing a ''scoping report'' after completion of the public scoping meetings and the close of the comment period identified in this **Federal Register** notice.

All comments received will be considered as Reclamation develops the proposed federal action, Purpose and Need, and scope of the analysis (*e.g.*, affected area, geographic scope, time horizon/term). Similar to operational guidelines currently in place, it is likely that the post-2026 operational guidelines will be interim. Despite their interim nature, it is the Department's intent that these operational guidelines and strategies are sufficiently robust and adaptive and can withstand a broad range of future conditions thereby providing greater operational and planning stability to water users and the public throughout the Colorado River Basin.

June 2022 Request for Input on Development of Post-2026 Colorado River Operational Strategies

In response to the June 2022 pre-scoping **Federal Register** notice, Reclamation heard from over 80 stakeholders and partners as well as over 2,000 members of the public. As noted above, in January 2023, Reclamation published a ''Pre-Scoping Comment Summary Report'' on its website describing and summarizing the input received and hosted a public outreach event on January 30, 2023, to communicate the findings.

The input received in response to the June 2022 **Federal Register** notice included a broad range of comments and suggestions, not all of which can be addressed in this proposed process or described in this NOI. In addition, some suggestions may be part of ongoing or future efforts. However, some widely expressed themes related to the nature of future operational guidelines and strategies are actively being considered in our approach during the early stages of planning for this NEPA process:

- Future operational guidelines and strategies must support proactive management to improve system stability and avoid continuously managing in response to crises. To achieve this, future operational guidelines and strategies must be capable of both withstanding a broad range of future hydrologic and operating conditions and minimizing system vulnerability, *i.e.*, they must be more robust and adaptive than current strategies.
- Future operational guidelines and strategies should incorporate a more holistic approach to Colorado River water management in a way that focuses on the long-term sustainability of both the Basin's population and natural environment, minimizes system vulnerability, and increases system resiliency.
- Coordinated operation of Lake Powell and Lake Mead is one of multiple ways that the system can be managed. Alternative paradigms, *e.g.*, basing reservoir operations on combined reservoir or system storage, should be explored.

Structure of the 2007 Interim Guidelines and Operating Experience

The purpose of the 2007 Interim Guidelines was determined in the early stages of the NEPA process to develop the 2007 Interim Guidelines and consists of three components. As stated in Section IV of the 2007 Interim Guidelines, the purpose is to:

- ''improve Reclamation's management of the Colorado River by considering trade-offs between the frequency and magnitude of reductions of water deliveries, and considering the effects on water storage in Lake Powell and Lake Mead, and on water supply, power production, recreation, and other environmental resources;
- provide mainstream United States users of Colorado River water, particularly those in the Lower Division states, a greater degree of predictability with respect to the amount of annual water deliveries in future years,

particularly under drought and low reservoir conditions; and

• provide additional mechanisms for the storage and delivery of water supplies in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions.''

Despite the additional agreements and actions undertaken since the adoption of the 2007 Interim Guidelines and ongoing processes, the four elements of the 2007 Interim Guidelines, collectively intended to meet the purpose, have remained intact. These elements are:

• *Shortage Guidelines:* Determines those conditions under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Lower Division states below 7.5 million acre-feet pursuant to the Consolidated Decree.

• *Coordinated Reservoir Operations:* Defines the coordinated operations of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions. As described in Section XI.G.6. of the Record of Decision, the objective of the operation of Lake Powell and Lake Mead is ''to avoid curtailment of uses in the Upper Basin, minimize shortages in the Lower Basin and not adversely affect the yield for development available in the Upper Basin.''

• *Storage and Delivery of Conserved Water:* Allows for the storage and delivery, pursuant to applicable federal law, of conserved Colorado River System and non-System water in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions.

• *Surplus Guidelines:* Determines those conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. Modifies the substance of the Interim Surplus Guidelines existing at the time the Guidelines were adopted by extending the term from 2016 to 2026 and terminating the most permissive provision.

The interim nature of the 2007 Interim Guidelines provided the opportunity to gain valuable experience in the management of Lake Powell and Lake Mead, improving the basis of understanding for future operational decisions. First implemented in 2008, Reclamation now has over 15 years of operational experience under the 2007 Interim Guidelines. Section XI.G.7.D. of the 2007 Interim Guidelines required the documentation of this experience and an evaluation of the effectiveness of the 2007 Interim Guidelines. In fulfilment of this provision, in December 2020, Reclamation published on its website ''Review of the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead'' (Available at *https://www.usbr.gov/ColoradoRiverBasin/#7.D.Review*) (the 2020 7.D. Review).

The 2020 7.D. Review found that while the 2007 Interim Guidelines were effective at meeting their overall purpose, the increasing severity of the drought and prolonged period of low runoff demonstrated that the 2007 Interim Guidelines were insufficiently robust to protect reservoir storage, requiring the adoption of the DCPs and other responsive adaptive actions, both within the United States and in cooperation with Mexico.

The 2020 7.D. Review also documented important considerations for enhancing future effectiveness: (1) enhanced flexibilities and transparency for water users; (2) expanded participation in conservation and Basin-wide programs; (3) increased consideration of the linkage that occurs through coordinated reservoir operations, particularly with respect to the uncertainties inherent in model projections used to set operating conditions; and (4) more robust measures to protect reservoir levels.

Following the publication of the 2020 7.D. Review, as low snowpack and runoff conditions worsened, Reclamation undertook emergency and other drought response actions in 2021 and 2022 to protect infrastructure and operations at Glen Canyon Dam. In the November 2022 **Federal Register** notice, the Department found that due to the existence of ''extraordinary circumstances'' per Section 7.D of the 2007 Interim Guidelines, modified operating provisions may be required in order to ensure Glen Canyon Dam continues to operate under its intended design and to protect Hoover Dam operations, system integrity, and public health and safety and initiated the on-going SEIS process.

Considering the past 15 years of operating experience, the findings described in the 2020 7.D. Review, the themes expressed in response to the June 2022 **Federal Register** notice, and the information included in this NOI; Interior is interested in receiving specific input on how the purpose and the elements of the 2007 Interim Guidelines should be retained, modified or eliminated to provide greater stability to water users and the public throughout the Colorado River Basin through robust and adaptive operational guidelines. This input will be used to inform our decision on the proposed federal action, Purpose and Need, and scope of the analysis (*e.g.*, affected area, geographic scope, time horizon/term).

Elements of Process Designed to Date

In the June 2022 **Federal Register** notice, Reclamation identified that it intends to design and implement a stakeholder process for this EIS that is inclusive, transparent, and encourages meaningful engagement. Using the input received during that comment period and correspondence from Basin partners, Reclamation is in the early stages of developing certain components of its engagement and outreach approaches.

With respect to developing alternatives, input received in response to the June 2022 **Federal Register** notice suggested that Reclamation expand beyond its traditional methods of engagement and requested an inclusive process that encourages collaboration and supports the exploration of a broad range of creative operational strategies. To this end, and among other potential approaches, Reclamation is working with experts to develop a web-based tool that enables users with different levels of technical skill to explore, create, and compare potential operating strategies to enhance development of alternatives. The use of this common, accessible platform is just one part of Reclamation's stated goals of improving stakeholder and partner knowledge and engagement that supports external parties in developing strategies and provides the public greater and more timely access to relevant technical information.

In anticipation of the target Fall 2023 launch of the tool, Reclamation has convened an Integrated Technical Education Workgroup that is actively working to ensure that stakeholders are better prepared and able to engage in a robust alternatives development process. While it is valuable during this comment period to communicate ideas about the concepts and structures that could be included in alternatives, it is not necessary to submit comprehensive alternatives before the more focused period of alternatives development begins this fall.

With respect to the timing and structure of outreach during the NEPA process, Reclamation intends to develop an approach that facilitates inclusion at multiple levels and enhances tribal engagement and inclusivity. This structure for partner, stakeholder and public engagement will include individualized outreach, leverage existing groups and forums, create new

groups and forums, and provide for clear and timely communication with the public.

Through the individualized partner and stakeholder outreach, Reclamation will be available for meetings upon request and will prioritize regular, meaningful, and robust consultation with Tribal Nations. Existing forums and groups will be continued and leveraged, such as the monthly Reclamation-hosted Tribal Information Exchanges. Reclamation is also exploring options for increasing tribal involvement through the potential development of new groups and forums. In addition to timely and clear communication with the public at regular NEPA milestones, Reclamation intends to set up a broad partner-stakeholder group to ensure a full understanding of each upcoming step in the NEPA process.

As discussed in the June 2022 **Federal Register** notice, the Department is also committed to identifying processes that can complement the efforts of the International Boundary and Water Commission (IBWC) to develop post-2026 agreements that would succeed current agreements contained in Minute 323 to the 1944 Water Treaty. The Department will continue to coordinate with the IBWC to ensure Interior-led domestic planning processes are implemented in a coordinated and complementary fashion to those of the IBWC with a goal of ensuring similar timelines for informed decision making.

Public Disclosure of Comments

Before including your address, phone number, email address, or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

Maria Camille Touton,

Commissioner, Bureau of Reclamation.

BILLING CODE 4332–90–P

DEPARTMENT OF THE INTERIOR

Bureau of Safety and Environmental Enforcement

[Docket ID BSEE–2023–0005; EEEE500000 234E1700D2 ET1SF0000.EAQ000; OMB Control Number 1014–0015]

Agency Information Collection Activities; Unitization

AGENCY: Bureau of Safety and Environmental Enforcement, Interior.

ACTION: Notice of information collection; request for comment.

SUMMARY: In accordance with the Paperwork Reduction Act (PRA) of 1995, the Bureau of Safety and Environmental Enforcement (BSEE) proposes to renew an information collection.

DATES: Interested persons are invited to submit comments on or before August 15, 2023.

ADDRESSES: Send your comments on this information collection request (ICR) by either of the following methods listed below:

- Electronically go to *http://www.regulations.gov*. In the Search box, enter BSEE–2023–0005 then click search. Follow the instructions to submit public comments and view all related materials. We will post all comments.
- Email *kye.mason@bsee.gov*, fax (703) 787–1546, or mail or hand-carry comments to the Department of the Interior; Bureau of Safety and Environmental Enforcement; Regulations and Standards Branch; ATTN: Nikki Mason; 45600 Woodland Road, Sterling, VA 20166. Please reference OMB Control Number 1014–0015 in the subject line of your comments.

FOR FURTHER INFORMATION CONTACT: To request additional information about this ICR, contact Nikki Mason by email at *nikki.mason@bsee.gov* or by telephone at (703) 787–1607. Individuals in the United States who are deaf, deafblind, hard of hearing, or have a speech disability may dial 711 (TTY, TDD, or TeleBraille) to access telecommunications relay services. Individuals outside the United States should use the relay services offered within their country to make international calls to the point-of-contact in the United States. You may also view the ICR at *http://www.reginfo.gov/public/do/PRAMain*.

SUPPLEMENTARY INFORMATION: In accordance with the PRA and 5 CFR 1320.8(d)(1), all information collections require approval under the PRA. We may not conduct, or sponsor and you are not required to respond to a collection of information unless it displays a currently valid OMB control number.

As part of our continuing effort to reduce paperwork and respondent burdens, we invite the public and other Federal agencies to comment on new, proposed, revised, and continuing collections of information. This helps us assess the impact of our information collection requirements and minimize the public's reporting burden. It also helps the public understand our information collection requirements and provide the requested data in the desired format.

We are especially interested in public comment addressing the following:

(1) Whether or not the collection of information is necessary for the proper performance of the functions of the agency, including whether or not the information will have practical utility;

(2) The accuracy of our estimate of the burden for this collection of information, including the validity of the methodology and assumptions used;

(3) Ways to enhance the quality, utility, and clarity of the information to be collected; and

(4) How might the agency minimize the burden of the collection of information on those who are to respond, including through the use of appropriate automated, electronic, mechanical, or other technological collection techniques or other forms of information technology, *e.g.,* permitting electronic submission of response.

Comments that you submit in response to this notice are a matter of public record. We will include or summarize each comment in our request to OMB to approve this ICR. Before including your address, phone number, email address, or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

Abstract: BSEE must approve any lessee's proposal to enter an agreement to unitize operations under two or more leases and for modifications when warranted. We use the information to ensure that operations under the proposed unit agreement will result in preventing waste, conserving natural resources, and protecting correlative rights including the government's interests.

Q.3 Colorado River Reservoir Operations: Development of Post-2026 Operational Guidelines and Strategies for Lake Powell and Lake Mead (October 20, 2023 – 88 FR 72535)

1976, 43 U.S.C. 1714(f), the Secretary determines that the withdrawal shall be extended.

(Authority: 43 U.S.C. 1714)

Shannon A. Estenoz,

Assistant Secretary for Fish and Wildlife and Parks.

Colorado River Reservoir Operations: Development of Post-2026 Operational Guidelines and Strategies for Lake Powell and Lake Mead

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice of availability.

SUMMARY: The Department of the Interior (Department) has issued a Scoping Summary Report on the Development of Post-2026 Operational Guidelines and Strategies for Lake Powell and Lake Mead. The Scoping Summary Report provides a summary of the comments received during the public scoping process and describes the Department's current, preliminary assessment of the proposed federal action, purpose and need, and scope of the environmental analysis to be included in the draft environmental impact statement (DEIS). The Department anticipates the DEIS will be published in December 2024 for public review.

ADDRESSES: The Scoping Summary Report is available on the Bureau of Reclamation's website at *https://www.usbr.gov/ColoradoRiverBasin/post2026/scoping/index.html*. Printed copies of the report are available upon request from the point of contact listed in the **FOR FURTHER INFORMATION CONTACT** section of this notice.

FOR FURTHER INFORMATION CONTACT: Amanda Erath, Colorado River Post-2026 Program Coordinator, Bureau of Reclamation, at (303) 445–2766, or by email at *crbpost2026@usbr.gov*. Please also visit the project website at *https://www.usbr.gov/ColoradoRiverBasin/post2026/index.html*. Individuals in the United States who are deaf, deafblind, hard of hearing, or have a speech disability may dial 711 (TTY, TDD, or TeleBraille) to access telecommunications relay services. Individuals outside the United States should use the relay services offered within their country to make international calls to the point-of-contact in the United States.

SUPPLEMENTARY INFORMATION: Pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended, and the Council on Environmental Quality's Regulations for Implementing the Procedural Provisions of NEPA, the Department is publishing the Scoping Summary Report as a voluntary effort to assist in public understanding of this important NEPA process. Based on the information summarized in the report, the Department is preparing a DEIS starting with the development of a reasonable range of alternatives that are technically and economically feasible and meet the purpose and need for the proposed federal action (40 CFR part 1508). Considering public input received to date, the Department's current, preliminary assessment of the proposed federal action, purpose and need, and scope of the environmental analysis to be included in the DEIS are described below and in the Scoping Summary Report.

Proposed Federal Action

The Bureau of Reclamation, acting on behalf of the Secretary of the Interior (Secretary), proposes to take action to adopt specific guidelines and coordinated reservoir management strategies to address operations of Lake Powell and Lake Mead through their full operating range. This action would provide improved predictability to all water users and managers in the Colorado River Basin by developing and adopting objective guidelines for the operation of Glen Canyon Dam and Hoover Dam to take effect when the current operating guidelines (the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead [2007 Interim Guidelines]) expire in 2026. In addition, this action is designed to provide for the sustainable management of the Colorado River system and its resources under a wide range of potential future system conditions due to a changing climate.

Based on public input, the Department anticipates the guidelines would include the following elements:

(1) Identification of circumstances under which the Secretary would allocate, reduce, or increase the annual amount of water available for consumptive use from Lake Mead to the Lower Division states (Arizona, California, and Nevada) at, below, or above 7.5 million acre-feet, pursuant to the Supreme Court Decree in *Arizona* v. *California*.[1]

(2) Coordinated operations of Lake Powell and Lake Mead, particularly under low reservoir conditions.

(3) Storage and delivery of conserved water in Lake Mead and/or Lake Powell to increase the flexibility to meet water use needs from both reservoirs, including the storage and delivery of non-system water; exchanges; and water conserved through extraordinary measures by or for tribal, agricultural, or municipal entities.

The proposed federal action allows for development of robust operating guidelines for Lake Powell and Lake Mead without precluding upstream or downstream actions needed to protect critical reservoir elevations at Lake Powell and Lake Mead, such as the following:

- Approaches that consider total system storage in all major Colorado River reservoirs and/or actual inflows to determine coordinated operations of Lake Powell and Lake Mead.
- Approaches that include opportunities for conservation, augmentation, demand management, or other water management strategies.
- Approaches that include opportunities for conservation, augmentation, demand management, or other water management strategies.
- Temporary emergency response operations at upstream Colorado River reservoirs to protect critical infrastructure at Glen Canyon Dam, so long as the project-specific operations of those reservoirs remain within their respective Records of Decision.

The Department intends that the guidelines be interim in nature and extend for at least the same duration as the 2007 Interim Guidelines (approximately 20 years), subject to further consideration during the NEPA process. Adoption of new guidelines for an interim (or limited) period provides the opportunity to gain additional experience for operating the reservoirs, thereby informing future operational and water management decisions.

Recognizing additional authorities may be developed, it is the intent of the Department to adopt and implement the guidelines in a manner consistent with the Law of the River.[2] It is also the

[1] The Department intends to meet any consultation requirements identified in Article II(B)(3) of the Supreme Court Decree in *Arizona* v. *California* through the ongoing NEPA process initiated by the **Federal Register** Notice of June 16, 2023 (88 FR 39455–39458) and the annual implementation of guidelines developed through this process.

[2] The treaties, compacts, decrees, statutes, regulations, contracts, and other legal documents

Continued

intent of the Department that the guidelines be used to implement the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (LROC).

Purpose and Need for the Proposed Federal Action

In accordance with NEPA implementing regulations, a statement of purpose and need is required in an EIS to explain why the agency is proposing the action. The ''need'' for the action may be described as the underlying problem or opportunity to which the agency is responding with the action; the ''purpose'' may refer to the goal or objective that the agency is trying to achieve (43 CFR 46.420).

The proposed federal action is needed for the following reasons:

- *The Secretary is legally required to coordinate operations of Colorado River reservoirs:* The Colorado River Basin Project Act of 1968 directs the Secretary to propose criteria for the coordinated long-range operation of Colorado River reservoirs. In compliance with this obligation, the LROC were developed and adopted by the Secretary in 1970. The LROC provide general narrative guidance regarding Lake Powell and Lake Mead operations but does not contain specific, objective criteria to guide annual operations. To address this inadequacy, the 2007 Interim Guidelines were developed to provide objective criteria used by the Department to implement the LROC. These guidelines have provided predictability needed by the entities that receive Colorado River water to better plan for and manage available water supplies from the Colorado River and other sources.
- *2007 Interim Guidelines are expiring:* Current operational guidelines expire during the 2026 operating year. The Department has determined that specific, objective operational guidelines are important to provide improved predictability and should be established for another interim period beyond 2026.
- *2007 Interim Guidelines have not sufficiently reduced risk:* Based on operational experience since 2007, the current guidelines are not robust enough to manage in a way that is sufficiently protective of the resources dependent on the Colorado River. Despite near-continuous drought-response actions in recent years, low-reservoir conditions have persisted and new infrastructure risks at Glen Canyon Dam have arisen. More robust and adaptive guidelines are needed for the efficient and sustainable management of the major mainstream Colorado River reservoirs and system resources.
- *Imbalance between water supply and demand will be exacerbated by increasingly likely low-runoff conditions:* Climate science indicates the Colorado River Basin is experiencing climate-change induced aridification and that long-term and sustained drought and low-runoff conditions should be expected in the future. These conditions will exacerbate the now widely recognized imbalance between water supply and demand in the Colorado River Basin. Robust and flexible guidelines are needed to manage the Colorado River system and its resources under a broad range of potential future hydrologic conditions.
- *Expanded and innovative use of conservation is needed:* Recognizing the anticipated future low-runoff conditions in the Colorado River Basin, the Department has also determined a need for guidelines that provide Colorado River water users, including Basin Tribes, expanded opportunities to conserve, store, and take subsequent delivery of water in and from Lake Mead and/or Lake Powell. The guidelines should also support and integrate future efficiency improvements and opportunities for augmentation.
- *Addressing tribal concerns regarding Colorado River Basin management is needed:* Basin Tribes have expressed concern that the current approach to Colorado River water management is insufficient to address the range of interests, needs, and fundamental rights of the Basin Tribes. The Department has determined a need for guidelines that provide flexibility and predictability for Basin Tribes to remain able to benefit from their water rights and have an opportunity to participate in voluntary conservation programs.

The purpose for the proposed federal action is to:

- update and expand management guidelines for Colorado River reservoirs, particularly for Lake Powell and Lake Mead;
- provide Colorado River water users, a greater degree of predictability with respect to the amount of annual water available in future years under anticipated increasing variability, low runoff and low reservoir conditions;
- provide additional mechanisms for the conservation, storage and delivery of water supplies in Colorado River reservoirs;
- provide new or enhanced opportunities for Basin Tribes to benefit from their water rights; and
- provide flexibility to build resilience and accommodate future needs and growth that are supported by Colorado River water supplies, including the integration of unquantified tribal water rights once they are resolved.

DEIS Approach

The DEIS will consider the best scientific information currently available; actual operating experience since 2007; updated information on infrastructure considerations at Glen Canyon Dam and Hoover Dam; trade-offs between the frequency and magnitude of reductions in water deliveries; mechanisms to encourage water conservation, efficiency improvements, and augmentation; and the effect of water storage in Lake Powell and Lake Mead on water supply, power production, recreation, environmental resources, cultural resources, and other relevant resources and factors.

The geographic scope of the environmental analysis in the DEIS is dependent upon the range of alternatives developed in the DEIS and therefore will be determined later in the NEPA process.

Next Steps

With this Notice, the Department is transitioning to the next phase of the NEPA process, which is to develop alternatives for analysis in the DEIS. Reclamation has developed state-of-the-art web-based tools to encourage and facilitate stakeholder collaboration during this phase and intends to deploy these tools in the early stages of this phase in the fall. It is the Department's intent that these tools support the exploration and development of a broad range of reasonable alternatives and foster collaborative consensus-based approaches to alternative development.

Maria Camille Touton,

Commissioner, Bureau of Reclamation.

[FR Doc. 2023–23127 Filed 10–19–23; 8:45 am]

BILLING CODE 4332–90–P

and agreements applicable to the allocation, appropriation, development, exportation, and management of the waters of the Colorado River Basin are often referred to as the ''Law of the River.'' There is no single, universally-agreed upon definition of the ''Law of the River,'' but it is useful as a shorthand reference to describe this longstanding and complex body of legal agreements governing the Colorado River.

Q.4 Environmental Impact Statements; Notice of Availability (U.S. Environmental Protection Agency, Federal Register, January 16, 2026; 91 FR 2131; FR Doc. No. 2026-00844)

The Draft Environmental Impact Statement for the Post-2026 Colorado River Reservoir Operations was filed with the U.S. Environmental Protection Agency on January 12, 2026. The Environmental Protection Agency published the Notice of Availability in the Federal Register on January 16, 2026 (91 FR 2131), initiating the 45-day public review and comment period pursuant to 40 CFR 1506.10.

EQUAL EMPLOYMENT OPPORTUNITY COMMISSION

Commission Meeting—Sunshine Act Notice

TIME AND DATE: Thursday, January 22, 2026, 10:00 a.m. Eastern Time.

PLACE: The meeting will be held at the Jacqueline A. Berrien Training Center, 131 M Street NE, Washington, DC 20507. The meeting will also be held as a listen-only audio dial-in by telephone. The public may attend in person or connect to the audio-only dial-in by following the instructions that will be posted on *www.eeoc.gov* at least 24 hours before the meeting. ASL services will be available for those attending the meeting in person and a closed captioning link will be posted on our website prior to the meeting.

If you wish to attend the meeting in person, you must email *commissionmeetingcomments@eeoc.gov* to register by providing your name as it appears on your driver's license or other government-issued identification at least 24 hours prior to the meeting. You will be asked to show your ID upon arrival.

STATUS: The meeting will be open to the public.

MATTERS TO BE CONSIDERED: The following item will be considered at the meeting:

- Rescission of Enforcement Guidance on Harassment in the Workplace
- Resolution Concerning the Commission's Authority to Commence or Intervene in Litigation
- Obligation of Funds Requiring Commission Approval

Note: In accordance with the Sunshine Act, the public will be able to observe the Commission's deliberations and voting. (In addition to publishing notices on Commission meetings in the **Federal Register**, the Commission also provides information about Commission meetings on its website, *www.eeoc.gov* and provides a recorded announcement one week in advance of future Commission meetings.) Public observation does not include participation. Observers seeking to take still photographs, video, or audio recordings of the meeting must seek permission by contacting the Executive Secretariat at *commissionmeetingcomments@eeoc.gov* at least 24 hours before the meeting to discuss the manner of recording and ensure it does not interfere with the meeting.

Please telephone (202) 921–2705, or email *commissionmeetingcomments@eeoc.gov* at any time for information on this meeting.

CONTACT PERSON FOR MORE INFORMATION: Raymond Windmiller, Executive Officer, (202) 921–2705.

Date: January 14, 2026.

Raymond D. Windmiller,

Executive Officer, Executive Secretariat.

Appendix R. Response to Public Comment

R.1 Introduction

A Notice of Availability of the Post-2026 Operational Guidelines and Strategies for Lake Powell and Lake Mead Draft Environmental Impact Statement (EIS) was published in the Federal Register on January 16, 2026, which kicked off a 45-day public review and comment period that ended March 2, 2026. The Draft EIS was available on the Bureau of Reclamation (Reclamation) project website along with an interactive tool designed to allow for easy comparison of impact analysis figures within the Draft EIS. This appendix provides an overview of the public review and comment process, how Reclamation addressed the comments, and details the grouping of similar comments into common themes with responses from Reclamation.

R.2 Summary of the Public Comment Period and Public Comment Analysis Process

Reclamation received 18,153 submissions during the Draft EIS comment period. Of the submissions, 7 were from state government entities, 23 from tribes, 4 from federal agencies, 28 from non-government organizations, 76 from local entities, 3 from academic or research institutions, 5 from elected officials, 21 from resource sector or business interests, and the remainder were from individuals. Twenty-three form letters were identified; 11,992 submittals had identical text to one of the 23 form letters and 5,298 had unique text in addition to the form letter text. Fifty-two submittals were noted as duplicate and only reviewed once. Unique submissions are available on the https://www.usbr.gov/uc/DocLibrary/Memos/20240326-EstablishmentInterimOperatingGuidanceGlenCanyonDamLowReservoirLevels-TechnicalDecisionMemo-508-TSC.pdf, and all public comments are retained in the project record.

All submissions were recorded and reviewed to identify substantive comments. A comment was considered substantive if it met one or more of the following criteria (United States [U.S.] Department of the Interior Handbook of National Environmental Policy Act Implementing Procedures [DOI NEPA Handbook 2026]):

- Questioned, with a reasoned basis related to the analysis, the accuracy of information in the EIS.
- Questioned, with a reasoned basis related to the analysis, the adequacy of, methodology for, or assumptions used for the analysis.
- Presented new information relevant to the analysis.
- Presented reasonable alternatives or issues outside those analyzed in the EIS.
- Presented relevant additional issues for analysis in the EIS.
- Prompted potential changes or revisions to one or more of the alternatives.

When multiple submissions had identical text, a form letter was established and reviewed once. The remaining copies of that submission were counted but not reviewed separately. If a submission had identical text but included additional unique text, the additional text was reviewed for substantive comments.

The comments received encompassed a wide array of policy and environmental issues, with many submissions addressing substantially similar subject matter or offering overlapping input. Given the high volume of substantive comments, and in accordance with Department guidance (DOI NEPA Handbook 2026, Appendix 1 Section 1), substantive comments were compiled in a database and organized into themes to allow similar comments to be reviewed and addressed collectively. This appendix presents those themes and Reclamation's responses. Using a theme-based approach provides a clear representation of the breadth and character of public input on each topic and offers greater context than a one-to-one comment-response format by reducing repetition and presenting comprehensive, synthesized responses. A table of contents (**Contents**, R-i) is provided to guide readers to specific subject areas reflecting the common themes and recurring issues identified in the comments received.

The themes summary and responses below were developed following the public comment period on the Draft EIS and during the development of the Final EIS. Many of the theme summaries and their associated comments led to changes in the Final EIS. Reclamation addressed comments consistent with the requirements of the DOI NEPA Handbook 2026. These requirements included but were not limited to analyzing a reasonable range of alternatives; using the best available scientific data; and not covering speculative analysis or analysis of impacts outside of the agency's control. In addition, this EIS does not attempt to interpret specific questions related to the Law of the River.

R.3 Public Comment Themes and Responses

R.3.1 Secretarial Authorities

Theme Summary

Commenters raised concerns that the Draft EIS does not adequately or accurately describe the Secretary's authorities and does not clearly identify which operational elements would require new or additional authority (e.g., statutory changes, new or modified Records of Decision (RODs), or interstate agreements). Commenters raised differing and conflicting interpretations of Secretarial authority and the Law of the River. For example, commenters in the Upper Colorado River Basin (Upper Basin) emphasize limits on Reclamation's role in administering Upper Basin apportionments, while Lower Colorado River Basin (Lower Basin) commenters urge broad authority to protect infrastructure and ensure Compact compliance, including through operation of Colorado River Storage Project (CRSP) facilities. Other areas of conflicting comments include how to distribute shortages in the Lower Basin, emergency authorities, and certain reservoir operations. These comments frequently fail to acknowledge that there are many conflicting legal views on Colorado River topics that have remained unresolved for the past century, and the comments then assert that the Secretary's decision not to endorse the commenter's particular view of a contested Colorado River legal theory is a flaw in the National Environmental Policy Act (NEPA) analysis.

Response

The Secretary of the Interior possesses broad authorities for the management and operation of the Colorado River System under applicable federal law and the Law of the River. While differing interpretations exist regarding the scope and application of certain authorities, this EIS is not intended to resolve or opine on such legal interpretations. Reclamation recognizes that implementation of certain operational elements analyzed in this EIS may or may not require additional authorities, and the Department of the Interior (Department) intends to implement any adopted guidelines in a manner consistent with applicable law and the Law of the River.

Particularly in the current context where Colorado River stakeholders have been unable to resolve disagreements over key aspects of applicable legal authorities, limiting the inclusion of operational elements in this EIS that are solely within an as yet nonexistent universal agreement regarding legal authority would unnecessarily constrain the reasonable range of alternatives and could limit the Department's ability to evaluate potential tools that could be developed or could be needed to address future operational and water supply challenges in the Colorado River Basin (Basin).

The EIS discusses additional authorities that may or may not be needed to implement the Preferred Alternative, and the Department may also wish to consider specific identification of authorities needed to implement future operations that could be the result of a consensus proposal.

R.3.2 1922 Colorado River Compact Compliance

Theme Summary

Commenters expressed differing views regarding 1922 Compact compliance and how 1922 Compact-related obligations between the Upper Basin and Lower Basin should be reflected in the range of alternatives and impact analysis. Lower Basin commenters stated that the Draft EIS does not analyze operations that are aligned with the Lower Basin interpretation of Compact compliance, including CRSP Upper Initial Unit operations, and that the Lower Basin would be disproportionately affected. Some commenters also expressed that the Draft EIS does not clearly articulate whether, or how, assumptions regarding 1922 Compact interpretations account for United Mexican States (Mexico)-related delivery obligations, Lower Basin tributaries, surplus determinations, or the extent to which Lake Powell releases should reflect those considerations. These comments generally seek greater integration of 1922 Compact compliance considerations into the alternatives and explanation of how differing interpretations are reflected in the analysis.

Response

Section 602 of the Colorado River Basin Project Act of 1968 (CRBPA) required the Secretary to propose and adopt criteria for the coordinated long-range operation of the reservoirs constructed and operated under the authority of the CRSP Act of 1956, the Boulder Canyon Project Act of 1928 (BCPA), and the Boulder Canyon Project Adjustment Act. The Secretary adopted such Long-Range Operating Criteria (LROC) in 1970 and has been operating the Colorado River consistent with the LROC since that time. The LROC and Guidelines (2001, 2007) were adopted in a manner designed to comply with the 1922 Compact.

As with the 2001 Interim Surplus Guidelines and the 2007 Interim Guidelines, it is the Department's intention that post-2026 guidelines be used to implement the LROC, and the Department is not modifying the LROC at this time. Further, with post-2026 guidelines, the Department is not interpreting the legal meaning of the 1922 Colorado River Compact or resolving differing interpretations by Basin States, Basin Tribes, and other stakeholders.

Reclamation will follow all relevant provisions of federal law to implement the proposed federal action, including relevant provisions of the Law of the River. Reclamation recognizes that, under Article II(2) of the LROC, the "objective shall be to maintain a minimum release of water from Lake Powell of 8.23 [million acre-feet (maf)]." Reclamation also recognizes that variation in releases of water above and below the minimum objective release of 8.23 maf can, in appropriate circumstances, be adopted. To inform Basin partners and stakeholders of the relevant considerations for the proposed federal action, Reclamation identified and published any annual deficits below the objective release of 8.23 maf, as well as relevant 10-year metrics of particular interest at Lee Ferry, such as the 10-year consecutive aggregate flow, along with any deficit in the 10-year consecutive aggregate flow (such as, any deficit from 82.5 maf and 75 maf), see **Section 1.8.2.2**, for further discussion.

While the LROC are "administered consistent with applicable federal laws," Reclamation intends and has expressly noted in the Final EIS that releases from Lake Powell pursuant to the LROC or any adopted guidelines "shall not prejudice the position of either the Upper or Lower Basin interests with respect to the required deliveries at Lee Ferry pursuant to the Colorado River Compact." (Article II(5) of the LROC), see **Section 1.8.7**, for further discussion.

R.3.3 Upper Initial Unit Operations

Theme Summary

Upper Basin stakeholders generally noted that the CRSP Upper Initial Unit use should not be included in alternatives as it is not in geographic scope and that inclusion of CRSP Upper Initial Units exceeds Secretarial authorities. Conversely, Lower Basin stakeholders generally noted that the alternatives should include more CRSP Upper Initial Unit use, including operations outside existing RODs for Compact compliance. Additionally, commenters noted that analysis of impacts from CRSP Upper Initial Unit operations is not adequate.

Response

Given that the description of the proposed federal action has, from the outset, contemplated the use of CRSP Upper Initial Units, it is appropriate to include the effects of these CRSP Upper Initial Unit releases on Lake Powell in the analysis. The range of CRSP Upper Initial Unit operations is within existing federal authorities and within the scope of their respective existing RODs, and these operations have therefore already undergone NEPA analysis. This EIS focuses on alternatives for changing operations within the geographic scope identified in **Section 1.5.1** of the Final EIS, which begins at full pool of Lake Powell and extends downstream along the mainstream Colorado River floodplain to the Southerly International Boundary with Mexico. There is no NEPA requirement that would require a broader geographic scope for this effort. Any operation of CRSP Upper Initial Units outside of RODs would occur only under emergency circumstances. While the Secretary will

consider and prioritize operations at these facilities that are consistent with existing RODs, the Secretary retains the authority to operate outside those RODs if necessary. The modeling assumptions regarding operation of the CRSP Upper Initial Units presented in this Final EIS are not intended to, and do not, limit the Secretary's ability to operate these facilities as necessary to respond to hydrologic conditions in accordance with applicable federal law, including operations for the authorized purposes stated in the CRSPA. Such operations are not addressed in this NEPA analysis. If emergency conditions arise, any operational decisions will be made at that time based on the then-current conditions with appropriate levels of analysis. Proactively changing operations of CRSP Upper Initial Units beyond their existing RODs, along with other connected actions, is not part of the proposed action and can be analyzed through separate NEPA processes if warranted. The alternatives represent a reasonable range of releases from CRSP Upper Initial Units, and the level of analysis provided is appropriate for this EIS. For discussion of issues related to Compact compliance, see **Section R.3.2**, 1922 Colorado River Compact Compliance.

R.3.4 Upper Basin Demands, Shortage, and Conservation

Theme Summary

Commenters raised concerns about assumptions related to Upper Basin demands, the treatment of hydrologic shortage in the Upper Basin, and the nature and feasibility of Upper Basin conservation measures.

Response

With respect to the Upper Basin depletion demands, it is important to distinguish between the depletion demands input to the model and the Upper Basin depletion calculated by the model. The Upper Basin baseline depletion demands used as input to the Colorado River Simulation System (CRSS) model were developed from the Upper Colorado River Commission's (UCRC) updated 2016 Depletion Demand Schedule (revised in 2022). In coordination with the Upper Division States, the UCRC developed decadal projections of depletions by sector at the state level to support long-term planning efforts. These projections represent anticipated demand under ideal hydrologic and economic conditions and are not supply-limited. The Arizona portion of the Upper Basin demand schedule was developed by Reclamation based primarily on the 2018 Tribal Water Study demand schedules and is primarily comprised of Navajo Nation uses. Collectively, these baseline demands represent the current best available data for input to CRSS.

In conjunction with incorporating this updated depletion demand schedule, CRSS was updated and calibrated to better characterize the variability and range of modeled Upper Basin depletions and to reduce streamflow bias during a historical verification period. **Figures I-1** to **I-6** in the Final EIS demonstrate that, although the depletion demands input to the model exceed historical depletion (i.e. consumptive uses and losses [CU&L]) and increase over time, Upper Basin modeled depletion is constrained by water availability (i.e., varying hydrologic conditions) and is therefore comparable to observed historical use. In the model, calibration was achieved by adjusting the water available for diversion by agricultural users. As a result, modeled depletions are better represented volumetrically (on a reach-by-reach basis in CRSS) but may not reflect actual sector- and water user-level depletions—which depend on demand, geographic location (e.g., tributary versus mainstem), priority, and water availability, and are not represented at the CRSS model scale.

With respect to hydrologic shortage, the difference between the Upper Basin depletion demand schedule input to CRSS and the Upper Basin depletion calculated by the model represents modeled hydrologic shortage given water availability. **Figure I-7** shows the Upper Basin modeled hydrologic shortage calculated using CRSS from 2027 to 2060. As noted above, while basin-wide Upper Basin modeled hydrologic shortage is better represented volumetrically due to model calibration, the volume does not account for important nuances that affect Upper Basin hydrologic shortage, such as water user-specific demand, geographic location (e.g., tributary versus mainstem), priority, and water availability. However, it is reasonable for the EIS analysis to represent the reality that, in many years, depletions by some Upper Basin users are constrained by available supply in their respective locations. For a historical representation of Upper Basin hydrologic shortage, refer to Reclamation's *Upper Colorado River System Consumptive Uses and Losses Report*, available online.

Refer to **Appendix L**, Upper Basin States Depletion Schedules, for additional information on the Upper Basin depletion schedules, **Appendix A,** CRSS Model Documentation, for CRSS calibration, and **Appendix I,** Sensitivity Analysis – Effects of Alternate Upper Basin Demand Scenarios on Operations at Lake Powell and Lake Mead, for additional information on the operational impacts of varying Upper Basin demands on Lake Powell and Lake Mead. Reclamation will continue to work with the UCRC and the Upper Division States and other stakeholders to update the depletion demand schedules as appropriate.

With respect to the nature and feasibility of Upper Basin conservation measures, the viability of the proposed conservation programs is unknown. For purposes of environmental impact analysis, and to analyze the full impacts of the alternatives, it was assumed that the voluntary conservation targets would be achieved. Because the specific entities that might participate in a voluntary conservation program are not known, additional analysis of impacts on specific entities is not possible.

Modeled Upper Basin conservation spans a broad range of volumes and operational approaches, some of which vary based on hydrologic conditions. **TA 3**, Hydrologic Resources, includes a sensitivity analysis comparing the impacts of including (conservation on) and excluding (conservation off) conservation activities within the alternatives, illustrating the range of impacts associated with varying levels of Upper Basin conservation.

R.3.5 LROC Implementation

Theme Summary

Commenters raised concerns regarding implementation of the 1970 LROC, particularly the role and interpretation of the "objective" to "maintain a minimum release of 8.23 maf" annually from Lake Powell and the calculation of the 602(a) storage. Some commenters asserted that the No Action Alternative improperly treats 8.23 maf as a fixed annual release requirement, while others contended that the Basic Coordination Alternative improperly allows releases below 8.23 maf. Additional comments asserted that 602(a) storage is calculated incorrectly or inconsistently with the LROC and related operating criteria.

Response

The Secretary of the Interior adopted LROC in 1970 in compliance with Section 602 of the CRBPA (Public Law 90-537). The narrative provisions of LROC are used to inform determinations with respect to storage reservoirs in the Basin under the No Action Alternative. While LROC provides that 8.23 maf is an objective for a minimum annual release, a reasonable representation of future hydrologic conditions, including releases below 8.23 maf, is necessary for comparison under the Basin Coordination Alternative.

Among other provisions, the LROC provide that "the objective shall be to maintain a minimum release of water from Lake Powell of 8.23 maf for that year." Reclamation recognizes that entities in the Basin have different legal positions regarding how this provision incorporates other Law of the River elements to determine annual releases. The Secretary has expressly recognized that variation in releases of water above and below the minimum objective release of 8.23 maf can, in appropriate circumstances, be adopted (Norton 2005). The LROC expressly note that releases from Lake Powell pursuant to the LROC or any adopted guidelines "shall not prejudice the position of either the Upper or Lower Basin interests with respect to the required deliveries at Lee Ferry pursuant to the Colorado River Compact."

Comments received on the Draft EIS illustrate a longstanding dispute between the Upper Basin and the Lower Basin about whether annual releases can be lower than 8.23 maf. This dispute was not resolved during the period from 1970-2007 when the LROC was the sole basis for coordinated reservoir operations, and conditions never presented themselves during this period that caused the Secretary to make a decision about releases lower than the LROC's 8.23 maf objective. Instead, poor hydrology in the early 2000s prompted development of the 2007 Guidelines that adopted objective criteria for annual release volumes that implemented LROC's narrative criteria concerning release objectives. This NEPA process builds on the approach of the 2007 Interim Guidelines to adopt new, objective criteria to implement LROC. The EIS accordingly applies LROC provisions consistently for purposes of evaluating environmental impact and does not resolve differing legal interpretations raised by commenters. No additional analysis is recommended.

Despite the operational challenges due to prolonged drought, the release from Lake Powell over the term of the 2007 Interim Guidelines has met or exceeded the minimum objective release of 8.23 maf in 13 out of 19 years, and has averaged 8.5 maf over the 2008-2026 period. Going forward, the Department recognizes the continued importance of operating to achieve a minimum objective release of 8.23 maf, but meeting this objective release has been and will be increasingly difficult in a constrained system of low reservoir elevations, declining river flows, and the need to protect the operational reliability of Glen Canyon Dam.

R.3.6 Glen Canyon Dam and Hoover Dam Infrastructure

Theme Summary

Commenters asserted that the Draft EIS does not adequately address infrastructure risks at Glen Canyon Dam and Hoover Dam. Specifically, commenters requested that the EIS consider potential infrastructure fixes, repairs, or physical modifications as part of the alternatives, and provide

additional information regarding ongoing or planned processes to address known and emerging infrastructure constraints.

Theme Response

The Department discussed the operational risks at Glen Canyon Dam in **Section 1.8.4.1** of the Final EIS, which is based upon the current operational guidance for the dam (Reclamation 2024), and expressly states that low reservoir conditions have brought to light risks that could compromise the reliability and operational flexibility of Glen Canyon Dam and affect the ability to meet critical downstream water supply needs.

Specific infrastructure modifications are not currently contemplated as components of individual alternatives within the EIS, since pursuing them would not be dependent on adopting specific operational guidelines. Infrastructure modifications are outside the scope of the EIS because they would constitute an action separate from operation of Glen Canyon and Hoover Dams. Reclamation is analyzing feasible paths for reducing risks and impacts related to infrastructure. Should Reclamation move forward with infrastructure modifications, it would need to complete additional studies, seek funding, and undertake separate NEPA compliance. Future operations would account for infrastructure modifications.

With respect to Glen Canyon Dam infrastructure specifically, which impacts releases to the Lower Basin, some alternatives include releases when Lake Powell elevation is below the critical threshold of 3,490 feet. Therefore, the possibility of releases at these low elevations is captured in the EIS. Operational actions within the scope of the EIS, such as additional releases from CRSP Upper Initial Units to release additional water if needed to protect critical infrastructure at Glen Canyon Dam, are also described. Furthermore, infrastructure modifications to access water stored below 3,490 feet would have a relatively insignificant impact on releases long-term because the volume of water stored below this elevation is relatively small—less than 3.743 maf—and would effectively only be able to be released downstream once.

R.3.7 Lower Basin Shortage and Use

Theme Summary

Comments on Lower Basin shortage and use covered topics associated with the interaction between conservation and shortage, the total volumes of shortage specified in the alternatives, the distributions of shortage within the Lower Basin, including dead pool-related reductions, preferences on allowable uses in the Lower Basin, and the quantification and modeling of Lower Basin demands. Each topic is summarized and responded to in the following sub-sections.

Theme Response

The EIS analyzed a broad range of release, delivery, shortage, and distribution options for Colorado River operations. Modeling assumptions regarding the distribution of Lower Basin shortages and Lower Basin conservation activities were developed to enable the analysis of the environmental effects across alternatives and to provide for a comparison of impacts given different methodologies of distributing shortages. These modeling assumptions are not intended to interpret specific

provisions of the Law of the River or the state law appropriation process of any of the Basin States. Responses to each topic are included below.

R.3.7.1. Interaction between Conservation and Shortage

Summary

Comments suggested that there should be a focus on conservation before shortages are implemented, and that conservation should not be allowed to reduce or satisfy required shortages.

Response

Voluntary conservation through Intentionally Created Surplus (ICS) and system conservation agreements has been a critical tool in the Lower Basin, helping reduce system risk and avoid involuntary reductions. Since 2012, approximately 10.4 maf of additional voluntary conservation has been created by the Lower Basin and Mexico, equivalent to approximately 150 feet in Lake Mead elevation. While future system conservation agreements funded by the federal government are subject to the availability of future federal funding, it is reasonable to expect that ICS-like tools will continue to be used in the Lower Basin to manage and may reduce the likelihood of large-scale mandatory reductions. Therefore, all action alternatives in the Draft EIS, except for the Basic Coordination Alternative (which assumes no future agreements are reached), included future conservation pools in Lake Mead. The different action alternatives also included a range of assumptions related to the ability to use conserved water to meet or offset required reductions. Additional details on Lower Basin Conservation are included in **Section R.3.8**, Lower Basin Conservation and Storage and Delivery of Conserved System and Non-System Water.

R.3.7.2. Total Shortage Volume

Summary

Comments spanned a wide range, from total shortages being insufficient to protect critical elevations at Lake Powell and Lake Mead (largely focused on the No Action and Basic Coordination alternatives), to the proposed shortage volumes being unacceptably high when considering potential socioeconomic impacts.

Response

The Draft EIS analyzed a range of shortage volumes up to 4 maf/year and reported "dead pool related reductions" – the reductions that occurred in modeling due to the physical limitations of infrastructure when Lake Mead is near or at dead pool. The maximum specified shortage volume was sufficiently protective under most conditions. For example, the Maximum Operational Flexibility Alternative, which included shortages up to 4 maf/year, avoided dead pool-related reductions in nearly 100 percent of years in dry conditions and 79 percent of years in critically dry conditions. Given the extremely dry streamflow conditions analyzed, which extend well beyond droughts in the observed historical record, it was not expected that shortages would be protective under all hydrologic conditions. See **Appendix F**, Approach to Hydrologic Uncertainty, for more details. Comparing the maximum specified shortage in each alternative and the associated dead pool-related reductions provides information on the tradeoffs between higher/lower shortages and higher/lower dead pool-related reductions. The maximum specified shortage volume analyzed was

4.0 maf while the maximum dead pool-related reduction analyzed was 6.54 maf. Reclamation acknowledges that there would be socioeconomic and other impacts from shortages, which were analyzed and disclosed in the Draft EIS, and which are unavoidable under any combination of alternatives.

R.3.7.3. Distribution of Shortage within the Lower Basin

Summary

An almost universal comment received was that entities other than the commenting entity should bear shortage reductions, or that the commenting entity should not be shorted at all or as much. There were additional variants on this topic, about which commenters held opposing views, including that a distribution of shortage other than by priority is illegal, that the existing priority distribution systems are not equitable, and that the priority system no longer serves the residents of the Lower Basin. Related comments on dead pool-related reductions were conflicting; some commenters recommended distributing reductions pro rata, while others recommended distributing them by priority, and still others identified specific users that should not be affected by dead pool-related reductions. Comments also identified that neither the population and land use nor the socio-economic impacts of dead pool-related reductions were analyzed.

Response

The Draft EIS analyzed shortages according to several different methodologies to provide a range of impacts across resources for the different shortage distributions. In accordance with the Consolidated Decree, the CRBPA, and other key provisions of the Law of the River, the Secretary has the authority to declare and allocate shortages to the Lower Division States. Some explicit guidance is given by the Supreme Court and Congress with regard to how shortages would be allocated according to priority, and additional detail is based on intra-state priority systems including as established by law and contract, and federal water delivery contracts executed pursuant to Section 5 of the BCPA. The methodologies incorporated this guidance and variations in distribution among users to encompass potential shortage sharing agreements. Modeling assumptions with respect to the distribution of shortages to the Lower Division States and Mexico were necessary in order to analyze potential impacts on hydrologic and other environmental resources.

The Draft EIS specifically includes a methodology that is inconsistent with the Decree and CRBPA (i.e. distribution of reductions pro rata to all entities that receive water from the mainstream in the Lower Basin pursuant to the Decree). Reclamation acknowledges that it would need additional agreements or other legal authority to implement any operations that are inconsistent with the Decree and CRBPA. But Reclamation has also determined that, based on public input received during the scoping and alternative development phases of the NEPA process, analysis of these operations will present a broader range of operations and impacts for agency and stakeholder consideration, review, and input, and will foster meaningful and informed decision-making among Reclamation and Basin stakeholders.

Reclamation's modeling assumptions for the distribution of dead pool-related reductions were documented in **Appendix A,** CRSS Model Documentation, and are meant for modeling purposes

only as no alternative included any specific criteria or methodology for the distribution of dead pool-related reductions. This distinction has been clarified in **Appendix A**.

While the population, land use, and socio-economic impacts of dead pool-related reductions were not specifically analyzed in the Draft EIS because they fall outside federal control, the range of modeled shortages under the alternatives is sufficient to provide for a general understanding of possible impacts, including a full reduction of domestic and irrigation water in some areas. The foreseeable consequences of full reductions in water supply are described in **TA 16,** Socioeconomics and **TA 17,** Population and Land Use; and Shortage Allocation Model and Alternative Distribution Model results are shown in **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, for shortages of 5 maf per year.

R.3.7.4. Preferences on Allowable Uses in the Lower Basin

Summary

Commenters expressed a variety of preferences for how water should be used. Golf courses, surf parks, and decorative lagoons were suggested to be eliminated from Lower Basin uses before shortage is considered as a policy tool. Other commenters urged protection of legal rights to use water, including for purposes that support community amenities.

Response

In general, the 1922 Colorado River Compact contemplated domestic and agricultural uses of Colorado River water, as defined in Article II(h). Relevant state or local laws may regulate or limit water use, or types of economic developments, within their jurisdictions. Any analysis of potential limitations on beneficial water use, including review under 43 Code of Federal Regulations (CFR) Part 417, are outside the scope of this EIS.

R.3.7.5. Quantification and Modeling of Lower Basin Water Demands

Summary

Some commenters expressed concern that modeled Lower Basin water demands, in the Shortage Allocation Models and CRSS modeling, were, for some users, unrealistically high and reached full use of entitlements sooner than should be expected. Other commenters expressed concern that their individual modeled consumptive use under-represented their planned increase of water use, and that the modeling resulted in limited availability of water to junior users and had the result of skewing risk to those users. Additionally, comments expressed that evaporation, system losses, and Lower Basin tributary use should be included in Lower Basin use to fully represent the balance of supply and demand.

Response

Modeling assumptions with respect to the projections of future water demand in the Lower Basin were necessary in order to analyze potential impacts on hydrologic and other environmental resources and are not intended to interpret specific provisions of the Law of the River or the state laws of any of the Basin States.

The Shortage Allocation Modeling was based on assumed full use (demand) of all entitlements. The Lower Basin demands used in CRSS were assumed to start near recent levels, including recent consumptive use efficiency, and then grow to full entitlement by 2040 for all users except the junior-most entitlement holder in each state. This approach resulted in an analysis that disclosed the maximum impacts to the junior users for priority based shortages; disclosed the maximum impacts to higher priority users for pro rata based shortages; analyzed a period where not all users were at full entitlement; analyzed a period where all higher priority users were at full entitlement; and provided a range of impacts on the other flow-based resources at and downstream of Hoover Dam due to the growing demands used in CRSS. This approach broadly encompasses any effects from actual uses and shortage sharing. Moreover, this approach is appropriate for the analysis as it provides maximum impacts to shortage levels and water users due to dry hydrology.

Lower Basin evaporation, system losses, and Lower Basin tributary use are all included to varying degrees in CRSS, meaning that all analyses show how the specified Lake Powell operations and Lower Basin shortage volumes affect the system conditions after Lower Basin evaporation, system losses, and historical levels of Lower Basin tributary use occur. CRSS explicitly models evaporation at Lake Mead, Lake Mohave, and Lake Havasu; **Appendix A,** CRSS Model Documentation has been updated to document this. System losses in the Lower Basin include flows to Mexico in excess of the 1944 Water Treaty, water bypassed pursuant to International Boundary Water Commission (IBWC) Minute 242, transmission losses, phreatophyte use, and other evaporative losses. Both flows to Mexico in excess of the 1944 Water Treaty and water bypassed pursuant to IBWC Minute 242 are explicitly modeled in CRSS using historical average values; **Appendix A** has been updated to document these values. Transmission losses, phreatophyte use, and other evaporative losses are included in the development of Lower Basin inflows used in CRSS. Any losses that occur downstream of Hoover Dam are implicitly included by lowering the computed intervening flow in these reaches. Then, CRSS uses these inflows, which reflect a historical range of these losses.

CRSS currently relies on historical gage inflow for the Lower Basin tributaries, including the Little Colorado, Virgin, and Bill Williams Rivers. The gage flow for these tributaries reflects all upstream uses, thus CRSS incorporates the historical range of use that has occurred in these tributaries. In the 2012 Colorado River Basin Water Supply and Demand Study, Reclamation committed to developing natural flows for the Little Colorado, Virgin, and Bill Williams Rivers. In January 2026, Reclamation published the updated and consistent 1971-2024 CU&L data for these tributaries. Reclamation is currently working to incorporate these data into the Natural Flow and Salt model to develop Lower Basin natural flow for these years; however, before these natural flows can be used in CRSS, future demand projections in these same tributaries need to be developed with Arizona, Nevada, Utah, and New Mexico, and Reclamation will need to consider extending the CU&L estimates back through 1906. While CRSS considers tributary use for modeling purposes, Lower Basin tributary uses are outside the scope of this EIS and separate from mainstream operations.

R.3.8 Lower Basin Conservation and Storage and Delivery of Conserved System and Non-System Water

Theme Summary

Comments on Lower Basin conservation and storage and delivery of conserved system and non-system water addressed two key areas. First, the comments discussed the storage and delivery of conserved water by users, currently referred to as ICS, and the extension or replacement of ICS. Second, they included comments on system conservation, the creation of which has historically been federally funded, to benefit Lake Mead elevations, and not recoverable by users. Comments were generally supportive of both system conservation and ICS, with specific concerns that varied by commentor, and with some comments noting the performance benefits and importance of incorporating flexible, adaptive tools for conserving, storing, and managing water. The comments received on system conservation expressed support for continued funding of system conservation, with some expressing the importance of it being verifiable.

Comments on ICS generally supported at least maintaining the existing ICS rules, with several comments expressing the need to expand participation in ICS, modify the rules for when and how ICS is used, and improve the consistency of what conservation is eligible for ICS. Multiple comments expressed the need for ICS to be operationally neutral with respect to reservoir operations. There were conflicting comments regarding whether ICS should be allowed to offset/meet required Lower Basin shortages. Some commenters noted that ICS storage must remain fully isolated downstream of Lee Ferry while others highlighted the benefits of being able to move stored water between Lake Powell and Lake Mead to manage water supply risks, benefit resources, and protect critical infrastructure. Some commenters are concerned that ICS deliveries effectively provide junior priority entitlement holders with a senior priority. Some comments stated that Reclamation failed to identify the agreements or authorities that are needed for protection pools in the Enhanced Coordination and Maximum Operational Flexibility Alternatives. Finally, some comments expressed that any future ICS program should include transparent accounting and verifiable tracking.

Theme Response

Voluntary conservation through ICS and system conservation agreements has been a critical tool in the Lower Basin, helping reduce system risk and avoid involuntary reductions. Since 2012, approximately 10.4 maf of additional voluntary conservation has been created by the Lower Basin and Mexico, equivalent to approximately 150 feet in Lake Mead elevation. While future system conservation agreements funded by the federal government are subject to the future availability of federal funding, it is reasonable to expect that ICS-like tools will continue to be used in the Lower Basin to manage and may reduce the likelihood of large-scale mandatory reductions. All conservation is verifiable, and Reclamation has documented users' and states' total water use and conservation in the Lower Colorado Mainstream Accounting and Water Use Report each year.

All alternatives modeled in the Draft EIS respected the delivery rules associated with ICS that exists in Lake Mead at the end of 2026, while all action alternatives (except for the Basic Coordination alternative) included a new storage and delivery mechanism with varying rules and additional flexibilities. Across these alternatives, the rules for the new mechanism evaluated both operationally

neutral and non-operationally neutral storage mechanisms, varied the maximum accumulation and annual storage and delivery constraints, and varied the conditions when delivery of ICS was not allowed (e.g., when Lake Mead is below a specified elevation). Additionally, the Maximum Operational Flexibility Alternative evaluated the ability to store water in Lake Mead or Lake Powell, while the other action alternatives limited the storage to Lake Mead. The Draft EIS evaluated a range of options so that the eventual preferred alternative would fall within the range of already evaluated options and conditions. The specific rules for any new storage and delivery mechanism would be based on consensus agreements.

Modeled water deliveries, which may include delivery of existing ICS or new stored water in a particular scenario, followed the storage and delivery rules outlined in each alternative in conjunction with how a water user's entitlement was modeled in the alternative. Modeled delivery of existing ICS or delivery of new stored water are independent of a water user's priority and only follow the rules explored in the alternative. **Section R.3.1**, Secretarial Authorities discusses the approach taken in the Draft EIS with respect to specific authorities for different options, including the protection pools in the Enhanced Coordination and Maximum Operational Flexibility Alternatives. ICS creation and delivery are documented in the Lower Colorado Mainstream Accounting and Water Use Report each year and would continue to be with any ICS-like program in the future.

R.3.9 Tribal Considerations

Theme Summary

Across the comment letters submitted by Basin Tribes, several overarching considerations emerged, including the protection of tribal rights and trust assets, interpretation of legal authorities, concerns with the adequacy of the technical impact analysis, and the lack of meaningful tribal consultation and involvement in the Post 2026 process. Comments from tribes that relate to particular issues are captured in specific themes and are addressed in the corresponding sections where those themes are discussed.

Tribes expressed that the Draft EIS does not adequately acknowledge, analyze, or protect tribal water rights, Indian trust assets, or the legal authorities that govern Colorado River operations. Concerns include the lack of clear recognition of existing tribal rights; the potential for unlawful or inequitable shortages to tribes; improper treatment of system losses; and inadequate analysis of cultural, environmental, and socioeconomic impacts. Tribes also emphasized the need for a dedicated Federally Managed Water Resources Pool or similar mechanism in Post 2026 operations to ensure tribal rights are protected and not diminished during shortages. Tribes stated that the Draft EIS exceeds Reclamation's operational authority and fails to analyze required Upper Basin delivery obligations. Tribes raised concerns that the Draft EIS lacks required NEPA analysis, including impacts of shortages, dead pool conditions, Central Arizona Project (CAP) water quality, system infrastructure constraints, socioeconomic impacts, and mitigation measures. Tribes also noted that viable alternatives were not considered or analyzed, such as the alternative that the Gila River Indian Community submitted. Comments also highlight that some modeling assumptions are inappropriate or incomplete, including assumptions about Upper Basin actions, hydrology, and Lower Basin priority structures. In addition, some tribes have expressed a general concern that their water rights are not always fully usable on their own lands, which can negatively affect their

communities and governance. For example, Colorado River Indian Tribes (CRIT) has commented that, as a result, despite being authorized under *Arizona v. California* and the Law of the River, CRIT experiences harm to its members, its culture, and its sovereignty when water allocated to CRIT is unable to be consumptively used on reservation lands and is diverted from the Colorado River for consumptive use elsewhere in the basin without CRIT's approval.

Tribes requested government-to-government consultation, both during the development of the Draft EIS and in future decision processes. They emphasized the need for consultation that encompasses cultural practices, traditional cultural places, sacred sites, treaty and Winters rights, and Indian trust assets, as well as for transparency about how tribal input influences alternative development. Tribes also stated that Reclamation failed to consult under the National Historic Preservation Act (NHPA) and that overall engagement to date has been insufficient. More broadly, tribes seek meaningful, formalized consultation processes aligned with existing mechanisms and a role in the Post 2026 process comparable to the Basin States.

Theme Response

Reclamation identified tribal water entitlements in the Basin (by tribe, and also grouped by priority, location, or other characteristics if applicable), Indian trust assets, and the legal authorities that govern Colorado River operations. Nothing in the EIS is intended to modify tribal water entitlements or preclude future tribal water rights settlements or adjudications. Reclamation acknowledged that the agency cannot unilaterally implement certain operational elements included and analyzed in the Draft EIS, as many of these actions would require implementation agreements among various Basin entities (see **Section 2.3**). Should Basin States and tribes develop agreements that avoid or mitigate any needed reductions or otherwise share shortages, the broad range of alternatives analyzed in the Draft EIS provides environmental compliance for alternative approaches to distributing water deliveries and any shortages, including approaches that differ from a priority-based shortage distribution in the Lower Basin. Many viable elements submitted through alternative proposals were incorporated into the broad range of alternatives evaluated in the Draft EIS. Reclamation also believes the Draft EIS adequately analyzes, to the extent required, the potential impacts of operations and shortage distribution on tribes and is consistent with the Department's trust responsibilities.

Throughout the Post-2026 NEPA process, Reclamation has consulted both formally and informally with Basin Tribes. This includes several invitations at critical milestones for government-to-government consultation, as well as regular communication and updates provided through the monthly Reclamation-hosted Tribal Information Exchanges and other tribal forums to which Reclamation leadership and staff are invited, such as Ten Tribes Partnership meetings and Inter Tribal Council of Arizona meetings. In addition, during the alternatives development phase, a tribal workgroup was convened and met regularly with tribal staff and representatives to identify and discuss tribal priorities and ensure these were reflected within the Draft EIS range of alternatives. The ROD will include language describing future tribal consultation requirements for implementation decisions related to post-2026 operations. Regarding NHPA consultation, this issue is outside the scope of the EIS process and is addressed through the NHPA process.

R.3.10 Hydrologic Modeling Assumptions

Theme Summary

Commenters argued that the technical analysis was inappropriate due to several modeling assumptions. Some described the initial reservoir conditions as optimistic and outdated. Others characterized the future hydrology assumptions as unrealistic, lacking predictability, and inconsistent with the best available science, including climate change. Commenters also described Upper Basin demand projections as showing unrealistic growth. With respect to Lower Basin demands and system losses, commenters stated that these were not fully represented, citing specific concerns including the exclusion of tributary uses and assumptions related to 2040 build-out. Additional comments noted that "gap water" is not clearly identified or consistently described throughout the Draft EIS, and that evaporation assessments on reservoir pools should be more clearly described.

Response

With respect to initial conditions, the choice in November 2024 to use a wide range of 2027 initial reservoir elevations for the Draft EIS analysis was appropriate given that modeling had to begin approximately 2 years before the start of the new guidelines, and there was significant uncertainty about hydrology in 2025 and 2026. The initial conditions were taken from the best available mid-term projections at that time. Because the Low initial conditions used in the Draft EIS are reasonably representative of where the system will be starting in 2027, the Final EIS shows impacts based only on the Low initial conditions. See **Appendix G,** CRSS Initial Conditions, for a comparison of current projections and the Low initial conditions.

With respect to hydrology, the choice to use Decision Making under Deep Uncertainty (DMDU) as the analysis framework necessitates incorporating a wide range of conditions, and the set of hydrologic model inputs is appropriate for this purpose. The DMDU framework evaluates how each alternative performs across a wide range of plausible future hydrologic and operational conditions. Rather than relying on a single predicted future, this approach provides insight into how an alternative performs across a broad range of future conditions. These methods and choices are well documented in **Appendix E,** DMDU Overview and Approach and **Appendix F,** Approach to Hydrologic Uncertainty.

In response to comments regarding climate change, Reclamation has been involved in scientific studies related to climate projections over the past several decades. Those efforts are reflected in some of the hydrologic inputs used in this analysis, and the DMDU framework evaluates the alternatives across a wide range of hydrologic uncertainty, including uncertainty associated with climate trends.

For discussion about Upper Basin demands, see **Section R.3.4**.

With respect to Lower Basin demands and system losses, including tributary use, Reclamation recently completed an effort to recalculate and release Lower Basin CU&L data through 2024, published in December 2025. Reclamation is also developing updated natural flow estimates, though these data were available in time for incorporation into this analysis. Additional analysis of Lower Basin evaporation and system losses, however, are outside the scope of this EIS. Methodologies for

developing these datasets are presented in "Estimates of Evapotranspiration and Evaporation Along the Lower Colorado River," published by Reclamation in early 2024; that report does not, however, make recommendations for implementing or accounting for system losses from the Lower Colorado River mainstem. For a discussion of modeling assumptions related to Lower Basin demand, including build-out assumptions, see **Section R.3.7.5**, Quantification and Modeling of Lower Basin Water Demands.

With respect to comments regarding "gap water," **Chapter 2** and **Appendix S**, Additional Description of Alternatives, provide a clear description of gap water, and detailed CRSS modeling assumptions are provided in **Appendix A**, CRSS Model Documentation. Additionally, **Appendix D**, Sensitivity Analysis - Effects of Natural Flow Percentage Used for the Supply Driven Alternative, provides a quantification of gap water.

In response to comments regarding the clarity of the evaporation assessment for the storage and delivery of conserved system and non-system water mechanism, the evaporation assumptions vary by alternative: some alternatives apply an annual percentage, while others are based on the actual evaporation of the reservoir in which the water is stored. These assumptions are described in detail in **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water.

R.3.11 Alternatives Development/Range of Alternatives

R.3.11.1. Range of Alternatives

Summary

Commenters state that the Draft EIS does not include a reasonable range of technically and economically feasible alternatives. Certain commenters note deficiencies in the treatment of Compact compliance, citing an over-reliance on Lower Basin reductions and a lack of clearly defined Upper Basin conservation and operational commitments. Commenters state that alternatives should disclose connected actions and operational details sufficient for meaningful public and decision-maker review.

Additional commenters assert that the range of alternatives is inadequate because certain submitted proposals or concepts (such as those advanced by the Upper Division States, Lower Division States, Gila River Indian Community, and Colorado River Indian Tribes) were not fully analyzed as standalone alternatives. Other commenters expressed the opposite view, that the Draft EIS considers too many concepts or includes operational elements they believe are outside the appropriate scope of this NEPA review, are infeasible, rely on speculative assumptions about actions outside Reclamation's control, are not in compliance with the Law of the River, or are otherwise beyond existing authority.

Response

Reclamation developed and screened alternatives in accordance with NEPA, which requires agencies to evaluate a reasonable range of alternatives that meet the Purpose and Need for the Proposed Federal Action. This Final EIS evaluates the environmental effects of six alternatives, including the

No Action Alternative, as required by NEPA, and five action alternatives. As described in **Chapter 2** and **Appendix S**, Additional Description of Alternatives, alternatives and operational elements were developed through multi-year engagement and then screened based on alignment with the Purpose and Need, technical and economic feasibility, a reasonable expectation that necessary authorities could be pursued, and the ability to meaningfully analyze environmental effects of the alternatives within the Final EIS.

In response to comments requesting a broader range of alternatives, Reclamation notes that numerous concepts, including proposals submitted by stakeholders and the Basin States, were considered during the alternatives development process. As described in **Chapter 2** and **Appendix S**, these concepts and proposals informed the development and screening of the alternatives carried forward for detailed analysis. An EIS is not required to analyze every alternative proposed during scoping or public review, but rather to rigorously explore and evaluate a reasonable range of alternatives that are feasible and that meet the Purpose and Need for the proposed action. The fact that a particular proposal was not advanced as a standalone alternative does not mean it was disregarded. Many elements of submitted proposals were incorporated into the development, refinement, or comparative analysis of the alternatives evaluated in the Final EIS.

With respect to the Upper Division States' and Lower Division States' proposals, Reclamation considered those proposals during alternatives development, considered the respective revisions submitted in winter 2024, and evaluated whether they provided an appropriate basis for comprehensive and coordinated operations of Lake Powell and Lake Mead consistent with the Purpose and Need. Reclamation worked extensively with both the Upper Division States and Lower Division States to not only understand and gather information, but also to model and perform detailed analysis of their respective proposals. As described in the Final EIS (see **Section 2.1**), the Basin State proposals, as submitted, were not included as standalone alternatives because they did not include appropriate bases for the comprehensive and coordinated operations of Lake Powell and Lake Mead.

Reclamation incorporated elements of the submitted proposals, along with concepts generated during Reclamation's engagement with the Basin States throughout 2025, to inform the development and refinement of the action alternatives that were carried forward for analysis. After continued work with all seven states throughout the spring and summer of 2025, the concept that became the Supply Driven Alternative was actively being considered by all states but had not achieved full agreement. Because there was no consensus-based alternative, the Draft EIS attempted to capture the state of discussions through inclusion of the Supply Driven Alternative but did not identify a preferred alternative. After publication of the Draft EIS, coordination with the States continued although the discussion had moved away from the concept of the Supply Driven Alternative.

In addition to the individual state comments submitted on the Draft EIS that contained proposed operational strategies, the Upper Division States and Lower Division States submitted additional proposals in May 2026 after the publication of the Draft EIS. The proposal submitted by the Lower Division States described a 2-year set of operating guidelines through 2028 as a bridge to allow future opportunity to reach a consensus-based long-term solution. The Preferred Alternative

identified in the Final EIS incorporates concepts from the States' proposals and leaves open the opportunity for Basin entities to subsequently arrive at a consensus-based path forward. Should no consensus emerge, the Preferred Alternative ensures that the Secretary will have the flexibility to make necessary operational decisions.

R.3.11.2. No Action Alternative

Summary

Commenters disagreed with the characterization of the No Action Alternative, stating that it did not represent a baseline for comparison and a return to implementation of the LROC under a pre-2007 Interim Guidelines framework. For example, commenters stated that the No Action improperly limits the Secretary's authorities to take actions to protect infrastructure and incorrectly limits Lower Basin shortages to 600 thousand acre-feet, the maximum Lower Basin shortage from the 2007 Interim Guidelines. Commenters expressed concern that limiting shortage to that amount would fail to protect infrastructure at Glen Canyon Dam. Commenters also stated that the No Action Alternative represented a misapplication of the LROC because itimproperly sets the annual release to a fixed volume of 8.23 maf. Finally, commenters state that the No Action Alternative fails to meet the Purpose and Need.

Response

As described in the Final EIS (**Appendix S**, Additional Description of Alternatives), Reclamation based the No Action Alternative on the operating guidance that was in place before the adoption of the 2007 Interim Guidelines ROD to provide a reasonable representation of how the system would continue to operate if no additional operating guidelines were adopted. Before the 2007 Interim Guidelines were in place, the basis for operations was the narrative provisions of the LROC, under which the Secretary made a number of determinations at the beginning of each operating year as described in the Annual Operating Plan for Colorado River Reservoirs, including the water supply available to users in the Lower Basin and the annual release from Lake Powell. The LROC does not include specific guidelines for such determinations, so the outcome of the annual determination in any particular year in the future could not be precisely known. However, a reasonable representation of future conditions under the No Action Alternative is needed for comparison to each action alternative. The modeling assumptions used for this representation are consistent with assumptions used in previous environmental compliance documents, most recently the 2007 Interim Guidelines, with appropriate refinements. The assumptions used in the No Action Alternative are not intended to limit or predetermine any future decision by the Department.

As the Final EIS explains in **Appendix S** and **Section 3.2.3**, the No Action Alternative appropriately describes an operational framework that reverts to implementing LROC similar to what occurred before the 2007 Interim Guidelines. The expiration of current domestic and international implementing agreements means that the No Action Alternative represents a change in operations. As a result, the No Action Alternative does not serve as an appropriate baseline to compare impacts. Therefore, a Continued Current Strategies Comparative Baseline scenario is provided to assess the impacts if operations were to continue under the current direction and strategies. While the Continued Current Strategies Comparative Baseline is not an action alternative,

it is a contemporary set of operations that stakeholders are familiar with that can be used to comparatively evaluate the performance of the alternatives (including the No Action Alternative).

Regarding Lower Basin shortages, as described in **Appendix S** of the Final EIS, in accordance with the Consolidated Decree and the LROC, the Secretary makes a determination each year as to whether the consumptive use requirements of mainstream users in the Lower Division States will be met under a Normal, Surplus, or Shortage Condition. The LROC specify that the Secretary will consider all relevant factors in making a shortage determination and list some of the factors to be considered. However, there is no specific LROC guidance as to exactly when, how, or to whom reductions in deliveries would be made under the No Action Alternative in the absence of set operating guidelines. Therefore, it is impossible to know exactly how the Secretary might make a shortage determination from year to year in the future. To provide a representation of how decisions may be made under the No Action Alternative for the purposes of analysis, the elevations and volumes adopted in that ROD are assumed for this alternative. The Final EIS considers a range of Lower Basin Shortage maximums to illustrate impacts and tradeoffs associated with each. Regardless of the alternative considered, the Secretary has the vested authority and responsibility to operate the System through coordinated operations, including the ability to respond to exigent and emergency conditions, pursuant to applicable federal law, the Decree, contractual obligations, and other elements of the Law of the River.

The narrative provisions of LROC are used to make determinations with respect to storage reservoirs in the Basin under the No Action Alternative. Annual releases from Lake Powell that vary from 8.23 maf are analyzed in other action alternatives in the Final EIS. For more information on LROC Implementation, see **Section R.3.5**.

The No Action Alternative is not required to meet the Purpose and Need for the proposed action. It is included as a baseline for comparison against the effects of the action alternatives.

R.3.11.3. Preferred Alternative

Summary

Commenters asserted that the absence of a preferred alternative in the draft EIS limited meaningful opportunity for public comment.

Response

The Draft EIS is designed to present and evaluate a reasonable range of alternatives with sufficient detail to support informed decision-making and allow for meaningful comparison of effects consistent with Purpose and Need. NEPA does not require identification of a preferred alternative in a Draft EIS, and an agency may choose to identify, develop, or refine a preferred alternative in the Final EIS. The Representative Preferred Alternative for this Proposed Federal Action was developed following the release of the Draft EIS, and is further described in **Chapter 2**, Description of Alternatives.

Several commenters requested additional detail regarding authorities, Compact compliance assumptions, and the treatment of actions outside Reclamation's control. Reclamation's evaluation

of alternatives is conducted within the context of the Law of the River and applicable authorities, and the EIS does not resolve disputed legal interpretations. For comment topics focused on authority or legal interpretation, see the Theme Summary/Response for **Section R.3.1**, Secretarial Authorities and **Section R.3.18**, Policy and Governance. For comment topics focused on Compact compliance concepts or differing Compact interpretations, see **Section R.3.2**, 1922 Colorado River Compact Compliance.

For comment topics requesting additional disclosure of connected actions, third-party actions, or operational details outside the scope of this EIS, see **Section R.3.21**, Connected Actions and Cumulative Effects and **Section R.3.19**, Scope. For comment topics requesting detailed analysis of specific concepts that were screened out, see **Section R.3.13**, Alternatives Considered but Eliminated. For comment topics seeking additional specificity regarding Upper Basin conservation assumptions and feasibility, see **Section R.3.4**, Upper Basin Demands, Shortage, and Conservation. No Action sub-theme: Cross-reference to LROC and infrastructure protection sections. Under NEPA, an agency is required to describe a "no action" alternative in an EIS. Consistent with the No Action Alternative analyzed in the 2007 Interim Guidelines Final EIS, the No Action Alternative is based upon operating guidance that was in place before the adoption of the 2007 Interim Guidelines ROD to provide a reasonable representation of how the system would continue to operate within existing authorities if no additional operating guidelines were adopted and absent additional agreements. It represents a return to operations preceding development of the 2007 Interim Guidelines and is necessary as a comparison for each action alternative. The No Action Alternative is not required to meet Purpose and Need.

R.3.12 Coordinated Operations of Lake Powell and Lake Mead

Theme Summary

Many commenters expressed views on how to prioritize resources and which criteria to use when determining coordinated operations, particularly for operations at Lake Powell. Commenters identified specific Lake Powell elevations that should be maintained, such as 3,570 feet for the purposes of protecting native fish in the Grand Canyon, and 3,525 feet to preserve the ability to perform high-low experiments (HFEs). Others suggested that prioritizing reservoir storage for water security or recreation purposes was important, or that ensuring reservoirs could continue to generate hydropower was critical. Some highlighted the importance of basing operations on observed inflows to Lake Powell, and to allow releases to reflect hydrologic variability in a more natural way.

Response

Reclamation recognizes that the Colorado River supports many important and valuable resources, and that stakeholders throughout the Basin prioritize these resources differently. During the alternatives development process, Reclamation ensured that the action alternatives in the Draft EIS reflected a wide range of Lake Powell operations that achieved different balances of performance across resources. The Enhanced Coordination and Maximum Operational Flexibility Alternatives were designed specifically to account for different resource values. Additionally, the Draft EIS alternatives capture a wide range of operating criteria, including the explicit use of hydrology in determining releases. Finally, the Draft EIS analysis describes how these resources perform and by looking at a wide range of resources, the tradeoffs across priorities are reflected.

R.3.13 Alternatives Considered but Eliminated

Theme Summary

Some commenters requested a detailed analysis of alternatives that were identified in the Draft EIS as considered but eliminated, including structural modifications to Glen Canyon Dam, such as a river-level bypass and improvements to outlet works. Requests were made to analyze one-dam alternatives that would prioritize the preservation and operation of a single mainstream reservoir—either Hoover Dam/Lake Mead or Glen Canyon Dam/Lake Powell—over the other. The majority of these commenters supported a 'Fill Mead First' alternative, including proposals to bypass or decommission Glen Canyon Dam. Other requests questioned the exclusion of ecosystem-first alternatives, and recreation-focused plans from analysis. Some comments expressed general agreement or disagreement with the elimination of an alternative from detailed analysis.

In some cases, commenters took issue with specific aspects of the rationale for not analyzing the alternative in detail. For example, some commenters questioned how the Ecosystem Alternative would not fully resolve the operational and legal requirements for managing Colorado River water and noted that, while an ecosystem-based alternative would include cuts to water allocations and implementation of water conservation measures, alternatives considered in detail also involve these elements. Other commenters stated that there were more flexibilities within the concept of a "Fill Mead First" Alternative that could allow it to be implemented in a manner consistent with the Law of the River.

Theme Response

Consistent with NEPA requirements and as described in **Chapter 2** and **Appendix S**, Additional Description of Alternatives, this Final EIS focuses detailed analysis on a reasonable range of alternatives. A reasonable range of alternatives under NEPA provides decision makers and the public with a meaningful basis to compare environmental impacts and make informed choices. NEPA does not require that the scope of alternatives included be exhaustive, and agencies do not need to consider alternatives that are infeasible, ineffective, or otherwise inconsistent with the objectives of the proposed federal action. Alternatives, operational concepts, or components of alternatives that were considered but not carried forward for detailed analysis are documented in **Appendix S** of the Final EIS, with explanations for the bases for their elimination. This response further clarifies the rationale for eliminating specific alternatives –Fill Mead First approach, ecosystem-first alternatives, and recreation-focused plans— from detailed analysis.

An ecosystem-first alternative generally refers to a management framework that prioritizes the long-term ecological function of the Colorado River system over congressionally authorized project purposes. An ecosystem-first operational framework would limit operational flexibility or require extensive changes to Colorado River operations and contracts and would reduce water supply for users based on prioritizing ecological thresholds and constraints. Thus, while specific ecosystem considerations and objectives were incorporated into the EIS, the EIS does not analyze a stand-alone ecosystem-first alternative.

A 'Fill Mead First' alternative proposes an operational strategy that prioritizes Lake Mead as the primary water storage facility on the mainstream Colorado River and subordinates Lake Powell as a

secondary water storage facility operationally dependent upon storage conditions at Lake Mead. This alternative was not included in the Final EIS because it would not meet the Purpose and Need of the proposed federal action, lacks fundamental compliance with the Law of the River, and would require extensive changes to Colorado River operations and contracts. A Fill Mead First approach likely would need to involve a novel inter-basin water storage exchange or conservation pool. It would alter the purpose of the guidelines for coordinated operations of both Lake Powell and Lake Mead, under the existing statutory and legal structure, without Congressional authorization. The purpose and need of this EIS supports the development of operational guidelines for the management of the existing reservoirs, which includes a fundamental assumption of the continued existence of and congressionally authorized purposes of Lake Powell and Lake Mead. This EIS analyzes alternatives within operational objectives designed to protect critical infrastructure, maintain water delivery reliability, preserve operational capability, and maintain system flexibility. A one-reservoir alternative, such as the Fill Mead First approach, would require significant legal, engineering, financial, and congressional action. The Fill Mead First alternative and other alternatives regarding decommissioning Glen Canyon Dam were rejected in the 1995 EIS on Glen Canyon Dam operations and in LTEMP for similar reasons.

Regarding modifications to Glen Canyon Dam infrastructure, specific infrastructure modifications are not currently contemplated as components of individual alternatives within the EIS, since pursuing them would be outside the scope of adopting specific operational guidelines, and operational guidelines must be adopted as a result of this process whether or not any infrastructure modifications are pursued in a separate action. See theme response **Section R.3.6**, Glen Canyon Dam and Hoover Dam Infrastructure, for additional information.

R.3.14 Sustainable, Reliable, and Adaptive Management

Theme Summary

Commenters advocate a proactive, science-based management framework that internalizes long-term aridification, employs realistic supply projections, and prioritizes demand reduction and conservation over perpetuating unsustainable allocations. Commenters call for transparent modeling and reporting and integrated ecological stewardship. Many commenters asked for the inclusion of riparian restoration, invasive species control, and sediment and temperature management. Requests were made for flexible tools that scale to actual hydrologic conditions and are developed within operational decision-making, rather than deferred to reactive compliance documents. Suggested instruments include enforceable efficiency standards, incentives and mandates for agricultural modernization and crop substitution, expanded off-stream storage and recharge, transparent accounting of avoided spills, and clearly specified ecological thresholds (e.g., Powell elevation targets for temperature control; minimum Grand Canyon flows; monthly release limits and HFE frequency contingent on sediment).

Response

Reclamation considered sustainable, reliable, and adaptive management while developing the Draft EIS and Final EIS. Many of the concepts that commenters requested have been incorporated into the Final EIS, including proactive and science-based management. However, some concepts raised by commenters were outside the scope of this EIS or were in the realm of state and local

jurisdictional decisions, including implementation of incentives and mandates for specific agricultural practices and development of expanded off-stream storage projects. Other requests will be addressed, where appropriate, through subsequent NEPA and Endangered Species Act (ESA) efforts or through programmatic and operational planning efforts beyond this EIS.

R.3.15 Mitigation

Theme Summary

Commenters asserted that the Draft EIS mitigation discussion is inadequate under NEPA/Council on Environmental Quality standards and seek integrated, enforceable, and funded mitigation tied to each alternative, with monitoring, adaptive triggers, and long-term management. Proposed measures include direct assistance and replacement supplies to tribes where deliveries are reduced; transactional flexibility and accounting for conserved water; compensation frameworks linked to modeled damages and improved conveyance infrastructure. Biological mitigation requests emphasize thresholds for critical habitat, native fish passage protection, non-native control, HFE regimes to rebuild habitat, and expanded conservation areas. Commenters suggested proactive coordination with stakeholders, including the National Park Service, to evaluate and implement adaptive management and infrastructure solutions to mitigate potential adverse effects on water-dependent recreational activities. Socioeconomic mitigation measures include workforce transition programs, compensated conservation that maintains agricultural viability, and targeted responses for the Salton Sea (dust suppression, habitat restoration, human health responses, and infrastructure investments).

Response

The Draft EIS complies with current Department regulations and guidance for NEPA compliance, including the DOI NEPA Handbook (516 DM 1, February 2026). The Handbook explains that although "NEPA requires bureaus to consider reasonable mitigation measures, it does not require bureaus to evaluate or select any specific form of mitigation." NEPA does not independently confer authority on agencies to require, fund, or enforce mitigation measures absent separate substantive authority.

The proposed federal action and alternatives include review of the environmental effects of mitigation measures, and such mitigation approaches are described at a programmatic level and are commensurate with the planning-level nature of this EIS. Compliance under other laws, including the ESA, may provide additional specific mitigation measures. Reclamation would continue to coordinate with the appropriate stakeholders during the implementation of a selected alternative. Historically, this coordination provides for additional tools to minimize impacts.

R.3.16 Decision Process

R.3.16.1. Preferred Alternative Selection

Summary

Commenters requested transparent decision criteria for selecting a Preferred Alternative, including explicit articulation of the Secretary's vision and clearer grounding in current hydrologic realities.

Several commenters argued that a Preferred Alternative should have been identified for public review in a revised or supplemental draft prior to issuance of the Final EIS.

Response

NEPA does not require a preferred alternative to be identified in the Draft EIS. The alternatives analyzed in this Final EIS include a broad range of operational elements incorporating over 4 years of input provided by stakeholders and the public and received through consultations with the Basin States and Basin Tribes, the alternatives development process is described further in **Chapter 2**. In the absence of a long-term consensus-based approach, Reclamation has developed a Preferred Alternative that consists of a decision framework to develop operating guidelines for Lake Powell and Lake Mead for operating years 2027 through 2036. This framework provides near-term certainty and predictability for Lake Powell and Lake Mead operations, establishes a transparent process for making operational decisions in the absence of long-term consensus, and allows for incorporation of future consensus recommendations while preserving the flexibility to respond to changing hydrologic conditions. The process and timeframes are explicitly designed to facilitate consideration of and response to hydrologic conditions. Should no consensus emerge, the Preferred Alternative ensures that the Secretary will have the flexibility to make necessary operational decisions.

R.3.16.2. Implementation of Annual Decision-making

Summary

Commenters requested improved stakeholder inclusion in annual operational decision-making. Specific suggestions for this include forming a basin-wide adaptive management advisory body with transparent data and annual criteria and sustaining ongoing consultation throughout implementation and adjustments over time.

Response

The Department is tasked with determining annual operations in consultation with the States. Additional consultations and processes, including engagement with tribes, are important for achieving a decision. However, it is not necessary to fully describe and analyze specific alternatives for annual operational decision-making as part of this NEPA process. The ROD will incorporate a consultation and outreach process to inform future post-2026 operational decisions.

R.3.17 Purpose and Need

Theme Summary

Commenters argue that the analyzed alternatives do not fully meet the stated Purpose and Need under dry and critically dry conditions and that performance thresholds are not coherently linked to stated objectives. For example, the Draft EIS identifies avoidance of Lake Powell dead pool-related reductions as a performance indicator for evaluating robustness, yet the analysis shows that none of the alternatives meet this criterion. Some commenters requested a broader, systemwide Purpose and Need that explicitly addresses structural deficit and Compact compliance, integrates ecological mandates and statutory responsibilities (Grand Canyon Protection Act of 1992 [GCPA], ESA, National Park Service Organic Act), and reflects persistent aridification rather than treating conditions as mere variability.

Theme Response

Under NEPA, a purpose and need statement is required to explain the basis for the federal action by identifying why the action is being considered and what the agency intends to accomplish. **Chapter 1** outlines the Purpose and Need for this Proposed Federal Action, as set forth in the *Federal Register* notice published on October 20, 2023 (88 *Federal Register* 72535). The purpose and need for this proposed federal action provides a framework for considering varied operational and management strategies within a reasonable range of alternatives by establishing management objectives, operational needs, and applicable legal or regulatory considerations. It is sufficiently broad to allow consideration of a reasonable range of alternatives, but not so broad that it becomes unbounded or speculative and defines a decision space that allows multiple implementable operational alternatives while remaining consistent with authority and physical system limits.

The scope of the federal action is the development of new guidelines and coordinated management strategies to address Lake Powell and Lake Mead through their full operating range to take effect when the current agreements expire in 2026. All the analyzed alternatives provide a wide range of operations that meet the purpose and need for the scope of this action, while highlighting the trade-offs between them in meeting the specific objectives of the purpose and need. As shown by the analysis, during dry and critically dry conditions, performance objectives may not be met, and the degree of impacts could be significant to users and resources. This is the inherent challenge with a finite resource in great demand. At this point, no other alternatives have been brought forward that would result in better performance and fewer impacts.

R.3.18 Policy and Governance

Theme Summary

Commenters emphasized adherence to the Law of the River and related authorities (or various interpretations thereof). Specific components mentioned by commenters included Articles III(c)–(d) of the 1922 Compact, the CRSP Act, CRBPA, the Consolidated Decree, LROC/602(a), and binational treaty obligations. Commenters requested Reclamation explain any perceived departures from their preferred interpretations, incorporate Compact compliance as an operational priority, and reconcile operations with obligations under GCPA and ESA. Additional comment themes include limitations regarding interstate and interbasin marketing, maintenance of hydropower production for authorized purposes while recognizing its subordination to agricultural and domestic uses, and attention to national policy linkages (e.g., critical minerals, energy, and security).

Response

The Secretary intends to consider, adopt, and implement the proposed federal action consistent with the Law of the River. The alternatives in this Final EIS are designed to cover a wide range of potential outcomes with respect to post-2026 operations; accordingly, they incorporate components that are within existing authorities along with components that would require new authorities and/or new agreements among Basin water users to fully implement, see **Section 2.3**. The EIS does not establish new legal interpretations, resolve contested questions about the 1922 Compact or other authorities, or modify existing governance frameworks. Rather, it evaluates the environmental consequences of potential federal actions across a range of alternatives, see further discussion in theme responses **Sections R.3.1** and **R.3.2**.

R.3.19 Scope

Theme Summary

Commenters indicated differing views on whether the analysis should be limited to Lake Powell and Lake Mead operations, or to expand the geographic scope, both upstream to include the CRSP Upper Initial Units and downstream to include Mexico. Other commenters asked for analysis of more localized impacts related to specific water users, water districts (e.g., Southern Nevada Water Authority, CAP contractors, and the Salton Sea). Comments also focused on the analysis scope, requesting additional analysis on their locally/privately owned non-Federal water delivery infrastructure, water leases, and quantification of effects on other water supplies, such as groundwater. Many point to analytical inconsistencies in which upstream releases or conservation are assumed but upstream impacts are not analyzed. Requests span analyzing Upper Basin shortages and conservation, incorporating transboundary effects under Executive Order 12114, and clarifying the geographic boundary relative to Lake Powell's full pool. Other comments cover a wide variety of topics that are not within the scope of this EIS, such as impacts on low-income and minority populations, impacts on water users who lease water from water right holders, impacts from sub-annual flows for ecological benefits, impacts related to infrastructure upgrades or modifications.

Response

Section 3.2 of the Draft EIS (Analysis Methods) includes a detailed discussion on how Reclamation defined the geographic, temporal, and analysis scope. The scope is expanded for certain resource analyses based on those particular resources, as described in the respective resource analysis sections. For many resources, expanding the scope of analysis introduces uncertainty into impact analysis because impacts and causal relationships will become more speculative, non-federal decision points are introduced, and Reclamation's authorities become more limited. These factors create a level of uncertainty that makes it impractical to analyze certain expanded resource areas. Reclamation clarified the text in **Section 3.2** of the Final EIS to better define the default geographic scope for analysis; specific resource topics (e.g., socioeconomic impacts) describe more expanded analysis scopes as applicable.

Proposed operations at the CRSP Upper Initial Units specifically contemplated in the alternatives informed the hydrological modeling in the Draft EIS. These operations are within the scope of each unit's existing RODs, and as such, the associated impacts are disclosed in the associated EISs. Specific conservation activities that may be undertaken in the Upper Basin are unknown at this time and would not necessarily require federal operational decision making. Any federal operational decisions associated with these conservation activities would undergo additional environmental compliance.

Deliveries to Mexico are determined by Treaty and international agreements. Modeling assumptions with respect to water deliveries to Mexico were necessary to analyze potential impacts on hydrologic and other environmental resources. Since Reclamation does not control the use and distribution of water in Mexico, direct impact analysis on specific resources would be speculative.

The Salton Sea is a terminal lake in Riverside and Imperial Counties, California. Lake levels are influenced by runoff from the surrounding Imperial Valley and Coachella Valley watersheds, as well

as agricultural drainage from the Imperial Irrigation District and Coachella Valley Water District. Reclamation does not manage or control the end use of water after the point of delivery. As such, Reclamation has no management authority over the distribution of end use or allocation by these water districts and individual users, including user decisions to participate in conservation programs. The State of California oversees management of the Salton Sea, and Reclamation has no management or enforcement authority over inputs to the Sea.

As a general matter, groundwater in Arizona is governed by state law, in particular the Arizona Groundwater Code, established by the Arizona Groundwater Management Act of 1980 as amended. See Arizona Revised Statutes (A.R.S.) Title 45, Chapter 2. The Arizona Groundwater Code is a "framework for the comprehensive management and regulation of the withdrawal, transportation, use, conservation and conveyance of rights to use the groundwater in this state." A.R.S. § 45-401(B). A state agency, the Arizona Department of Water Resources, has "general control and supervision" of groundwater in the state as provided by A.R.S. Title 45. See also 43 United States Code (U.S.C.) § 617q. Regulation of state groundwater thus is generally outside Reclamation's jurisdiction, with limited exceptions based in federal law. For example, exceptions may include federal actions under federal trust responsibilities and statutes related to Indian tribes, certain releases of hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (42 U.S.C. §§9601 et seq.), and in relation to the Colorado River, the subflow zone (e.g., A.R.S. § 45-596.01) and specific limitations related to CAP subcontracts as provided in the CRBPA, 43 U.S.C. 1524. Therefore, analysis related to any decisions made by Arizona water users to change or supplement water sources due to federal actions would be speculative. The purpose of this EIS is to analyze and disclose the reasonably foreseeable effects from the proposed action and alternatives within the defined area of analysis, and items outside this scope are therefore not included in the analysis. See **Section 1.5** of the Final EIS for additional details on the geographic scope affected by the proposed federal action. The Final EIS complies with current Executive Orders and Department regulations and guidance for NEPA compliance, including the DOI NEPA Handbook (516 DM 1, February 2026). The Handbook supplements the Council on Environmental Quality regulations (40 CFR 1500–1508) and Department regulations (43 CFR Part 46). The Draft EIS also complies with current Executive Orders related to NEPA analysis. For example, pursuant to Executive Order 14154, Unleashing American Energy (January 20, 2025), and the Presidential Memorandum entitled Ending Illegal Discrimination and Restoring Merit-Based Opportunity (January 21, 2025).

R.3.20 Data Sources

Theme Summary

Commenters requested that Reclamation use updated and transparent data sources, including the incorporation of updated capacity surveys, CU&L datasets (including Upper Basin and Lower Basin CU&L and evaporation), published materials related to drought science, and independent peer review. Commenters urged transparency around Lower Basin uses and losses and asked that model assumptions be refined to reflect current storage conditions, depletion schedules, and hydrologic conditions.

Response

Reclamation incorporated the best available science and all necessary data for the development of the Final EIS. Data sources, assumptions, and methodologies are documented in the EIS and supporting appendices to support transparency and reproducibility.

With respect to updated capacity surveys and Upper CU&L and evaporation data, the selection of data sources for the CRSS model had to occur 2 and 3 years, respectively, before EIS modeling began. At that time, these data sources represented the best available datasets. Lake Powell modeling relied on the 2017 Lake Powell Stage-Area-Capacity survey, which remains the most recent survey published and continues to represent the best available science. Upper Basin CU&L and evaporation were based on Upper Colorado River System CU&L data released in February 2022, covering the 1971-2020 period and including upper system reservoir evaporation.

These CU&L data are essential inputs for two critical datasets used in CRSS for the EIS modeling. The natural flow data and the UCRC depletion demand schedule. The 1906-2020 natural flow data was released in December 2022. The UCRC depletion schedule followed a more complicated development timeline.

The UCRC first released a supply-limited depletion schedule in June 2017, providing decadal depletion demand projection by state and major consumptive use sectors. Working with the UCRC and the Upper Division States, Reclamation translated these decadal projections into monthly, CRSS reach-scale inputs in November 2020. This supply-limited schedule pre-shorts demands in high Upper Basin tributaries that historically receive less than a full water supply, before inputting these schedules in CRSS.

In August 2021, the State of Colorado asked Reclamation to further refine and improve CRSS. One enhancement enabled the model to use a full-supply (rather than supply-limited) depletion demand schedule. In March 2023, Reclamation released CRSS version 6, which included the ability to short high-tributary water users dynamically during a model run. The UCRC then produced and published an updated 2016 depletion demand schedule compatible with CRSS version 6 in June 2022.

Reclamation released updated 1971-2023 Upper Basin CU&L data in June 2024. This update incorporated methodological changes to irrigated agriculture CU estimates, shifting CU among the Upper Division States. These shifts require development of a new UCRC depletion schedule when time allows. However, because EIS modeling commenced in November 2024, there was not sufficient time for the Upper Division States, the UCRC, and Reclamation to develop a second updated depletion demand schedule for CRSS version 6. Under typical conditions, this process takes about one year.

Given these modeling and timing constraints, Reclamation used the best available Upper Basin CU&L data for the EIS modeling.

With respect to published materials related to drought science, see **Section 5.3.10** in response to hydrology choice.

With respect to independent peer review in accordance with Executive Order 14303—Restoring Gold Standard Science (May 23, 2025) and the U.S. Department of the Interior Information Quality Guidelines Pursuant to Section 515 of the Treasury and General Government Appropriations Action for Fiscal Year 2021, Reclamation implemented a peer review process for the EIS. All models used for analysis went through a peer review process by the responsible agency. Reclamation conducted a peer review of the CRSS hydrological model, and the EIS went through a two-phase review process: (1) cooperating agency peer review of the preliminary Draft EIS and (2) an independent peer review of the Draft EIS. Results from the former were incorporated in the Draft EIS, and the results from the latter are included in the Final EIS. Peer review plans and reports for Reclamation generated products are available at Reclamation's Quality of Information Peer Review website.

For discussions about Lower Basin tributary CU&L and evaporation, see **Section R.3.7**.

For discussions about initial and hydrologic conditions see **Section R.3.10**.

R.3.21 Connected Actions and Cumulative Effects

Theme Summary

Commenters requested that alternatives disclose connected actions and operational details sufficient to support meaningful public and decision-maker review. Commenters asserted that the cumulative effects analysis is overly qualitative and incomplete, and requested expanded treatment of connected and indirect effects within Reclamation's purview. Specific requests included more comprehensive socioeconomic and public-health impacts, groundwater resources, and associated impacts such as depletion, subsidence, and water quality. Commenters also asked Reclamation to address how other foreseeable actions, such as urban growth, land use changes, and water-management projects, could contribute to cumulative effects.

Response

The EIS considers connected actions consistent with NEPA and regulations, focusing on impacts that are reasonably foreseeable from the proposed action and alternatives within the defined area of analysis and within Reclamation's authority.

As described in **Section 3.14.1.2**, cumulative effects analysis such as the potential socioeconomic consequences or impacts to local groundwater supplies due to shortages occurring in the municipal and industrial sector were qualitatively assessed since it was not known to what degree a specific economic sector considered a municipal and industrial use would be affected. The effects on individual cities or communities are indeterminate for various reasons. Each city or community has a different mix of water supplies, and in most cases, has formulated a shortage or drought response plan that is specific to their respective community. Also, individual response plans typically include varying combinations of demand-side and supply-side actions, and these differ by community. The use or acquisition of other water supplies and development and implementation of response plans would vary according to then-current state, tribal, and local laws, regulations, policies, or governing board or council actions, which are outside of Reclamation's jurisdiction.

Further, Reclamation is not required to consider environmental effects, including ecological, aesthetic, historic, cultural, economic, social, local custom and cultural, and health effects, from other projects that (1) are separate in time or place from the project at hand, (2) fall outside an agency's regulatory authority, or (3) are carried out independently by third parties. Ultimately, "where an agency has no ability to prevent a certain effect due to its limited statutory authority over the relevant actions, the agency cannot be considered a legally relevant 'cause' of the effect." (516 DM 1 - DOI NEPA Handbook 2026).

Additional information on connected actions and cumulative impacts on specific resources is provided in the resource themes below (**Sections R.3.26-R.3.41**).

R.3.22 Decision-Making under Deep Uncertainty and Approach to Analysis

Theme Summary

Commenters ask Reclamation to provide clearer explanations and figures for the DMDU analysis.

Commenters note that, in robustness analyses, alternatives do not meet important performance levels in 100 percent of hydrologic futures, and commenters ask if such results indicate none of the alternatives are robust.

Commenters ask Reclamation to focus on drier conditions and remove the mid and high initial condition scenarios.

Commenters ask Reclamation to attribute various performance outcomes to different operational components.

Response

We agree with commenters that the Draft EIS was insufficient in the description and interpretation of results. To address this, explanations have been improved for clarity throughout **Chapter 3** and the technical appendices. The vulnerability analysis figures have been updated with a new legend to aid interpretation, and the descriptions of the results have been improved.

Due to recent hydrologic conditions and reservoir storage, the analysis has been updated by removing the middle and high initial reservoir storage scenarios. The Final EIS considers only the low initial condition scenario.

Critically, Colorado River hydrology is highly variable year-to-year; the severity, frequency, duration, and sequencing of future hydrology is unknown; there is no consensus in the scientific or planning communities on how to characterize future hydrology probabilistically; and the types of hydrologic futures that are most relevant for evaluating critical system risks varies across alternatives, by resource, and often by individual analyses within a resource. Due to this deep uncertainty and high degree of inter-resource variation, a tailored ensemble of dry hydrology traces would be insufficient to analyze risks to all resources in this EIS.

The DMDU framework therefore analyzes a broad range of hydrologic conditions. The set of 400 hydrologic traces intentionally includes severely dry and wet traces (well outside the range of what

has been observed in the past) such that every alternative can fail critical performance goals (i.e., results in undesirable performance) in some percentage of futures. This is necessary so that, in vulnerability analysis, the expected hydrologic tipping point between preferred minimum performance and undesirable performance can be identified. Then, the vulnerability results, in combination with the reference hydrology, are used to interpret these results with the DMDU decision framework. Notably, descriptions of vulnerability results have been improved with concise conclusions about the alternatives. For example, this alternative [the Representative Preferred] is not likely to be vulnerable in the next 10 years because these conditions have not been observed and they occur in fewer than 10 percent of traces in the Drying with Variability Ensemble, which represents how hydrologic conditions may change in a warmer future' (see **Figure TA 4-3**). Please also refer to **Section 3.2.6**, **Appendix E**, DMDU Overview and Approach, and **Appendix F**, Approach to Hydrologic Uncertainty, for more information.

Regarding the presence of wet conditions in the 400 hydrologic traces, it is critical to understand the types of hydrology that result in undesirable performance that can occur under moderate or high reservoir conditions, such as cooler water temperatures that inhibit the growth and reproduction of native fish species (**TA 8**, Biological Resources – Fish and Other Aquatic Species), the availability of sediment for beach building in the Grand Canyon (**TA 5**, Geomorphology and Sediment), and use of the Glen Canyon Dam and Hoover Dam spillways (**TA 15**, Dams and Electrical Power Resources).

Simultaneously, Reclamation acknowledges that dry conditions pose significant risks. Vulnerability analysis identifies the specific dry conditions that are problematic for each alternative, then it compares those conditions to recent historical observations and plausible conditions under a drying future (the Drying with Variability reference hydrology). Further, results for the Representative Preferred alternative focus on Dry and Critically Dry conditions, and the 10-year tradeoff analysis for all alternatives in **Figure ES-5** focuses on conditions similar to and drier than recently observed. The Final EIS also frames the interpretation of results by explaining in **Chapter 3** that "Recent history combined with the increasing temperature trend, which is associated with lower streamflow, suggests that focusing more on the Average and Dry categories is warranted. However, Critically Dry conditions have been observed and could become more common".

A piece-wise sensitivity analysis of all or most operational elements to support an extensive attribution analysis was not practical due to the number of alternatives, number and complexity of operational elements, and associated modeling requirements. However, throughout the analysis there are opportunities to consider the impacts of different elements. For example, the influence of conservation pools on reservoir levels is demonstrated in **TA 3-16** and **TA 3-17** and on shortages in **Figure TA 4-5**. A comparison of Lake Mead elevations in **TA 3-17** without conservation pools demonstrates the relative effectiveness of different maximum shortage volumes. **Figure TA 4-6** was also added in the Final EIS to show the impacts of conservation pools on dead pool-related delivery reductions.

R.3.23 Water with Mexico

Theme Summary

Commenters emphasized the need for formal binational engagement, a shared responsibility for 1944 Water Treaty deliveries between the Upper and Lower Division States, and the inclusion of Mexico's participation in water delivery reductions alongside water conservation opportunities. Commenters caution that water delivery reductions from yet undetermined agreements with Mexico pose analytical risk and request the integration of the impacts of salinity compliance (i.e., Minute 242) into modeling and decision criteria.

Response

The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State. The modeled annual depletions in water deliveries to Mexico include modeling assumptions for reductions in water deliveries to Mexico and deferred deliveries that are available to Mexico for future delivery. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. Within this Final EIS analysis, the assumptions used for reductions in water deliveries to Mexico applied a fixed 16.67 percent of any total shortages applied to the Lower Basin, as well as any dead pool-related reductions. This assumption was applied uniformly across all alternatives, including the No Action Alternative. This percentage is computed by taking the ratio of Mexico's allotment to the sum of the Lower Basin U.S. apportionments and Mexico's allotment (1.5 maf/(7.5 maf + 1.5 maf) = 0.1667 or 16.67 percent) and ensures that the water delivery reductions to Mexico are proportional to the shortages to the U.S. users in the Lower Basin.

Both the Draft and Final EIS include a comparative assessment of the long-term implications of the proposed alternatives on salinity levels reaching both the Imperial Dam and the Northerly International Boundary. Regarding compliance with the obligations of Minute 242 to the 1944 Water Treaty with Mexico, the modeling reflects one explicit assumption for the volume of pumped groundwater that can be used to meet Mexico's delivery while complying with Minute 242. If the volume of pumped groundwater that can be used to meet the delivery requirement has to be reduced, absent any binational agreements to address salinity impacts, then there might be additional impacts to Lake Mead. The actual impacts to Lake Mead would depend on complex operations below Imperial Dam, including the volume of pumped groundwater that could be used to meet Mexico's delivery while complying with Minute 242. A supplementary analysis was added to **Appendix N**, International Border Region of the Colorado River, to bound the potential impacts on Lake Mead, using two assumptions for the volume of pumped groundwater that can be used while operating to meet the salinity requirement specified in Minute 242.

R.3.24 Consultation: Biology/ESA

Theme Summary

Commenters seek ESA consultation concurrent with NEPA and completed before the ROD. They request that the Biological Assessments (BA) focus on dry and critically dry scenarios and that the

Biological Opinions (BO) address specific river reaches and operational effects. Commenters also request a clearer and side-by-side analysis of how alternatives may affect listed species under the ESA, critical habitat, and conservation areas, including those associated with the GCPA and Lower Colorado River Multi-Species Conservation Program (LCR MSCP). Additional requests include explicit linkage of elevation and release patterns to ecological effects, improving analysis of impacts on conservation areas and habitats, and identifying mitigation or adaptive management measures that could address potential impacts under varying hydrologic conditions.

Response

The EIS evaluates potential impacts on fish and wildlife, including ESA listed species and species covered by the LCR MSCP, using the best available scientific information and modeling approaches appropriate for basin-scale analysis under uncertain future hydrologic conditions. Species covered by the LCR MSCP are included as special status species in the EIS. The analysis uses a DMDU framework to evaluate potential effects across a range of hydrologic scenarios. Because future river flows, habitat conditions, and species responses are highly uncertain, the analysis relies on modeled system outcomes rather than predicting impacts for specific species at individual locations. The EIS acknowledges that resource tradeoffs may occur under different alternatives and scenarios.

The purpose of the EIS is to evaluate and compare environmental consequences for each alternative under NEPA. Providing side-by-side comparisons with the ESA, the LCR MSCP, or the GCPA is not an objective of this EIS, as those authorities operate under separate statutory and regulatory processes. The relative impacts of alternatives on ESA listed and other special status species and critical habitat is assessed in **TA 8**, Biological Resources – Fish and Other Aquatic Species, and summarized in **Figure TA 8-31** for aquatic species, **TA 9,** Vegetation Including Special Status Species, and **TA 10,** Terrestrial Wildlife Including Special Status Species for terrestrial habitat type, vegetation, and associated wildlife. ESA compliance, including evaluation of incidental take and conservation measures, occurs through the Section 7 consultation process that Reclamation is working through with the U.S. Fish and Wildlife Service (FWS). Reclamation coordinated with FWS and other agencies during the development of the EIS.

Reclamation has multiple existing ESA consultations aligned with the Upper Basin and Lower Basin programs. In the Lower Basin, ESA analyses and incidental take are covered and permitted through the LCR MSCP Section 7 BOs/Section 10 Habitat Conservation Plan. The most recent consultation between Reclamation and the FWS occurred in 2024. This consultation provides full analysis and coverage through January 31, 2028, for reductions in flow from Hoover Dam up to 3.0 maf. Reclamation and the LCR MSCP are currently developing a BA and a Habitat Conservation Plan permit amendment to ensure adequate analysis and coverage for the range of operations associated with the length of the EIS. As described in the document, the operational plan for Hoover Dam is not anticipated to exceed the flow coverage analyzed in the 2024 BO.

Additionally, a BA is being prepared to determine whether the Preferred Alternative may affect listed species in the Upper Basin (from full pool of Lake Powell to Pearce Ferry Rapid). This BA may include Conservation Measures that lessen the impact of the action on listed species. The FWS will then issue a BO determining whether the action is likely to jeopardize the continued existence of listed species or destroy or adversely modify critical habitat. If jeopardy or adverse modification is

determined, a Reasonable and Prudent Alternative will be developed with appropriate measures and Conservation Recommendations.

R.3.25 Consultation and Coordination

Theme Summary

Commenters recommended broadening consultation and coordination to include all affected governments and user groups, including tribes; engaging other federal departments to address national-scale consequences. Commenters also stated that there was inadequate consultation on the preferred alternative.

Response

Reclamation conducted extensive public outreach, held public scoping meetings and meetings on the public Draft EIS, and consulted formally and informally with representatives from the cooperating agencies, Basin States, tribes, non-governmental organizations, and other interested parties to obtain input on the EIS. Reclamation reached out to other federal agencies with jurisdiction or special expertise to participate as cooperating agencies in this process. Additional details on this outreach are provided in **Chapter 4**. Reclamation will continue to coordinate future operations with affected stakeholders as appropriate.

For additional information regarding consultation on the Preferred Alternative, see **Section R.3.16**, Decision Process.

R.3.26 Air Quality

Theme Summary

Commenters stated that the Draft EIS and supporting technical appendices do not sufficiently assess air quality impacts, particularly at the community scale. Commenters requested that the air quality analysis expand its geographic scope to include impacts on the Salton Sea, Coachella Valley, and Imperial Valley. They asked for additional analysis of increased dust emissions associated with fallowing, as well as a more robust discussion of greenhouse gas and climate change-related effects. Commenters were also interested in the risks associated with increased emissions from low reservoir elevations.

Response

Reclamation acknowledges that reductions in water deliveries under the alternatives could result in increases in fallowed agricultural acreage and that, under certain conditions, fallowed lands may contribute to fugitive dust emissions. The Final EIS has been revised to expand the discussion of the relationship between fallowed agricultural lands and potential air quality impacts. Specifically, **TA 7**, Air Quality, now incorporates a screening-level evaluation of fugitive dust emissions from fallowed acreage using generalized emission factors derived from U.S. Environmental Protection Agency guidance (AP-42). This addition provides a representative range of potential PM_{10} emissions per acre of fallowed land. The Final EIS further clarifies the relationship between the air quality analysis and the fallowed acreage estimates presented in **TA 16**, Socioeconomics. Due to uncertainty in the location and extent of fallowing, the analysis remains regional rather than site-specific, which

is consistent with NEPA requirements. For more information on the geographic scope, see **Section R.3.19** theme response.

The Draft EIS addresses climate projections through hydrologic modeling that reflects observed and projected reductions in flows. The analysis evaluates how these conditions influence reservoir elevations, and hydropower generation. NEPA does not require attribution of specific hydrologic changes solely to climate trends where those effects are already embedded in the modeling framework. The analysis uses operational thresholds (e.g., minimum power pool elevations) as proxies to evaluate air quality and greenhouse gas impacts. Specifically, the shoreline exposure and associated emissions metrics are based on conditions corresponding to minimum power pool elevations. Accordingly, the Draft EIS takes a reasoned and technically supported approach to evaluating reservoir conditions, climate-related stressors, and associated air quality impacts. Additional figures showing long-term reservoir elevation trends have been added to strengthen the analysis.

The Technical Appendices include a comprehensive regional-scale analysis using established modeling methods, emissions estimates, and exposure indicators. The level of detail is appropriate for the scale and scope of operations considered in this EIS and supports comparison of alternatives. Community-by-community analysis is not appropriate because the project affects air quality at a broad, regional scale across multiple air basins. Additionally, the localized effects on air quality would depend on decisions by individual water users that are unknown and/or beyond Reclamation's control, e.g., voluntary participation in conservation activities. The analysis instead relies on regional modeling, emissions estimates, and surrogate exposure indicators (such as $PM_{2.5}$ concentrations and shoreline exposure) to capture potential impacts. This approach aligns with NEPA guidance and avoids misleading precision that would result from attempting highly localized predictions given uncertainties in emissions, hydrology, and atmospheric processes.

R.3.27 Dams and Electrical Power

Theme Summary

Commenters requested that operations maintain protective elevations to ensure reliable hydropower at Glen Canyon Dam and Hoover Dam. They asked Reclamation to clarify minimum power pool constraints. There were requests to analyze the impacts on the hydropower market and rates, including the consequences for the Basin Fund. Commenters also emphasized the need to prioritize proactive infrastructure planning and ensuring reliable releases at low elevations. In addition, they requested evaluation of bypass options or phased decommissioning scenarios, as well as wear and maintenance needs under extended low elevations. Additional requests were made to clarify the legal status of hydropower's role relative to Compact compliance. Finally, commenters asked for an evaluation of additional upstream and downstream facilities, including the downstream safety implications of flow variability at Davis Dam and of extended low-flow operations at CRSP facilities.

Response

Reclamation recognizes the need to clarify minimum power pool and turbine operability constraints by evaluating how often, how long, and how severely reservoir elevations fall below key operational

thresholds under different management approaches. **TA 15,** Dams and Electrical Power Resources, provides figures such as **TA 15-13**, illustrating how frequently Lake Powell remains above elevations necessary for sustained turbine operation, while **Figures TA 15-11** and **TA 15-6** show how turbine availability and generating capacity at Lake Mead/Hoover Dam decline as reservoir levels decrease. Together, these results demonstrate that protective elevation thresholds are used as risk-screening tools to understand infrastructure vulnerability and operational tradeoffs under uncertain future conditions, rather than as fixed operational requirements that dictate reservoir management. Operations and management plans are ongoing and evolving to the conditions of lowered water elevations.

Within **TA 15**, **Section TA 15.1.3** evaluates the infrastructure conditions and operational capabilities of the dams analyzed in this study. Reclamation utilizes the Dam Safety Priority Rating (DSPR) system at all dams evaluated in this analysis to conduct routine monitoring, support maintaining infrastructure, and identifying any potential risk. Under this system, Glen Canyon Dam and Hoover Dam were rated as a DSPR 5 category, indicating a low-priority level with normal urgency of action. This reflects that no immediate safety concerns have been identified. Davis Dam and Parker Dam were equally classified as a DSPR 4 Category, indicating a low urgency of action. Both dams were magnitude below Reclamation's PPG threshold. Both dams were determined to be in good overall condition and do not display any risks to safety.

Extended low-flow operations have been modeled by the Western Area Power Association at CRSP facilities, and potential effects on the Upper Colorado River Basin Fund. Concepts such as bypass construction or phased decommissioning represent separate, long-term infrastructure planning considerations that would require independent engineering evaluation, legal review, and project-specific environmental analysis outside the scope of this EIS.

Rate impact analyses have been developed to help evaluate how forecasted hydrologic and operational outcomes may influence market conditions and financial pressures under sustained low-storage scenarios at dams evaluated in this study. Updated modeling for Glen Canyon Dam and Hoover Dam, with clarifying language, is available in the Final EIS and **TA 15** addressing Wholesale Rate Analysis, Power Marketing, and, for CRSP and Glen Canyon Dam, discussion of considerations for the Basin Fund.

R.3.28 Geomorphology and Sediment

Theme Summary

Commenters expressed support for establishing a maximum monthly release volume to reduce the potential for sediment scour. They also supported a requirement for HFEs to occur within a specified time period after sediment delivery thresholds are met. Additionally, commenters suggested adopting binding HFE criteria that are aligned with sediment conditions and timing that reflects a natural hydrograph. They requested expanded analysis of system-scale sediment balance and sediment processes within Lake Powell, including delta evolution, storage loss, and mobilization under low pools.

Response

Reclamation acknowledges the recommendations for a fixed monthly release limit to protect sediment for HFEs and fixed timing for HFEs. The EIS evaluates operational guidelines and strategies and recognizes that future operations must remain responsive to hydrology, system conditions, and applicable legal and operational requirements. Reclamation will use LTEMP guidelines, including the planning and implementation team process that helps assess monthly release volumes. Existing LTEMP guidelines were incorporated in the modeling for the EIS analysis, and modifications to the LTEMP framework are outside the scope of this analysis.

The EIS is focused on post-2026 guidelines and coordinated management strategies for Lake Powell and Lake Mead. A basin wide sediment management plan for the entire CRSP system would be a broader effort outside the scope of this EIS.

Since 1963, Lake Powell has lost approximately 1.8 maf (6.8 percent) of storage capacity (Root and Jones 2022), with most sediment deposited in upstream areas above elevation 3400 feet. As reservoir elevations decline under all EIS alternatives, sediment deltas in Glen Canyon National Recreation Area are increasingly exposed, eroded, and incised by river channels, particularly along the Colorado River and major tributaries. These processes are already documented in the EIS with respect to visual resources, shoreline conditions, invasive vegetation, and exposed sediment surfaces. Quantitative prediction of sediment redistribution under alternative reservoir levels would require a reservoir-scale sediment transport model, which does not currently exist for Lake Powell. While continued reservoir lowering is expected to increase delta erosion and downstream redeposition of sediment, this redistribution does not change total sediment volume. If deltaic sediments shift from upstream areas into deeper portions of the reservoir, the migration of such sediments is not expected to impact withdrawals from Glen Canyon Dam. While available data and modeling limitations constrain quantitative assessment of alternative-specific sediment behavior within Lake Powell, Reclamation has clarified in the EIS that Lake Powell has sufficient dead storage capacity to trap most incoming sediments, with only a small amount reaching areas near the Glen Canyon Dam. Thus, sedimentation is not projected to impact dam safety, power generation, or the sediment concentration of Glen Canyon Dam during the analysis timeframe of this EIS.

R.3.29 Hydrologic Resources

Theme Summary

Commenters requested an expanded quantitative groundwater analysis, including groundwater levels, pumping, subsidence, water quality, springs, alluvial aquifers, and secondary impacts from increased groundwater pumping to offset surface water shortages.

Commenters also requested analysis of daily flow, ramping, and timing effects in the Grand Canyon, and asked that the timing, frequency, and duration of resource impacts receive the same level of attention as whether impacts occur at all.

Additional comments addressed Upper Basin and Lower Basin conservation pools, requesting more detailed analysis of their effects and greater clarity on how conservation activities influence reservoir

storage, releases, and system water, including how often conservation tools are used and how they help mitigate risk.

Response

The EIS recognizes the role of groundwater in supporting surface water processes, ecosystems, and water supplies. Regional-scale changes to groundwater are complex and difficult to quantify without extensive data records and groundwater models, and current data on groundwater at a regional scale is limited in both scope and historical duration. As a result, groundwater conditions, including levels, pumping, and connectivity to surface waters, are addressed at a qualitative level where applicable. Where more recent groundwater data is available, it has been used to explore trends near Lake Powell (**Section TA 3.1.3**) and Lake Mead (**Section TA 3.1.6**), drawing on the Arizona Department of Water Resources' groundwater site inventory.

With respect to the timing, frequency, and duration of resource impacts, the metrics and thresholds used in this analysis reflect the most important dimensions of system performance without implying more certainty than is warranted. Including additional analysis of the timing and duration of impacts would emphasize outcomes that are highly dependent on the specific sequencing of future flows and would therefore be more speculative than the analyses presented in the EIS. Robustness figures presented in the EIS are broken out by decade to provide insight into how performance may vary over time, and the text describing these figures has also been revised for clarity in response to comments. Daily flow, ramping, and timing effects in the Grand Canyon, however, are outside the scope of this EIS.

With respect to conservation pools, analysis of the effects of conservation activity on Lake Powell and Lake Mead storage can be found in **Figures TA 3-16** and **TA 3-17**, respectively. This includes the effects of both Upper Basin and Lower Basin conservation mechanisms. Additional information on the conservation mechanism is provided in **Section R.3.8**, Lower Basin Conservation and Storage and Delivery of Conserved System and Non-System Water.

R.3.30 Indian Trust Assets

Theme Summary

Tribes expressed concerns that the Draft EIS does not adequately address the Federal Government's trust responsibility because there may be water shortages to tribes. Similarly, tribes expressed concerns about some alternatives not honoring their water rights, which may have senior priorities. Tribes commented that post-2026 operations must respect the U.S.'s fiduciary obligations: decreed, settled, and federally reserved tribal rights are trust property that cannot be impaired, reallocated, or subordinated through administrative guidelines. Commenters seek transparency, analysis of leasing and storage arrangements, and tools (i.e., conservation, storage, protection pools, etc.) that are voluntary, compensated, time-limited, and explicitly non-prejudicial. Tribes also noted that unquantified, undeveloped, or unused tribal water should remain attributed to tribes and not be presumed available to other users in modeling or converted to system water. Tribes noted that reductions in water allocations would reduce the ability of tribes to manage their own resources and be self-sufficient and would negatively impact culturally important farming activities. Some commenters desired more tribe-specific analysis and representation in published

figures and tables. Finally, some commenters stated that the potential socioeconomic impacts associated with potential impacts on Indian trust assets should be analyzed more thoroughly and for individual tribes.

Theme Response

Reclamation recognizes the importance of tribal sovereignty, tribal water rights, and Reclamation's trust obligations consistent with congressional directives. Reclamation also recognizes the wide range of tribal perspectives expressed in the comments. Reclamation's Proposed Federal Action would be adopted and implemented consistent with the Law of the River, as explained **in Section 1.2**. Some components of the alternatives analyzed are within Reclamation's existing authorities, and some are outside existing authorities, as explained further in **Section 2.3** and therefore Reclamation would need additional agreements or other authorities to implement some of the analyzed operations. The assumptions used in Shortage Allocation Models and Alternative Distribution Models are not intended to represent current or future policy with respect to shortage sharing or to limit Secretarial discretion to distribute shortages, as noted on Page C-5 of **Appendix C,** Shortage Allocation Model and Alternative Distribution Model Documentation.

Tribal participation in any potential conservation pools would be voluntary; any modeling assumptions regarding participation in potential conservation pools are for the purposes of modeling only and are not binding, as further explained in **Chapter 2**.

Tribe-specific modeling results related to tribal water deliveries or shortages to tribal entitlements are available for the Shortage Allocation Models and Alternative Distribution Models (see **Appendix C**). In the technical appendices, the DMDU analysis was not applied to any individual users, including tribes. This approach to analysis is appropriate given the level of uncertainty in hydrology and distribution of impacts, and because entitlement-specific results are provided in **Appendix C** for the full range of modeled shortages. The DMDU analysis is designed to provide representative information to the public to compare the modeled frequency of shortage events to groups that experience similar impacts due to water entitlement priorities. This is not intended to imply that Reclamation believes the impacts are the same to all water users in a priority group. Reclamation recognizes that potential impacts on Indian Trust Assets, particularly potential reductions in water deliveries, could have adverse socioeconomic impacts to tribes. **TA 16**, Socioeconomics, includes discussion of potential changes to agricultural and recreational economies, as well as broad negative socioeconomic consequences that are representative for tribes and others. Because of unique circumstances for each tribe, the potential socioeconomic impacts would vary by tribe but are captured within the range of impacts identified in the Final EIS.

Reclamation intends that any new tools (i.e., conservation, storage, protection pools, etc.) would be voluntary and non-prejudicial to a tribe's ability to develop and use its entitlement. Additionally, for tribal water entitlements, the operational guidelines do not lose, forfeit, or abandon the corpus of the trust asset. The trust asset would be administered as defined in the statute, decree, and/or contract defining and establishing the entitlement, including any conditions relating to the obligation of the U.S. to deliver water subject to availability under the provisions of Federal law, including the Colorado River Compact, the BCPA, and the Consolidated Decree in *Arizona v. California*. Shortage administration of the entitlement would not limit greater future deliveries to tribes under improved

hydrology in normal or surplus Colorado River conditions, nor would it alter the applicable authority that defines the entitlement. Nor do the guidelines alter or amend any Indian water rights settlements or decrees, nor preclude or limit future Indian water rights settlements. Nothing in the analysis should be construed to limit ongoing or future quantification or development of tribal water rights.

R.3.31 Population and Land Use

Theme Summary

Commenters stated that the Draft EIS does not adequately explain how modeled reductions in domestic (municipal) water deliveries, particularly in Arizona and other Lower Basin municipal service areas, could affect population- and land-use-related outcomes, including concrete economic and social consequences. Commenters stated that the Draft EIS presents modeled delivery reductions but does not adequately explain what those reductions could mean for specific industries and users, development, housing, essential services, operations, adaptation efforts, and broader socioeconomic conditions. To reflect the wide-ranging themes raised by commenters and support efficient cross-referencing to summary responses, the discussion is organized using subheaders.

Development, housing, and growth plans: Commenters stated that reduced reliability of domestic water delivery could constrain residential and commercial development and affect housing supply in communities. Commenters emphasized the role of planning and regulatory requirements for reliable water supply and stated that reduced domestic water reliability could affect the ability of communities to meet existing plans for growth and development.

Existing communities and essential services: Reduced reliability of domestic water delivery could affect existing residents and essential services, including potable water, sanitation, fire protection, and other critical community functions. Commenters also raised concerns that an abrupt or severe domestic shortage could occur and impact essential services.

Infrastructure and operational thresholds: Municipal systems and conveyance/treatment infrastructure and distribution systems may not be designed to accommodate abrupt or deep reductions, and that short-duration disruptions can create operational challenges that differ from long-term average conditions. Commenters highlighted operational thresholds and system constraints and requested clearer discussion of how infrastructure constraints could affect community outcomes, particularly under extreme Shortage Conditions.

Adaptation capacity: Several commenters highlighted that adaptation capacity varies widely by provider and location, noting that while conservation and portfolio management can reduce vulnerability, other responses may be limited by physical availability, legal/jurisdictional constraints, cost, and the time required for planning, permitting, financing, and implementation.

Conservation and demand: Some commenters emphasized that population and land use are not direct proxies for water demand and that conservation and demand management can decouple water use from population growth. Others noted that existing conservation efforts and remaining

conservation potential vary by community, affecting how shortages may translate into land-use-related outcomes.

Model interpretation and limitations: Some commenters questioned how domestic deliveries are modeled and how results are interpreted and requested a clearer explanation of assumptions and limitations. Commenters also raised concerns about how the analysis treats extreme conditions and key thresholds and how such conditions could affect municipal reliability and community outcomes.

Secondary effects: Commenters requested more explicit consideration of secondary effects, including economic pressures, housing affordability, local tax base implications, land conversion pressures, and impacts on public services and community well-being. Some commenters also described indirect pathways tied to substitution (e.g., increased reliance on groundwater and associated depletion/subsidence/water-quality concerns) and broader community consequences.

Economic analysis: Many commenters also requested more robust, quantitative analysis of economic impacts on municipal and industrial sectors. Commenters requested Reclamation implement a range of approaches to quantify domestic water delivery impacts, including but not limited to, macroeconomic and regional economic impact analysis; sector-specific impact analysis; municipal- or utility-level economic analysis; housing and development quantification; infrastructure cost and damage estimates; public health and essential services quantification; adaptation cost and feasibility analysis; distributional or equity impact analysis; national or supply-chain impact analysis; and temporal and risk-based quantification.

Agricultural Lands Use: Commenters requested review of baseline data related to irrigated lands. In addition, they requested additional information regarding impacts on the agricultural system as a whole. Some commenters requested information pertaining to Upper Basin geographies as well as analysis of groundwater as a replacement source and potential for crop-switching.

Theme Response

Development, housing, and growth plans: The Final EIS has been revised to clarify that potential impacts could include changes to planning assumptions for water supply related to residential and commercial development and links the discussion to modeled delivery outcomes reported in **TA 4,** Water Deliveries.

Existing communities and essential services: The Final EIS has been revised to further clarify the potential qualitative impact from reduced municipal delivery reliability and recognizes that the feasibility and timing of adaptation vary by community. The Final EIS also recognizes that reduced municipal delivery reliability may affect essential services and public health and safety in some communities, particularly under severe or rapid shortage, and acknowledges that local emergency response planning and implementation actions would occur outside the scope of this EIS.

Infrastructure and operational thresholds: Reclamation recognizes that severe or abrupt delivery reductions can create operational challenges for conveyance and treatment systems and may affect service reliability depending on local infrastructure and operational constraints. The Final EIS

discusses these effects as qualitative pathways linked to modeled delivery outcomes; due to data limitations, it does not adopt facility-specific cost or damage estimates.

Adaptation capacity: The Final EIS recognizes that adaptation measures (e.g., new supplies, infrastructure, treatment, interconnections, and financing) can require substantial time and resources and may not be available on the same schedule for all communities. Accordingly, the Final EIS discusses adaptation feasibility qualitatively and focuses on the modeled frequency and magnitude of delivery reductions to characterize exposure, while noting that specific local project decisions would occur outside the scope of this EIS.

Conservation and demand: The Final EIS clarifies that population and land-use context are not treated as direct proxies for consumptive water demand. The Final EIS recognizes that conservation and demand-management measures can decouple water use from population growth and uses modeled shortage and conservation outputs to describe potential future conditions.

Model interpretation and limitations: The Final EIS acknowledges that Shortage Allocation Model and Alternative Distribution Model results reflect the modeled allocation frameworks and assumptions documented in **Appendix C,** Shortage Allocation Model and Alternative Distribution Model Documentation, and do not represent all possible future place of use transfers or programmatic adjustments; therefore, the Final EIS uses **TA 4,** Water Deliveries, outputs to describe exposure and potential pathways for effects while identifying limitations where appropriate. The Final EIS also addresses key reservoir elevation thresholds and associated operational risks through the robustness and vulnerability analyses and resource-specific evaluations.

Secondary effects: Reclamation acknowledges that secondary effects may extend beyond direct domestic delivery changes. Where these outcomes are raised as reasonably foreseeable pathways, Reclamation addresses them qualitatively and, where appropriate, notes that such effects may be influenced by connected actions and cumulative effects outside Reclamation's direct authority, consistent with the framing in **Appendix R**, **Section R.3.21**.

Economic analysis: The Final EIS discusses domestic water delivery impacts as indicators of potential effects on communities and land-use related conditions by providing a qualitative discussion of municipal impact pathways using the modeled delivery-reliability and shortage outputs from **TA 4**, Water Deliveries, and documents limitations in **Appendix C,** Shortage Allocation Model and Alternative Distribution Model Documentation. This approach recognizes that local outcomes depend on many factors outside federal operational control (including land-use decisions, provider-specific portfolio composition, and the timing and feasibility of adaptation measures).

Reclamation acknowledges concerns about potential effects on industrial and manufacturing sectors and other industries that rely on water supplies. The Final EIS has been revised to clarify the socioeconomic connection between modeled domestic water deliveries and employment sectors that rely on domestic water. It does not adopt sector-specific production or employment forecasts without consistent, comparable datasets and modeling inputs across the analysis area.

Agricultural Land Use: Baseline data was reviewed per comments and verified to accurately represent the cited data. Reclamation added an acknowledgment that other industries, such as

transportation and warehousing, manufacturing, which rely on the farming industry, could experience additional impacts. Broader economic relationships and indirect effects of changes in agricultural activity are addressed at a summary level in the Socioeconomics analysis (**Section 3.16**).

It is not possible to do a quantitative analysis on the impacts from switching to groundwater due to the uncertainties surrounding the quantity of groundwater switching, groundwater availability, and groundwater cost. See **Section R.3.19**, Scope, related to Upper Basin analysis.

The analysis addresses adaptive actions at a programmatic level to describe potential changes in land use patterns and consumptive water use. The Final EIS does not assume crop substitution is feasible or would result in sustained consumptive use reductions in all cases, and it does not distinguish quantitatively between crop substitution and fallowing in the land use analysis.

R.3.32 Recreation

Theme Summary

Commenters requested that the analysis be expanded to include recreation areas and resources beyond the defined analysis area, such as tributaries to the Colorado River, downstream national park infrastructure, and river-based recreation below Parker Dam. In addition, some commenters suggested reevaluating optimal flow ranges for whitewater boating based on available literature. Others requested further analysis of sediment-related hazards, including features such as perched channels and waterfalls, and their implications for whitewater recreation.

Response

Reclamation acknowledges the request to analyze additional recreational resources beyond those within the defined analysis area. The recreation analysis is consistent with the geographic scope defined in **Section 3.2.1**, Geographic Scope, of the EIS. Tributaries to the Colorado River are beyond the scope of the EIS. Recreational uses below Parker Dam are described in **Section TA 14.1.6**, **TA 14.1.7**, and **TA 14.1.8** of **TA 14**, Recreation. Flows below Hoover Dam are consistently low due to upstream diversions and delivery obligations. As a result, the range of operational changes evaluated across the alternatives would not meaningfully alter flow conditions in a manner that would measurably affect recreation opportunities in this reach. This rationale has been added to **TA 14**, Recreation.

The analysis relies upon available studies and the best available scientific information. These sources and literature were reviewed again, and it was determined that optimal flow ranges reported in the analysis were consistent with reported whitewater boater preferences.

In response to comments requesting analysis of sediment-related hazards to whitewater boating, Reclamation acknowledges that changing sedimentation dynamics resulting from low water have resulted in the creation of waterfalls, including the Piute Farms Waterfall and Pearce Ferry Rapid, which are acknowledged in the EIS as they relate to fish passage, and in **TA 14**, Recreation, in relation to whitewater navigability. Additional discussion regarding the potential development of another waterfall near Hite has been added to the EIS and **TA 14**.

R.3.33 Socioeconomics

Theme Summary

Note that comments related to concerns about economic analysis of municipal and industrial impacts are addressed under the theme summary and response in **Section R.3.31**, Population and Land Use. Comments related to concerns about impacts on economic conditions from changes in hydropower generation at Lake Powell are addressed under the theme summary and response in **Section R.3.27**, Dams and Electrical Power.

Commenters expressed concern that certain impacts on economic and social conditions from changes in agriculture were not included in the analysis, such as impacts on indirect industries, health and education services, the well-being of communities from potential increases in dust, and the national food supply chain. They recommended inclusion of additional sector-specific data sources and reports, additional costs that agricultural entitlement holders would incur, and recognition that agricultural decisions extend beyond simple fallowing of least-profitable crops. Some commenters are concerned that the analysis of socioeconomic impacts did not fully represent the magnitude and severity of impacts from changes in agriculture, especially when the results represented the fallowing of entire crops or acreages in a region. Other commenters requested consideration of conservation programs and adaptation measures, such as crop switching or conservation incentives, that would likely be used to lessen the reported impacts. Commenters expressed concern that the impacts on economic and social conditions from changes in agriculture were inaccurate because the analysis considered changes in water deliveries to agricultural entitlement holders, rather than changes in water deliveries to end users through certain leasing or transfer arrangements with the entitlement holders. Additionally, commenters requested that the results of the analysis be provided on a more granular scale than state-level.

Commenters further noted that recreation, particularly on Lake Powell, Lake Mead, and the Colorado River, represents an important economic contribution to the region and that a reduction in water in the reservoir would impact the tourism industry and the communities that depend on it. They also noted the economic importance of hydropower operations. Commenters also requested the addition of analysis related to recreation economic contributions associated with Lake Mohave and Lake Havasu and the vicinity of these areas.

In addition, commenters requested that Reclamation revise the socioeconomic discussion to include a more comprehensive analysis of the market and non-market river recreation values, as well as a review of non-market analysis to ensure consistency with other resource sections.

Theme Response

As discussed in **Section TA 16.2.1**, the modeling of impacts on economic conditions from changes in agriculture includes indirect impacts, which are impacts that result from changes in economic activity in industries that sell inputs to the industries that may be directly affected (for example, indirect impacts include changes in supply purchases made by agricultural producers or farmers). To provide context to the impacts analysis and address commenters' concerns, in the Affected Environment of the Final EIS, Reclamation added an acknowledgment that the farming industry supports other non-farming industries such as the transportation and warehousing, manufacturing

(including food manufacturing), and retail trade (including food and beverage and grocery stores) industries. In **Section TA 16.2.2** of the Draft EIS, there is a discussion about the impact on quality and access to nonmarket values and social conditions from changes in water allocation for irrigation entitlement holders, including impacts on affordable health and dental care. In the Final EIS, Reclamation added additional detail that there could be impacts on funding to support public services such as education and that these impacts could affect communities that rely on agriculture to support the economy and public services. Additionally, to address the concerns of commenters, in the Final EIS, Reclamation added an acknowledgment of the impacts on the national food supply chain due to changes in regional and local agriculture as well as the impacts on communities' quality of life from changes in dust associated with increased fallowed lands.

In the Final EIS, Reclamation referenced the reports provided and added a table with the new data source as well as added qualitative discussions on the assumption of fallowing lower valued crops first and the additional costs associated with fallowing that agriculture entitlement holders could incur.

To address the views that the analysis did not fully represent the magnitude and severity of impacts from changes in agriculture, in the Final EIS, Reclamation added additional detail highlighting the alternatives and shortage levels that would result in the potential fallowing of entire crops or acreages in a region.

To address commenters' requests to consider conservation programs and adaptation measures, Reclamation clarified that although the analysis does not assume funding or incentives for fallowing or conservation—as compensation measures are out of scope of this EIS—conservation programs and adaptation measures could be implemented in the future and would lessen the impacts discussed in the EIS. Additionally, as discussed in the Assumptions subsection of **Section TA 16.2.1** of the Draft EIS, Reclamation acknowledges that there could be crop switching rather than crop fallowing as a response to irrigation water shortages; however, the assumption that farmers would fallow irrigated crops in response to water shortages provides a bound to the analysis and any changes in this assumption would likely result in fewer impacts than discussed.

As discussed in the Assumptions subsection of **Section TA 16.2.1**, the Shortage Allocation and Alternative Distribution Models do not attempt to replicate arrangements where an entitlement holder leases its entitlement to other end users, and Reclamation cannot predict how the entitlement holder and its lessee(s) would respond to shortage. In the Final EIS, Reclamation added a note that if an entitlement holder leases water to another type of user, then a shortage in water deliveries would likely result in a financial impact on the entitlement holder as well as an impact from a reduction in water availability on the end users, similar to those impacts discussed for agricultural end users or discussed in **TA 17**, Population and Land Use, for municipal and industrial end users. The economic impact of the reduced delivery to the lessor would be to some degree mitigated by the financial payment from the lessee, while the benefits to the lessee of increased water delivery would possibly exceed the negative economic impact of reduced deliveries to the lessor.

Regarding the granularity of the analysis, the analysis was conducted commensurate with the level of decision making and based on the best available data at the time of the report. While the magnitude

of impacts might vary across entitlement holders, the nature and type of impacts that are discussed in the Draft EIS are consistent across all entitlement holders. In the Final EIS, Reclamation acknowledges that impacts on economic and social conditions from changes in agriculture across the alternatives vary across priority groups within each state, and Reclamation revised the results shown in **TA 16**, Socioeconomics, of the Final EIS to show impacts by priority group within each state as well as at the state level. Priority groups are used to represent the individual entitlement holders who would experience similar application of potential shortages under a given shortage scenario as defined in the Shortage Allocation Model and Alternative Distribution Model (**Appendix C**).

Recreation economic analysis was included in the Draft EIS at a level corresponding to that of a programmatic analysis (see **Section 3.16** and **TA 16** for economic contributions of recreation and tourism). Additional analysis related to economic contributions from recreation below Hoover Dam was not included as flows below the Dam are consistently low due to upstream diversions and delivery obligations. As a result, the range of operational changes evaluated across the alternatives would not meaningfully alter flow conditions in a manner that would measurably affect recreation opportunities or associated economic contributions in this reach.

R.3.34 Cultural Resources

Theme Summary

Commenters raised concerns about how reservoir operations and fluctuating water levels affect cultural and archaeological resources, noting that both shoreline exposure and re-inundation can damage or degrade sites. Commenters also called for improved transparency in the cultural resources analysis, including discussion of the limitations of survey coverage, clearer explanation of the preservation risk model, and continued government-to-government consultation with tribes to ensure culturally significant resources are accurately identified and protected.

Response

Reclamation acknowledges that changing water levels at Lake Powell and Lake Mead may expose previously undocumented cultural resources and that the potential effects of post-2026 operating Guidelines upon such cultural resources are not yet fully known, in large part because uncontrollable hydrology will determine such effects. The analysis incorporated available information from existing studies, prior consultation, cultural resources inventories, tribal input received during scoping and ongoing consultation, and resource analyses prepared for related Colorado River operation programs. As described in the Draft EIS cultural resource analysis, Reclamation conducted a Class I cultural resources inventory, consisting of a records search and literature review of previously identified cultural resources and prior survey efforts along the Colorado River corridor to help inform the analysis, identify data gaps and areas with limited survey coverage, and support development of the preservation risk model.

Section 106 of the NHPA requires that federal agencies consider the effects of their projects on historic properties and consult with stakeholders to avoid, minimize, or mitigate potential adverse effects. Reclamation, in consultation with the Arizona, California, Utah, and Nevada State Historic Preservation Offices, land managing agencies, tribes, and other consulting parties, is currently developing a programmatic agreement in accordance with Section 106 of the NHPA to address

potential adverse effects from post-2026 operating guidelines. The programmatic agreement is intended to establish a framework for ongoing identification efforts, consultation, monitoring, and treatment of historic properties that may be affected by the implementation of post-2026 operating guidelines. Reclamation will continue to engage with tribes and consulting parties throughout this process to help ensure that culturally significant resources are properly identified and considered.

R.3.35 Tribal Resources

Theme Summary

Commenters, including tribal representatives, stated that impacts on tribal resources should be analyzed at the tribe-specific level with explicit linkages between operational alternatives and ecological, cultural, subsistence, and spiritual uses, unique to each tribe. Commenters also request recognition of landscape-scale traditional cultural properties (e.g., Grand Canyon), emphasizing that these areas hold cultural, spiritual, and ecological significance extending beyond individual sites. Commenters recommended integration of Indigenous ecological knowledge and tribal perspectives into the analysis and decision-making process and further protections for trails and traditional water systems (e.g., acequias).

Theme Response

Reclamation recognizes that tribes maintain unique cultural, spiritual, ecological, and subsistence relationships with lands and waters within the Basin and that these relationships may vary substantially among tribes. The analysis in the Draft EIS was intended to evaluate potential environmental impacts at a programmatic operational level appropriate to the development of post-2026 operating guidelines and analyzed categories of potential effects associated with changes in reservoir elevations, hydrologic, and river operations across the Basin.

Portions of the affected area, including resources within the Grand Canyon corridor, are subject to ongoing consultation, monitoring, and treatment measures under the Glen Canyon Dam LTEMP Programmatic Agreement (PA). The LTEMP PA and corresponding Historic Preservation Plan provide an established framework for continued consultation with tribes and consulting parties regarding cultural resources and traditional cultural properties affected by operations associated with Glen Canyon Dam. Reclamation anticipates coordinating, as appropriate, with existing commitments and processes under the LTEMP PA to support continued consideration of effects in areas where authorities and agreements may overlap.

Reclamation acknowledges that certain areas of the Basin have been identified by tribes as traditional cultural properties or broader cultural landscapes that possess cultural, spiritual, historical, and ecological significance. Reclamation recognizes that the significance of these areas may derive not only from the presence of individual archaeological sites or historic properties, but from the interconnected character of the landscape as a whole, including natural features, traditional use areas, trails, water sources, and cultural relationships. Areas such as the Colorado River and the Grand Canyon have been identified by tribes as possessing this type of landscape-scale cultural significance, and Reclamation will continue to consider tribal input regarding these resources through ongoing consultation and related compliance processes, including Section 106 of the NHPA and coordination under existing agreements such as LTEMP in applicable areas.

Reclamation is grateful for the efforts tribes have made to consult on this EIS, and Reclamation remains committed to consultation with tribes throughout the NEPA and Section 106 processes and will continue to coordinate with tribes regarding culturally significant resources, traditional knowledge, and potential effects to tribal interests. Tribal input received through consultation helps inform Reclamation's understanding of culturally important places, traditional resource uses, trails, water systems, and other features and considerations that may not be fully captured through conventional archaeological or environmental review methods. Information provided through consultation, where appropriate and consistent with tribal confidentiality concerns, may inform future identification efforts, management strategies, and implementation measures. Impacts on vegetation, fish, and wildlife are addressed in other sections.

R.3.36 Vegetation

Theme Summary

Commenters requested a more comprehensive and transparent analysis of vegetation and wetlands, including a better definition of historic conditions, clearer explanations of modeled results, and updates to acres exposed since 2011. Commenters noted the lack of detailed information about where impacts would happen and how many acres could be affected. Commenters also requested that additional information regarding newly exposed side canyons around Lake Powell be added to the analysis.

Response

The EIS was updated to address comments regarding wetlands and vegetation to clarify the analytical approach used to establish baseline conditions and effects under each alternative. The vegetation analysis evaluates marsh and woody riparian vegetation using the DMDU framework to assess potential impacts across alternatives under highly uncertain conditions. Given the high level of hydrologic uncertainty, it is difficult to predict under each alternative exactly where or how much habitat might be lost or gained over the 34-year time period. Therefore, results are provided as a comparative analysis rather than species-specific or site-specific evaluations. Where long-term monitoring data is available, the analysis includes modeled estimates of suitable habitat for marsh and woody riparian habitat. Additional information was added to the EIS to further address impacts to newly emerged side canyons around Lake Powell.

R.3.37 Visual Resources

Theme Summary

Commenters requested additional analysis of the visual impacts related to dead pool conditions at Lake Powell, recognition of re-emerging side canyons becoming available for recreation access, and broader inclusion of "attraction features" or other viewing locations in the analysis.

Response

Text was added discussing the re-emergence of side canyons, directing readers to the Recreation section regarding public access related to reservoir inundation, and clarifying the "attraction features" concept, with additional viewers (viewing locations) currently described under Issue Statement 2. The concept of Lake Powell reaching dead pool elevation is described under Issue

Statement 3 as the effects on visual character would occur from water being unable to flow past Glen Canyon Dam, affecting landscape character along the Colorado River and downstream, therefore no additional analysis has been included.

R.3.38 Water Deliveries

Theme Summary

This section summarizes comments on the framing and analysis of the water deliveries section of **Chapter 3** and **TA 4**, Water Deliveries. Comments related to the volume and distribution of Lower Basin shortages, distribution of dead pool-related reductions, and the use of conservation mechanisms and their interaction with shortages are addressed in **Section R.3.7**, Lower Basin Shortage and Use, and **Section R.3.8**, Lower Basin Conservation and Storage and Delivery of Conserved System and Non-System Water.

Commenters requested additional information on how evaporation associated with conservation mechanisms is assessed. Commenters also requested additional information and greater transparency regarding the modeling assumptions and methodologies used to evaluate water deliveries and reservoir operations, including the reliability of water deliveries under low-flow conditions. In addition, commenters noted that dead pool-related reductions were mostly separate or absent from analyses across multiple resources and that the analysis should include information about the frequency and duration of such reductions to better demonstrate the effectiveness of operational elements across alternatives. Finally, commenters requested greater transparency regarding the minimum water deliveries available to municipal users to meet health and safety needs.

Theme Response

Reclamation acknowledges the comments requesting additional information and greater transparency regarding the evaluation of water deliveries and reservoir operations. **TA 4**, Water Deliveries, provides an overview of how water deliveries vary among the alternatives, including the effects of different shortage distribution approaches across the range of modeled hydrologic conditions. For more detailed information on how different shortage distribution methods represented by the alternatives affect water deliveries to individual water users by priority group, see **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, which documents the modeling assumptions and results used to evaluate alternative approaches to distributing Colorado River water supplies under the alternatives analyzed in this EIS.

TA 4 has also been revised to improve transparency regarding the effects of conservation activity modeling assumptions on Lake Mead dead pool-related reductions (see **Figure TA 4-6**). Information describing the conservation mechanisms incorporated into each alternative, including the associated evaporation assessment, is provided in **Appendix B,** Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water. The volumes of water needed to meet municipal health and safety needs are highly variable depending on water user infrastructure, water supply portfolios, and many other factors. If more detailed evaluation of municipal health and safety deliveries becomes necessary in the future, Reclamation would conduct more targeted analyses and communicate the process and results to the public.

R.3.39 Water Quality

Theme Summary

Commenters requested additional information on salinity, including whether salinity impacts were considered for each alternative, and what thresholds were used to determine significance.

Commenters also requested clarifications on the description of perchlorate, including characterizing perchlorate in Las Vegas Wash flows to Lake Mead as an active and ongoing concern, removing the characterization of this contamination source as a point source, and clarifying the difference between the human health impacts associated with exposure duration to per- and polyfluoroalkyl substances versus perchlorate.

Commenters requested discussion or analysis of water quality concerns in the CAP system if deliveries are significantly reduced.

Commenters also provided general water quality comments that did not raise substantive issues requiring further response.

Response

Reclamation analyzed salinity under each alternative in **Chapter 3** and **TA 6**, Water Quality; therefore, no further changes were made to the salinity analysis.

The water quality section was updated to address concerns with the characterization of perchlorate in the EIS by noting the active and ongoing concerns with perchlorate in the Las Vegas Wash and its associated monitoring and mitigation. The water quality section was also updated to remove the description of perchlorate contamination at Las Vegas Wash as a point source and to define health impacts associated with perchlorate by its human health impacts associated with acute and intermediate exposure.

Reclamation updated **Section 3.2** to clarify the geographic scope for analysis. Reclamation also updated the methodology in the water quality section (**TA 6** and EIS **Section 3.6**) to clarify that the analysis does not include impacts on municipal users since operations of municipal water providers fall outside of Reclamation's regulatory authority and are carried out independently by these third parties. Reclamation delivers raw (untreated) water along the Mainstream and CAP, and Reclamation does not warrant the quality of Colorado River water deliveries. Groundwater in Arizona is governed by state law, which is generally outside of Reclamation's jurisdiction, with limited exceptions based in federal law. Therefore, analysis of economic impacts associated with water quality was not included in the EIS.

Reclamation did not update the EIS based on general water quality comments that did not raise substantive issues requiring further response; however, Reclamation considered these comments as part of the NEPA process.

R.3.40 Wildlife: Fish and Other Aquatic Species

Theme Summary

Commenters requested clearer analysis linking dam operations, such as flow timing, flow quantity, and release temperatures, to aquatic habitat conditions, including riparian change, erosion, and habitat complexity, that support native fish communities. Many commenters emphasized the importance of minimizing nonnative fish entrainment through Glen Canyon Dam and maintaining temperature conditions protective of native species while also supporting recreational fisheries and hatchery operations. Commenters also requested an evaluation of potential ecological effects under low-flow conditions through the Grand Canyon, including algal blooms, fish die-offs, and impacts on downstream wetlands. Additional comments recommended evaluating operational and infrastructure tools, such as reservoir elevation management, selective withdrawal, temperature control measures, barriers, and mechanical removal programs, to address invasive species risks and maintain ecological thresholds for fish and aquatic resources.

Response

The EIS evaluates aquatic habitat and fish resources using the best available scientific information and modeling approaches appropriate for basin-scale analysis under uncertain hydrologic conditions. Habitat analysis links reservoir elevation and river stage to fish habitat using stage-to-habitat relationships derived from scientific literature. These relationships connect water surface elevation to the amount and type of habitat available to fish. Surface area and longitudinal analyses were used to evaluate changes in habitat extent in reservoir and river environments, with interpretation supported by the DMDU framework. The technical appendix also describes how different lake elevations affect fish habitat by species and life-history strategies.

The EIS includes analysis of listed fish species and other species of concern, with descriptions of distribution and abundance, habitat, and life history provided in the technical appendix and Attachment. Important tributaries, such as the Little Colorado River and Havasu Creek, are also addressed for their significance to humpback chub populations.

The analysis relies on available studies, comparisons with historical flow conditions experienced by fish communities over the past several decades, species life-history information, and modeling tools such as the Smallmouth Bass Model. The analysis evaluates connections among flow, reservoir elevation, water temperature (where data are available), and the potential for nonnative fish entrainment at Glen Canyon Dam. Temperature thresholds used in the analysis include maintaining temperatures below 16 degrees Celsius to limit smallmouth bass reproduction as far downstream as the Little Colorado River and to support the rainbow trout population in the Lees Ferry reach, and above 12 degrees Celsius to support humpback chub downstream of the Little Colorado River.

The EIS evaluates alternatives prior to selecting a preferred alternative and identifies potential trade-offs among resources using the DMDU framework. Conservation measures and mitigation to address potential impacts on listed species, including risks such as nonnative fish entrainment, will be developed during the ESA consultation process through preparation of a BA for the selected alternative.

R.3.41 Wildlife: Terrestrial

Theme Summary

Commenters requested a more comprehensive and transparent analysis of wildlife and habitat impacts. They stated that the document underestimates or omits significant effects on endangered species, LCR MSCP species, migratory birds, amphibians, and other wildlife across key ecosystems such as the Lower Colorado River, Glen Canyon restoration areas, urban landscapes, and the Salton Sea. Overall, commenters requested expanded biological analysis, clearer disclosure of impacts, and stronger consideration of habitat protection and water management measures to support sensitive species.

Response

The EIS evaluates wildlife impacts based on impacts on vegetation, as determined through modeling exercises to identify where habitat may change compared to the interim guidelines period. Given the high level of hydrologic uncertainty, it is difficult to predict under each alternative exactly where or how much habitat might be lost or gained over the 30-year time period. Therefore, results are provided as a comparative analysis rather than species-specific or site-specific evaluations. Many requested actions are outside of the geographic scope or jurisdiction of the EIS.

Appendix S. Additional Description of Alternatives

S.1 No Action Alternative

Under the National Environmental Policy Act, an action agency is required to describe and analyze a "no action" alternative in an environmental impact statement (EIS). The design of a no action alternative is highly dependent on whether the proposed action would be a wholly new activity or would be a part of ongoing or continuing actions. The proposed action for this Post-2026 process represents ongoing activities because the Bureau of Reclamation (Reclamation) has been and must continue to operate the system.

In developing the No Action Alternative, Reclamation carefully reviewed the No Action Alternative included in the Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead Final EIS (2007 Final EIS; Reclamation 2007a). Consistent with that No Action Alternative, with refinements, Reclamation based the No Action Alternative in the Draft EIS on the operating guidance that was in place before the adoption of the Record of Decision for Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead (2007 ROD; Reclamation 2007b) to provide a reasonable representation of how the system would continue to operate if no additional operating guidelines were adopted.

Before the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead (2007 Interim Guidelines) were in place, the basis for operations was the LROC, under which the Secretary made a number of determinations at the beginning of each operating year through the development and execution of the AOP, including the water supply available to users in the Lower Colorado River Basin (Lower Basin) and the annual release from Lake Powell. The Long-Range Operating Criteria (LROC) does not include specific guidelines for such determinations, so the outcome of the annual determination in any particular year in the future could not be precisely known. However, a reasonable representation of future conditions under the No Action Alternative is needed for comparison to each action alternative. The modeling assumptions used for this representation are consistent with assumptions used in previous environmental compliance documents, most recently the 2007 Interim Guidelines, with appropriate refinements. The assumptions used in the No Action Alternative are not intended to limit or predetermine the decision in any future Annual Operating Plan (AOP) determination.

Under this alternative, following the expiration of current domestic and international implementing agreements in 2026, Reclamation operations are assumed to immediately revert to the assumptions embedded in the No Action Alternative beginning October 1, 2026. This approach would represent a change from current operations (which are most closely captured in the Continued Current

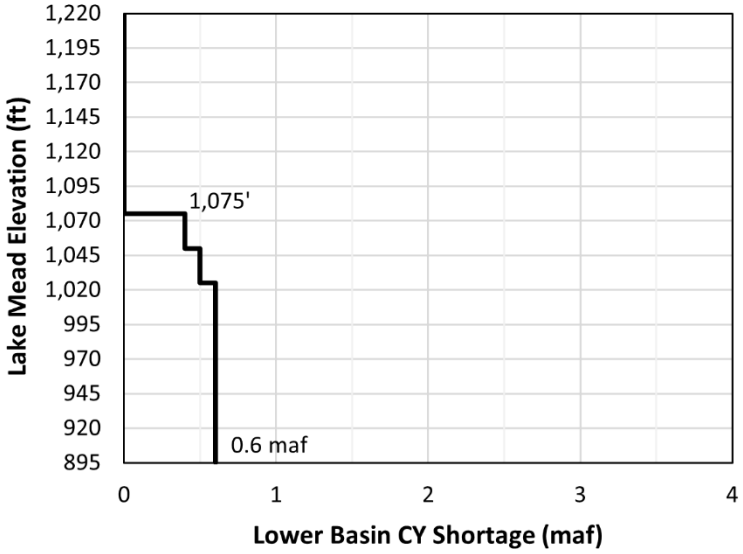
Strategies (CCS) Comparative Baseline - see **Section 3.2.3**) but would not represent a decision by Reclamation to adopt a new set of long-term operating guidelines.

S.1.1 Guidelines to Reduce or Increase Deliveries from Lake Mead

S.1.1.1. Shortage Conditions

In accordance with the Consolidated Decree and the LROC, the Secretary makes a determination each year as to whether the consumptive use requirements of mainstream users in the Lower Division States will be met under a Normal, Surplus, or Shortage Condition. The LROC specify that the Secretary will consider all relevant factors in making a shortage determination and list some of the factors to be considered. However, there is no specific guidance as to exactly when, how, or to whom reductions in deliveries would be made. Therefore, it is impossible to know exactly how the Secretary might make a shortage determination from year to year in the future.

The Consolidated Decree, the Colorado River Basin Project Act of 1968 (CRBPA), water delivery contracts, and applicable provisions of the Law of the River provide some guidance with regard to how shortages would be allocated in the Lower Basin (e.g., Present Perfected Right (PPR)[1] deliveries must be met without regard to state lines, California does not incur shortages until Arizona post-1968 contracts are reduced completely), but there are no specific guidelines in place to further inform the Secretary's decision with respect to how shortages or surplus might be shared by Arizona, California and Nevada, and water users in those states.



Considering the experience gained implementing shortages according to the 2007 Interim Guidelines, the elevations and volumes adopted in that ROD are assumed for this alternative. Operational zones are summarized below and shown in **Figure S-1**. The distribution of the shortages, summarized in **Table S-1**, would be based on the interpretation of priority from the Consolidated Decree and CRBPA;[2] not the distribution adopted in expiring guidelines. The shortage volume would be determined for the upcoming calendar year (CY) based on January 1 Lake Mead elevation.

- When Lake Mead is projected to be below elevation 1,075 feet and at or above elevation 1,050 feet on January 1, a shortage of 400.0 thousand acre-feet (kaf) would be imposed for that year.
- When Lake Mead is projected to be below elevation 1,050 feet and at or above elevation 1,025 feet on January 1, a shortage of 500.0 kaf would be imposed for that year.
- When Lake Mead is projected to be below elevation 1,025 feet on January 1, a shortage of 600.0 kaf would be imposed for that year.

[1] Certain Lower Basin Colorado River water rights are "present perfected rights" or "PPRs," which the Consolidated Decree quantified and defined as existing on June 25, 1929 (the effective date of the Boulder Canyon Project Act). PPRs are the highest priority Colorado River water rights.

[2] **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, describes assumptions associated with the Priority Shortage Allocation Model (SAM), which represents an interpretation of the lower Colorado River priority systems among and within the Lower Division states absent additional agreements.

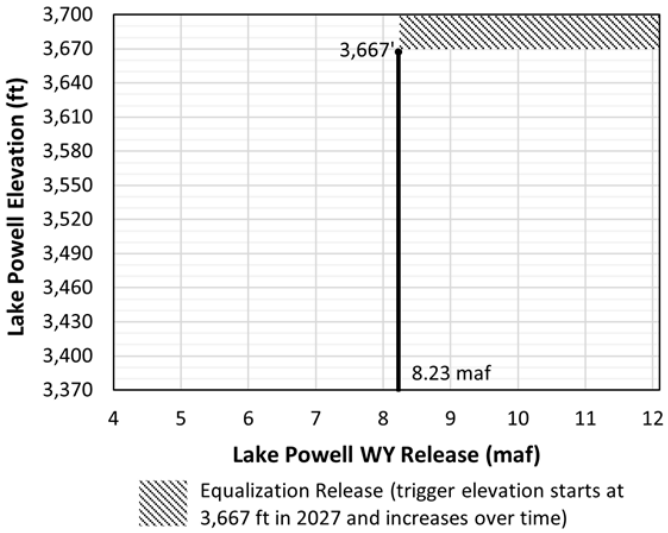
Figure S-1
Shortage* Guidelines to Reduce Deliveries from Lake Mead, No Action Alternative

Note: Shortage volumes include modeling assumptions for reductions in water deliveries to the United Mexican States (Mexico). Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 United States-Mexico Treaty on Utilization of Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Water Treaty) or to represent current United States (U.S.) policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the International Boundary and Water Commission (IBWC) in consultation with the Department of State.

Table S-1
Shortage Distribution*, No Action Alternative

Entity	Percentage of Total Shortages
Arizona	77.4
California	0
Nevada	5.93
Mexico	16.67
Total	**100**

Note: Shortage distributions include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.



S.1.1.2. Surplus Conditions

Volumes above normal apportionment would be distributed only when criteria are met in Lake Mead for a 70R Surplus Condition[3] or a Flood Control Surplus Condition.[4]

S.1.2 Coordinated Reservoir Operations (Lake Powell and Lake Mead)

The WY release volume from Lake Powell would be calculated based on the October 1 elevations of Lake Powell and Lake Mead using the curve depicted in **Figure S-2**. The curve is used to determine Lake Powell's releases in accordance with the LROC. Pursuant to the LROC, the objective is to maintain a minimum release of water from Lake Powell of 8.23 million acre-feet (maf) unless a higher release is required for equalization.

Figure S-2
Coordinated Operations of Lake Powell and Lake Mead, No Action Alternative

Article II(2) of the LROC states the "objective shall be to maintain a minimum release of water from Lake Powell of 8.23 [maf]." Reclamation recognizes that entities in the Colorado River Basin (Basin) have different legal positions regarding how this LROC statement incorporates other Law of the River elements to determine annual releases. The Secretary has expressly recognized that variation in releases of water above and below the minimum objective release of 8.23 maf can, in appropriate circumstances, be adopted (Norton 2005). The LROC expressly note that releases from Lake Powell pursuant to the LROC or any adopted guidelines "shall not prejudice the position of

[3] The 70R Strategy is a modeling approach used by Reclamation since the 1980s to understand the need to distribute additional water, and it was documented in the 2007 Final EIS. Under the strategy, a Surplus Condition is based on the system space requirement at the beginning of each year. Based on the 70th percentile historical runoff, a normal 7.5 maf delivery to the Lower Division States, the Upper Basin scheduled use, and Lake Powell and Lake Mead volumes at the beginning of the year, the volume of water in excess of the system space requirement at the end of the year is estimated. If that volume is greater than zero, a Surplus is declared.

[4] If flood control releases are anticipated to be required given the current inflow forecast, the Secretary declares Flood Control Surplus conditions for that year.

either the Upper or Lower Basin interests with respect to the required deliveries at Lee Ferry pursuant to the Colorado River Compact."

S.1.2.1. Primary Operations

If the October 1 elevation at Lake Powell is below the elevation specified by the equalization line for that year and spill avoidance releases are not required, a release of 8.23 maf would be made.

S.1.2.2. Coordination at High Elevations

A determination to potentially adjust releases from 8.23 maf for the purpose of equalizing storage in Lake Powell and Lake Mead would be made based on Lake Powell elevation using an extrapolation of the line adopted in the 2007 Interim Guidelines and documented in the 2007 Final EIS. This series of increasing Lake Powell elevations was developed as a translation of "602(a) Storage."[5] In 2027, equalization would be triggered at 3,667 feet; it would reach 3,698 feet in 2060 (the final year of the analysis period). A table showing specific years and elevations is included in **Appendix A**, CRSS Model Documentation. **Appendix J**, Sensitivity Analysis – Effects of Assumed Parameter Values on 602(a) Storage, describes the 602(a) storage calculation that forms the basis for the equalization line from the 2007 Interim Guidelines. It documents the parameters used in the 2007 calculation, which are also used in this extension through 2060. **Appendix J** also presents a comparison illustrating how different parameter assumptions would influence the resulting 602(a) storage values. If Lake Powell is above the equalization elevation in any month, water year (WY) releases would be adjusted above 8.23 maf if needed to bring Lake Powell elevation down to the equalization line based on the 2007 Interim Guidelines[6] or to equalize storage between Lake Powell and Lake Mead to the extent practicable, whichever is reached first.

S.1.2.3. Infrastructure Protection and Other Considerations

While assumptions for adjustments to Lake Powell releases to forestall reaching physical elevation 3,490 feet have not been developed for this alternative, Reclamation maintains the authority to modify operations to protect Glen Canyon Dam infrastructure.

S.1.3 Storage and Delivery of Conserved System and Non-System Water

S.1.3.1. Lake Powell and Lake Mead Mechanisms

There would be no new mechanisms to proactively conserve and store water in Lake Powell or Lake Mead.

S.1.3.2. Treatment of Pre-2027 Intentionally Created Surplus

Intentionally Created Surplus (ICS) created under the 2007 Interim Guidelines and 2019 DCP that remains in Lake Mead in 2027 would be delivered in accordance with existing agreements. Modeling

[5] CRBPA, section 602(a); LROC, section II(1). The 602(a) storage requirement specifies the amount of storage in Upper Basin reservoirs necessary to assure deliveries to the Lower Basin in compliance with the Compact without impairment to the annual consumptive use in the Upper Basin.

[6] For modeling purposes in this alternative, Reclamation intends that the equalization line concept used in the 2007 Interim Guidelines be applied and extended in the same manner as adopted in the 2007 Interim Guidelines with reference to 602(a) considerations.

assumptions for the timing of these deliveries can be found in **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water.

S.1.4 Additional Activities Above Lake Powell

S.1.4.1. Upper Basin Conservation

No Upper Colorado River Basin (Upper Basin) conservation would be included.

S.1.4.2. Releases to Protect Glen Canyon Dam

While specific assumptions for releases from Colorado River Storage Project (CRSP) Upper Initial Units have not been developed for this alternative, Reclamation maintains the authority to operate these reservoirs to protect Glen Canyon Dam infrastructure.

S.2 Basic Coordination Alternative

The Basic Coordination Alternative was designed to be implementable without agreements among Basin water users regarding distributions of lower Colorado River mainstream shortages, storage and delivery of conserved water from system reservoirs, or other voluntary agreements.

Management of the Colorado River has to date been informed by negotiated stakeholder agreements. In the absence of such agreements, efficient and sustainable management of the reservoirs and system resources under an increasingly broad range of potential future hydrologic conditions would be more challenging than under historical operations and would result in a number of highly undesirable consequences for many users.

With or without new agreements, the U.S. Secretary of the Interior (Secretary) has the vested authority and responsibility to operate the System through coordinated operations, including the ability to respond to exigent and emergency conditions, pursuant to applicable federal law, the Decree, contractual obligations, and other elements of the Law of the River. Reclamation's description of how this alternative would be implemented relies on legal, operational, and engineering judgment regarding future operations under a broad range of hydrologic conditions.

While Reclamation has experience under high-flow conditions, including flood control operations, at Lake Powell and Lake Mead, Reclamation has not had to operate these reservoirs with extreme low-flow conditions imminently threatening critical infrastructure, which makes it difficult to predict operational outcomes. Reclamation would need to balance the needs of water users with infrastructure concerns in real time under such conditions.

S.2.1 Guidelines to Reduce or Increase Deliveries from Lake Mead

S.2.1.1. Shortage Conditions

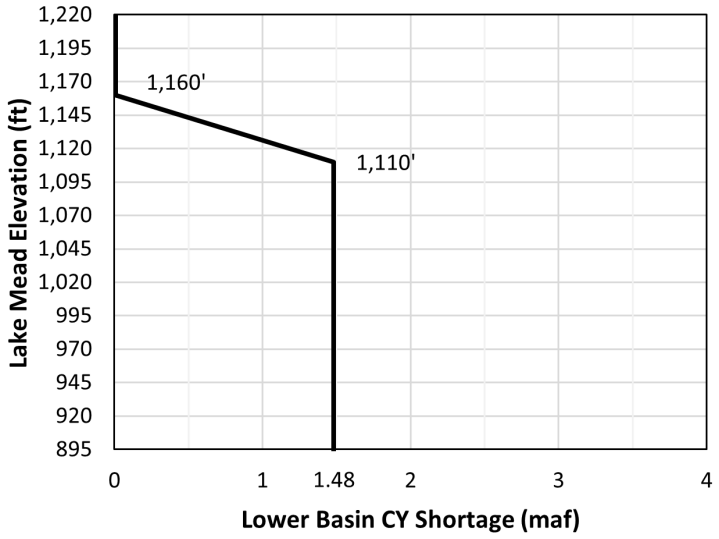
This alternative includes shortages of up to 1.48 maf, distributed based on priority (see **Table S-2**). The maximum shortage volume is set at a level estimated by Reclamation to ensure that an assumed minimum flow is available for infrastructure protection and delivery for municipal use by Central

Arizona Project (CAP) users and other Fourth Priority mainstream entitlement holders in Arizona when mainstream shortage is distributed by priority.

Table S-2
Shortage Distribution,
Basic Coordination Alternative

Entity	Percentage of Total Shortages
Arizona	77.40
California	0
Nevada	5.93
Mexico	16.67
Total	**100**

Note: Shortage distributions include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.



The shortage volume would be determined for the upcoming CY based on October 1[7] Lake Mead elevation. The shortage volumes are expressed as total Lower Basin shortage and include an assumption that the deliveries to Mexico are also reduced. The shortage guidelines are summarized below and shown in **Figure S-3**.

- When Lake Mead is at or below elevation 1,160 feet and at or above 1,110 feet, a shortage volume would be imposed for that year based on a function of elevation, with 0.0 maf of shortage at 1,160 feet increasing linearly to 1.48 maf at 1,110 feet.
- When Lake Mead is below elevation 1,110 feet, a shortage of 1.48 maf would be imposed for that year.
- When Lake Mead is approaching 1,000 feet, the Secretary would determine and implement additional measures as necessary to protect critically low elevations, consistent with the Law of the River.[8]

[7] For modeling purposes, assumptions regarding the use of projected or actual Lake Mead elevations to set operational conditions have been made. These assumptions are for modeling purposes only, and precise implementation details would be developed in a ROD.

[8] This alternative proposes that the Secretary may seek new authorities to implement additional measures to protect critically low elevations at Lake Mead including additional shortages to Lower Basin water users. The possible outcomes of such a process are unknown; therefore, for modeling purposes it was assumed that shortages of 1.48 maf would continue to be applied at Lake Mead elevations below 1,000 feet unless constrained by infrastructure. The Secretary would ensure appropriate consultation with Basin entities would occur consistent with the Law of the River.

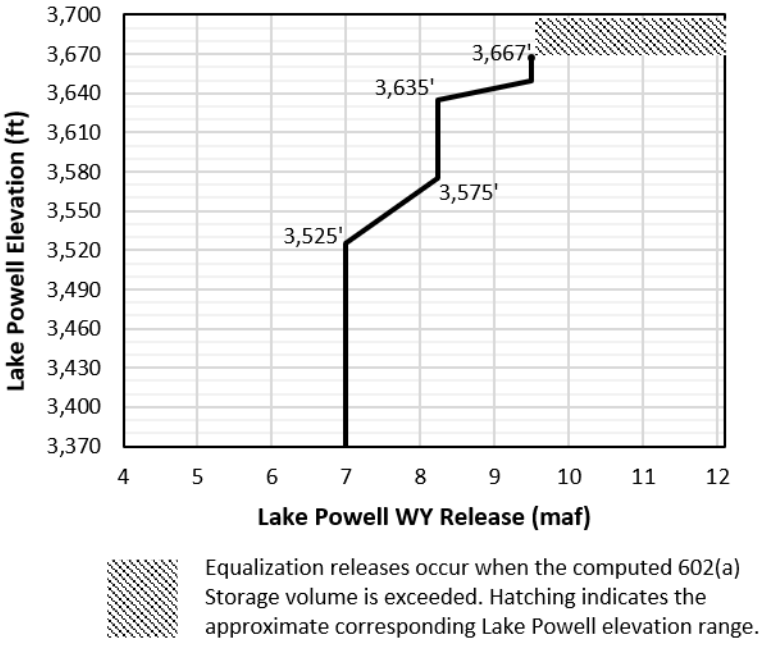
Figure S-3
Shortage Guidelines to Reduce Deliveries from Lake Mead, Basic Coordination Alternative

Note: Shortage volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

S.2.1.2. Surplus Conditions

Volumes above normal apportionment would be distributed only when criteria are met in Lake Mead for a 70R Surplus Condition or a Flood Control Surplus Condition, see footnotes 3 and 4 for details.

S.2.2 Coordinated Reservoir Operations (Lake Powell and Lake Mead)



The WY release volume from Lake Powell would be based on flexible implementation of the LROC and provides for specified releases both above and below 8.23 maf. The 2007 Interim Guidelines, designed to implement the LROC for an interim period, incorporate such an approach. The operations summarized below and depicted in **Figure S-4** represent a systematic approach to releasing 8.23 maf while protecting high- and low-elevation infrastructure.

S.2.2.1. Primary Operations

- If the October 1 Lake Powell elevation is above elevation 3,650 feet and an Equalization determination has not been made, the WY release would be 9.5 maf.
- If the October 1 Lake Powell elevation is between 3,635 feet and 3,650 feet, the WY release volume linearly increases from 8.23 maf at elevation 3,635 feet to 9.5 maf at elevation 3,650 feet.
- If the October 1 Lake Powell elevation is between 3,575 feet and 3,635 feet, the WY release would be 8.23 maf.

- If the October 1 Lake Powell elevation is between 3,525 feet and 3,575 feet, the WY release volume linearly increases from 7.0 maf at elevation 3,525 feet to 8.23 maf at elevation 3,575 feet.
- If the October 1 Lake Powell elevation is below 3,525 feet, the WY release would be 7.0 maf.
- If on October 1 Lake Powell is projected to fall below 3,500 feet within the upcoming WY, Reclamation would consider additional measures as necessary to protect critically low elevations, consistent with the Law of the River.[9]

Figure S-4
Coordinated Operations of Lake Powell and Lake Mead, Basic Coordination Alternative

S.2.2.2. Coordination at High Elevations

A determination to potentially increase releases for the purpose of equalizing storage between Lake Powell and Lake Mead is made for the upcoming year if, on October 1, the net storage of all CRSP reservoirs exceeds the 602(a) storage volume, computed using the parameters from the 2007 Final EIS. **Appendix J**, Sensitivity Analysis – Effects of Assumed Parameter Values on 602(a) Storage, describes the 602(a) storage calculation and documents the parameters used in the 2007 calculation, which are also used in this alternative. **Appendix J** also presents a comparison illustrating how different parameter assumptions would influence the resulting 602(a) storage values. Under

[9] This alternative proposes that the Secretary may implement additional measures to protect critical infrastructure at Glen Canyon Dam including further reductions to releases from Lake Powell and additional use of the CRSP Upper Initial Units. The possible outcomes of such measures are unknown; therefore, for modeling purposes it was assumed that Glen Canyon Dam would continue to attempt to release a minimum of 7.0 maf unless constrained by infrastructure. The Secretary would ensure appropriate consultation with Basin entities would occur consistent with the Law of the River.

Equalization, Lake Powell would release a minimum of 9.5 maf and may release more to balance storage with Lake Mead (see **Appendix A**, CRSS Model Documentation, for details).

S.2.2.3. Infrastructure Protection and Other Considerations

If Lake Powell is projected to fall below 3,490 feet after additional releases are made from CRSP Upper Initial Units (refer to **Section S.2.4**), Reclamation would consider adjusting operations in consultation with the Basin States to protect critical infrastructure.

S.2.3 Storage and Delivery of Conserved System and Non-System Water

S.2.3.1. Lake Powell and Lake Mead Mechanisms

There would be no new mechanisms to conserve and store water in Lake Powell or Lake Mead since agreements among Basin water users would be required.

S.2.3.2. Treatment of Pre-2027 ICS

ICS created under the 2007 Interim Guidelines and 2019 Drought Contingency Plan (DCP) that remains in Lake Mead in 2027 would be delivered in accordance with existing agreements. Modeling assumptions for the timing of these deliveries can be found in **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery.

S.2.4 Additional Activities Above Lake Powell

S.2.4.1. Upper Basin Conservation

No Upper Basin conservation would be included since it would require agreements outside of Reclamation's control.

S.2.4.2. Releases to Protect Glen Canyon Dam

If Lake Powell's physical elevation is projected to go below 3,525 feet, CRSP Upper Initial Units would increase their releases within their RODs to increase elevations at Lake Powell contingent on hydrologic conditions. Reclamation would identify triggers for when additional Upper Basin actions would be required to protect critical infrastructure. Any volumes released for the protection of Glen Canyon Dam would begin to be recovered when Lake Powell is no longer projected to go below 3,525 feet by assuming that the Upper Initial Units return to their normal annual operating targets. The frequency and volumes of the assumed releases to protect Glen Canyon Dam are assessed in **Appendix O**, Analysis of Powell Infrastructure Protection Releases.

S.3 Enhanced Coordination Alternative

The Enhanced Coordination Alternative is based on proposals and concepts from specific Basin Tribes, federal agencies (U.S. Fish and Wildlife Service, National Park Service, and representing principles put forth by the Western Area Power Administration), and other stakeholders. This alternative seeks to protect critical infrastructure while benefitting key resources (such as environmental, hydropower, and recreation) through an approach to distributing storage between Lake Powell and Lake Mead that

enhances the reservoirs' abilities to support the Basin. It applies a pro rata[10] Lower Basin shortage distribution to evaluate the potential impacts of distributing reductions among all mainstream lower Colorado River water users in Arizona, Nevada, and California.

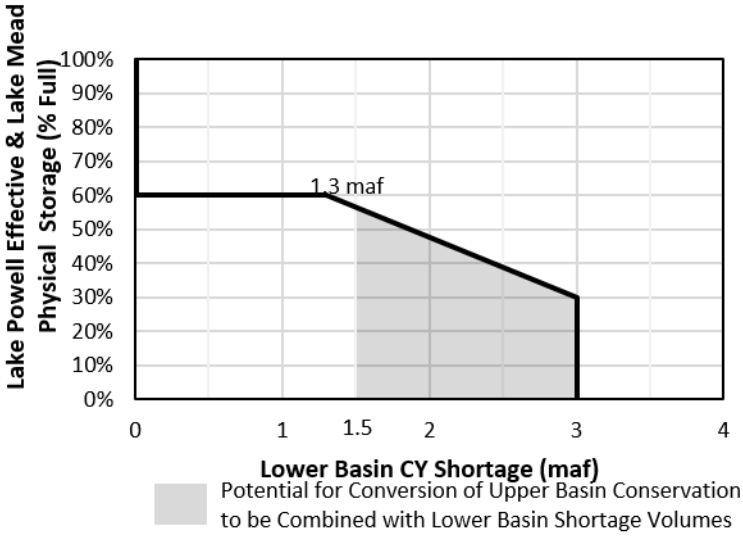
S.3.1 Guidelines to Reduce or Increase Deliveries from Lake Mead

S.3.1.1. Shortage Conditions

Shortage volumes up to 3.0 maf would be determined for the upcoming CY based on the October 1 sum of effective[11] storage in Lake Powell and physical storage in Lake Mead and be distributed pro rata among Lower Basin water users independent of state (see **Table S-3**). Required shortages could be partially or fully offset by delivering or converting previously conserved water, subject to provisions described in **Section S.3.3**. The shortage guidelines are summarized below and shown in **Figure S-5**.

- When the sum of Lake Powell effective storage and Lake Mead physical storage is equal to or less than 60 percent of combined capacity and greater than or equal to 30 percent combined capacity, a shortage volume would be imposed for that year based on a function of storage, with 1.3 maf of shortage at 60 percent of capacity increasing linearly to 3.0 maf at 30 percent of capacity.
- When the sum of Lake Powell effective storage and Lake Mead physical storage is less than 30 percent of combined capacity, a shortage volume of 3.0 maf would be imposed for that year.

Table S-3
Shortage Distribution,
Enhanced Coordination Alternative



Entity	Percentage of Total Shortages
Arizona	31.11
California	48.89
Nevada	3.33
Mexico	16.67
Total	**100**

Note: Shortage distributions include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

[10] Additional agreements and other legal authorities would be needed to implement any pro rata operations that are inconsistent with the Decree. See **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, for additional information on considerations related to use of pro rata shortage distributions in alternatives.

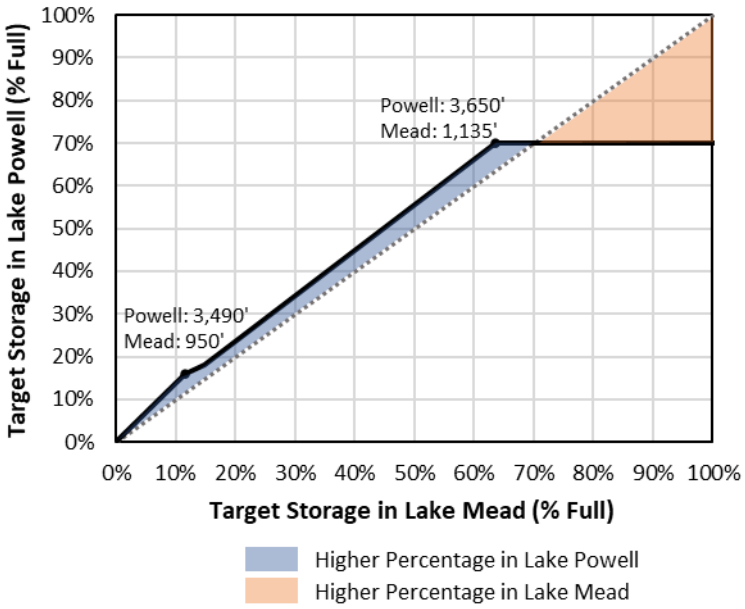
[11] "Effective" elevation or storage is calculated as physical elevation (storage) minus any conserved volume that is held in the respective reservoir.

Figure S-5
Shortage Guidelines to Reduce Deliveries from Lake Mead, Enhanced Coordination Alternative

Note: Shortage volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

The pro rata distribution would occur outside the priority system. Shortages would be distributed on a proportional basis (i.e., at the same percentage reduction from each user's entitlement) across all Lower Basin water users, including Mexico (see **Appendix C**, Shortage Allocation Model [SAM] and Alternative Distribution Model [ADM] Documentation, for additional detail on assumptions for this distribution method).

S.3.1.2. Surplus Conditions



Volumes above normal apportionment would be distributed only when criteria are met in Lake Mead for a 70R Surplus Condition or a Flood Control Surplus Condition, see footnotes 3 and 4 for details.

S.3.2 Coordinated Reservoir Operations (Lake Powell and Lake Mead)

Operations would target a specific distribution of storage across Lake Powell and Lake Mead for any given total volume of water. The curve in **Figure S-6**, called the "target storage distribution curve," depicts the target storage in Lake Powell versus the target storage in Lake Mead. The dotted diagonal line marks a 50/50 split for reference, and the target storage curve is variable across that line, indicating the portion where Lake Powell is at higher percent capacity than Lake Mead (emphasized with blue shading) and the portion where Lake Mead is at higher percent capacity than Lake Powell (emphasized with orange shading). From 0 percent to 63 percent combined storage (the total combined percent full when Lake Powell is at elevation 3,650 feet and Lake Mead is at

elevation 1,135 feet), operations would target keeping more water in Lake Powell. Above 63 percent full, a greater portion of water would be proactively sent to Lake Mead to prevent unplanned spill-avoidance releases and protect Glen Canyon Dam at high elevations.

Figure S-6
Coordinated Operations of Lake Powell and Lake Mead, Enhanced Coordination Alternative

S.3.2.1. Primary Operations

Each year, an initial WY release volume from Lake Powell would be calculated on October 1 using four factors:

1. October 1 physical[12] storage in Lake Powell and Lake Mead
2. Target storage distribution curve in **Figure S-6**
3. Preceding 10-year running average inflow to Lake Powell
4. Lower Basin delivery reductions for the upcoming CY

If the relative storage in Lake Powell and Lake Mead was exactly at the target distribution per the curve, Lake Powell's release would be equal to its 10-year running average inflow minus the volume of Lower Basin shortage for the upcoming CY. Since it is unlikely that the previous year exactly achieved the target storage distribution due to hydrologic uncertainty, a volume equal to the discrepancy, which could be positive (too much water was held in Lake Powell) or negative (too much was released to Lake Mead) would be factored into the upcoming WY release to align storage with the previous year's intended target. The maximum release each month is 900.0 kaf to prevent

[12] Using physical storage instead of effective storage for Lake Powell releases would prevent conservation from affecting the intended target storage distribution.

large monthly release volumes from causing sand evacuation below Glen Canyon Dam, which can potentially lead to negative impacts on multiple resources in the Grand Canyon. Therefore, the maximum WY release is 10.8 maf to avoid releasing volumes that could cause sediment scouring below Glen Canyon Dam.[13] The minimum WY release is 4.7 maf, which is the volume that still maintains minimum Long-Term Experimental and Management Plan releases.

In the spring, a one-time adjustment would be made to the remaining WY initial release volume if the end-of-water-year forecast shows that the end-of-water-year Lake Powell storage is off target by more than 1.0 maf. This would provide an opportunity to avoid a very large or very small WY release in the subsequent year. If an adjustment is warranted, the volume increase or decrease would be distributed among the remaining 6 months while ensuring that the adjustment would not cause the monthly release to be greater than 900.0 kaf, or less than Long-Term Experimental and Management Plan minimum flows.

S.3.2.2. Coordination at High Elevations

This alternative is based on a target distribution of storage between Lake Powell and Lake Mead throughout the range of combined storage volumes and does not have specific coordinated operations at high elevations.

S.3.2.3. Infrastructure Protection and Other Considerations

As combined Lake Powell and Lake Mead storage fall, planned WY releases from Lake Powell decline to help protect critical infrastructure at Glen Canyon Dam. No actions to protect critical infrastructure beyond the conservative target storage distribution curve and additional releases from CRSP Upper Initial Units (refer to **Section S.3.4**) are included in this alternative.

Annual releases above 10.8 maf would be made if required to avoid spills and protect Glen Canyon Dam at high elevations.

At Reclamation's discretion and in coordination with appropriate Basin entities, additional adjustments to Lake Powell WY release volumes could be made to mitigate potential negative impacts on resources between Glen Canyon Dam and Hoover Dam. These adjustments would be reconciled in the subsequent year through the end-of-water-year target storage adjustment.

S.3.3 Storage and Delivery of Conserved System and Non-System Water

This alternative incorporates specific elements that are designed to provide enhanced flexibility and predictability for water users via a storage and conversion mechanism in Lake Powell and storage and delivery mechanisms in Lake Mead. The storage, conversion and delivery mechanisms include assumptions for contributions of both consumptively used and unused tribal water, which may require additional authorities and represents the concept of enabling Basin Tribes to realize additional benefits from quantified water rights (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water and **Appendix H**, Sensitivity

[13] While sediment scour is often driven by short-duration, high-flow events (i.e., instantaneous flow rates), not by steady-state or annual volumes, incorporating monthly release limits into this alternative helps to ensure that operationally mandated high WY and monthly release volumes do not negatively impact sediment.

Analysis – Effects of Demand Schedule Assumptions on Modeled Unused Tribal Water Available for Storage in the Enhanced Coordination Alternative).

Three pools capture a range of opportunities to store, convert and deliver water for the benefit of water users and the system: the Lake Powell mechanism, the water user-controlled Lake Mead mechanism, and the Lake Mead Protection Pool, which was informed by a group of Basin Tribes and would be controlled by Reclamation for Lower Basin-wide benefits. The design of these mechanisms supports proactive conservation and water user flexibility while the relatively lower accumulation limits represent a goal of ensuring that system storage is not overtaken by user-controlled conservation.

S.3.3.1. Lake Powell Mechanism

Water conserved by Upper Basin users would be stored in a pool in Lake Powell that can reach a maximum volume of 2.0 maf. Water in this conservation pool would be included for purposes of determining Lake Powell releases but excluded from determinations of shortage volumes until it is converted to system water. Upper Division States and Upper Basin Tribes would have equal access to contribute to the conservation pool and to use their conserved water in intra- and interstate transactions with other Upper Basin users. Upper Basin Tribes would receive credit for the contribution of both conserved consumptive use and unused water to the pool. Assumptions related to contributions to the Lake Powell conservation pool are described in **Section S.3.4.1**.

Water held in the Lake Powell conservation pool would be converted to system water and combined with Lower Basin shortages to provide system benefits based on the shortage curve in **Figure S-5**. When Lower Basin CY shortages are greater than 1.5 maf, a volume equal to one-third of the volume above 1.5 maf would be converted from the Lake Powell pool into system water such that the total of Lower Basin shortages and conversion of Upper Basin water equal the required total shortage volume (i.e., above 1.5 maf, there is a two-to-one Lower Basin shortage-to-Upper Basin conversion ratio). If the prescribed two-to-one volume is not available in the Lake Powell conservation pool, 100 percent of the available volume would be converted, and the Lower Basin would take the balance of shortages.

S.3.3.2. Lake Mead Mechanism

Water conserved by Lower Basin users would be stored in a pool in Lake Mead that can reach a maximum volume of 5.0 maf, which includes the storage of pre-2027 ICS. Annual total and state-based limits for conservation volumes and delivery of conserved water are presented in **Table S-4**. All conserved water stored in Lake Mead would be included in determinations of Lake Powell releases and shortage volumes. Lower Colorado River entitlement holders, including Lower Basin Tribes, consistent with applicable implementation agreements, would be able to contribute to the conservation pool and to use their conserved water for delivery and/or in intra- and interstate transactions with other Lower Basin users.

Table S-4
Volume Limitations of Storage and Delivery of Conserved Water, Enhanced Coordination Alternative

Entity	Maximum Annual Contribution (kaf)	Maximum Cumulative Storage (kaf)	Maximum Annual Conversion or Delivery (kaf)
Arizona	466.67	700	620
California	733.333	1,900	980
Nevada	50	700	70
Mexico	250	1,700	330*
Total	**1,500**	**5,000**	**2,000**

*According to the modeling assumption for Mexico, water stored in the bank may only be used to mitigate Mexico's reductions exceeding 250.0 kaf. This activity is considered a "delivery" (i.e., conversion) from the bank. As a result, banking activity will not cause Mexico's delivery to exceed 1.7 maf. The 1944 Water Treaty authorizes scheduled delivery of up to 200.0 kaf in excess of the 1.5 annual allotment to Mexico.
Note: Volumes include modeling assumptions for Mexico's storage and delivery limits. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Water users could contribute and convert or deliver water previously stored under this new mechanism at their discretion within the annual volume constraints related to the pool. At the time the water is conserved, a one-time, seven-percent assessment would be deducted from the conserved volume and added to the Protection Pool. Conserved water could be used to offset up to 1.5 maf of required shortages. Conversion and delivery of conserved water would not be allowed when Lake Mead's physical elevation is below 1,025 feet.

S.3.3.3. Lake Mead Mechanism (Protection Pool)

The Protection Pool would be a pool of water controlled by Reclamation that can reach a maximum volume of 2.0 maf. It would acquire water through multiple mechanisms, including but not limited to system assessments on water user-created conservation, potentially compensated Lower Basin tribal water (conserved consumptive use and unused), system efficiency projects and potentially compensated nontribal conservation. Contents of the Protection Pool would be included in determinations of Lake Powell releases and shortage volumes.

The Protection Pool could be used for a range of purposes, including, but not limited to, meeting federal firming obligations,[14] other federal delivery obligations, protecting Lower Basin water supplies, protecting infrastructure, and providing environmental benefits. Modeling assumptions related to logic for creation and use of Protection Pool volumes can be found in **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water. There are no annual creation or delivery constraints.

[14] The Secretary is obligated to firm certain volumes of CAP non-Indian agricultural water provided as part of Indian water rights settlements to specific tribes in Arizona, including under Section 105(a) of the Arizona Water Settlements Act of 2004, Pub. L. 108-451, 118 Stat. 3478.

The Protection Pool was designed with significant input from representatives of Basin Tribes. The elements are modeled within the Enhanced Coordination Alternative, but the intention is to allow for their implementation within any operational framework that includes a storage and delivery mechanism (including frameworks where conservation is excluded from all release and shortage determinations).

S.3.3.4. Treatment of Pre-2027 ICS

ICS created under the 2007 Interim Guidelines and 2019 DCP that remains in Lake Mead in 2027 would be transferred to the Post-2026 Lake Mead water user-controlled mechanism immediately and would be subject to all provisions described in the previous section.

S.3.4 Additional Activities Above Lake Powell

S.3.4.1. Upper Basin Conservation

Exact volumes of Upper Basin conservation over time are uncertain, but for the purposes of modeling, volumes up to a maximum volume per year may be added depending on hydrologic conditions. The maximum phases in over time: from 2027 to 2031, the maximum is 200.0 kaf; from 2032-2036, the maximum is 275.0 kaf; after 2036, the maximum is 350.0 kaf. Conservation is modeled as a single lumped volume; no assumptions are made with respect to contributions from different entities or via specific activities. Assumptions related to the storage of unused Upper Basin tribal water are included in these volumes.

S.3.4.2. Releases to Protect Glen Canyon Dam

The coordinated operations included in this alternative, due to their storage distribution approach and lower releases at Lake Powell (down to 4.7 maf) are very effective at protecting critical infrastructure at Glen Canyon Dam. Therefore, while specific assumptions for releases from CRSP Upper Initial Units have not been developed for this alternative, Reclamation maintains the authority to operate its reservoirs to protect Glen Canyon Dam infrastructure.

S.4 Maximum Operational Flexibility Alternative

The Maximum Operational Flexibility Alternative is informed by a proposal submitted by a consortium of conservation organizations. This alternative incorporates proactive responses, targeted reservoir management strategies, and innovative and flexible tools to address an increasingly variable set of future hydrologic conditions. The operations are designed to help stabilize system storage, incentivize proactive water conservation, and extend the benefits of conservation and operational flexibility to a wide range of resources.

This alternative is based on "dual indicator" operations for determining annual releases from Lake Powell and Lake Mead: system storage and recent hydrology[15] are used in combination to determine

[15] The submission by the conservation organizations proposes the use of a Climate Response Indicator as part of the "dual indicator" approach. For modeling purposes, this concept has been translated into the previous 3-year average Lees Ferry natural flow.

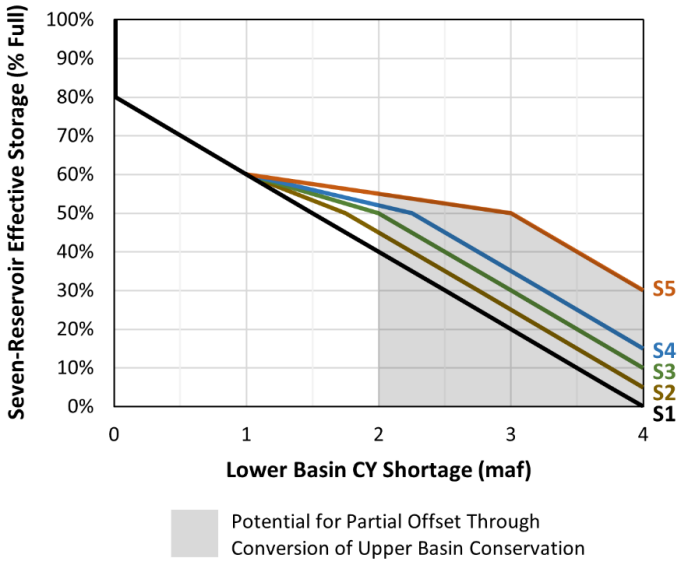
operations. Additionally, it introduces the Conservation Reserve as a flexible tool for water conservation and management.

S.4.1 Guidelines to Reduce or Increase Deliveries from Lake Mead

S.4.1.1. Shortage Conditions

Shortage volumes up to 4.0 maf would be determined for the upcoming CY based on October 1 total system[16] effective storage and the previous 3-year average natural flow at Lees Ferry, Arizona. Shortages would be distributed based on priority as described in Approach 1 of the Supply Driven Alternative (refer to **Section S.5.1**). Required shortages could be partially or fully offset by delivering or converting previously conserved water, subject to provisions described in **Section S.4.2.2**. The shortage guidelines and relevant conditions are summarized below and shown in **Figure S-7** and **Table S-5**.

- When total system effective storage is at or below 80 percent of capacity and at or above 60 percent of capacity, a shortage volume would be imposed for that year based on a function of storage, with 0.0 maf of shortage at 80 percent of capacity increasing linearly to 1.0 maf at 60 percent of capacity.
- When total system effective storage is below 60 percent of capacity and at or above 50 percent of capacity, the shortage volume depends on the previous 3-year average Lees Ferry natural flow:
    - If the previous 3-year average Lees Ferry natural flow is greater than 14.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 1.0 maf of shortage at 60 percent of capacity increasing linearly to 1.5 maf at 50 percent of capacity (S1 curve in **Figure S-7**).
    - If the previous 3-year average Lees Ferry natural flow is less than 14.0 maf and greater than or equal to 12.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 1.0 maf of shortage at 60 percent of capacity increasing linearly to 1.75 maf at 50 percent of capacity (S2 curve in **Figure S-7**).
    - If the previous 3-year average Lees Ferry natural flow is less than 12.0 maf and greater than or equal to 10.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 1.0 maf of shortage at 60 percent of capacity increasing linearly to 2.0 maf at 50 percent of capacity (S3 curve in **Figure S-7**).
    - If the previous 3-year average Lees Ferry natural flow is less than 10.0 maf and greater than or equal to 8.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 1.0 maf of shortage at 60 percent of capacity increasing linearly to 2.25 maf at 50 percent of capacity (S4 curve in **Figure S-7**).
    - If the previous 3-year average Lees Ferry natural flow is less than 8.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 1.0 maf of shortage at 60 percent of capacity increasing linearly to 3.0 maf at 50 percent of capacity (S5 curve in **Figure S-7**).



[16] Flaming Gorge, Blue Mesa, Navajo, Lake Powell, Lake Mead, Lake Mohave, and Lake Havasu Reservoirs.

- When total system effective storage is 50 percent of capacity or less, the shortage volume depends on the previous 3-year average Lees Ferry natural flow:
  - If the previous 3-year average Lees Ferry natural flow is greater than 14.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 1.5 maf of shortage at 50 percent of capacity increasing linearly to 4.0 maf at 0 percent of capacity (S1 curve in **Figure S-7**).
  - If the previous 3-year average Lees Ferry natural flow is less than 14.0 maf and greater than or equal to 12.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 1.75 maf of shortage at 50 percent of capacity increasing linearly to 4.0 maf at 5 percent of capacity (S2 curve in **Figure S-7**). Below 5 percent of capacity, a shortage of 4.0 maf would be imposed for that year.
  - If the previous 3-year average Lees Ferry natural flow is less than 12.0 maf and greater than or equal to 10.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 2.0 maf of shortage at 50 percent of capacity increasing linearly to 4.0 maf at 10 percent of capacity (S3 curve in **Figure S-7**). Below 10 percent of capacity, a shortage of 4.0 maf would be imposed for that year.
  - If the previous 3-year average Lees Ferry natural flow is less than 10.0 maf and greater than or equal to 8.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 2.25 maf of shortage at 50 percent of capacity increasing linearly to 4.0 maf at 15 percent of capacity (S4 curve in **Figure S-7**). Below 15 percent of capacity, a shortage of 4.0 maf would be imposed for that year.
  - If the previous 3-year average Lees Ferry natural flow is less than 8.0 maf, a shortage volume would be imposed for that year based on a function of storage, with 3.0 maf of shortage at 50 percent of capacity increasing linearly to 4.0 maf at 30 percent of capacity (S5 curve in **Figure S-7**). Below 30 percent of capacity, a shortage of 4.0 maf would be imposed for that year.

Table S-5
Shortage Curves and Relevant Conditions,
Maximum Operational Flexibility Alternative

Shortage Curve	Previous 3-Year Average Lees Ferry Natural Flow (maf)	Shortage Increase Compared to S1 Curve at 50% Full (kaf)
S1	≥ 14	N/A
S2	< 14 to ≥ 12	250
S3	< 12 to ≥ 10	500
S4	< 10 to ≥ 8	750
S5	< 8	1,500

Figure S-7
Shortage Guidelines to Reduce Deliveries from Lake Mead, Maximum Operational Flexibility Alternative

Note: Shortage volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

S.4.1.2. Surplus Conditions

Volumes above normal apportionment would be distributed only when criteria are met in Lake Mead for a Flood Control Surplus Condition, see footnotes 3 and 4 for details.

S.4.2 Coordinated Reservoir Operations (Lake Powell and Lake Mead)

The WY release from Lake Powell would be determined based on the combined effective storage of CRSP reservoirs (Lake Powell, Flaming Gorge, Blue Mesa, and Navajo) on October 1 and the previous 3-year average natural flow at Lees Ferry, Arizona. The operational zones and relevant conditions are summarized below and shown in **Figure S-8** and **Table S-6**.

Figure S-8
Coordinated Operations of Lake Powell and Lake Mead,
Maximum Operational Flexibility Alternative

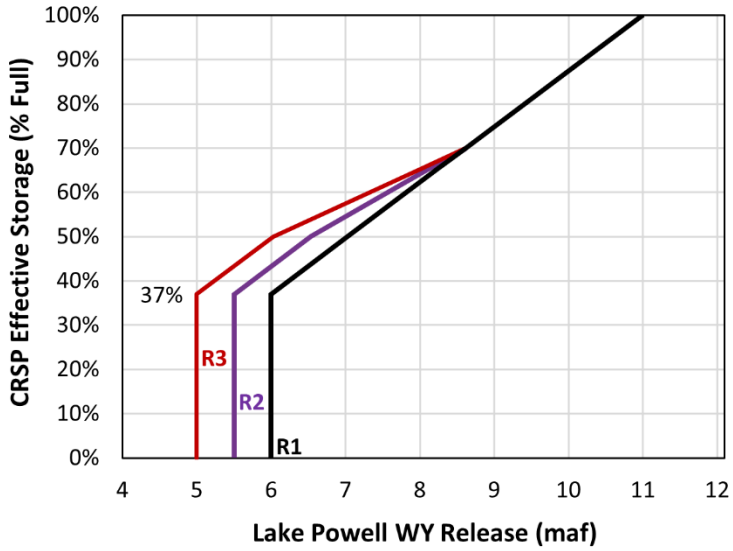


Table S-6
Release Curves and Relevant Conditions,
Maximum Operational Flexibility Alternative

Lake Powell Release Curve	Previous 3-Year Average Lees Ferry Natural Flow (maf)	Release Decrease Compared to R1 Curve at 50% Full (kaf)
R1	≥ 10	N/A
R2	< 10 to ≥ 8	500
R3	< 8	1,000

S.4.2.1. Primary Operations

- When CRSP effective storage is at or below 100 percent of capacity and at or above 70 percent of capacity, a release volume would be determined for that year based on a function of storage, with 11.0 maf release at 100 percent of capacity decreasing linearly to 8.6 maf at 70 percent of capacity.
- When CRSP effective storage is at or below 70 percent of capacity and at or above 50 percent of capacity, the release volume depends on the previous 3-year average Lees Ferry natural flow:
    - If the previous 3-year average Lees Ferry natural flow is greater than or equal to 10.0 maf, a release volume would be determined for that year based on a function of storage, with a release of 8.6 maf at 70 percent of capacity decreasing linearly to 7.0 maf at 50 percent of capacity (R1 curve in **Figure S-8**).
    - If the previous 3-year average Lees Ferry natural flow is less than 10.0 maf and greater than or equal to 8.0 maf, a release volume would be determined for that year based on a

function of storage, with a release of 8.6 maf at 70 percent of capacity decreasing linearly to 6.5 maf at 50 percent of capacity (R2 curve in **Figure S-8**).

- If the previous 3-year average Lees Ferry natural flow is less than 8.0 maf, a release volume would be determined for that year based on a function of storage, with a release of 8.6 maf at 70 percent of capacity decreasing linearly to 6.0 maf at 50 percent of capacity (R3 curve in **Figure S-8**).

- When CRSP effective storage is at or below 50 percent of capacity, the release volume depends on the previous 3-year average Lees Ferry natural flow:
  - If the previous 3-year average Lees Ferry natural flow is greater than or equal to 10.0 maf, a release volume would be determined for that year based on a function of storage, with a release of 7.0 maf at 50 percent of capacity decreasing linearly to 6.0 maf at 37 percent of capacity (R1 curve in **Figure S-8**). Below 37 percent of capacity, the determined release would be 6.0 maf.
  - If the previous 3-year average Lees Ferry natural flow is less than 10.0 maf and greater than or equal to 8.0 maf, a release volume would be determined for that year based on a function of storage, with a release of 6.5 maf at 50 percent of capacity decreasing linearly to 5.5 maf at 37 percent of capacity (R2 curve in **Figure S-8**). Below 37 percent of capacity, the determined release would be 5.5 maf.
  - If the previous 3-year average Lees Ferry natural flow is less than 8.0 maf, a release volume would be determined for that year based on a function of storage, with a release of 6.0 maf at 50 percent of capacity decreasing linearly to 5.0 maf at 37 percent of capacity (R3 curve in **Figure S-8**). Below 37 percent of capacity, the determined release would be 5.0 maf.

S.4.2.2. Coordination at High Elevations

This alternative uses the Conservation Reserve pool to coordinate Lake Powell and Lake Mead throughout the range of elevations and does not have specific coordinated operations at high elevations.

S.4.2.3. Infrastructure Protection and Other Considerations

When physical elevation at Lake Powell is below 3,510 feet, Lake Powell monthly releases would be equal to the minimum of either monthly inflow minus losses or the monthly volume corresponding to the WY release determined by the curve. The minimum monthly release would be based on 5,000 cubic feet per second (cfs) unless it is reduced by Glen Canyon Dam infrastructure constraints below physical elevation 3,490 feet.

Lake Powell WY releases could be adjusted based on flexibilities provided by the Conservation Reserve as described in **Section S.4.3**.

S.4.3 Storage and Delivery of Conserved System and Non-System Water

S.4.3.1. Combined Lake Powell and Lake Mead Mechanism

The Conservation Reserve is a pool that would store water conserved by Colorado River water users in either basin (including Mexico) and would be distributed strategically across Lake Powell and Lake

Mead to protect infrastructure and benefit a range of resources including the Colorado River Delta, Lower Colorado River Multi-Species Conservation Plan, and Grand Canyon. Except when Lake Powell or Lake Mead is near a critically high or low elevation, water in the Conservation Reserve would be excluded from determining basic (curve-based) WY releases from Lake Powell and shortage volumes until it is converted to system water. The timing and volume criteria for this conversion are described below.

The maximum volume of the Conservation Reserve would be 8.0 maf, with 3.0 maf of space allocated to Upper Basin users and 5.0 maf allocated to Lower Basin users, which includes the storage of pre-2027 ICS. There would be no maximum total storage for any single user or state, though there would be total annual creation and delivery limits as shown in **Table S-7**. At the time the water is conserved, a one-time 10-percent assessment would be deducted from the conserved volume and added to system water. Transactions, including interstate transactions, could occur between users within the basin of origin.

Table S-7
Annual Total Conservation Creation and Delivery or Conversion Limits by Basin

Basin	Maximum Annual Contribution Limits (kaf)	Maximum Annual Delivery or Conversion Limits (kaf)
Upper	500	Conversion volume required to bring Lower Basin shortage to 2.0 maf
Lower	3,000 minus shortage (total of shortage and creation cannot exceed 3,000)	3,000

Note: Volumes include modeling assumptions for Mexico's storage and delivery limits. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Reclamation would determine how to allocate the Conservation Reserve volume between reservoirs and could increase or decrease Lake Powell's basic WY release volume to meet infrastructure needs or resource goals. Operation of the Conservation Reserve would not affect tracking of Lee Ferry flows.

Upper Basin users' conserved water would be converted to system water based on the shortage curve in **Figure S-8**. When Lower Basin shortages are greater than 2.0 maf, the volume above 2.0 maf would be converted from Upper Basin users' Conservation Reserve water to system water, subject to availability in the Reserve. The required Lower Basin shortage volume would be reduced by whatever volume of previously conserved Upper Basin water is converted.

Lower Basin water users could conserve and request delivery of stored water in their accounts at their discretion to offset up to the full required shortage amount, subject to annual creation and delivery limits and constrained by the priority of using Conservation Reserve water to keep Lake Powell above 3,510 feet and Lake Mead above 1,000 feet.

S.4.3.2. Treatment of Pre-2027 ICS

ICS created under the 2007 Interim Guidelines and 2019 DCP that remains in Lake Mead in 2027 would be transferred to the Conservation Reserve in 2027 and would be subject to all provisions described in the previous section.

S.4.4 Additional Activities Above Lake Powell

S.4.4.1. Upper Basin Conservation

Exact volumes of Upper Basin conservation over time are uncertain, but for the purposes of modeling, volumes up to 500.0 kaf per year may be added depending on hydrologic conditions. The framework targets an average conservation volume of 200.0 kaf per year. Conservation is modeled as a single lumped volume; no assumptions are made with respect to contributions from different entities or via specific activities.

S.4.4.2. Releases to Protect Glen Canyon Dam

Based on the proposal submitted by the conservation organizations on which this alternative is based, this alternative does not include adjustments to the releases of the CRSP Upper Initial Units to protect infrastructure at Glen Canyon Dam. However, Reclamation maintains the authority to operate these reservoirs to protect Glen Canyon Dam infrastructure.

S.5 Supply Driven Alternative

The Supply Driven Alternative provides a Lake Powell operation based solely on historical natural flow. It also incorporates concepts from the separate proposals submitted by the Upper Division and Lower Division States, as well as ideas emerging from discussions with the Basin States during spring 2025. In this alternative, annual Lake Powell releases would be determined based on a set percentage of the preceding 3-year average natural flow at Lees Ferry, and Lower Basin deliveries would be determined based on Lake Mead elevation.

S.5.1 Guidelines to Reduce or Increase Deliveries from Lake Mead

S.5.1.1. Shortage Conditions

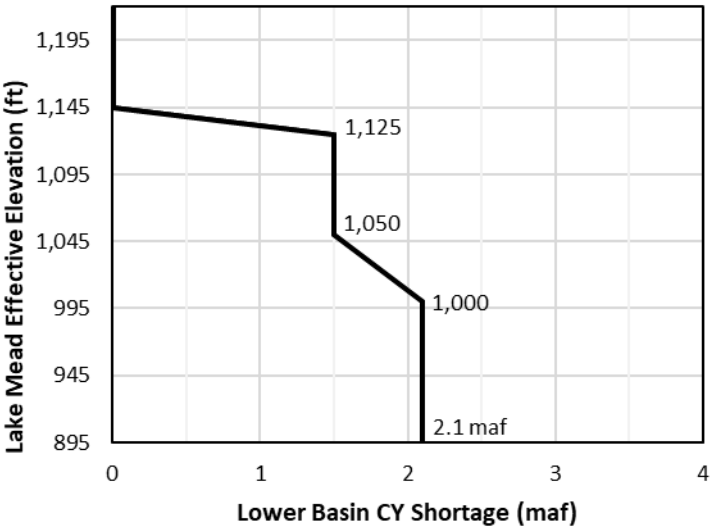
Shortage volumes up to 2.1 maf would be determined for the upcoming CY based on August 1 Lake Mead effective elevation. To analyze a wide range of potential impacts, at the request of the Lower Division States, this alternative considers two different approaches to the distribution of shortages among mainstream Lower Colorado River users:

1. Lower Basin Priority (LB Priority): up to 1.5 maf, intra-state priority using state distributions submitted by Lower Division States; above 1.5 maf, priority using a state distribution based on the interpretation of priority as described in the No Action Alternative (**Section S.1.1.1**).

2. Lower Basin Pro Rata (LB Pro Rata): up to 1.5 maf, intra-state pro rata using state distributions submitted by Lower Division States; above 1.5 maf, intra-state pro rata distributed to states proportionally based on unreduced apportionments.

Table S-8 reports how shortage volumes would be divided among the states and Mexico for each approach up to 1.5 maf. **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, includes the results of additional modeling to understand how excluding tribes from shortages in both distribution schemes would impact water deliveries.

Table S-8
Lower Division State-Submitted Shortage Distributions



Entity	Shortage (%) from 0 to 300 kaf	Shortage (%) from 300 to 1,500 kaf	Total Shortage (kaf) when Lower Basin-wide Shortage is 1,500 kaf	Shortage (%) 1,500 kaf to 2,100 kaf	
	LB Priority and LB Pro Rata	LB Priority and LB Pro Rata	LB Priority and LB Pro Rata	LB Priority	LB Pro Rata
Arizona	80.00	43.33	760	76.26	27.20
California	0	36.67	440	0	52.80
Nevada	3.33	3.33	50	7.08	3.33
Mexico	16.67	16.67	250	16.67	16.67

Note: Shortage distributions include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

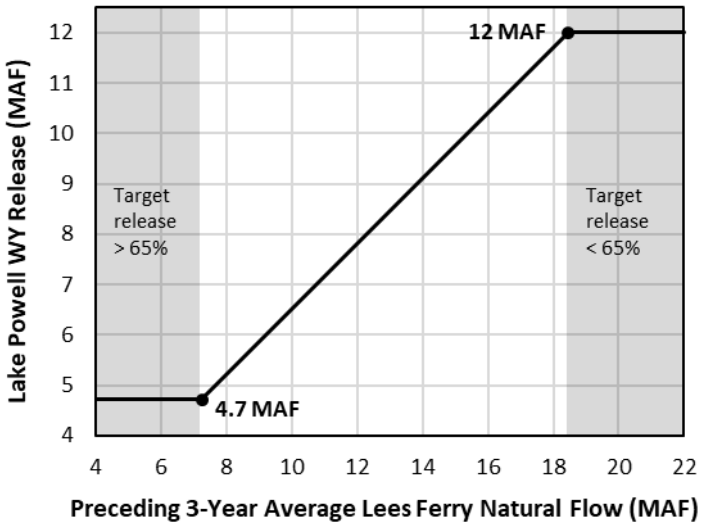
Required shortages could be partially or fully offset by delivering or converting previously conserved water, subject to provisions described in **Section S.5.3**. The shortage guidelines are summarized below and shown in **Figure S-9**.

- When Lake Mead effective elevation is at or below 1,145 feet and at or above 1,125 feet, a shortage volume would be imposed for that year based on a function of elevation, with 0.0 maf of shortage at 1,145 feet increasing linearly to 1.5 maf at 1,125 feet.
- When Lake Mead effective elevation is at or below 1,125 feet and at or above 1,050 feet, a shortage volume of 1.5 maf would be imposed for that year.
- When Lake Mead effective elevation is at or below 1,050 feet and at or above 1,000 feet, a shortage volume would be imposed for that year based on a function of elevation, with 1.5 maf of shortage at 1,050 feet increasing linearly to 2.1 maf at 1,000 feet.
- When Lake Mead effective elevation is below 1,000 feet a shortage volume of 2.1 maf would be imposed for that year.

Figure S-9
Shortage Guidelines to Reduce Deliveries from Lake Mead, Supply Driven Alternative

Note: Shortage volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

S.5.1.2. Surplus Conditions



This alternative incorporates three categories of surplus: Flood Control and 70R, which are described in **Section S.1.1.2**, and Domestic Surplus. A Domestic Surplus would be determined anytime the August 1 Lake Mead effective elevation is at or above 1,165 feet and Flood Control or 70R Surplus is not triggered. Up to 500.0 kaf of surplus volumes would be distributed.

S.5.2 Coordinated Reservoir Operations (Lake Powell and Lake Mead)

S.5.2.1. Primary Operations

Lake Powell WY release volumes would be determined on October 1 as a fixed percentage (65 percent) of the preceding 3-year average natural flow at Lees Ferry, Arizona (see **Figure S-10**). **Appendix D**, Sensitivity Analysis – Effects of Natural Flow Percentage Used for the Supply Driven Alternative, explores the implications of using different natural flow percentages. Other than considerations related to critical high or low elevations, WY releases would be constrained to between 4.7 and 12.0 maf regardless of the volume determined by the natural flow-based calculation.

Figure S-10
Coordinated Operations of Lake Powell and Lake Mead, Supply Driven Alternative

S.5.2.2. Coordination at High Elevations

This alternative does not coordinate operations at high elevations.

S.5.2.3. Infrastructure Protection and Other Considerations

This alternative assumes that no adjustments to Lake Powell releases would be made to protect physical elevation 3,490 feet; however, Reclamation maintains the authority to modify operations to protect Glen Canyon Dam infrastructure.

S.5.3 Storage and Delivery of Conserved System and Non-System Water

S.5.3.1. Lake Powell Mechanism

Water conserved by Upper Basin users would be stored in a pool in Lake Powell that could reach a maximum volume of 3.0 maf. Upper Division States' water and Upper Basin Tribes' water would be able to contribute to the conservation pool and to use their conserved water in intra- and interstate transactions with other Upper Basin users. Water in the Lake Powell conservation pool can be released if needed to meet the determined WY volume.

S.5.3.2. Lake Mead Mechanism

Water conserved by Lower Basin users would be stored in a pool in Lake Mead that could reach a maximum volume of 8.0 maf, which includes the storage of pre-2027 ICS. Annual total and state-based limits for conservation volumes and delivery of conserved water are presented in **Table S-9**, but each state can choose to share its dedicated space. All water stored in the Lake Mead conservation pool would be excluded from determinations of shortage volumes until it is converted to system water by a user to offset their required shortages. Lower Colorado River entitlement holders, including Lower Basin Tribes, consistent with applicable implementation agreements,

would be able to contribute to the Lake Mead conservation pool and to use their conserved water in intra- and interstate transactions with other Lower Basin users.

Water users could contribute and convert or deliver water previously stored under this new mechanism at their discretion within the annual volume constraints related to the pool. In the year the water is conserved, a 5-percent assessment would be deducted from the conserved volume and added to system water. In every subsequent year, 3 percent of the stored volume would be deducted and converted to system water. Delivery of conserved water would not be allowed when Lake Mead's physical elevation is below 1,025 feet.

Table S-9
Supply Driven Alternative Volume Limitations of Storage of Conserved Water

Entity	Maximum Annual Contribution (kaf)	Maximum Cumulative Storage (kaf)	Maximum Annual Conversion or Delivery (kaf)
Arizona	880	3,000	465
California	880	3,000	745
Nevada	225	1,000	90
Mexico	500	1,000	100
Total	**2,485**	**8,000**	**1,400**

Note: Volumes include modeling assumptions for Mexico's storage and delivery limits. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

S.5.3.3. Treatment of Pre-2027 ICS Conservation

ICS created under the 2007 Interim Guidelines and 2019 DCP that remains in Lake Mead in 2027 would be used or converted to the Post-2026 Lake Mead mechanism using a phased approach over 10 years. Once transferred to the new mechanism, it would be subject to all provisions described in the previous section.

S.5.4 Additional Activities Above Lake Powell

S.5.4.1. Upper Basin Conservation

Exact volumes of Upper Basin conservation over time are uncertain, but for the purposes of modeling, conservation up to 200.0 kaf per year is included, with variable annual volumes based on hydrologic conditions as described in the Enhanced Coordination Alternative. Conservation is modeled as a single lumped volume; no assumptions are made with respect to contributions from different entities or via specific activities. Additional hydrology-dependent volumes may be added to the Lake Powell pool based on annual unused Upper Basin tribal water.

S.5.4.2. Releases to Protect Glen Canyon Dam

If Lake Powell's elevation falls below 3,525 feet CRSP Upper Initial Units would increase their releases within their RODs to increase elevations at Lake Powell, up to 500.0 kaf per year

contingent on hydrologic conditions. Any volumes released for the protection of Glen Canyon Dam would begin to be recovered when Lake Powell is above 3,535 feet by assuming that the Upper Initial Units return to their normal annual operating targets. The frequency and volumes of the assumed releases to protect Glen Canyon Dam are assessed in **Appendix O**, Analysis of Powell Infrastructure Protection Releases.

S.5.4.3. Additional Modeling Assumptions

In years when Lake Powell cannot meet its required WY release because of low elevation infrastructure constraints, additional water is introduced into the system to (partially) make up the shortfall. For modeling purposes, this supplemental volume is termed "gap water" and is modeled both to provide an estimate of the supplemental volume of water needed in the Upper Basin to ensure the required WY release can be made from Lake Powell and associated downstream impacts of meeting the required WY release. This supplemental water is injected into Lake Powell and released when conditions allow, subject to the same low-elevation release constraints. Any portion not released in a given WY is tracked as carryover and released in subsequent years. The annual amount of gap water is limited to no more than 23 percent[17] of the Upper Basin's modeled depletion for that year, minus any Upper Basin conservation Additional detail is provided in **Appendix A**, CRSS Model Documentation.

S.6 Alternatives Considered but Eliminated from Detailed Analysis

Reclamation received a number of submissions representing commenters' proposed operations of Colorado River reservoirs. Some submissions presented sufficient detail to potentially be considered as an action alternative, while others offered operational concepts or components of an alternative. In either case, the following "alternatives" were brought forward during internal and public scoping. These alternatives were considered but eliminated from detailed analysis because they (1) would not fully meet the purpose and need of the Post-2026 action; (2) are infeasible or inconsistent with the policy objectives for Colorado River operations, including consistency with applicable federal law;[18] or (3) are addressed or encompassed by the range of alternatives analyzed.

S.6.1 Boating Alternative – Maintaining Lake Powell Levels for Recreation

Comments related to boating alternatives focused on maintaining water levels at Lake Powell (and Lake Mead) to serve recreational boating needs. Many commenters wrote in support of the BlueRibbon Coalition's "Path to 3588' Plan," which proposes to maintain Lake Powell at an elevation of 3,588 feet. One commenter proposed maintaining Lake Powell at 3,600 feet, and three commenters proposed filling Lake Powell to full pool. Other commenters suggested maintaining Lake Powell at an elevation of 3,588 feet to allow the Castle Rock Cut to be navigable. Additionally,

[17] The 23-percent limit is based on the ratio of the maximum Lower Basin shortage (2.1 maf) to the total Lower Basin apportionment to the U.S. and Mexico (9.0 maf).

[18] Inclusive of existing legal authorities and contractual obligations. This would not preclude the reasonably foreseeable acquisition of certain new or modified legal authorities necessary to implement new interim guidelines. However, new legal authorities that would result in impracticalities or are unlikely to be widely acceptable among stakeholders are too speculative to include in this Final EIS.

some commenters asked that Reclamation reconsider how release rates are determined—one noted potential effects on the trout fishery below Glen Canyon Dam, while another recommended evaluating minimum flows of 8,000 cfs from April 1 through September 22 to preserve safe whitewater boating below the dam.

This alternative was not carried forward because a recreation-focused target elevation does not fully meet the purpose and need of the Post-2026 action. Focusing solely on boating would risk noncompliance with water delivery obligations and operational requirements, which would be inconsistent with Reclamation's policy objectives. However, maintenance of higher Lake Powell elevations, as feasible, is integrated into the range of alternatives, primarily the Enhanced Coordination and Maximum Operational Flexibility Alternatives. These operations were designed in recognition of their potential to benefit multiple resources and uses, including recreation. With respect to minimum flows below Glen Canyon Dam, targeting specific releases from Lake Powell at the sub-annual level is outside the scope of this National Environmental Policy Act effort, which is focused on annual releases.

S.6.2 Ecosystem Alternative

Comments regarding an ecosystem alternative called for Reclamation to prioritize the ecosystem health of the Colorado River by protecting key components such as wildlife, vegetation, habitats, tributary ecosystems, and wetlands. Specific wildlife habitats mentioned included the Grand Canyon, the Lower Colorado River, the Salton Sea, and the Colorado River Delta. Several commenters emphasized that consumptive water use from agriculture, lawns, and golf courses be decreased to protect these habitats. In addition, one commenter suggested that Reclamation analyze and implement releases of cold water with high dissolved oxygen from Glen Canyon Dam to protect the threatened humpback chub, noting that low water levels at Lake Mead creating the Pearce Ferry rapid may serve as an effective management strategy for protecting native and listed fish species. Another commenter urged the development of a "Protect Grand Canyon Alternative" to "ensure high-flow experiments, safe and navigable flows, a healthy ecosystem including protecting the sediment resource and our native fish and preserving precious cultural resources in this sacred landscape."

Critical ecosystem needs were considered in the development of every action alternative, including alternatives such as the Enhanced Coordination and Maximum Operational Flexibility Alternatives, which incorporate protection as part of coordinated reservoir operations. However, this Ecosystem Alternative was not advanced because it would prioritize ecosystem protection over the operational and legal requirements associated with Colorado River water deliveries and management. While several action alternatives include conservation measures, operational flexibility, and actions intended to benefit ecosystem resources, those alternatives were developed to balance ecosystem considerations with the primary purposes of the Colorado River system as specified in statute, judicial decisions, international treaties, and existing legal and operational requirements. An ecosystem-based alternative would also include problematic cuts to water allocations and implementation of implausible water conservation measures. Any operation would need to meet the applicable ecosystem-based requirements under applicable law or would require extensive and contentious modifications to law and contracts to be implementable.

S.6.3 One-Dam Alternative

Reclamation received comments related to one-dam alternatives focused on prioritizing the preservation of one dam and its reservoir—either Hoover Dam/Lake Mead or Glen Canyon Dam/Lake Powell—over the other. The majority of commenters supported an alternative that would prioritize filling Lake Mead, either by bypassing or decommissioning Glen Canyon Dam. Several commenters referenced maintaining Lake Powell at 3,550 feet and sending all excess water to Lake Mead. Others noted that low water levels in Lake Powell could result in additional resources emerging from Glen Canyon and called for these impacts to be considered. Additionally, three commenters expressed support for a "Grand Canyon Restoration Alternative"—such as a bypass tunnel around Glen Canyon Dam—to ensure high-flow experiments that protect both ecosystem and cultural resources, while four commenters supported preserving Lake Powell for recreation.

This alternative was not advanced because prioritizing one dam over the other would not yield an integrated, resilient system. Such a focus would undermine the balanced operations required to meet water delivery, environmental, and legal obligations under the Post-2026 action. Reclamation operates and maintains the two dams and reservoirs consistent with Law of the River, including the Boulder Canyon Project Act of 1928 that authorized the construction of Hoover Dam and the CRSP Act of 1956 that authorized the construction of Glen Canyon Dam, and all acts amendatory and supplemental. A one-dam alternative would require such extensive statutory modifications or amendments that it is unlikely to be acceptable among stakeholders and would be inconsistent with federal law.

Appendix T. Preliminary Description and Analysis of Anticipated Operating Guidelines for 2027 and 2028

T.1 Introduction

As described in **Chapter 2**, Description of Alternatives, the Preferred Alternative is a 10-year decision framework through 2036. The decision framework establishes operational principles, sideboards (key thresholds and ranges for operational elements), and a process that would govern development and issuance of operating guidelines covering anticipated 2-year intervals, unless consensus-based agreements provide for a longer duration.

As of the date of this Final EIS, the anticipated guidelines for the first operating interval (2027 and 2028) are still being refined. These anticipated guidelines are based on extensive engagement with the Basin States and incorporate tribal input. For the purpose of this appendix, these anticipated guidelines are referred to as "2027-2028 Operating Guidelines." For the purpose of describing the potential upcoming operating guidelines and their associated impacts, a preliminary description and analysis of the 2027-2028 Operating Guidelines is included in this appendix. This appendix also analyzes how the impacts of the 2027-2028 Operating Guidelines compare to those of the Representative Preferred Alternative.

T.2 Preliminary Description of 2027-2028 Operating Guidelines

The four operational elements for the 2027-2028 Operating Guidelines are described in the subsequent sections. The specific Colorado River Simulation System (CRSS) modeling assumptions are provided in **Appendix T, Attachment T1**.

T.2.1 Guidelines to Reduce or Increase Deliveries from Lake Mead

Shortage Conditions

The 2027–2028 Operating Guidelines include a total Lower Basin shortage volume of 1.5 million acre-feet (maf) (inclusive of Mexico) in both 2027 and 2028.[1] Shortages above 1.5 maf are not modeled as shown in **Figure T-1**; however; if Lake Mead is projected to decline below elevation 1,000 feet during any 12-month period, consultation would occur to evaluate whether additional

[1] Based on the initial conditions, all 400 simulated futures apply a total Lower Basin shortage of 1.5 maf in 2027. The maximum December 2027 Lake Mead elevation across all 400 futures is 1,106 feet. As such all 400 simulated futures also apply a total Lower Basin shortage of 1.5 maf in 2028.

actions are necessary to reduce the risk of Lake Mead declining below elevation 950 feet. The modeled shortage volume is distributed among the Lower Division States (see **Table T-1**) consistent with the Lower Division States May 1 proposal.

Figure T-1
Shortage Guidelines to Reduce Deliveries from Lake Mead, 2027-2028 Operating Guidelines

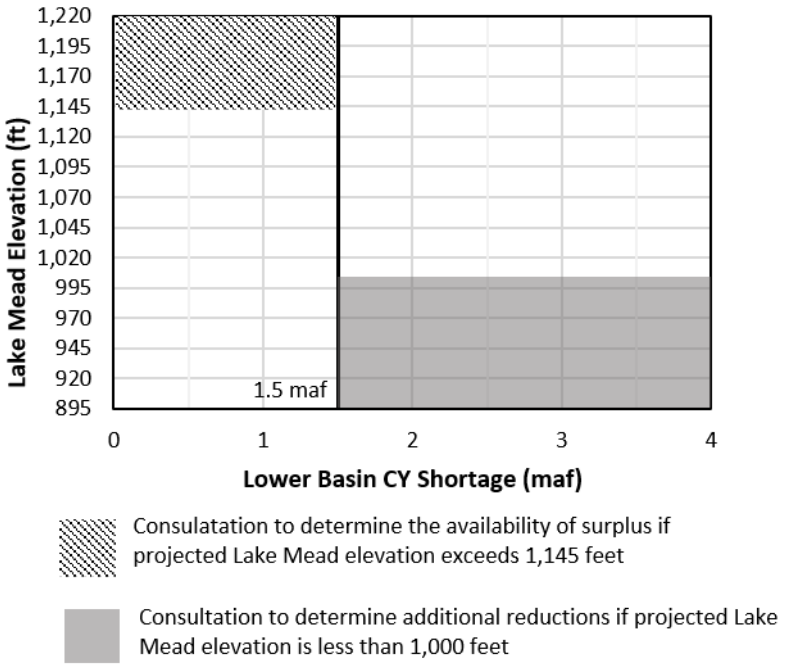

Table T-1
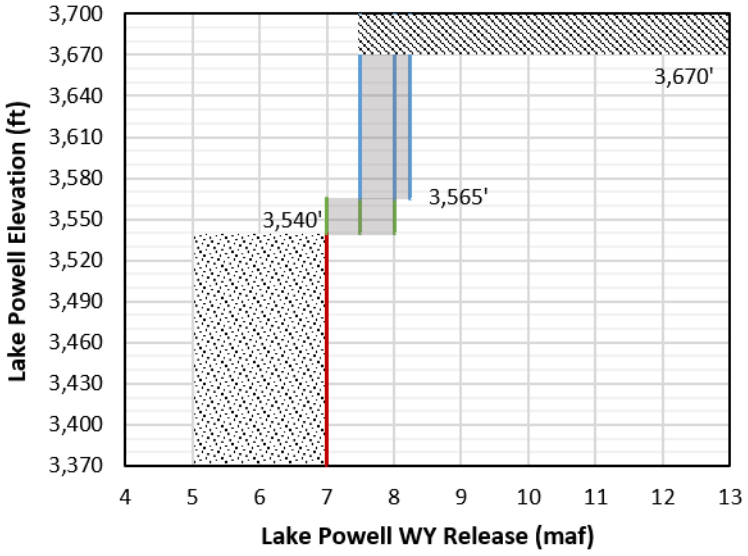
Shortage Distribution, 2027-2028 Operating Guidelines

Entity	Shortage (kaf)	Shortage (%)
Arizona	760	43.33
California	440	36.67
Nevada	50	3.33
Mexico	250	16.67

Note: Shortage distributions include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current United States (U.S.) policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.



Normal and Surplus Conditions

If Lake Mead is projected to exceed elevation 1,145 feet, consultation regarding reduced shortage volumes or the availability of Surplus would occur. As described in footnote 1, the maximum December 2027 elevation is 1,106 feet; thus, neither Normal nor Surplus conditions are modeled in the analysis of the 2027-2028 Operating Guidelines.

T.2.2 Coordinated Reservoir Operations (Lake Powell and Lake Mead)

In 2027 and 2028, the annual water year releases from Lake Powell are determined based on projected reservoir conditions at the beginning of the water year, with the potential for adjustments during the water year in response to changing hydrologic conditions. These operations are designed to preserve the operational flexibility to protect critical infrastructure at Glen Canyon Dam and meet other operational objectives consistent with applicable federal law. The operations are summarized below and depicted in **Figure T-2.**

Figure T-2
Coordinated Operations of Lake Powell and Lake Mead, 2027-2028 Operating Guidelines

Equalization releases occur when the computed 602(a) Storage volume is exceeded. Hatching indicates the approximate corresponding Lake Powell elevation range.

WY release is selected from canditage releases by selecting the maximum release that maintains a projected elevation of at least 3,510' during the WY.

At any elevation, the release may be adjusted down to a minimum of 6.0 maf or 5.0 maf if Lake Powell is projected to decline below 3,510' or 3,500', respectively.

Primary Operations

Initial Water Year Release

The initial water year release is selected from a set of potential release volumes corresponding to the October 1 Lake Powell elevation as shown in **Table T-2** and **Figure T-2**. Potential release volumes are first evaluated to identify those projected to maintain a Lake Powell elevation of at least 3,510 feet during the following spring. The initial release is then selected from among those potential release volumes to preserve operational flexibility, allowing releases to be adjusted upward or downward over the course of the water year as hydrologic conditions evolve. The next section describes the potential adjustments to this initial water year release volume during the water year in response to changing hydrologic conditions.

When the October 1 Lake Powell elevation is below 3,540 feet, the modeled implementation evaluates an initial water year release of 7.0 maf. If that release is projected to result in Lake Powell declining below elevation 3,510 feet, the determination of the water year release is deferred until April, and monthly releases are adjusted to maintain elevation 3,510 feet. In April, the water year release is set, likely between 6.0 and 7.0 maf, contemporaneously with the additional releases from Colorado River Storage Project (CRSP) Upper Initial Units to protect critical infrastructure at Glen Canyon Dam, as described in the *Mid-Year Release Adjustments* section and in **Section T.2.4**.

Table T-2
Potential Initial Water Year Releases by Lake Powell Pool Elevation, 2027-2028 Operating Guidelines

Lake Powell October 1 Pool Elevation (feet)	Potential Initial Lake Powell Water Year Releases (maf)
> 3,565	8.23, 8.0, and 7.5
3,565 to 3,540	8.0, 7.5, and 7.0
< 3,540	7.0

Mid-Year Release Adjustments

There is potential for either an upward or a downward mid-year adjustment to the initial water year release. For modeling purposes, these adjustments occur in April.

An upward adjustment occurs if the end of water year (EOWY) projected Lake Powell elevation exceeds elevation 3,565 feet. In this case, the initial water year release is increased by half of the projected storage above elevation 3,565 feet, up to a maximum water year release of 12.0 maf.

A downward adjustment is evaluated to reduce the risk that Lake Powell will decline below elevation 3,510 feet during the next spring. If the projected Lake Powell elevation in the next spring is below 3,510 feet, the volume needed to maintain 3,510 feet is determined and used to adjust releases. First, the Lake Powell water year release is reduced to 7.0 maf if the initial release was greater than 7.0 maf. If additional reductions are necessary to meet the volume needed to maintain 3,510 feet, then the Lake Powell release is further reduced while CRSP Upper Initial Unit releases are increased. There is

an attempt to maintain a 1:1 ratio between the additional Lake Powell release reductions and the increased CRSP Upper Initial Unit releases, subject to a maximum CRSP Upper Initial Units release of 1.0 maf and a minimum Lake Powell water year release of 6.0 maf. The ***Infrastructure Protection and Other Considerations*** section describes the potential to reduce releases below 6.0 maf.

Coordination at High Elevations

For modeling purposes, a determination to potentially increase releases for the purpose of equalizing storage between Lake Powell and Lake Mead is made for the upcoming year if, on October 1, the net storage of all CRSP reservoirs exceeds the 602(a) storage volume and Lake Powell storage is greater than Lake Mead storage. The 602(a) storage volume is computed using the parameters from the 2007 Final EIS. **Appendix J**, Sensitivity Analysis – Effects of Assumed Parameter Values on 602(a) Storage, describes the 602(a) storage calculation and documents the parameters used in the 2007 calculation, which are also used in this analysis.

Infrastructure Protection and Other Considerations

If Lake Powell is projected to decline below elevation 3,510 feet during the current water year, annual releases may be reduced to as low as 6.0 maf. If Lake Powell is projected to decline below elevation 3,500 feet after these reductions are considered, water year releases may be further reduced to as low as 5.0 maf to protect critical Glen Canyon Dam infrastructure, subject to consultation. Monthly releases are adjusted to protect 3,510 and 3,500 feet subject to a minimum daily release established under the Long-Term Experimental and Management Plan.

T.2.3 Storage and Delivery of Conserved System and Non-System Water

The following sections reflect concepts included in the Lower Division States May 1 proposal. There are additional details on the specific modeling assumptions for the storage and delivery of conserved system and non-system water included in **Attachment T1**.

Lake Mead Mechanism

Water conserved by Lower Basin users would be stored in a pool in Lake Mead that can reach a maximum volume of 5.3 maf, which includes the storage of pre-2027 Intentionally Created Surplus (ICS) except for System Efficiency ICS. Annual total and state-based limits for conservation volumes and delivery of conserved water are presented in **Table T-3**. All conserved water stored in Lake Mead would be included in determinations of equalization releases from Lake Powell and in projections of Lake Mead's elevation for consultations regarding additional/reduced Lower Basin shortage or availability of Lower Basin surplus. Lower Colorado River entitlement holders, including Lower Basin Tribes, consistent with applicable implementation agreements, would be able to contribute to the conservation pool and to use their conserved water for delivery and/or in intra- and interstate transactions with other Lower Basin users.

Table T-3
Volume Limitations of Storage and Delivery of Conserved Water, 2027-2028 Operating Guidelines

Entity	Maximum Annual Contribution (kaf)	Maximum Cumulative Storage (kaf)	Maximum Annual Delivery (kaf)	Maximum Cumulative 2027-2028 Delivery (kaf)
Arizona	125	1,000	300	800
California	400	2,000	400	
Nevada	125	800	300	
Mexico[1]	250	1,500	N/A[2]	160
Total	**900**	**5,300**	**1,160**	**960**

1) Volumes include modeling assumptions for Mexico's storage and delivery limits. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.
2) There is an assumed maximum cumulative delivery to Mexico of 160 kaf for 2027–2028. No annual maximum is specified; the annual delivery is constrained only by the two-year cumulative limit of 160 kaf.

Water users could contribute or deliver water previously stored under this new mechanism at their discretion within the annual volume constraints related to the pool (**Table T-3**) and the elevation constraints described below. At the time the water is conserved, a one-time 10 percent system assessment would be applied, followed by an annual 3 percent evaporation deduction calculated based on the volume remaining in the Lake Mead mechanism at the end of the preceding calendar year.

Delivery of conserved water would be prohibited if Lake Mead begins the year with a pool elevation below 1,000 feet. For modeling purposes, if the beginning-of-year pool elevation is between 1,000 feet and 1,025 feet, delivery volumes are proportionally reduced so that the forecasted end of calendar year pool elevation does not fall below 1,000 feet. The cumulative delivery to the Lower Division States is limited to 800 thousand acre-feet (kaf) through the end of 2028. Additionally, deliveries from the Lake Mead mechanism would be limited to ensure that a state's annual apportionment or Mexico's annual allotment is not exceeded.

Lake Mead Mechanism (Federally Managed Water Resources Pool)

Although not included in this analysis, the 2027-2028 Operating Guidelines are anticipated to include a Federally Managed Water Resources Pool. For more information on the Federally Managed Water Resources Pool, see **Chapter 2**, Description of Alternatives, **Section 2.4.3.3.3**. The modeling of the Representative Preferred Alternative includes representative modeling of this pool.

Treatment of Pre-2027 Intentionally Created Surplus

For modeling purposes, ICS created under the 2007 Interim Guidelines, except for System Efficiency ICS, that remains in Lake Mead in 2027 is transferred to the Post-2026 Lake Mead water

user-controlled mechanism immediately and would be subject to all provisions described in the previous section.

System Conservation

As described in the Lower Division States May 1 proposal the Lower Division States intend to contribute a cumulative minimum of 700 kaf of system conservation through 2028. For modeling purposes, the 700 kaf is allocated as 300 kaf from Arizona, 300 kaf from California, and 100 kaf from Nevada. Each state's contribution is assumed to be split equally between 2027 and 2028. These volumes are separate from ICS, not stored in individual state pools, and in addition to the previously described shortage volumes (**Section T.2.1**).

T.2.4 Additional Activities Above Lake Powel

Upper Basin Conservation

No Upper Basin conservation is assumed to occur in the analysis of the 2027-2028 Operating Guidelines.

Releases to Protect Glen Canyon Dam

Releases from the CRSP Upper Initial Units to protect critical Glen Canyon Dam infrastructure would be considered, after appropriate consultations, within their RODs and contingent on hydrologic conditions, if Lake Powell is projected to go below elevation 3,510 feet. For modeling purposes, increased CRSP Upper Initial Unit releases occur contemporaneously with a reduction in the Lake Powell water year release below 7.0 maf. There is an assumed maximum additional CRSP Upper Initial Unit release of 1.0 maf. Releases would consider historical practices and volumetric reductions in Lake Powell releases. For modeling purposes, there is an attempt to maintain a 1:1 ratio between the Lake Powell release reductions below 7.0 maf and the increased CRSP Upper Initial Unit releases. Should Lake Powell begin to recover sufficient elevation, Reclamation would consult regarding opportunities for recovery of volumes of previous releases from the CRSP Upper Initial Units.

T.3 Analysis of 2027-2028 Operating Guidelines

This section analyzes the potential impacts associated with implementation of the 2027–2028 Operating Guidelines on hydrologic resources, water deliveries from the mainstream Lower Colorado River, and other applicable resources. The analyses in these sections mirror those include in **Chapter 3**, Affected Environment and Environmental Consequences, **Section 3.2**, Hydrologic Resources, and **Section 3.3**, Water Deliveries, and their corresponding Technical Appendices, **TA 3**, Hydrologic Resources, and **TA 4**, Water Deliveries, respectively.

To provide context, the analysis compares the 2027–2028 Operating Guidelines (described in **Section T.2**) with the Continued Current Strategies (CCS) Comparative Baseline scenario (summarized in **Chapter 3, Table 3.2**), the No Action Alternative (described in **Appendix S,** Additional Description of Alternatives), and the Representative Preferred Alternative (described in **Chapter 2**). These comparisons illustrate where the impacts associated with the 2027–2028

Operating Guidelines fall within the range of impacts analyzed for the Representative Preferred and No Action Alternatives in the Final EIS. As with the rest of the analysis in the Final EIS, the CCS Comparative Baseline scenario is provided to assess the impacts if operations were to continue under the current direction and strategies.[2] While the CCS Comparative Baseline is not an action alternative, it is a contemporary set of operations that stakeholders are familiar with that can be used to comparatively evaluate the performance of the alternatives.

T.3.1 Methodology

The analysis presented in this appendix is based on output from the CRSS, Reclamation's long-term planning model for the Colorado River Basin. CRSS simulates Basin conditions throughout the 2027–2060 Final EIS analysis period, accounting for hydrologic uncertainty while generating monthly projections of reservoir elevations, releases, river flows, and other operational metrics. Additional information about the No Action Alternative, CCS Comparative Baseline and Representative Preferred Alternative modeling assumptions can be found in **Appendix A**, CRSS Model Documentation and **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water. **Attachment T1** details the 2027-2028 Operating Guidelines modeling assumptions.

The comparisons presented in this appendix are based on the Decision Making under Deep Uncertainty (DMDU) framework used in this Final EIS. DMDU is a non-probabilistic evaluation framework that compares alternatives across a broad range of plausible future conditions and evaluates their performance under varying hydrologic conditions. Additional background and technical information on the DMDU framework are provided in **Appendix E**, DMDU Overview and Approach.

Analyses of the 2027–2028 Operating Guidelines are based on results for 2027–2028, whereas analyses of the CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative are based on the full 34-year Final EIS analysis period (2027–2060).

Results are summarized using conditional boxplots and summary statistics. Conditional boxplots group results by the preceding 3-year average Lees Ferry natural flow to facilitate comparisons among alternatives under similar hydrologic conditions (for example, average or dry conditions). Each figure includes results from all analysis years across 400 simulated futures, representing 800 data points for the 2027–2028 Operating Guidelines (two years) and 13,600 data points (34 years) for each of the CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative. Additional guidance for interpreting these figures is provided in **Chapter 3**, Affected Environment and Environmental Consequences, **Section 3.2.6**. Statistical summary tables that correspond to every boxplot in the following sections are included at the end of this appendix.

The difference in the underlying volume of data included for the 2027-2028 Operating Guidelines analysis versus the Representative Preferred Alternative may lead to the conclusion that the two-year operations would result in substantively different performance than the Representative Preferred

[2] This framework relies on strategies and agreements that expire in 2026, including the 2007 Interim Guidelines (as amended), the 2019 DCP, Minute 323 of the 1944 Water Treaty, and other agreements.

Alternative, but this is not an appropriate conclusion. The results over the shorter period are heavily influenced by the initial reservoir conditions in 2027, which are similar to what the 2027-2028 Operating Guidelines will be reacting to. In contrast, the results for Representative Preferred Alternative effectively incorporate hundreds of different initial reservoir conditions, including elevations significantly higher and significantly lower than current conditions. The expanded range of potential reservoir conditions is useful for evaluating a wide range of impacts, but not necessary for evaluating the range of potential near-term impacts. The relevant information is that, given the expected conditions in 2027, the potential impacts of the 2027-2028 Operating Guidelines are within the range of potential impacts associated with the Representative Preferred Alternative.

T.3.2 Hydrologic Resources

Impact Analysis Area

The geographic scope of the hydrologic resources analysis is the Colorado River corridor from the upstream limits of full pool elevation of Lake Powell to the downstream limits of the Southerly International Boundary (SIB). Reservoirs upstream of Lake Powell are operated pursuant to their own Records of Decision, which are not altered by the proposed alternatives.

Impact Indicators

The following indicators were used to assess impacts on hydrologic resources:

- **Reservoir elevations**: impacts on reservoir elevations due to operational activities
- **System storage**: impacts on system storage due to operational activities
- **Reservoir releases:** impacts on reservoir releases due to operational activities
- **River flows:** impacts on river flows due to operational activities
- **Groundwater**: qualitative impacts on groundwater adjacent to reservoirs and river reaches due to operational activities

Reservoir Elevation

This section evaluates how operational activities would affect reservoir elevations by comparing the 2027–2028 Operating Guidelines, CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative using the following metrics:

- Lake Powell pool elevations
- Lake Mead pool elevations

Lake Powell

This section presents a comparison of the 2027–2028 Operating Guidelines with the CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative with respect to minimum water year (WY) and EOWY elevations at Lake Powell. A description of critical Lake Powell elevations is listed in **TA 3**, Hydrologic Resources, **Table TA 3-2**. The total live storage capacity of Lake Powell at the full pool elevation of 3,700 feet is 23.31 maf (excluding approximately 1.9 maf of flood control space).

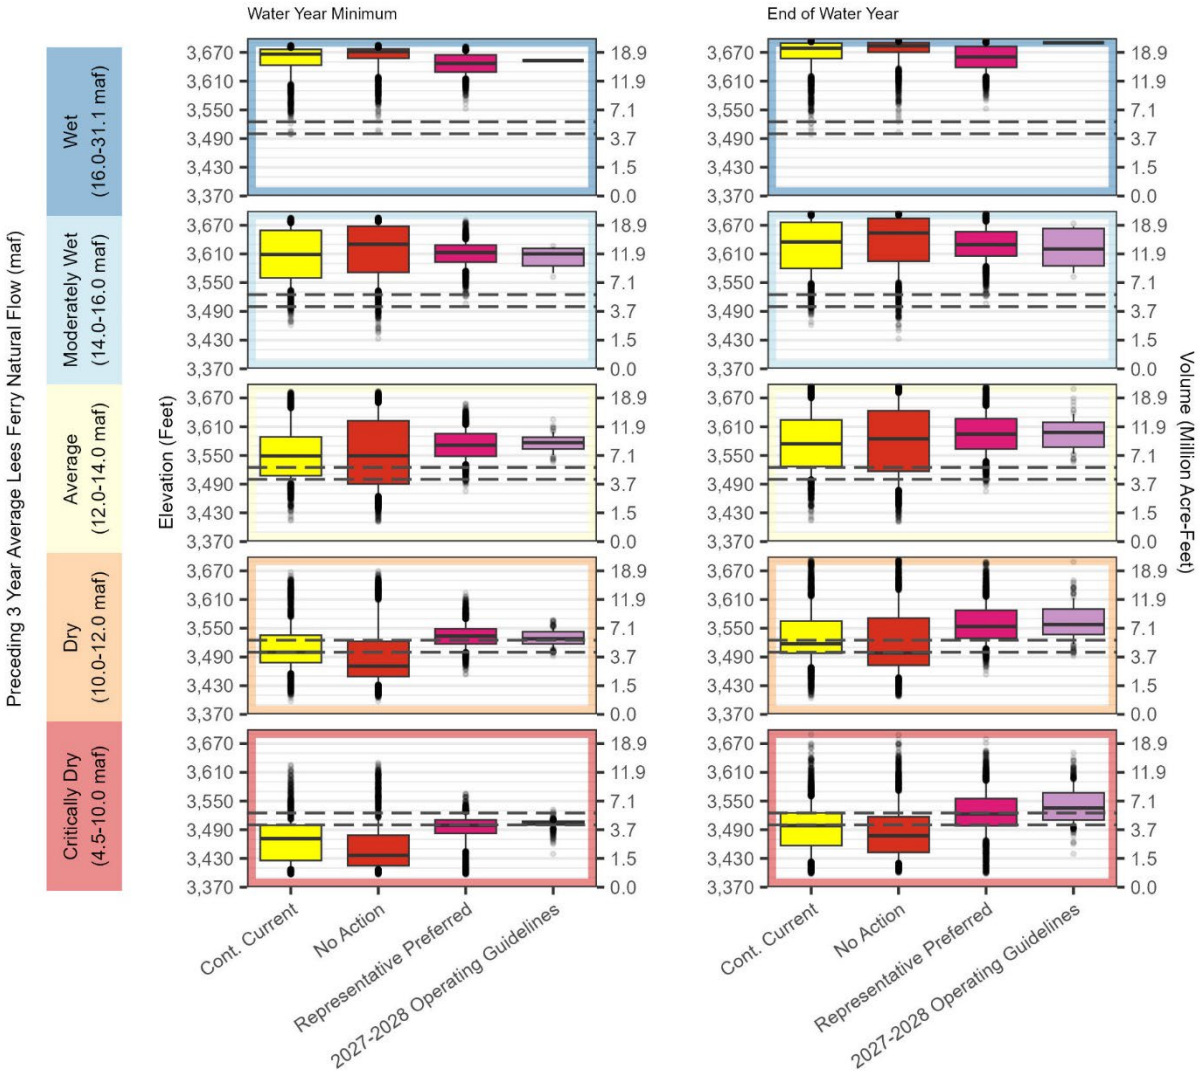


Figure T-3 shows minimum WY elevations and EOWY elevations at Lake Powell (feet) for each alternative using conditional boxplots. The boxplots show how the alternatives perform under varying hydrologic conditions, defined by the preceding three-year average of Lees Ferry natural flow. The bottom and top of each box captures the 25th to 75th percentile of the modeled results, respectively. The lines extend to the 10th and 90th percentiles, and outliers are shown as dots. To enable easier comparison of all flow categories, the vertical axes may have been truncated at the high end, and some outliers may have been omitted. Statistical summaries of the left and right columns are provided in **Table T-5** and **Table T-6** at the end of this appendix**.**

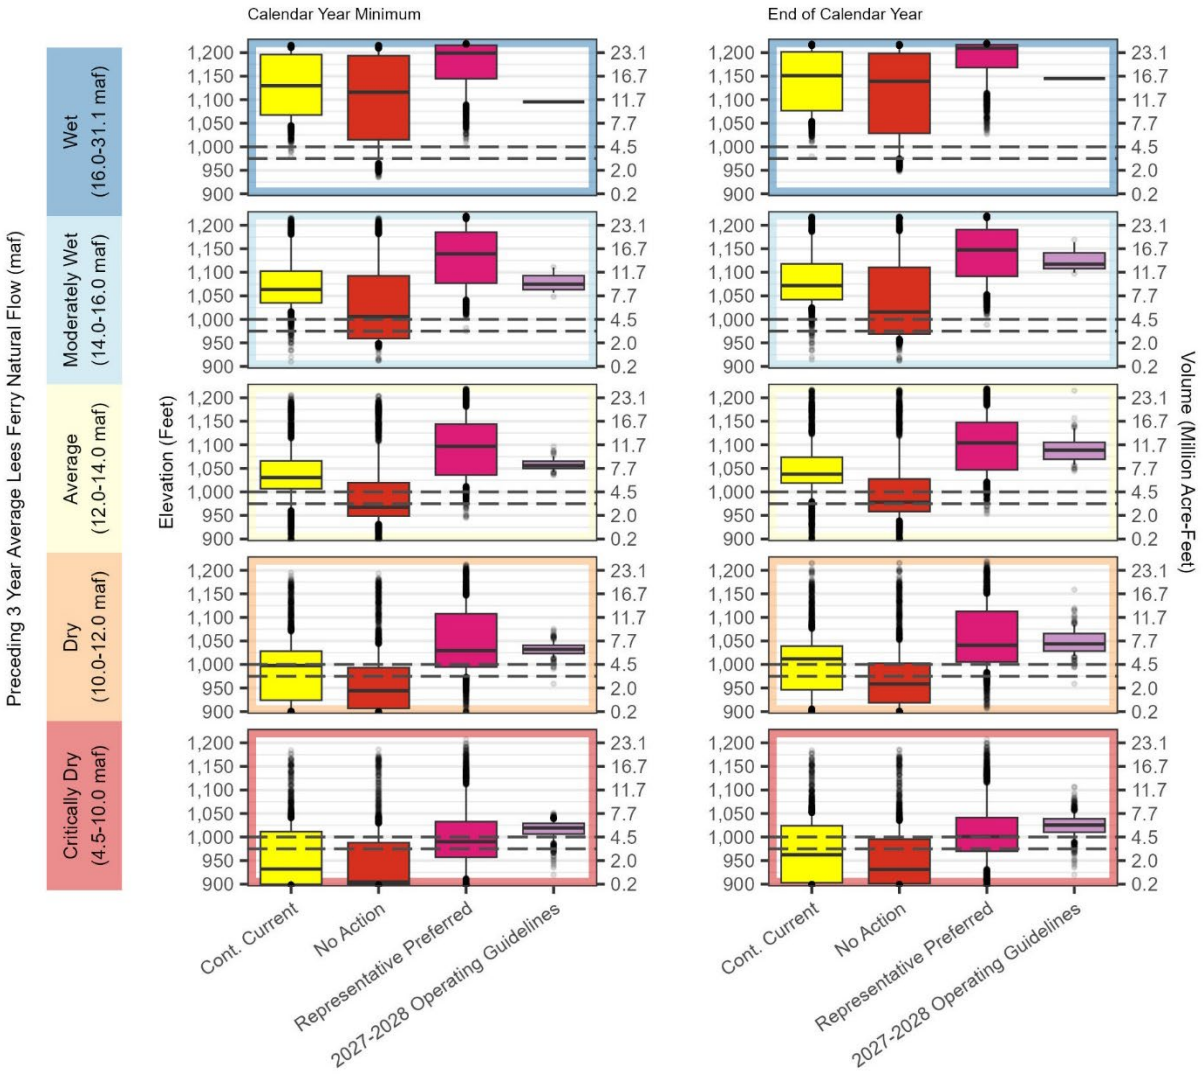
In each flow category shown in the boxplots, the critical elevation thresholds of 3,525 feet and 3,500 feet are identified with dashed lines. These elevations are important because they provide a 10-foot and a 35-foot buffer above 3,490 feet—the elevation below which water can only be released through the river outlet works. Operating below 3,490 feet limits the volume of water that can be released, since water can only pass through the river outlet works. As described in **Chapter 1**, Purpose and Need, **Section 1.8.4.1**, there are infrastructure concerns associated with the uncertainty of extended operations through the river outlet works as the sole means of sustained water releases from Glen Canyon Dam that could compromise the reliability and operational flexibility of Glen Canyon Dam and affect the ability to meet critical downstream water supply needs. There are additional impacts to hydropower associated with operating below 3,490 feet as this is minimum power pool.

The 2027-2028 Operating Guidelines result in median WY minimum elevations of 3,577, 3,528, and 3,505 feet in the Average, Dry, and Critically Dry Flow Categories, respectively. In the Critically Dry Flow Category, the 10th percentile minimum elevation falls below 3,500 feet, with outliers dropping below 3,500 feet in the Dry Flow Category. The median WY minimum elevations of the 2027-2028 Operating Guidelines are similar to those of the Representative Preferred Alternative, with all of the 2027-2028 Operating Guidelines WY minimum elevations falling within the range of elevations from the Representative Preferred Alternative. The modeled Lake Powell operations in the 2027-2028 Operating Guidelines, which adjust to maintain elevation 3,510 feet, are effective at avoiding elevation 3,500 feet. Only the outliers below the 10th percentile in the Dry Flow Category and the 25th percentile and below in the Critically Dry Flow Category fall below elevation 3,500 feet.

For the EOWY elevations at Lake Powell, the 2027-2028 Operating Guidelines result in median elevations of 3,598, 3,558, and 3,535 feet in the Average, Dry, and Critically Dry Flow Categories, respectively. Similar to the WY minimum elevations, the 10th percentile EOWY elevation falls below 3,500 feet in the Critically Dry Flow Category, whereas elevations below 3,500 feet occur only as outliers in the Dry Flow Category. Median EOWY elevations are slightly higher than those of the Representative Preferred Alternative in the Average, Dry, and Critically Dry Flow Categories. Overall, the WY minimum and EOWY elevations in the 2027-2028 Operating Guidelines fall within the range of the elevations in the Representative Preferred Alternative.

Figure T-3
WY Minimum and EOWY Elevations and Storage Volumes of Lake Powell



Lake Mead

This section presents a comparison of the 2027–2028 Operating Guidelines with the CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative with respect to minimum calendar year (CY) and end of calendar year (EOCY) elevations at Lake Mead. Critical elevations at Lake Mead listed in **TA 3**, Hydrologic Resources, **Table TA 3-5** preserve infrastructure and ensure Hoover Dam continues to operate under its intended design for purposes of downstream water releases. The total live storage capacity of Lake Mead at the full pool elevation of 1,219.6 feet is 26.12 maf (excluding approximately 1.5 maf of Flood Control storage available above the maximum operating elevation).

Figure T-4 shows minimum CY and EOCY elevations at Lake Mead (feet) for each alternative using conditional boxplots. Statistical summaries of data are provided in **Table T-7** and **Table T-8**

at the end of this appendix. In each flow category, the critical thresholds of 1,000 feet and 975 feet are identified with dashed lines. These elevations are important because they provide a 50-foot and a 25-foot buffer from 950 feet—the elevation below which water can only be released through the intake towers, constraining both the volume of water able to be released as well as the ability to generate power. Lake Mead requires larger buffers above the hydropower and critical infrastructure elevations than Lake Powell because Reclamation is required to deliver water orders that have already been approved. As a result, there is generally less flexibility to adjust releases from Hoover Dam than from Glen Canyon Dam.

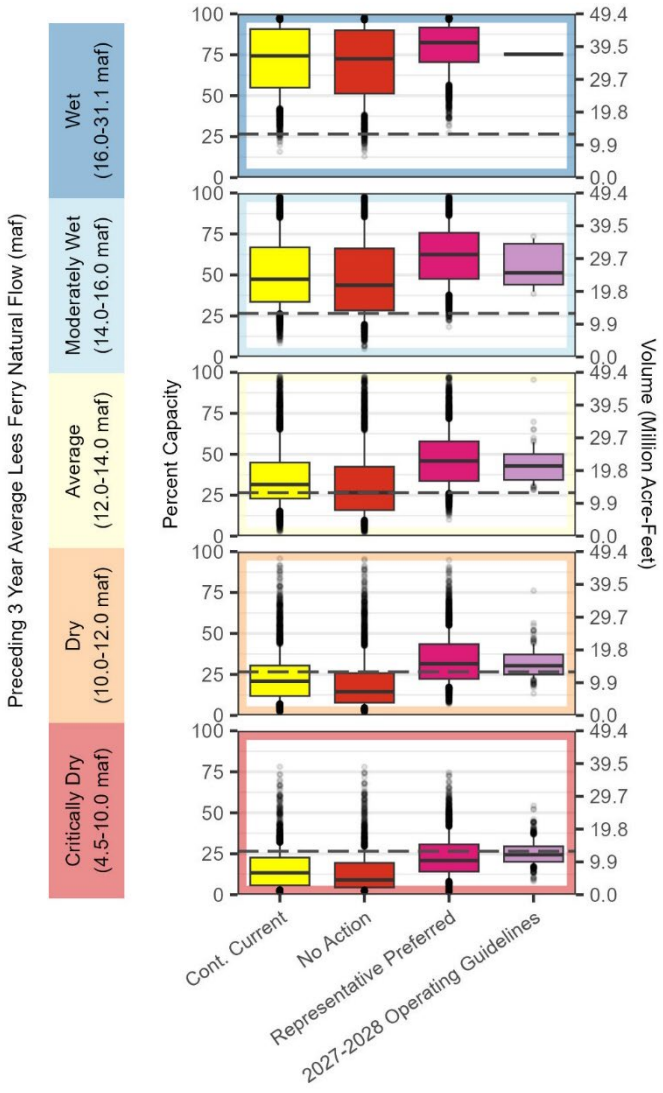
Figure T-4
CY Minimum and EOCY Elevations and Storage Volumes of Lake Mead

The 2027-2028 Operating Guidelines have median CY minimum elevations of 1,056, 1,032, and 1,019 feet in the Average, Dry, and Critically Dry Flow Categories, respectively. In the Critically Dry Flow Category, the 10th percentile elevation falls below 1,000 feet, with outliers dropping below 975 feet. In the Dry Flow Category, minimum elevations below 975 feet occur only as outliers. The

range of CY minimum elevations is much narrower than that of the Representative Preferred Alternative because the 2027-2028 Operating Guidelines boxplot includes data only for the two-year period, which is heavily influenced by the initial conditions as previously discussed. Additionally, the 2027-2028 Operating Guidelines model a total Lower Basin shortage of 1.5 maf, while the Representative Preferred Alternative models shortages up to 3.6 maf, which affects Lake Mead's elevation.

For the EOCY elevations at Lake Mead, the median EOCY elevations of the 2027-2028 Operating Guidelines are 1,089, 1,044, and 1,025 feet in the Average, Dry, and Critically Dry Flow Categories, respectively. Like the CY minimum elevations, in the Critically Dry Flow Category, the 10th percentile EOCY elevation falls below 1,000 feet, with outliers dropping below 975 feet. In the Dry Flow Category, EOCY elevations below 975 feet only occur as outliers. Overall, CY minimum and EOCY elevations at Lake Mead under the 2027–2028 Operating Guidelines fall within the range of impacts evaluated for the Representative Preferred Alternative.

System Storage



This section evaluates how operational activities would affect system storage by comparing the 2027–2028 Operating Guidelines, CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative using the EOWY combined system storage at Lake Powell and Lake Mead.

This metric provides insight into overall system conditions because Lake Powell and Lake Mead account for approximately 85 percent of the total storage volume in the major Colorado River system reservoirs. Excluding space allocated for surcharge and flood control, the live storage capacity is 23.31 maf at Lake Powell and 26.12 maf at Lake Mead, for a maximum combined live storage capacity of 49.43 maf.

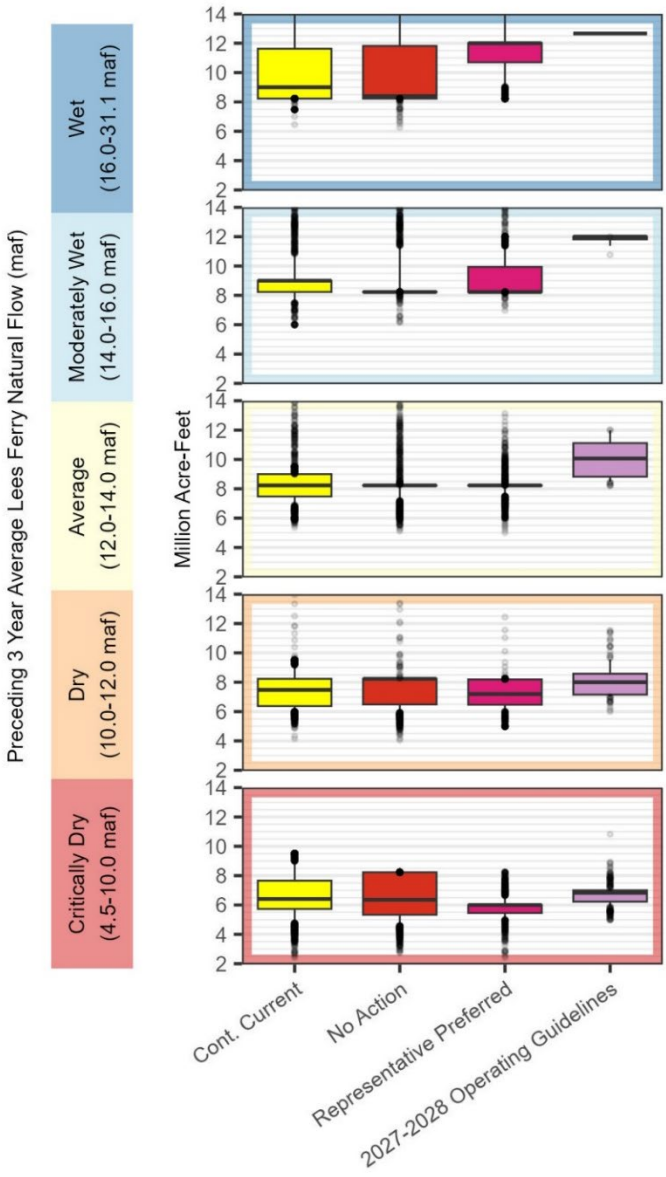
Figure T-5 presents conditional boxplots of EOWY combined storage in Lake Powell and Lake Mead. The vertical axis shows combined percent full on the left and volume of storage on the right. A threshold line indicates the lowest observed EOWY combined storage, which occurred in September 2022, at 26.55 percent full (equivalent to 13.1 maf). A statistical summary of the data is provided in **Table T-9** at the end of this appendix.

The 2027-2028 Operating Guidelines result in a median EOWY combined storage at Lake Powell and Lake Mead of 42.9, 30.3, and 24.4 percent capacity in the Average, Dry, and Critically Dry Flow Categories, respectively. Compared to the Representative Preferred Alternative, the median combined storage is lower in the 2027-2028 Operating Guidelines in all flow categories except the Critically Dry Flow Category. The 25th percentile combined storage falls below the minimum observed combined storage in the Dry Flow Category, while the median combined storage falls below the minimum observed combined storage in the Critically Dry Flow Category. Overall, EOWY combined Powell and Mead storage under the 2027–2028 Operating Guidelines fall within the range of impacts evaluated for the Representative Preferred Alternative.

Figure T-5
EOWY Combined Storage at Lake Powell and Lake Mead

Reservoir Releases

This section evaluates how operational activities would affect reservoir releases by comparing the 2027–2028 Operating Guidelines, CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative using the following metrics:



- WY Releases from Glen Canyon Dam
- 10-Year Releases from Glen Canyon Dam
- 10-Year Flows at Lee Ferry Compact Point
- CY Releases from Hoover Dam
- CY Releases from Davis Dam
- CY Releases from Parker Dam

Glen Canyon Dam

Releases from Glen Canyon Dam, at Lake Powell, are based on the operations as summarized in **Section T.2.2**.

Figure T-6 presents conditional boxplots of WY releases (maf) from Glen Canyon Dam. The y-axis has been truncated to facilitate easier comparison of the alternatives, see **Table T-10** at the end of this appendix for the full statistical summary.

Figure T-6
WY Releases from Glen Canyon Dam[3]

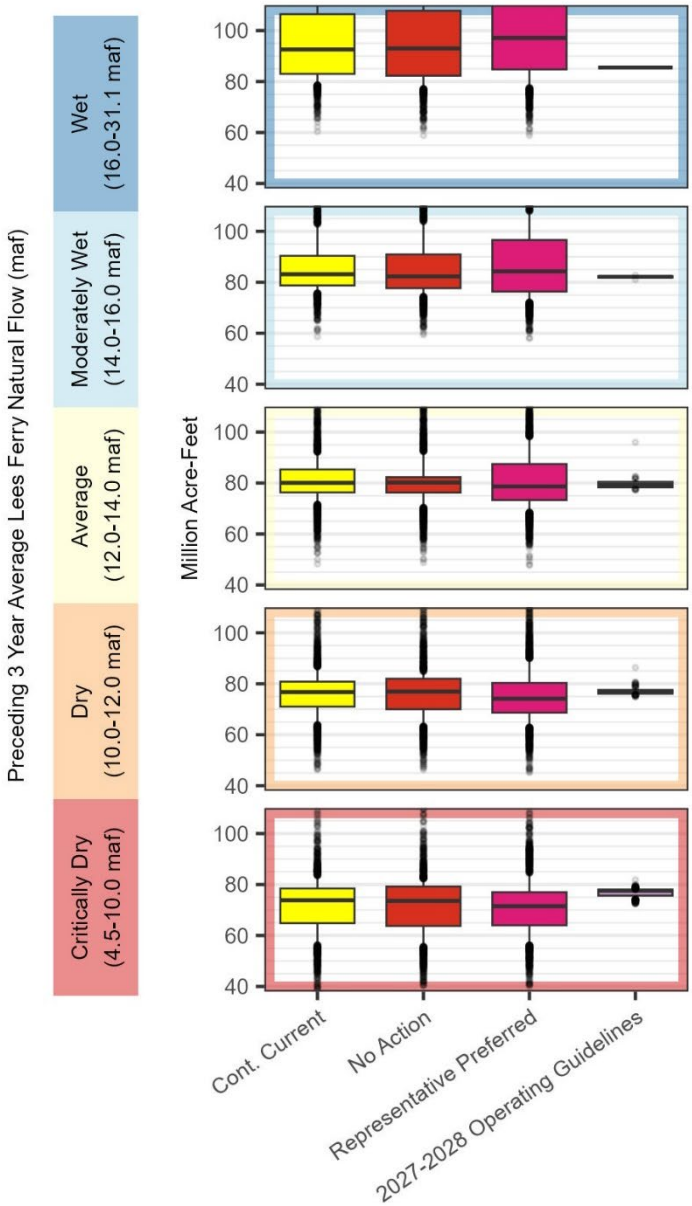
[3] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-10** for the full range of the data.

The 2027-2028 Operating Guidelines result in median WY Glen Canyon Dam release of 10.07, 8.00, and 6.83 maf in the Average, Dry, and Critically Dry Flow Categories, respectively. The median WY Glen Canyon Dam release in the 2027-2028 Operating Guidelines is higher than in the Representative Preferred Alternative in all flow categories. As previously discussed, the releases for the 2027-2028 Operating Guidelines are heavily influenced by initial conditions, and the number of data points analyzed compared to the other alternatives. The minimum WY Glen Canyon Dam release in the 2027-2028 Operating Guidelines is as low as 5.0 maf in the Critically Dry Flow Category. Overall, the WY Glen Canyon Dam release under the 2027–2028 Operating Guidelines fall within the range of impacts evaluated for the Representative Preferred Alternative.

Glen Canyon Dam 10-Year Releases

Figure T-7 presents conditional boxplots of cumulative 10-year releases from Glen Canyon Dam. The y-axis is truncated to enable easier comparison of alternatives. See **Table T-11** at the end of this appendix for the full statistical summary.

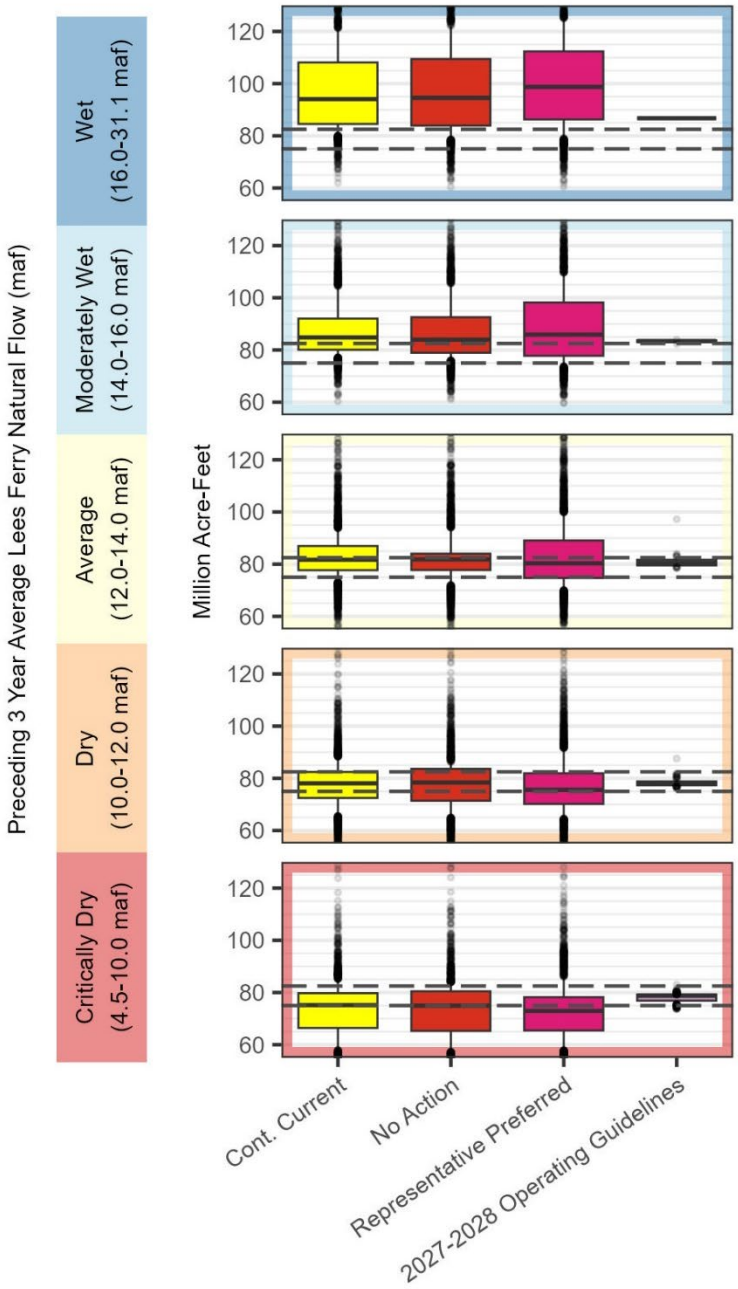
The 2027-2028 Operating Guidelines result in median 10-year releases from Glen Canyon Dam of 79.3, 77.0, and 77.6 maf in the Average, Dry, and Critically Dry Flow Categories, respectively. The median release volumes in the 2027-2028 Operating Guidelines are higher than the Representative Preferred Alternative in the Average, Dry and Critically Dry Flow Categories, largely due to the influence of initial conditions, which is even more influential in this metric, and the number of data points. The 10-year release volumes are all very similar since they are driven by the prior 9 or 8 years of historical flows. Overall, the 10-year releases from Glen Canyon Dam under the 2027–2028 Operating Guidelines fall within the range of impacts evaluated for the Representative Preferred Alternative.



Cumulative 10-Year Lee Ferry Flows

The Lee Ferry Compact Point is the division point between the Upper Basin and the Lower Basin, as established by the 1922 Colorado River Compact. The Lee Ferry Compact point is in Arizona, approximately 17 miles downstream of Glen Canyon Dam and approximately 1 mile downstream of the confluence with the Paria River. Refer to **TA 3**, Hydrologic Resources, **Figure TA 3-2** in the Affected Environment Section for a map of the Lee Ferry Compact Point.

Figure T-8 presents conditional boxplots of cumulative 10-year Lee Ferry flow volumes (maf). In each flow category, 75.0 maf and 82.5 maf are shown with dashed lines**.** To facilitate easier comparison of alternatives, the y-axis is truncated. See **Table T-12** at the end of this appendix for the full statistical summary.

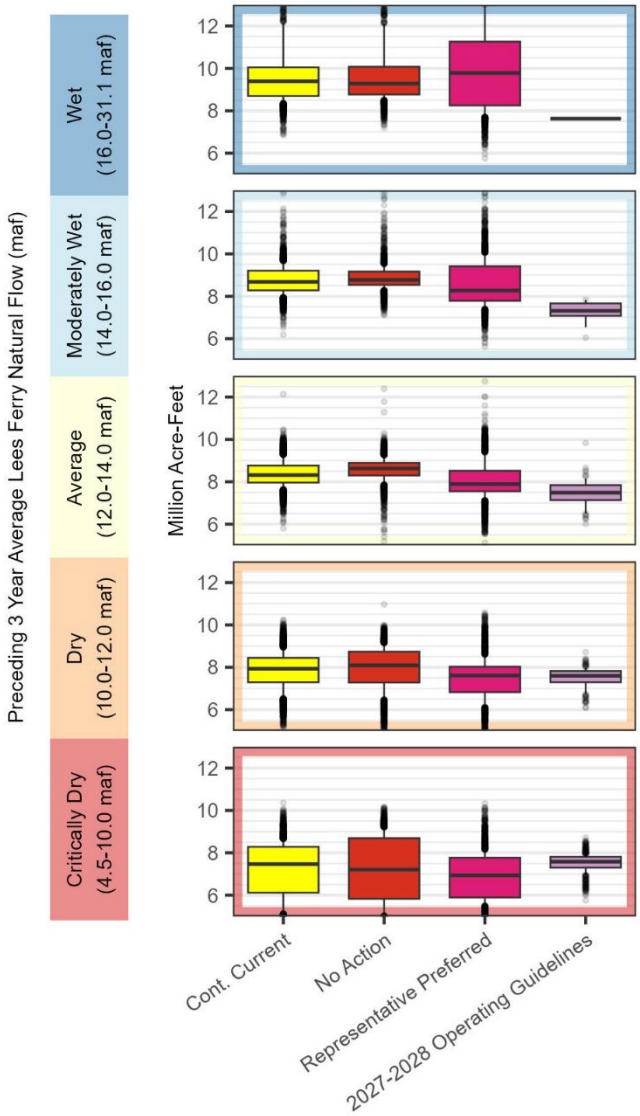


The 2027-2028 Operating Guidelines result in median 10-year cumulative Lee Ferry flow volumes of 80.5, 78.2, and 78.8 maf in the Average, Dry, and Critically Dry Flow Categories, respectively. These median volumes are below the 82.5 maf threshold, while only the outliers in the Critically Dry Flow Category fall below the 75 maf threshold. The 10-year cumulative Lee Ferry flow volumes are all very similar since they are driven by the prior 9 or 8 years of historical flows. Overall, the 10-year cumulative Lee Ferry flow volumes under the 2027–2028 Operating Guidelines fall within the range of impacts evaluated for the Representative Preferred Alternative.

Figure T-7
10-Year Cumulative Releases from Glen Canyon Dam[4]

[4] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-11** for the full range of the data.

Figure T-8
Compact Point 10-Year Volume[5]



[5] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-12** for the full range of the data.

Hoover Dam

Releases from Hoover Dam, at Lake Mead, are based on downstream diversions and Lower Basin intervening flows. Diversions are impacted by the Lower Basin condition and the Lower Basin conservation, storage, and delivery of conserved system and non-system water. **Figure T-9** presents conditional boxplots of CY releases (maf) from Hoover Dam. The range of releases has been truncated to facilitate comparison of the alternatives, see **Table T-13** at the end of this appendix for the full range of data.

Figure T-9
CY Releases from Hoover Dam[6]

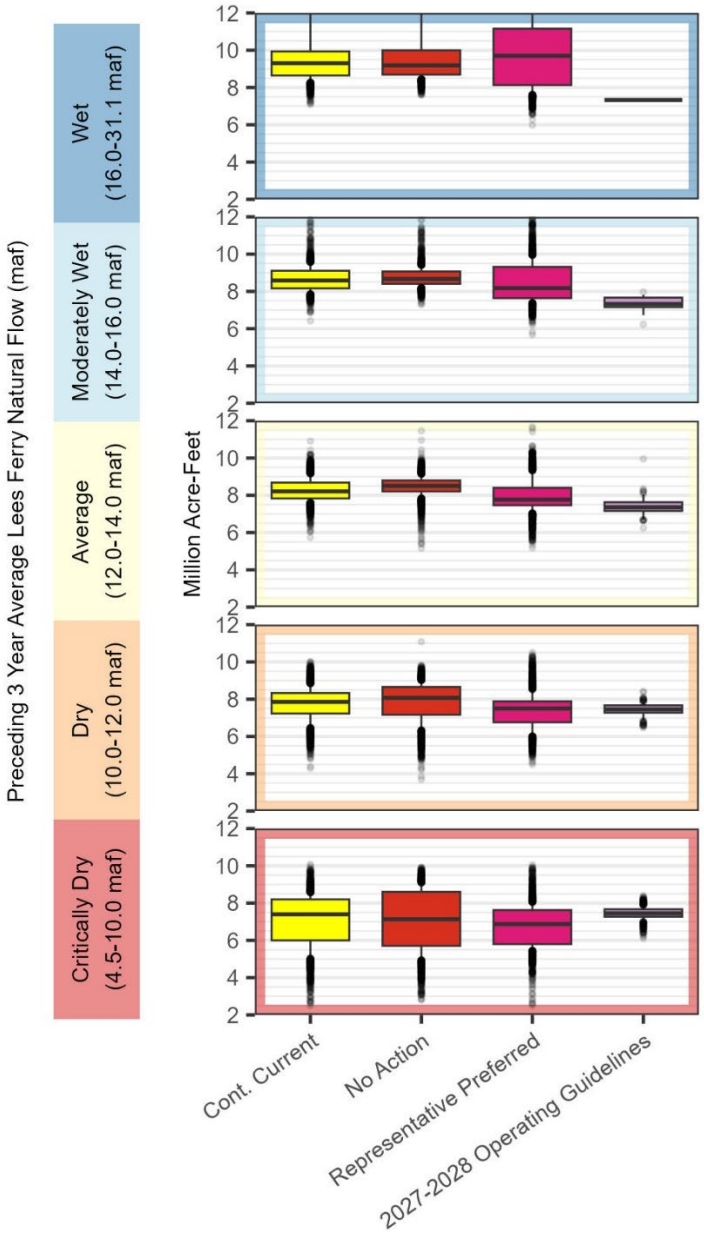
[6] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-13** for the full range of the data.

The 2027-2028 Operating Guidelines have median CY Hoover releases of 7.5, 7.6, and 7.6 maf in the Average, Dry, and Critically Dry Flow Categories, respectively. The median CY Hoover release under the 2027-2028 Operating Guidelines is lower than under the Representative Preferred Alternative in all flow categories except the Critically Dry Flow Category. The range of CY Hoover releases is much narrower than that of the Representative Preferred Alternative because the 2027-2028 Operating Guidelines only include data from the two-year period, which model a total Lower Basin annual shortage of 1.5 maf for all years and futures analyzed. In contrast, the Representative Preferred Alternative models shortages up to 3.6 maf, which explains the lower releases that are shown for it. Variability in Hoover releases is mainly driven by intervening inflows and diversions below Hoover. Overall, the CY Hoover release under the 2027–2028 Operating Guidelines falls within the range of impacts evaluated for the Representative Preferred Alternative.

Davis Dam

Releases from Davis Dam, at Lake Mohave, are based on target elevations defined by the existing rule curve (refer to **TA 6**, Water Quality). Inflows into Lake Mohave vary across alternatives, and because elevations are kept to the range determined by the rule curve, releases from Davis Dam subsequently vary across alternatives.

Figure T-10 presents conditional boxplots of CY releases from Davis Dam. The range of releases has been truncated to facilitate comparisons of alternatives, see **Table T-14** at the end of this appendix for the full statistical summary and full range of values.



The 2027-2028 Operating Guidelines result in median CY Davis Dam releases of 7.4, 7.5, and 7.5 maf in the Average, Dry, and Critically Dry Flow Categories, respectively. Similar to Hoover releases, the median CY Davis release under the 2027-2028 Operating Guidelines is less than or equal to that under the Representative Preferred Alternative in all flow categories except the Critically Dry Flow Category. The boxplots for the 2027-2028 Operating Guidelines Davis release are similar to the Hoover release though there is slightly less variability. Variability in releases is driven by the same factors as the Hoover release (i.e., downstream diversions and intervening inflows). Overall, the CY Davis release under the 2027–2028 Operating Guidelines falls within the range of impacts evaluated for the Representative Preferred Alternative.

Parker Dam

Releases from Parker Dam, at Lake Havasu, are based on target elevations defined by the existing rule curve (refer to **TA 6**, Water Quality). Inflows into Lake Havasu vary across alternatives, and because elevations are kept to the range determined by the rule curve, releases from Parker Dam subsequently vary across alternatives.

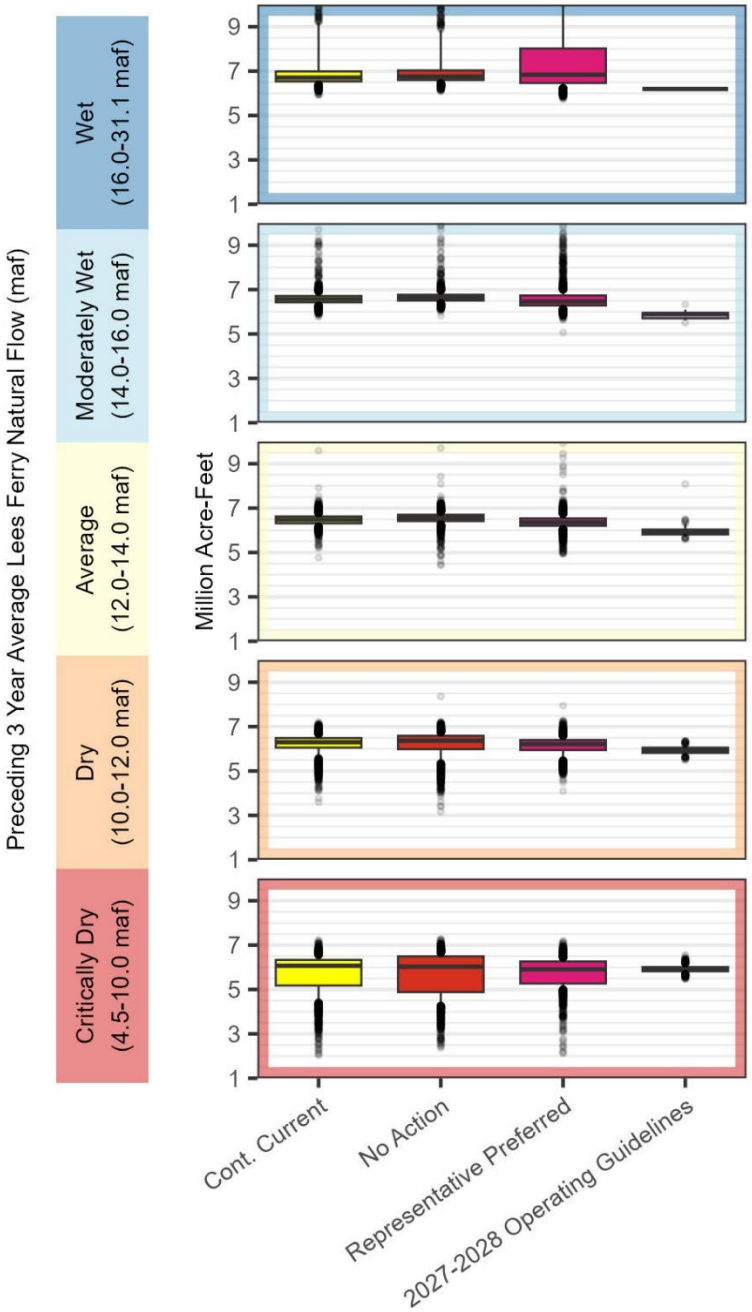


Figure T-11 presents conditional boxplots of CY releases from Parker Dam. The range of releases is truncated to facilitate comparisons between the alternatives, see **Table T-15** at the end of this appendix for the full statistical summary.

Figure T-10
CY Releases from Davis Dam[7]

[7] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-14** for the full range of the data.

Figure T-11
CY Releases from Parker Dam[8]

The 2027-2028 Operating Guidelines result in median CY Parker Dam releases of 5.9 maf in the Average, Dry, and Critically Dry Flow Categories. Similar to Hoover and Davis releases, the median CY Parker release under the 2027-2028 Operating Guidelines is lower than under the Representative Preferred Alternative in all flow categories except the Critically Dry Flow Category. The releases

[8] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-15** for the full range of the data.

from Parker Dam are affected by the assumed location (i.e., which CRSS water user) of the shortages and system conservation. **Attachment T1** provides details on these assumptions. Overall, the CY Parker release under the 2027–2028 Operating Guidelines falls within the range of impacts evaluated for the Representative Preferred Alternative.

River Flows

This section evaluates how operational activities affect river flows by comparing the 2027–2028 Operating Guidelines, CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative using the following metrics

- Annual Colorado River flows below Glen Canyon Dam
- Annual Colorado River flows below Hoover Dam
- Annual Colorado River flows below Davis Dam
- Annual Colorado River flows below Parker Dam
- Annual Colorado River flows at Imperial Dam
- Annual Colorado River flows below Imperial Dam
- Annual Colorado River flows below Morelos Diversion Dam

Reach 1: Glen Canyon Dam to Lake Mead

This reach of the river extends 292-miles from Glen Canyon Dam to Lake Mead through a series of narrow canyons, including Grand Canyon National Park. River flows in this reach primarily consist of controlled releases from Glen Canyon Dam at Lake Powell. Refer to **Section T.3.2** Reservoir Releases—Glen Canyon Dam, for the analysis of WY releases (**Figure T-6**) and 10-year cumulative releases (**Figure T-7**). While the results of the CRSS analysis are on an annual basis, monthly releases from Lake Powell at Glen Canyon Dam meet the 2016 LTEMP ROD (Reclamation 2016) minimum flows. Reclamation has the option to conduct high flow experiment releases from Glen Canyon Dam under certain conditions to reduce sediment deposition, which usually occurs in durations ranging from 60 hours to 10 days. Refer to **TA 5**, Geomorphology and Sediment, and **TA 8**, Biological Resources – Fish and Other Aquatic Species, for the analysis of high flow experiment flows from Glen Canyon Dam.

This reach also includes contributions from the Paria River and Little Colorado River, two perennial tributaries that discharge to the Colorado River between Glen Canyon Dam and Lake Mead. Based on historical USGS gage data, inflows from the Paria River and Little Colorado River make up approximately three percent of the total flow in this reach of the Colorado River (USGS 2025a). From 1906 to 2005, the annual inflow of the Paria River averaged 21.0 kafy and the Little Colorado River inflow averaged 180.0 kafy. Since 2007, the annual inflow from the Paria River averaged 17.0 kafy, and the Little Colorado River inflow averaged 274.0 kafy. Inflows from the Paria River and Little Colorado River were modeled in CRSS the same across alternatives.

Reach 2: Hoover Dam to Lake Mohave

This reach of the Colorado river) extends 67-miles from Hoover Dam at Lake Mead through Black Canyon, El Dorado Canyon, and Pyramid Canyon. Lake Mohave is on the downstream end of the reach, and acts hydraulically like a tailwater to Hoover Dam. River flows in this reach primarily

consist of releases from Hoover Dam, with small contribution from tributary inflows. According to the 2007 Final EIS, tributary inflows, mostly from side washes, comprise less than 1 percent of the total annual flow (Reclamation 2007a). Refer to **Section T.3.2** Reservoir Releases—Hoover Dam for the analysis of CY releases from Hoover Dam (**Figure T-9**).

Reach 3: Davis Dam to Lake Havasu

This reach of the Colorado River extends 84-miles from Davis Dam at Lake Mohave to Lake Havasu. River flows are primarily composed of releases from Davis Dam and tributary inflow from the Bill Williams River. Inflows from the Bill Williams River discharge directly into Lake Havasu and are regulated by the USACE operations of Alamo Dam. Annual inflow from the Bill Williams River averaged 102,000 af from 1906 through 2007, and 105,000 af from 2008 to 2022 (USGS 2025b).

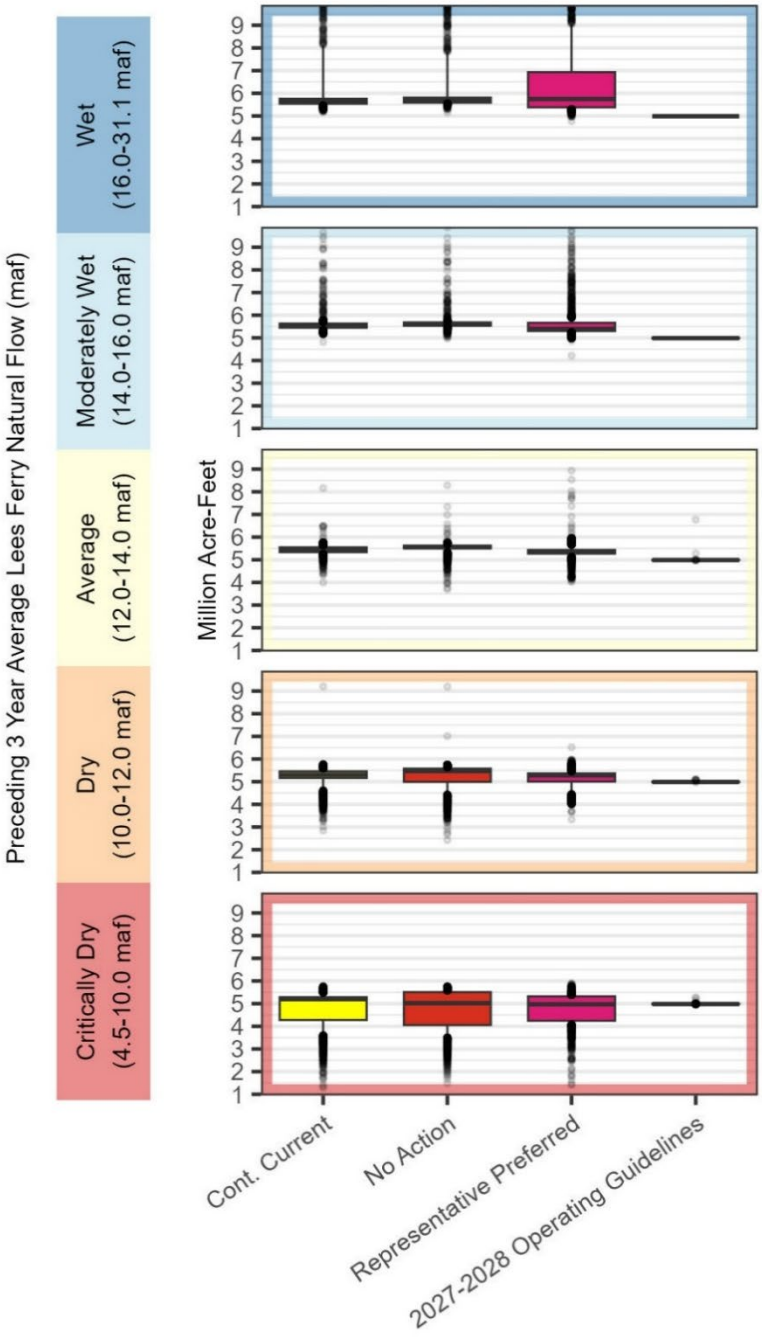
Because releases from Davis Dam are the primary component that differs among alternatives, they are used as the basis for comparison. Refer to **Section T.3.2** Reservoir Releases—Davis Dam for the analysis of CY releases from Davis Dam (**Figure T-10**).

Reach 4: Parker Dam to Cibola Gage

This reach of the Colorado river extends 105-miles from Parker Dam at Lake Havasu to Reclamation's Cibola Gage. Flows in this reach primarily consist of releases from Parker Dam. Two major diversion dams are located in this reach of the river: Headgate Rock Dam and Palo Verde Diversion Dam. The impoundments of these dams are used to facilitate the diversion of water for the Colorado River Indian Tribes and Palo Verde Irrigation District.

The analysis of flows for this reach is based on CY release volumes from Parker Dam. Refer to **Section T.3.2** Reservoir Releases—Parker Dam for the analysis of CY releases from Parker Dam (**Figure T-11**).

Reach 5: Cibola Gage to Imperial Dam



This reach of the river extends 38-miles from Reclamation's Cibola Gage to Imperial Dam at Imperial Reservoir. Flows in this reach consist primarily of releases from Parker Dam but are impacted by diversions and return flows. The Imperial Dam impoundment in this reach operates at a nearly constant elevation to meet water delivery requirements.

Figure T-12 presents conditional boxplots of annual flow volume at Imperial Dam. The range of volumes is truncated at the high end to facilitate comparisons between alternatives, see **Table T-16** at the end of this appendix for the full statistical summary.

The 2027-2028 Operating Guidelines result in median annual flow volume at Imperial Dam of 5.0 maf in the Average, Dry, and Critically Dry Flow Categories. The median annual flow volume at Imperial Dam under the 2027-2028 Operating Guidelines is less than or equal to that under the Representative Preferred Alternative in all flow categories. The annual flow volume boxplots at Imperial Dam for the 2027-2028 Operating Guidelines show variability only in the outliers, which are driven by intervening flows because releases from Hoover Dam are set to meet the downstream demands in consideration of the intervening flows. The annual flow volume at Imperial Dam is affected by the assumed location (i.e., which CRSS water user) of the shortages and system

conservation. **Attachment T1** provides details on these assumptions. Overall, the annual flow volume at Imperial Dam under the 2027–2028 Operating Guidelines falls within the range of impacts evaluated for the Representative Preferred Alternative.

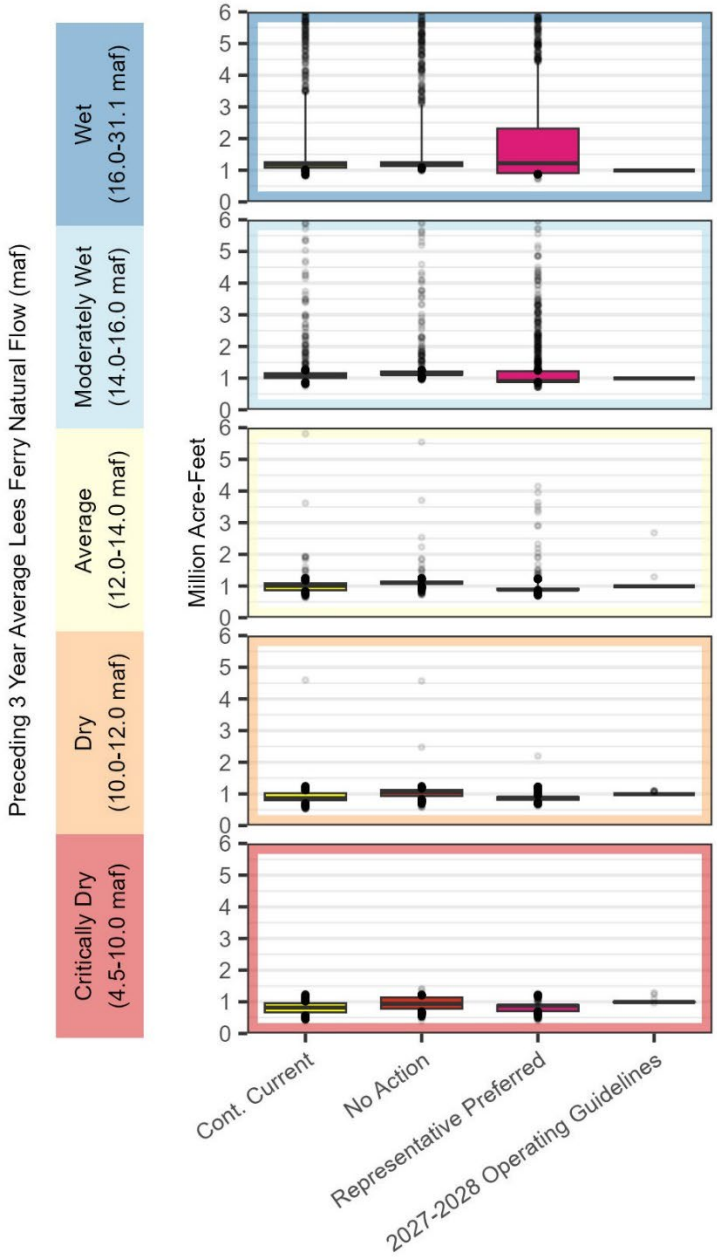
Figure T-12
Annual Flow Volume at Imperial Dam[9]

[9] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-16** for the full range of the data.

Reach 6: Imperial Dam to Northerly International Boundary
This reach of the Colorado river extends 26-miles from Imperial Dam to the Northerly International Boundary (NIB) between the U.S. and Mexico. Flows in this reach primarily consist of releases from Imperial Dam to meet downstream delivery requirements. They also include leakage from the All-American Canal (AAC) sluiceway gates and return flows from Imperial Dam diversions.

Figure T-13 presents conditional boxplots of annual flow volume below Imperial Dam. The range of volumes is truncated at the high end to facilitate comparisons between alternatives, see **Table T-17** at the end of this appendix for the full statistical summary

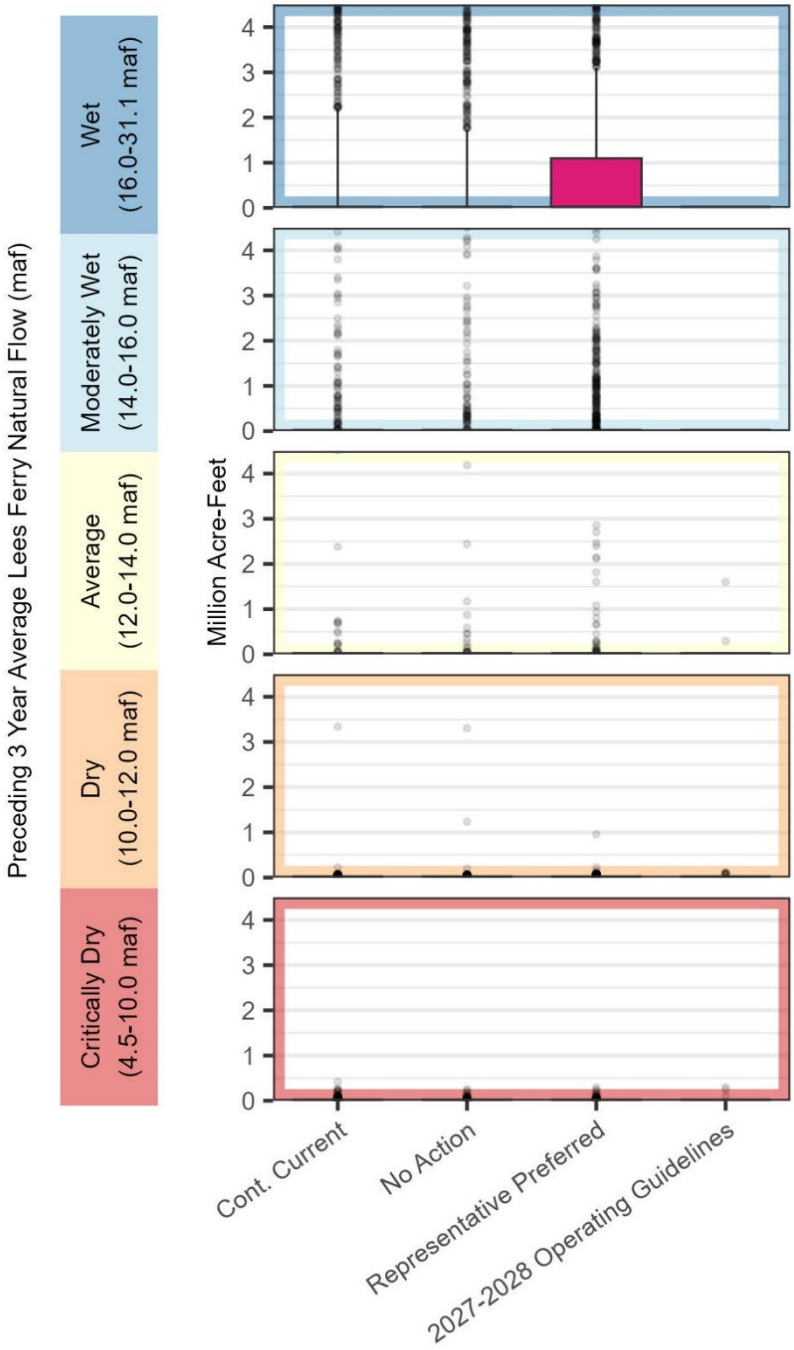
The 2027-2028 Operating Guidelines result in median annual flow volume below Imperial Dam of 1.0 maf in the Average, Dry, and Critically Dry Flow Categories. The median annual flow volume below Imperial Dam under the 2027-2028 Operating Guidelines is lower than under the Representative Preferred Alternative in the Wet flow category but slightly higher in all other flow categories. Differences in the median performance are due to the lower shortage volume (1.5 maf) under the 2027-2028 Operating Guidelines compared to the shortages up to 3.6 maf included in the Representative Preferred Alternative. Overall, the annual flow volume below Imperial Dam under the 2027–2028 Operating Guidelines falls within the range of impacts evaluated for the Representative Preferred Alternative.



Reach 7: Northerly International Boundary in the Limitrophe to Southerly International Boundary
This reach of the river, beginning at the NIB, is divided into two sub reaches. Approximately 1.1-miles downstream from the NIB is Moreles Dam, where, under normal operations, the remaining Colorado River flow is diverted into Mexico's Reforma Canal for water supply.

Downstream of Morelos Diversion Dam, the reach continues to the SIB and the Colorado River Delta. Flows in this reach, referred to as the limitrophe, consist of water in excess of Mexico's scheduled delivery. Excess flows may result from flood control operations at Hoover Dam, seepage from Morelos Diversion Dam, irrigation return flows, groundwater inflows, or water released for environmental purposes in the Colorado River Delta.

Figure T-14 presents conditional boxplots of annual flow volume below Morelos Diversion Dam. The range of volumes is truncated to facilitate comparisons between alternatives, se**e Table T-18** at the end of this appendix for the full statistical summary.



The 2027-2028 Operating Guidelines result in median annual flow volume below Morelos Diversion Dam of 0.0 maf in all flow categories. Although annual flows below Morelos Diversion Dam are infrequent in the two-year period coved by the 2027-2028 Operating Guidelines, flows in the limitrophe can exceed 10 maf (see **Table T-18**) when they do occur. These are the result of exceptionally high intervening flows included in some of the hydrologic futures included in the modeling analysis. Overall, the annual flow volume below Morelos Diversion Dam under the 2027–2028 Operating Guidelines falls within the range of impacts evaluated for the Representative Preferred Alternative.

Figure T-13
Annual Flow Volume Below Imperial Dam[10]

[10] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-17** for the full range of the data.

Figure T-14
Annual Flow Volume Below Morelos Diversion Dam[11]

[11] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table T-18** for the full range of the data.

Groundwater

Regional scale changes to groundwater are complex and hard to quantify without extensive data records and groundwater models. Current data on groundwater at a regional scale is limited in scope and historical duration.

There are no legal requirements to not deplete groundwater for nearby wells, although decreasing reservoir elevations may contribute to decreased groundwater elevations depending on hydraulic connectivity. Secondary impacts on groundwater are not considered in this analysis (e.g., if actions under the various alternatives would result in more groundwater pumping occurring in order to supplement decreased supply). See **TA 3**, Hydrologic Resources, *Issue 5: Groundwater*, for a discussion of impacts.

T.3.3 Water Deliveries

Impact Analysis Area

The geographic scope of the water deliveries analysis is the Colorado River corridor from the upstream limit of full pool elevation of Lake Powell to the downstream limit of the Southerly International Boundary. The geographic scope of this EIS does not extend above Lake Powell and accordingly does not include an analysis of the impact on Upper Basin water users. Although some of the alternatives include assumptions about Upper Basin conservation, they do not specify where conserved water is generated or the specific activities used to create those conservation volumes (see **Appendix B**, Modeling Assumptions, for more information).

Impact Indicators

This section discusses impacts on the Lower Division States' water deliveries, deliveries to Mexico, and the distribution of shortages within the Lower Division States. To quantify impacts, the following indicators are used:

- Magnitude of shortage volumes
- Distribution of shortages and depletions among the Lower Division States

Lower Division States Water Supply Determinations

This section evaluates the effects of operational activities on water deliveries to the Lower Division States and Mexico by comparing the 2027–2028 Operating Guidelines, CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative using the following metrics:

- Annual Lower Basin Reductions (Shortage and Lake Mead Dead Pool–Related Reductions)
- Annual Lower Basin Shortage
- Annual Shortage by State (Arizona, California, Nevada) and water delivery reductions to Mexico
- Annual Depletions by State (Arizona, California, Nevada) and Mexico
- Surplus

Shortages & Dead Pool–Related Reductions

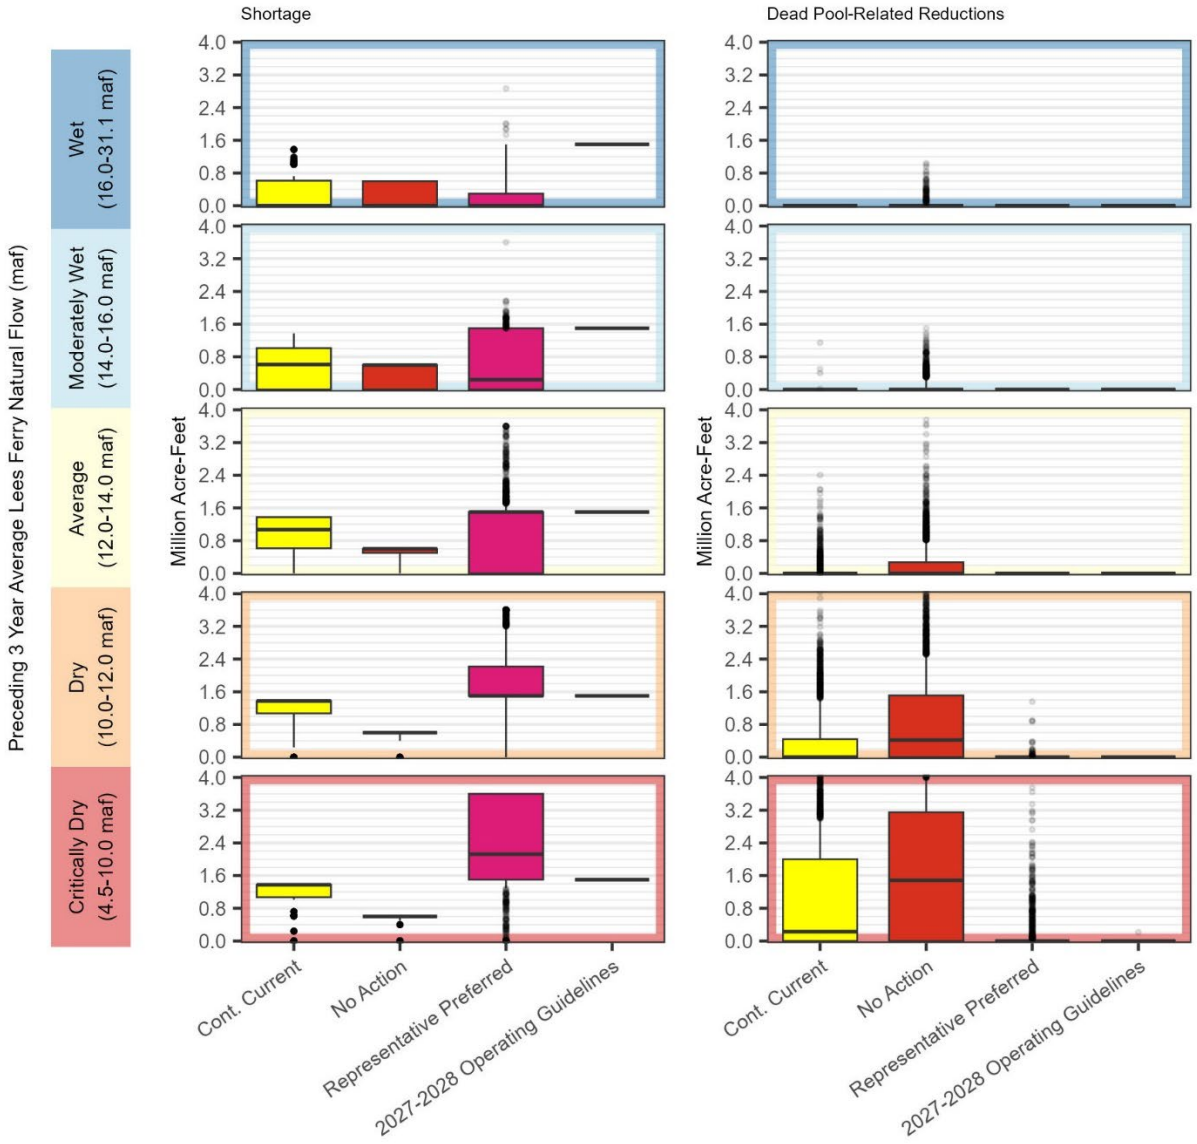
Shortage refers to delivery reductions at the Basin, state, or individual apportionment level that are defined and distributed as part of an alternative's shortage operations. Volumes and distributions of shortage are described in **Chapter 2,** Description of Alternatives. Dead pool–related reductions occur when there is not enough water in Lake Mead to fully meet downstream demands and/or when Hoover Dam infrastructure constraints result in releases below the demand volume. In some cases, these unplanned reductions occur because Lake Mead is approaching dead pool (elevation 895 feet) and in some cases they occur higher (up to elevation 950 feet).

The approach to distributing unplanned reductions associated with dead pool is not a component of any alternative. Although itis important for the impact analysis to show the volumes of these reductions, it is not appropriate to evaluate their effects on specific states or users. Accordingly, the results included beyond this section focus on shortages only. Any impacts associated with dead pool–related reductions are specifically noted.

Annual Lower Basin Reductions

Figure T-15 shows annual Lower Basin shortages and dead pool–related reductions for each alternative using conditional boxplots. The boxplots show how the alternatives perform under varying hydrologic conditions, defined by the preceding three-year average of Lees Ferry natural flow. The bottom and top of each box captures the 25th to 75th percentile of the modeled results, respectively. The lines extend to the 10th and 90th percentiles, and outliers are shown as dots. To enable easier comparison of all flow categories, the vertical axes may have been truncated at the high end and some outliers in the Critically Dry Flow Category may have been omitted. Statistical summaries of the left and right columns are provided in **Table T-19** and **Table T-20** at the end of this appendix.

Under the 2027–2028 Operating Guidelines, an annual shortage of 1.25 maf is distributed among the Lower Division States. For this analysis, an assumed reduction to Mexico increases the total annual Lower Basin shortage to 1.5 maf. Accordingly, as shown in **Figure T-15**, the 2027–2028 Operating Guidelines result in a fixed annual Lower Basin shortage of 1.5 maf across all flow categories. This shortage falls within the range of outcomes evaluated for the Representative Preferred Alternative, which has annual shortages ranging from 0 to 3.6 maf.



In general, smaller maximum shortage volumes correspond to more frequent and larger dead pool–related reductions, seen most prominently in the No Action Alternative. Dead pool–related reductions occur when there is not enough water in Lake Mead to fully meet downstream demands and/or when Hoover Dam infrastructure constraints result in releases below the demand volume. As shown in **Figure T-15**, the 2027–2028 Operating Guidelines result in relatively small dead pool–related reductions. This primarily reflects the short two-year analysis period and the initial reservoir conditions, rather than indicating that a 1.5 maf shortage is sufficient to avoid dead pool–related reductions under longer-term conditions.

In the Average Flow Category, neither the 2027–2028 Operating Guidelines nor the Representative Preferred Alternative results in dead pool–related reductions. In the Dry Flow Category, the 2027–2028 Operating Guidelines result in no dead pool–related reductions, whereas the Representative Preferred Alternative has a median dead pool–related reduction of zero and a maximum reduction

of 1.4 maf. This reflects the influence of the 2027 initial reservoir conditions rather than a significant distinction in performance (see **Section T.3.1**, Methodology) In the Critically Dry Flow Category, the Representative Preferred Alternative has a median dead pool–related reduction of zero and a maximum reduction of 3.8 maf, compared with a maximum reduction of 0.2 maf under the 2027–2028 Operating Guidelines.

Overall, impacts under the 2027–2028 Operating Guidelines fall within the range of impacts evaluated for the Representative Preferred Alternative.

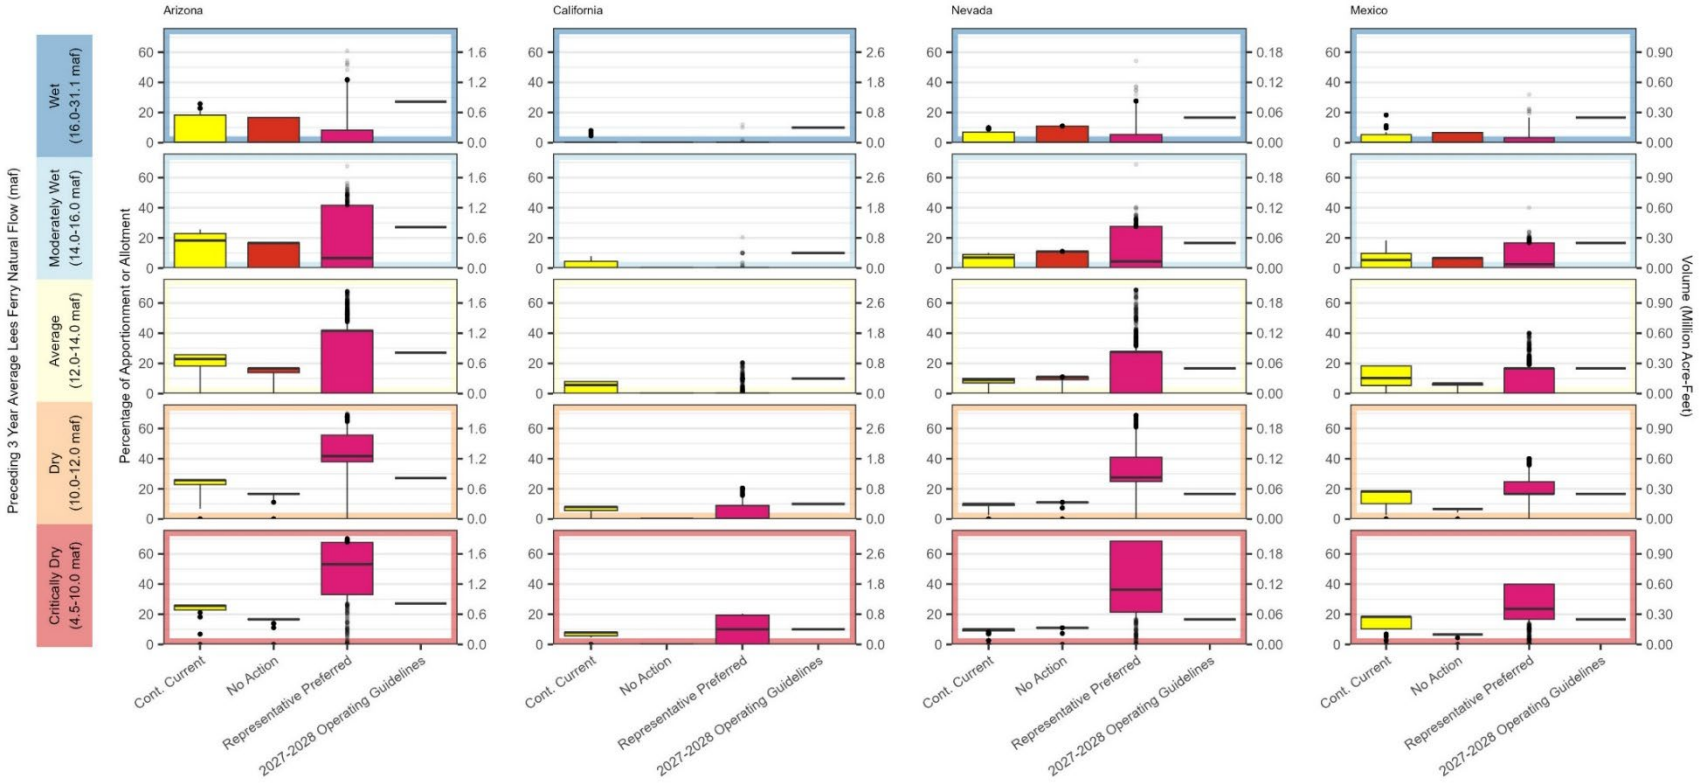
Figure T-15
Annual Lower Basin Reductions

Note: Shortage and dead pool-related reduction volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions

Annual Lower Basin Shortage

Figure T-16 shows shortages to each Lower Basin State and Mexico using four columns of conditional boxplots. The vertical axis for each state's column is scaled based on its respective volume of apportionment or allotment; the percent apportionment is shown on the left side of each column, and the absolute volume of shortage is shown on the right. Statistical summaries of the data are provided in **Table T-21** through **Table T-24** at the end of this appendix.

As shown in **Figure T-16**, the 2027–2028 Operating Guidelines result in an Arizona shortage of 760 kaf, or 27.1 percent of Arizona's apportionment, in each flow category. This shortage is lower than the Representative Preferred Alternative median shortage in the Average, Dry, and Critically Dry Flow Categories. In the Average Flow Category, the Representative Preferred Alternative has a median shortage of 41.7 percent of Arizona's apportionment and a maximum of 68.3 percent. In the Dry Flow Category, the median remains at 41.7 percent, while the maximum increases to 70.2 percent. In the Critically Dry Flow Category, the median increases to 53.1 percent, the maximum remains at 70.2 percent, all of which exceed the shortage under the 2027–2028 Operating Guidelines.



The 2027–2028 Operating Guidelines result in a California shortage of 440 kaf, or 10.0 percent of California's apportionment, in each flow category. This shortage exceeds the Representative Preferred Alternative median shortage in the Average and Dry Flow Categories and is equal to the median shortage in the Critically Dry Flow Category. In the Average Flow Category, the Representative Preferred Alternative has a median shortage of 0 percent of California's apportionment and a maximum of 20.5 percent. In the Dry Flow Category, the median remains at 0 percent and the maximum remains at 20.5 percent, with the shortage under the 2027–2028 Operating Guidelines exceeding the median but remaining below the maximum. In the Critically Dry Flow Category, the median increases to 10.0 percent of California's apportionment, equal to the shortage under the 2027–2028 Operating Guidelines, while the maximum remains at 20.5 percent.

For Nevada, the 2027–2028 Operating Guidelines result in a shortage of 50 kaf, or 16.7 percent of Nevada's apportionment, in each flow category. This shortage is lower than the Representative Preferred Alternative median shortage in the Average, Dry, and Critically Dry Flow Categories. In both the Average and Dry Flow Categories, the Representative Preferred Alternative has a median shortage of 27.6 percent of Nevada's apportionment and maximum of 68.7 percent. In the Critically Dry Flow Category, the median increases to 36.3 percent, the maximum remains at 68.7 percent, all of which exceed the shortage under the 2027–2028 Operating Guidelines.

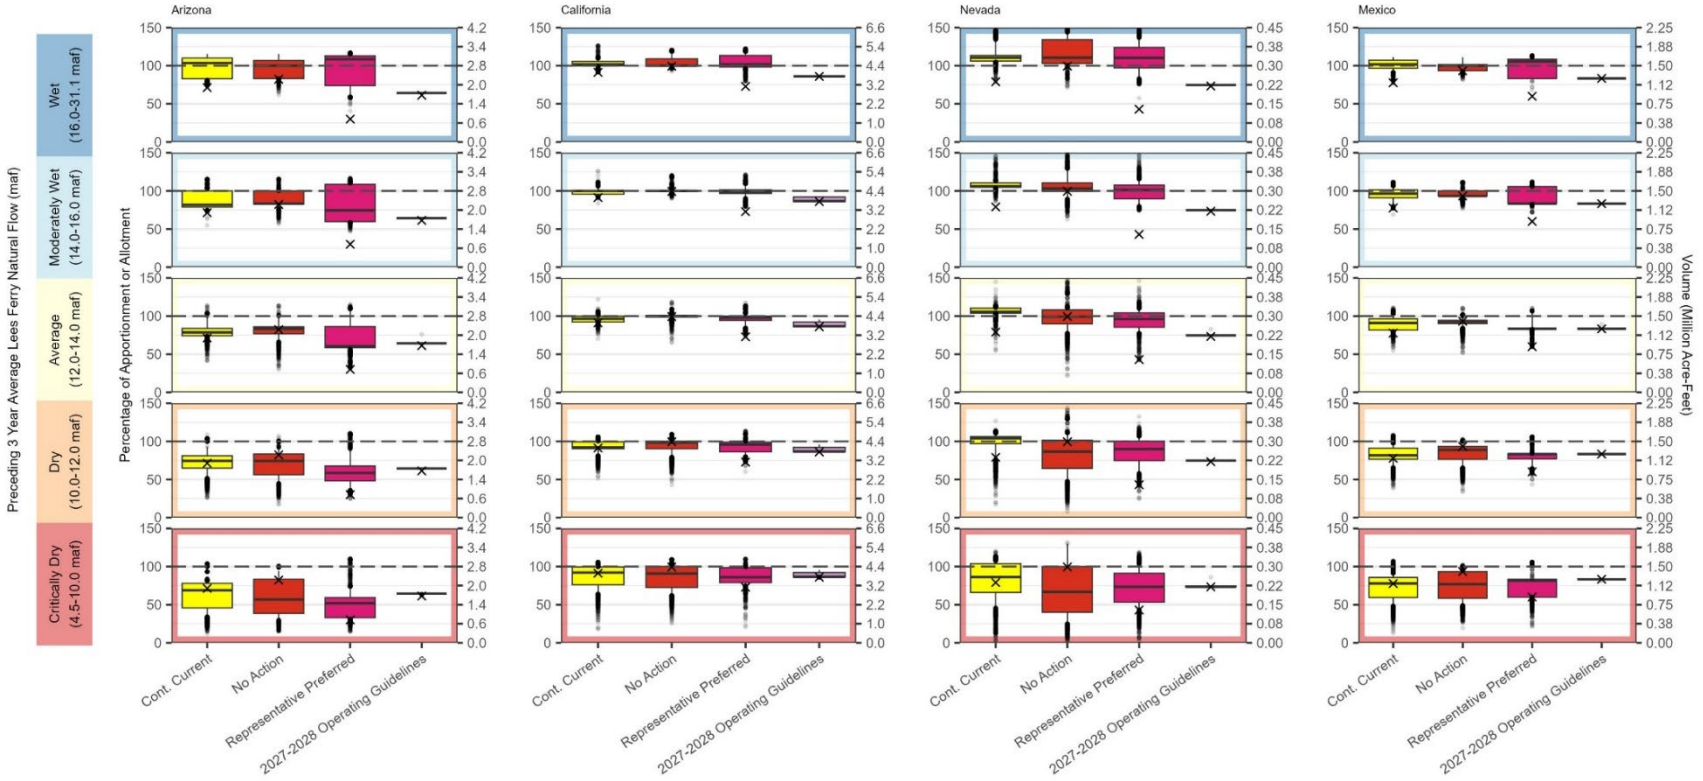
For purposes of this analysis, the 2027–2028 Operating Guidelines are evaluated assuming a reduction to Mexico of 250 kaf, or approximately 16.67 percent of Mexico's allotment. This reduction is equal to the Representative Preferred Alternative median reduction in the Average and Dry Flow Categories and lower than the median reduction in the Critically Dry Flow Category. In both the Average and Dry Flow Categories, the Representative Preferred Alternative has a median reduction of 16.67 percent of Mexico's allotment and a maximum of 40.0 percent. In the Critically Dry Flow Category, the median increases to 23.6 percent, the maximum remains at 40.0 percent, all of which exceed the reduction under the 2027–2028 Operating Guidelines.

Overall, impacts under the 2027–2028 Operating Guidelines fall within the range of impacts evaluated for the Representative Preferred Alternative.

Figure T-16
CY Shortage by State and Water Delivery Reductions to Mexico

Note: The modeled annual delivery reductions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Depletions



This section compares annual depletions for the Lower Division States and Mexico under the 2027–2028 Operating Guidelines, the Representative Preferred Alternative, the No Action Alternative, and the CCS Comparative Baseline. Depletion (also referred to as total consumptive use) is the net amount of water used and is calculated as the amount of water diverted from the river minus the return flow. Return flow is the portion of diverted water that is not consumed and returns to the river for subsequent downstream use. Depletions are influenced by the total shortage volume, the approach used to distribute shortages among the Lower Division States and Mexico, and modeling assumptions related to voluntary conservation mechanisms. Dead pool–related reductions are reflected in the depletion results presented in this section.

Figure T-17 shows annual depletions for each Lower Basin State and Mexico using four columns of conditional boxplots. Results are presented as both a percentage of apportionment or allotment (left axis) and a depletion volume (right axis). Unless otherwise noted, results are described in terms of percentage of apportionment or allotment. A dashed line at 100 percent of apportionment or allotment is included in each panel for reference. Each alternative also includes an "X" marker indicating the smallest depletion volume unaffected by dead pool–related reductions from Lake Mead; data points below the marker reflect depletions affected by infrastructure constraints at Lake Mead elevations near dead pool. The depletion volume associated with the marker differs among alternatives because shortage volumes vary, affecting the occurrence and magnitude of dead pool–related reductions. Statistical summaries of the data are provided in **Table T-25** through **Table T-28** at the end of this appendix.

Note, for the 2027–2028 Operating Guidelines, variability in depletions across flow categories reflects modeling assumptions related to Lake Mead storage and the delivery of conserved water rather than differences in shortage volumes (there is no variation in shortage volumes for 2027-2028 Operating Guidelines, as described in **Section T.2.1** and shown in **Figure T-16**). See **Attachment T1** for additional information on modeling assumptions specific to the 2027–2028 Operating Guidelines.

As shown in **Figure T-17**, the 2027–2028 Operating Guidelines result in Arizona depletions of approximately 1,802 kaf, or approximately 64.4 percent of Arizona's apportionment, in each flow category. This depletion exceeds the Representative Preferred Alternative median depletion in the Average and Dry Flow Categories and falls within the range of Representative Preferred Alternative outcomes in the Critically Dry Flow Category. In the Average Flow Category, the Representative Preferred Alternative has a median depletion of 60.4 percent of Arizona's apportionment and a maximum of 115.9 percent. In the Dry Flow Category, the median decreases to 58.5 percent, while the maximum decreases to 111.3 percent. In the Critically Dry Flow Category, the median decreases to 51.8 percent, the maximum decreases to 110.0 percent. The 2027–2028 Operating Guidelines depletions fall within the range of Representative Preferred Alternative outcomes.

Figure T-17
Annual Lower Basin Depletions

The 2027–2028 Operating Guidelines result in California depletions of approximately 3,810 kaf, or approximately 86.6 percent of California's apportionment, in each flow category. This depletion is lower than the Representative Preferred Alternative median depletion in the Average and Dry Flow Categories and falls between the median and maximum in the Critically Dry Flow Category. In the Average Flow Category, the Representative Preferred Alternative has a median depletion of 98.3 percent of California's apportionment and a maximum of 117.5 percent. In the Dry Flow Category, the median decreases to 95.8 percent, while the maximum decreases to 113.4 percent. In the Critically Dry Flow Category, the median decreases to 86.0 percent, the maximum decreases to 109.8 percent, with the 2027–2028 Operating Guidelines depletions falling within this range.

For Nevada, the 2027–2028 Operating Guidelines result in depletions of approximately 224 kaf, or approximately 74.7 percent of Nevada's apportionment. This depletion is lower than the Representative Preferred Alternative median depletion in the Average and Dry Flow Categories. In the Average Flow Category, the Representative Preferred Alternative has a median depletion of 96.1 percent of Nevada's apportionment and a maximum of 146.5 percent. In the Dry Flow Category, the median decreases to 89.7 percent, while the maximum decreases to 132.4 percent. In the Critically Dry Flow Category, the median depletion decreases to 73.3 percent—equal to the 2027–2028 Operating Guidelines median depletion—while the maximum decreases to 119.0 percent, placing the 2027–2028 Operating Guidelines depletions within the range Representative Preferred Alternative outcomes.

For purposes of this analysis, the 2027–2028 Operating Guidelines are evaluated assuming an annual reduction to Mexico of 250 kaf, resulting in annual depletions of approximately 1,250 kaf, or approximately 83.3 percent of Mexico's allotment. In the Average Flow Category, the Representative Preferred Alternative has a median depletion of 83.3 percent of Mexico's allotment and a maximum of 110.6 percent. In the Dry Flow Category, the median remains at 83.3 percent, while the maximum decreases to 106.5 percent. In the Critically Dry Flow Category, the median decreases to 81.5 percent, the maximum decreases to 105.6 percent. The 2027–2028 Operating Guidelines median depletion is equal to the Representative Preferred Alternative median depletion in the Average and Dry Flow Categories and exceeds the median but remains below the maximum in the Critically Dry Flow Category.

Overall, depletions under the 2027–2028 Operating Guidelines fall within the range of Representative Preferred Alternative outcomes.

Surplus

As noted in **Section T.2.1**, the 2027–2028 Operating Guidelines require consultation regarding reduced shortage volumes or the availability of Surplus when the EOCY Lake Mead elevation is projected to exceed 1,145 feet. For this analysis, the maximum EOCY Lake Mead elevation in 2027 is approximately 1,106 feet, which is below the 1,145-foot threshold. Although modeled EOCY elevations in 2028 exceed 1,145 feet **(Figure T-4)**, any resulting Surplus determination would apply to 2029 and is, therefore, beyond the scope of this analysis.

See **TA 4**, Water Deliveries, for additional information on the percentage of years with Surplus deliveries for the CCS Comparative Baseline, No Action Alternative, and Representative Preferred Alternative.

T.3.4 Other Environmental Resource Areas

Impacts to other resources are expected to fall within the range shown for the Representative Preferred Alternative in the technical appendices (**Volume III**). This is because impacts to these resources are driven primarily by reservoir elevations and releases, which are similar under the 2027-2028 Operating Guidelines and the Representative Preferred Alternative, as discussed in **Section T.3.1** above.

Specifically, results for the Dry and Critically Dry Flow Categories under the Representative Preferred Alternative best represent the range of potential impacts under the 2027-2028 Operating Guidelines. Impacts in 2027 fall within the Critically Dry Flow Category because of dry Lees Ferry natural flow conditions in 2024-2026 (see **Appendix G**, CRSS Initial Conditions, **Table G-2**). Although the flow category in 2028 depends on 2027 hydrology, impacts within the Dry and Critically Dry Flow Categories are the most plausible. Achieving the Average Flow Category in 2028 would require a Lees Ferry natural flow greater than 17.9 maf to occur in 2027, which occurred only once this century (2011). The Moderately Wet Flow Category would require a Lees Ferry natural flow greater than 23.9 maf, which has occurred only once in the historical record (1984), while the Wet Flow Category would require a Lees Ferry natural flow greater than 29.9 maf, which has never occurred in the historical record.

Modeling results for the 2027-2028 Operating Guidelines also show that annual releases from Glen Canyon Dam (**Figure T-6**) and Hoover Dam (**Figure T-9**) are generally greater than those under the Representative Preferred Alternative, particularly in the Dry and Critically Dry Flow Categories, while remaining within the range of Representative Preferred Alternative outcomes. These larger releases may mitigate adverse impacts to several resources, including hydropower, air quality, socioeconomics, population and land use, and indian trust assets.

Table T-4 below summarizes how the potential environmental impacts under the 2027-2028 Operating Guidelines compare with the modeled impacts for the Representative Preferred Alternative shown in **Volume III**. The *Explanation* column provides the basis for these comparisons by relating reservoir elevations and releases under 2027-2028 Operating Guidelines to those under the Representative Preferred Alternative, as shown in in **Figure T-3** (Lake Powell pool elevation), **Figure T-4** (Lake Mead pool elevation), **Figure T-6** (Glen Canyon Dam WY releases), and **Figure T-9** (Hoover Dam CY releases), with a focus on the Dry and Critically Dry Flow Categories.

Table T-4
Potential Environmental Impacts of the 2027-2028 Operating Guidelines Compared to the Representative Preferred Alternative

Resource	Potential Environmental Impact	Explanation
Geomorphology and Sediment (TA-5)	Similar to the Representative Preferred Alternative.	Lake Powell elevations are similar between the 2027-2028 Operating Guidelines and the Representative Preferred Alternative, indicating impacts on the ability to perform High Flow Experiments are expected to be similar.
Water Quality (TA-6)	Salinity concentration below Hoover Dam could be similar to or lower than the Representative Preferred Alternative. Impacts to dissolved oxygen and temperature below Glen Canyon Dam are expected to be similar to the Representative Preferred Alternative.	Calendar year releases from Hoover Dam under the 2027-2028 Operating Guidelines tend to be larger than under the Representative Preferred Alternative. Dissolved Oxygen and temperature are heavily impacted by Lake Powell elevations, which are similar.
Air Quality (TA-7)	Shoreline dust emissions from Lake Powell and Lake Mead are expected to be similar to the Representative Preferred Alternative.	2027-2028 Operating Guidelines have similar elevations but higher releases from Glen Canyon Dam and Hoover Dam, which could result in more hydropower production, mitigating the need for ancillary power sources. Similar reservoir elevations indicate similar shoreline dust emissions.
Fish and Aquatic Resources (TA-8)	Smallmouth bass (SMB) growth rate (lambda), SMB entrainment, and temperatures below Glen Canyon Dam are expected to be similar to the Representative Preferred Alternative. Important barriers to upstream fish movement (Lake Powell elevations 3,598, 3,600, 3,666.5 feet and Lake Mead elevation 1,090 feet) are expected to be maintained except under average or wetter hydrology. Minimum monthly releases from Hoover Dam and instream flows in reaches below Hoover Dam are expected to be higher than under the Representative Preferred Alternative.	Lambda, entrainment, and temperatures are heavily influenced by reservoir elevations, which are similar to the Representative Preferred Alternative. Important fish barriers are expected to be maintained in 2027-2028 due to low initial reservoir conditions. Flows in reaches below Hoover Dam are expected to be similar or greater than under the Representative Preferred because modeled Lower Basin shortages do not exceed 1.5 maf compared to 3.6 maf in the Representative Preferred Alternative.

Resource	Potential Environmental Impact	Explanation
Vegetation (TA-9)	Impacts to vegetation at Lake Powell are expected to be similar to the Representative Preferred Alternative. Impacts in the Grand Canyon are expected to be similar, as well, but with potentially less encroachment towards the river channel. Similar or less negative impacts to vegetation at Lake Mead and in reaches below Lake Mead are expected.	Lake Powell annual releases are similar enough that variability in inflows could have a greater impact on Lake Powell vegetation, and inflows are very similar between alternatives. Less encroachment in the Grand Canyon may occur because of larger releases under the Critically Dry Flow Category compared to the Representative Preferred Alternative. Releases from Lake Mead are less variable under the 2027-2028 Operating Guidelines, which may benefit marsh and woody vegetation.
Terrestrial Wildlife (TA-10)	Same as Vegetation	Same as Vegetation
Cultural Resources (TA-11)	Impacts similar as shown for the Representative Preferred Alternative.	Reservoir elevations are similar to Representative Preferred Alternative.
Paleontological Resources (TA-12)	Impacts similar as shown for the Representative Preferred Alternative.	Reservoir elevations are similar to the Representative Preferred Alternative.
Tribal Resources (TA-13)	Impacts similar as described for the Representative Preferred Alternative, but with potentially less exposure of sites near the riverbank.	Reservoir elevations are similar to the Representative Preferred Alternative, but releases under Critically Dry and Dry Flow Categories tend to be greater than the Representative Preferred Alternative.
Recreation (TA-14)	Proportion of recreation sites open is expected to be similar. Access to boat ramps at or above 1,040 feet at Lake Mead and above 3,590 feet at Lake Powell may be limited. Boating hazards due to elevations below 1,170 feet at Lake Mead and below 3,620 feet at Lake Powell are expected. Flows above 8,000 cfs and 5,000 cfs below Glen Canyon for whitewater boating are expected to be maintained at similar or higher frequencies. compared to the Representative Preferred Alternative.	Low initial reservoir conditions result in a low proportion of recreation sites open and suggest boat ramps at or above 1,040 feet at Lake Mead and 3,590 feet at Lake Powell may not be available unless hydrologic conditions improve. Likewise, elevations above 1,170 feet at Lake Mead and 3,620 at Lake Powell are unlikely in 2027-2028. Flows below Glen Canyon are expected to be similar or higher because the 2027-2028 Operating Guidelines tend to release larger annual volumes in Dry and Critically Dry Flow Categories than the Representative Preferred Alternative.

Resource	Potential Environmental Impact	Explanation
Dams and Electrical Power Resources (TA-15)	Both Glen Canyon Dam and Hoover Dam generation and capacity could be similar or greater than what is shown for the Representative Preferred Alternative. Minimum power pool elevations of 3,490 feet at Glen Canyon Dam and 950 feet at Hoover Dam are expected to be maintained. Loss of hydropower production due to Lake Mead elevations below 1,035 feet can occur under the Dry and Critically Dry Flow Categories. Risk to infrastructure due to high reservoir elevations is unlikely.	Similar elevations but larger releases compared to the Representative Preferred Alternative could result in greater capacity and generation. Elevations below 3,490 and 950 feet occur only as the outliers in the Critically Dry category. Elevations below 1,035 feet at Lake Mead occur frequently in the Dry and Critically Dry category due to low initial conditions and a maximum shortage of 1.5 maf. High reservoir elevations only occur in the Moderately Wet and Wet Flow Categories.
Socioeconomics (TA-16)	Impacts to cropland, market value, jobs, labor income, and total economic output are the same as reported for 'Representative Preferred (2027-2028)', but only up to 1.5 maf of shortage. The economic values of angling and rafting below Glen Canyon Dam are expected to be similar or higher than the Representative Preferred Alternative.	TA-16 reports impacts to cropland, market value, jobs, labor income, and total economic output under the LB Priority distribution and 1.5 maf of shortage, consistent with the 2027-2028 Operating Guidelines. Similar elevations but larger releases may increase the projected economic value of angling and rafting.
Population and Land Use (TA-17)	Impacts similar to or less than what is shown for the Representative Preferred Alternative are expected.	2027-2028 Operating Guidelines implement a maximum shortage of 1.5 maf whereas the Representative Preferred Alternative has a maximum of 3.6 maf.
Indian Trust Assets (TA-18)	Impacts similar to or less than what is shown for the Representative Preferred Alternative are expected.	2027-2028 Operating Guidelines implement a maximum shortage of 1.5 maf whereas the Representative Preferred Alternative has a maximum of 3.6 maf.
Visual Resources (TA-19)	Height of calcium carbonate rings at Lake Powell and Lake Mead are expected to be similar to what is shown for the Representative Preferred Alternative. Cathedral in the Desert is expected to be visible and accessible.	Elevations are similar to what is shown for the Representative Preferred Alternative. Due to low initial conditions, elevations are expected below 3,550 feet in 2027-2028 unless hydrologic conditions are Average or wetter.

T.4 Summary

This analysis shows that the anticipated 2027-2028 Operating Guidelines generally have similar or higher Lake Powell and Lake Mead elevations than the Representative Preferred Alternative, particularly in the Dry and Critically Dry Flow Categories at the median and lower percentiles. Where there are differences, these mainly reflect the shorter timeframe for the 2027-2028 Operating Guidelines and the influence of the 2027 initial reservoir conditions rather than a significant distinction in performance (see **Section T.3.1**, Methodology) The analysis of Lake Powell elevations shows that the modeled Lake Powell operations in the 2027-2028 Operating Guidelines, which adjust to maintain elevation 3,510 feet, are effective at avoiding elevation 3,500 feet. Only the outliers below the 10th percentile in the Dry Flow Category and the 25th percentile and below in the Critically Dry Flow Category fall below elevation 3,500 feet.

The 2027-2028 Operating Guidelines do not model shortages above 1.5 maf, but do include 700 kaf of additional system conservation, while the Representative Preferred Alternative includes shortages up to 3.6 maf. This affects the variability in releases from Hoover Dam as well as the flows in all reaches below Hoover Dam. This variability is also reflected in the analysis of Lower Basin shortages and deliveries, which only vary due to the assumed ICS behavior. The analysis of Lake Mead elevation and the dead pool-related reductions indicates that given the expected initial conditions in 2027, the 2027-2028 Operating Guidelines are effective at protecting elevation 950 feet at Lake Mead; however, there are still some cases where Lake Mead declines below elevation 1,000 feet in the two-year period, particularly in the Critically Dry Flow Category.

For all of the analyzed impact indicators in the Hydrologic Resources and Water Deliveries, and given the expected initial conditions in 2027, the potential impacts of the 2027-2028 Operating Guidelines are within the range of potential impacts associated with the Representative Preferred Alternative. Impacts to other resources are expected to fall within the range shown for the Representative Preferred Alternative in the technical appendices. This is because impacts to these resources are driven primarily by reservoir elevations and releases, which are similar under the 2027-2028 Operating Guidelines and the Representative Preferred Alternative.

Note: Dead pool-related delivery reduction volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

[12] Dead pool–related reductions are in addition to shortages specified in each alternative. Shortages are shown in **Table T-19**.

Note: The modeled annual depletions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State

Attachment T1

Modeling Assumptions for Anticipated Operating Guidelines for 2027-2028

This page intentionally left blank.

Attachment T1. Modeling Assumptions for Anticipated Operating Guidelines for 2027-2028

As of the date of this Final EIS, the anticipated guidelines for the first operating interval (2027 and 2028) are still being refined. These anticipated guidelines are based on extensive engagement with the Basin States and incorporate tribal input. For the purpose of this attachment, these anticipated guidelines are referred to as "2027-2028 Operating Guidelines."

The Colorado River Simulation System (CRSS) model is used to simulate operations of the major reservoirs on the Colorado River system for the 2027-2028 Operating Guidelines. This attachment includes detailed modeling assumptions used for the 2027–2028 Operating Guidelines, which are described in **Appendix T, Section T.2**. For additional information on the CRSS model background, overview, hydrology inputs, and initial reservoir conditions, see **Appendix A**, CRSS Modeling Assumptions.

T1.1 Operations Upstream of Lake Powell

The operations of the Upper Basin reservoirs upstream of Lake Powell for the 2027-2028 Operating Guidelines are the same as other alternatives as described in **Appendix A**, CRSS Modeling Assumptions, except as noted below for Powell Infrastructure Protection (PIP) releases when additional releases from CRSP Upper Initial Units are needed to protect critical infrastructure at Glen Canyon Dam.

T1.1.1 Powell Infrastructure Protection Releases

Section T.2.4, Releases to Protect Glen Canyon Dam, describes the additional releases from the CRSP Upper Initial Units to protect critical infrastructure at Glen Canyon Dam. The following sections detail the modeling representation of that description for the 2027-2028 Operating Guidelines. For the remainder of this attachment, these are referred to as PIP releases.

PIP releases are modeled as releases from Upper Initial Units under low elevation conditions at Lake Powell in the 2027-2028 Operating Guidelines. The PIP release modeling assumptions are simplifications of the actual PIP process, which, like the Drought Response Operations Agreement (DROA), involves collaborative decision-making among stakeholder workgroups and includes subjective judgments that cannot be captured in a model. The modeled PIP releases represent a potential range of releases; actual releases may be lower, higher, or may not occur, and do not reflect the views of all stakeholders. These modeling assumptions are intended solely for NEPA analysis and do not reflect a position by Reclamation on operations that might be implemented under a PIP collaborative process.

For modeling purposes, all PIP releases are assumed to be made from Flaming Gorge Reservoir.

2027 PIP Releases and Model Initialization

For modeling purposes, Flaming Gorge Reservoir's December 31st starting elevation and May 1 target were adjusted based on the June 2026 24-Month Study (24-MS) Most Probable projection. This adjustment was made to align the model with projected 2026-2027 DROA operations year, which projects a PIP release of 1.0 maf.

Powell Trigger

PIP releases from Flaming Gorge Reservoir are assumed to occur in coordination with Lake Powell operations. PIP releases are triggered when Lake Powell water year release is reduced below 7.0 maf through a mid-year adjustment, which occurs in April. This operational adjustment is modeled to occur in April to initiate PIP releases at the start of the Flaming Gorge operating year (May – April). See **Section T1.2.2**, *Mid-Year Annual Release Adjustment*, for details.

Available Volume

The total volume from Flaming Gorge Reservoir available for a PIP release is limited to the amount of water stored above the designated lower limit elevation. A forecasting algorithm estimates the elevation for the future annual operating target month. These forecasts assume daily spring flow release patterns followed by baseflow releases under the same hydrologic conditions throughout the forecast period.

The lower limit elevation and annual operating target month for Flaming Gorge Reservoir is 5,890 feet in April (May 1), which is 19 feet above minimum power pool. Typical May 1 targets range from 6,027 to 6,023 feet depending on the hydrologic conditions.

The lower limit elevation is used to determine the available volume and the annual operational target, but there is no modeled logic to protect and/or maintain lower limit storage on a month-to-month basis. Flaming Gorge Reservoir can fall below the lower limit, which may prevent it from meeting future environmental targets.

Releases

Maximum Annual Release

For modeling purposes, the maximum annual PIP release from Flaming Gorge Reservoir is assumed to be 1.0 maf. This corresponds with the potential to reduce Lake Powell releases from 7.0 maf to 6.0 maf and the attempt to maintain a 1:1 ratio between the Lake Powell release reductions and the increased CRSP Upper Initial Unit releases (PIP release).

Distribution of Releases

The total PIP release contribution is the smaller of two values: the volume by which Lake Powell's release is reduced below 7.0 maf, or the total volume available from Flaming Gorge Reservoir. Because Flaming Gorge Reservoir is the only CRSP Upper Initial Unit modeled to make PIP releases, the full PIP release volume is assigned to it.

Flaming Gorge Reservoir Operational Adjustments

Flaming Gorge Reservoir operations are adjusted within their Records of Decision to release an additional volume equal to the assigned contribution by modifying their operating targets. The annual contribution from Flaming Gorge Reservoir is estimated at the end of each operating year.

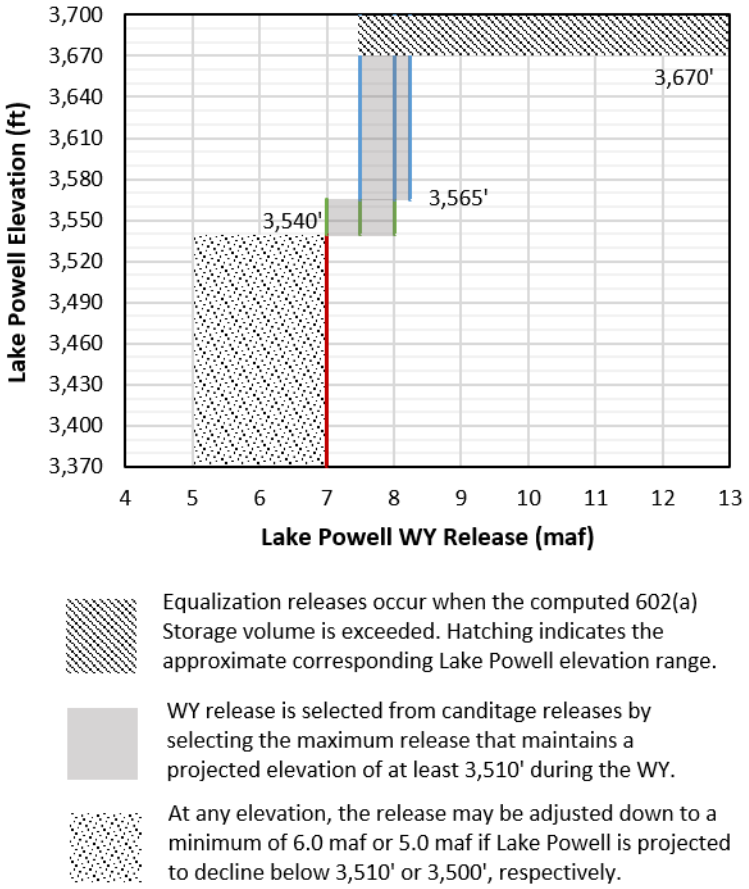
Flaming Gorge Reservoir's May 1 target is lowered by its assigned contribution. If the reservoir did not reach its normal May 1 target in the previous year due to PIP releases, the prior May 1 elevation is adjusted by the new assigned contribution. The May 1 target elevation cannot be lower than 5,890 feet (lower limit elevation). Operations are adjusted based on the sub annual flow regime as follows:

- Spring: No changes to the spring operations are modeled. Spring operations are modeled by a daily hydrograph that ramps up from baseflow to peak and back to baseflow. Operations vary by hydrologic classification and peak timing.
- Baseflow: The release in baseflow is the greater of the steady release to achieve the May 1 target or the minimum for Reach 2 (Jensen, UT) for the hydrologic classification. The release in all baseflow months is constrained further by the minimum and maximum for Reach 1 (below Flaming Gorge Reservoir). All maximum and minimum flows are from the 2022 Drought Response Operation Plan,[1] which uses the +/- 40 percent or 25 percent flexibility in the Record of Decision and vary by season.
- Transition: Releases during the transition period in March and April are constrained to a maximum of 2,000 cfs, which is based on an operator estimate of F&WS/Recovery Program preference.[2]

Recovery

Recovery is not explicitly modeled. Instead, Flaming Gorge Reservoir is modeled to naturally recover in years without PIP releases as it returns to the normal annual operating targets.

T1.2 Lake Powell Operation



Lake Powell is the most downstream reservoir in the Upper Basin, impounded by Glen Canyon Dam near Page, Arizona. Lake Powell operates on a water year (October through September) basis with an annual release set at the beginning of the water year with possible adjustments throughout the year. Modeling assumptions common to all alternatives, including methods for disaggregating annual releases to monthly flows, safe operating capacity, and infrastructure constraints at low elevations, are summarized in **Appendix A**, CRSS Modeling Assumptions.

Under the modeled representation of the 2027–2028 Operating Guidelines, the Lake Powell water year release is established at the beginning of each water year based on the previous end of water year (EOWY) (September 30) Lake Powell pool elevation.

[1] Attachment C - Appendix 1, Estimated Normal / Maximum / Minimum Summer to Winter Baseflows in the Green River downstream from Flaming Gorge Dam, page 84-85.
[2] Typically, the transition period is the unconstrained release to achieve the May 1 target.

Figure T1-1 summarizes the Lake Powell release in the 2027-2028 Operating Guidelines. If the assumed 602(a) storage criteria are met (described in the subsequent section), Lake Powell operations are described in **Section T1.2.1**. Otherwise, Lake Powell operations are described in **Section T1.2.2**.

Figure T1-1
Coordinated Operations of Lake Powell and Lake Mead, 2027-2028 Operating Guidelines

T1.2.1 Coordination at High Elevations

If the combined Colorado River Storage Project (CRSP) storage is above the 602(a) storage volume at the previous EOWY and Lake Powell EOWY storage is greater than Lake Mead EOWY storage, equalization operations determine the water year release. A detailed description of the 602(a) storage volume calculation and parameters used in the calculation is found in **Appendix J**. For modeling purposes, the same parameters that were used to compute the 602(a) storage volume for the 2007 Interim Guidelines Equalization line are used for modeling the equalization operations in the 2027-2028 Operating Guidelines. **Appendix J** also presents a comparison illustrating how different parameter assumptions would influence the resulting 602(a) storage values.

The 602(a) storage volume is not converted to a Lake Powell elevation. The water year release is set to the minimum of the volume needed to bring the CRSP storage down to the calculated 602(a)

storage volume or to balance the Lake Powell and Lake Mead projected EOWY storage, but no lower than the computed maximum release using the primary operations. The modeled 602(a) storage volume grows over time; in 2027, the volume is 25,082,344 af and in 2060 it reaches 29,647,144 af. Equalization may only be triggered at the start of the water year, and once an equalization determination is made, Lake Powell operates in the Equalization Tier for the remainder of the water year.

T1.2.2 Primary Operations

Initial Water Year Release

The initial water release is determined in October based on the September 30 Lake Powell pool elevation and a series of potential initial Lake Powell Water Year Releases as shown in **Table T1-1** and **Figure T1-1**. Before selecting an initial release, the potential releases are evaluated to identify which annual release volumes maintain a projected Lake Powell elevation of at least 3,510 feet during the following spring. For modeling purposes, and in order to evaluate the maximum impacts on Lake Powell, the initial release is determined by selecting the maximum release from the potential release volumes meeting the criterion. The next section describes the potential adjustments to this initial water year release volume during the water year in response to changing hydrologic conditions.

The corresponding monthly releases are then calculated using the method described in **Appendix A, Section A.6.1,** *Disaggregation from Annual to Monthly Release*.

Table T1-1
Potential Initial Water Year Releases by Lake Powell Pool Elevation, 2027-2028 Operating Guidelines

Lake Powell End-of-September Pool Elevation (feet)	Potential Initial Lake Powell Water Year Releases (maf)
> 3,565	8.23, 8.0, and 7.5
3,565 to 3,540	8.0, 7.5, and 7.0
< 3,540	7.0

When Lake Powell's September 30 elevation is below 3,540 feet, the modeled implementation evaluates an initial water year release of 7.0 maf. If Lake Powell is projected to remain above 3,510 feet in March, the 7.0 maf release is selected and monthly releases are calculated as described above. If Lake Powell is projected to decline below 3,510 feet in March, releases from October through March are instead set using a dynamic monthly release pattern rather than a prescribed water year release pattern deferring the determination of the water year release until April. This pattern is designed to avoid elevation 3,500 feet while respecting the Long-Term Experimental Management Plan (LTEMP) minimum daily release of 6,521 cfs. In April, the water year release is set, likely between 6.0 and 7.0 maf, contemporaneously with the modeled PIP releases to protect critical infrastructure at Glen Canyon Dam, as described in the *Mid-Year Release Adjustments* section and in **Section T1.1.1**

The projections used to evaluate the potential initial water year releases are designed to approximate the inputs that would be used in an actual 24-Month Study. In practice, the 24-Month Study relies on the current Lake Powell unregulated inflow forecast from the Colorado Basin River Forecast Center, which in August is typically close to the historical average unregulated inflow, adjusted for antecedent conditions such as soil moisture carried over from the previous year. For modeling purposes, CRSS estimates the March elevation using the historical median Lake Powell inflow (1991-2020), along with any PIP releases assigned for the current PIP year. Because CRSS does not know in advance the volume of PIP releases that will occur, a proportional PIP volume is assumed to occur between October and March for this projection. This volume is calculated by multiplying the assigned annual PIP volume by the proportion of the 2026-2027 PIP volume that was projected to occur between October and March based on the June 2026 Most Probable 24-Month Study.

Mid-Year Release Adjustments

There is potential for either an upward or a downward mid-year adjustment to the initial water year release. For modeling purposes, these adjustments occur in April. After these adjustments are made to the annual release, monthly releases are calculated using the method described in **Appendix A, Section A.6.1,** *Disaggregation from Annual to Monthly Release*.

An upward adjustment occurs if the projected EOWY Lake Powell elevation is above 3,565 feet. In this case, the initial water year release is increased by half of the projected volume above the storage corresponding to elevation 3,565 feet, up to a maximum release of 12.0 maf. This adjustment can occur with any selected initial water year release.

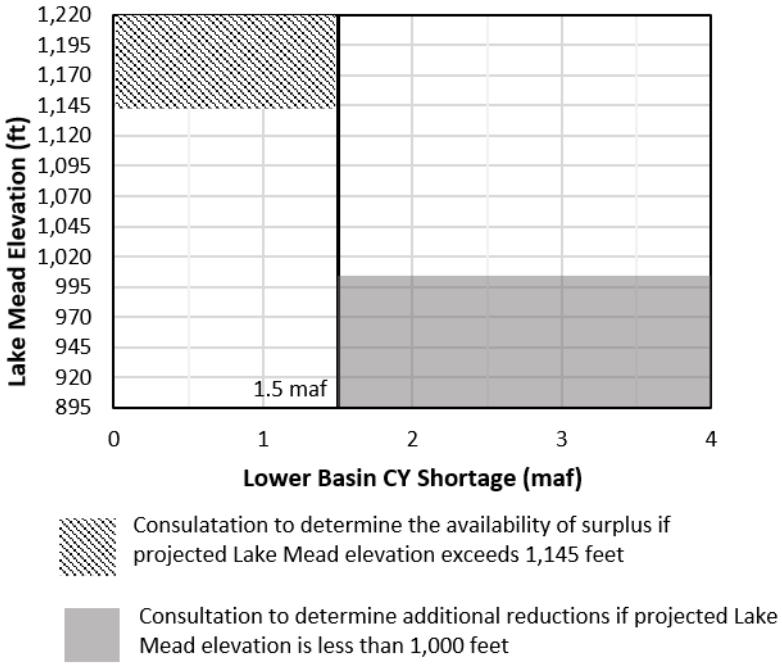
A downward adjustment is evaluated to reduce the risk that Lake Powell will decline below elevation 3,510 feet during the next spring. The downward adjustment can occur with any selected initial water year release. To determine whether a downward adjustment is needed, Lake Powell's projected elevation in March of the following year is evaluated. This projection assumes forecasted Lake Powell inflow (see **Appendix A, Section A.6.2**, *Lake Powell Inflow Forecast*) for the remainder of the current water year and median Lake Powell inflow (1991-2020) for the following water year. For the water year release, the selected initial release for the current water year is used (7.0 maf if in the lowest tier) followed by an assumed 7.0 maf release in the following water year using the standard monthly release pattern. No PIP release is assumed in this projection since this projection determines if a PIP release is necessary in conjunction with a reduced Lake Powell release.

If Lake Powell is projected to be above 3,510 feet in March of the following water year, the initial annual release set at the beginning of the current water year is retained, and no PIP releases are initiated. If Lake Powell is projected to be below 3,510 feet, the volume needed to maintain 3,510 feet is determined and used to adjust releases. First, the Lake Powell water year release is reduced to 7.0 maf if the initial release was greater than 7.0 maf. If additional reductions are necessary to meet the volume needed to maintain 3,510 feet, then the Lake Powell release is further reduced while PIP releases are increased. There is an attempt to maintain a 1:1 ratio between the additional Lake Powell release reductions and the PIP releases, subject to a maximum assumed PIP release of 1.0 maf and a minimum Lake Powell water year release of 6.0 maf. The subsequent section describes the potential to reduce releases below 6.0 maf.

Reduced Releases for Infrastructure Protection

Lake Powell releases can be reduced to a minimum of 6.0 maf if Lake Powell is projected to drop below 3,510 feet during the water year, and releases can be reduced to a minimum of 5.0 maf if Lake Powell is projected to drop below 3,500 feet during the water year. In CRSS, first the current month's Lake Powell pool elevation is evaluated, and then the projected EOWY Lake Powell pool elevation with an assumed 5.0 maf and 6.0 maf release for the water year is used to determine the monthly release.

- If the projected EOWY Lake Powell pool elevation with a 5.0 maf release is less than 3,500 feet, the monthly release is calculated using the method described in **Appendix A, Section A.6.1,** *Disaggregation from Annual to Monthly Release*. with an assumed the annual release of 5.0 maf.
- If the projected EOWY Lake Powell pool elevation with a 6.0 maf release is less than 3,510 feet but greater than 3,500 feet, the monthly release is calculated using the method described in **Appendix A, Section A.6.1,** *Disaggregation from Annual to Monthly Release*. with an assumed annual release of 6.0 maf.
- If the projected EOWY Lake Powell pool elevation with a 6.0 maf release is less than 3,500 feet but projected EOWY Lake Powell pool elevation with a 5.0 maf release is greater than 3,500 feet, the monthly release is calculated using the method described in **Appendix A, Section A.6.1,** *Disaggregation from Annual to Monthly Release*. assuming the annual release of the volume needed to end the water year at 3,500 feet (computed to be between 5.0 and 6.0 maf).
- If the current Lake Powell pool elevation is below 3,500 feet but the projected EOWY Lake Powell pool elevation with a 5.0 maf release is greater than 3,500 feet and the projected EOWY Lake Powell pool elevation with a 6.0 maf release is greater than 3,510 feet, the current month's release is decreased such that the Lake Powell pool elevation is maintained at or above 3,500 feet; however, it is subject to the following constraints: the minimum water year release is 5.0 maf, and the monthly release will be no less than the volume necessary to meet the minimum daily LTEMP release (6,521 cfs).



If releases are adjusted to protect 3,500 or 3,510 feet during a given month of the water year and Lake Powell pool elevation increases above 3,500 or 3,510 feet, monthly releases can be increased to release up to the original selected water year release.

T1.3 Lake Mead Operation

Lake Mead is the uppermost reservoir in the Lower Basin. In CRSS, Lake Mead operations are modeled by solving for the Lower Basin condition, Lower Basin and Mexico diversions, and the conservation, storage, and delivery of conserved system and non-system water, then setting Lake Mead's outflow to meet all downstream diversions. For detailed information on the modeling assumptions—including water user depletions, water passing to Mexico in excess of treaty requirements and water bypassed pursuant to International Boundary and Water Commission (IBWC) Minute 242, flood control operations, infrastructure constraints at low elevations, and dead pool-related reductions—see **Appendix A**, CRSS Modeling Assumptions.

Figure T1-2 summarizes the modeled Lake Mead operations in the 2027-2028 Operating Guidelines, and they are described more in the following sections.

Figure T1-2
Shortage Guidelines to Reduce Deliveries from Lake Mead, 2027-2028 Operating Guidelines

T1.3.1 Normal and Surplus Conditions

If Lake Mead is projected to exceed elevation 1,145 feet, consultation regarding reduced shortage volumes or the availability of surplus would occur. Neither normal nor surplus conditions are modeled in the analysis of the 2027-2028 Operating Guidelines.

T1.3.2 Shortage Condition

In 2027 and 2028, an annual shortage volume of 1.25 maf would be distributed among the Lower Division States, with an assumed reduction to Mexico bringing the total Lower Basin-wide shortage to 1.5 maf. This 1.5 maf shortage volume is applied in all 400 simulated futures in both 2027 and 2028. Shortages above 1.5 maf are not modeled as shown in **Figure T1-1**; however; if Lake Mead is projected to decline below elevation 1,000 feet during any 12-month period, consultation would occur to evaluate whether additional actions are necessary to reduce the risk of Lake Mead declining below elevation 950 feet. The modeled shortage volume is distributed among the Lower Division States and Mexico as shown in **Table T1-2** below. For modeling purposes only, the Arizona shortage is distributed proportionally to all Arizona Priority 4 water users; the California shortage is assumed to be applied to the Metropolitan Water District (MWD); and the Nevada shortage is assumed to be applied to the Southern Nevada Water Authority (SNWA).

Table T1-2
Shortage Distribution,
2027-2028 Operating Guidelines

Entity	Shortage (kaf)	Shortage (%)
Arizona	760	43.33
California	440	36.67
Nevada	50	3.33
Mexico	250	16.67

Note: Shortage distributions include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

T1.4 Storage and Delivery of Conserved System Water

T1.4.1 Lake Powell Mechanism

There is no modeled Lake Powell mechanism nor is there any modeled Upper Basin conservation in the analysis of the 2027-2028 Operating Guidelines.

T1.4.2 Lake Mead Mechanism

Water conserved by Lower Basin users would be stored in a pool in Lake Mead that can reach a maximum volume of 5.3 maf, which includes the storage of pre-2027 Intentionally Created Surplus (ICS) except for System Efficiency ICS. All conserved water stored in Lake Mead would be included in determinations of equalization releases from Lake Powell and in projections of Lake Mead's elevation for consultations regarding additional/reduced Lower Basin shortage or availability of Lower Basin surplus. Lower Colorado River entitlement holders, including Lower Basin Tribes, consistent with applicable implementation agreements, would be able to contribute to the conservation pool and to use their conserved water for delivery and/or in intra- and interstate transactions with other Lower Basin users.

The subsequent sections provide a detailed description of the modeling assumptions and associated constraints. Specific assumptions for the creation and delivery of ICS in 2027 and 2028 were based on the assumptions used for the Representative Preferred Alternative (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

Treatment of Pre-2027 Intentionally Created Surplus

For modeling purposes only, except for System Efficiency ICS, ICS created under the 2007 Interim Guidelines and 2019 Drought Contingency Plan (DCP) that remains in Lake Mead in 2027 is converted to the post-2026 Lake Mead mechanism on January 1, 2027.

General Assumptions

The maximum capacity of the Lake Mead mechanism, along with individual annual creation and delivery limits, is provided in **Table T1-3** below. The Lake Mead mechanism – State Pools operate on a calendar year to align with reservoir operations.

Table T1-3
Volume Limitations of Storage and Delivery of Conserved Water, 2027-2028 Operating Guidelines

Entity	Maximum Annual Contribution (kaf)	Maximum Cumulative Storage (kaf)	Maximum Annual Delivery (kaf)	Maximum Cumulative 2027 2028 Delivery (kaf)
Arizona	125	1,000	300	800
California	400	2,000	400	
Nevada	125	800	300	
Mexico[1]	250	1,500	N/A	160
Total	**900**	**5,300**	**1,160**	**960**

1) Volumes include modeling assumptions for Mexico's storage and delivery limits. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.
2) There is an assumed maximum cumulative delivery to Mexico of 160 kaf for 2027–2028. No annual maximum is specified; the annual delivery is constrained only by the two-year cumulative limit of 160 kaf.

Water users could contribute or deliver water previously stored under this new mechanism at their discretion within the annual volume constraints related to the pool (**Table T1-3**). At the time the water is conserved, a one-time 10 percent system assessment is applied, followed by an annual 3 percent evaporation deduction calculated based on the volume remaining in the Lake Mead mechanism at the end of the preceding calendar year.

For modeling purposes only, additional delivery constraints include the following:

- Delivery from the Lake Mead mechanism is prohibited when Lake Mead begins the year with a physical pool elevation below 1,000 feet. When the beginning-of-year pool elevation is between 1,000 feet and 1,025 feet, delivery/conversion volumes are proportionally reduced so that the forecasted EOCY pool elevation does not fall below 1,000 feet. Note, because the constraint is based on forecasted conditions, modeled elevations may still fall below 1,000 feet.
- The cumulative delivery by the Lower Division States is limited to 800 kaf through the end of 2028. As a modeling simplification, this constraint is applied to California's 2028 delivery when applicable. Based on the delivery assumptions (described in the following sections), the constraint applies only when California receives its maximum delivery of 400 kaf in 2027. Because the other States' delivery logic does not produce maximum deliveries, any necessary reduction to stay within the 800 kaf limit was applied to California.

- Delivery of stored water from the Lake Mead mechanism is limited such that a state's annual apportionment or Mexico's annual allotment is not exceeded.
- Delivery/conversion of existing DCP ICS (Arizona) and Binational Water Scarcity Contingency Plan credits (Mexico) is allowed when Lake Mead's pool elevation exceeds 1,110 feet.

Arizona Creation and Delivery Assumptions

In general, Arizona's creation and delivery of conserved water is inversely related to the physical elevation at Lake Mead and the state shortage volume. For modeling purposes only, Arizona's conservation activity is modeled using the Central Arizona Project (CAP) and Colorado River Indian Tribe-Arizona (CRIT-AZ) water users.

Creation

Arizona is modeled to create up to 125 kaf annually, depending on the state's total shortage volume. As in the Representative Preferred Alternative, the annual creation volume is calculated as the lesser of 1,200 kaf minus Arizona's policy shortage of 760 kaf and Arizona's maximum annual creation volume of 125 kaf (**Table T1-3**). For the modeled 2027 and 2028 Operating Guidelines, the annual shortage of 760 kaf to Arizona results in a modeled annual creation of 125 kaf.

The computed state creation volume is then split to the CAP and CRIT-AZ water users using the methodology described in the Enhanced Coordination Alternative (see **Appendix B, Section B.6.2.3**, *Creation*).

Delivery

For the modeled 2027 and 2028 Operating Guidelines, Arizona is assumed to take delivery of storage credits from the Lake Mead mechanism as a modeling representation of federal tribal firming obligations,[3] with delivery volumes based on specified CAP shortage thresholds shown in **Table T1-4**. This assumption was adapted from the No Action, Enhanced Coordination, and Representative Preferred Alternatives (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

Table T1-4
Storage Credit Delivery/Conversion Volumes by Shortage Threshold, 2027-2028 Operating Guidelines

Current Year Shortage for CAP (kaf)	Delivery Volume (kaf)
≥ 592	36.924
< 592 to ≥ 512	24.325

[3] Please see the Arizona Water Settlements Act, Pub. L. 108-451, 118 Stat. 3478 (Dec. 10, 2004), section 105, for a general description of the firming program. All firming deliveries in any given year would be made in accordance with applicable law. This appendix is not a legal interpretation of the firming program or of federal obligations. Actual firming deliveries may vary from the modeling approximations contained in this appendix, and Reclamation retains discretion to include legally required tribal deliveries in this priority mechanism.

As a result of the 760 kaf shortage to Arizona, Arizona is assumed to take delivery of 36.924 kaf of storage credits in both 2027 and 2028 modeled as a delivery to CAP.

California Creation and Delivery Assumptions

In general, California's creation and delivery of conserved water is based on the Sacramento River Water Year Type (SRWYT), described more in **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water. For modeling purposes, California's ICS creation and delivery is modeled using MWD.

Creation

The annual assumed creation volumes are shown below in **Table T1-5**.

Table T1-5
California's Assumed Creation Volumes,
2027-2028 Operating Guidelines

SRWYT	Total (kaf)
C	0
D	0
BN	100
AN	200
W	400

Conservation is assumed to first go towards meeting any shortages in the same year it occurs. Any remaining conserved water is stored in the Lake Mead mechanism. Because there is an assumed shortage of 460 kaf in 2027 and 2028 to California, there is no modeled creation of additional ICS in 2027 or 2028.

Delivery

The annual assumed delivery volumes are shown below in **Table T1-6**.

Table T1-6
California's Assumed Delivery Volumes,
2027-2028 Operating Guidelines

SRWYT	Total (kaf)
C	400
D	240
BN	0
AN	0
W	0

Nevada Creation and Delivery Assumptions

Creation

SNWA is modeled to store two types of water in the Lake Mead mechanism: conserved water and Tributary Conservation. With respect to Tributary Conservation, which represents conservation on the Virgin and Muddy Rivers, 35 kaf per year is created. This water is stored in the Lake Mead mechanism if space is available, after the applicable 10 percent system assessment is applied. In CRSS, this is modeled as a gain to Lake Mead.

For conserved water, SNWA's annual creation is calculated using following equation:

$$Annual\ Creation = Maximum(\ 300{,}000\ af - Annual\ Shortage_{NV} - AnnualSystemConservation_{NV} + TributaryConservation - Annual\ Demand_{NV}, 0\ af)$$

The system conservation assumptions are described in **Section T1.4.4**, and the Tributary Conservation is the volume after the system assessment is applied. Based on the assumed depletion schedules, SNWA creates ICS in 2027 and 2028 because the assumed depletions are below the state's annual apportionment in both years (see **Appendix M**, Lower Division States Depletion Schedules).

Delivery

In the Representative Preferred Alternative, Nevada's water stored in the Lake Mead mechanism is assumed to mitigate shortages; however, based on the assumed shortage volumes in the modeling of the 2027-2028 Operating Guidelines, no deliveries are necessary to mitigate shortages.

If Nevada's account in the Lake Mead mechanism is full or dead pool-related reductions occur, SNWA is assumed to take full delivery of its Tributary Conservation.

Mexico Creation and Delivery Assumptions

Reclamation developed modeling assumptions for the storage and delivery of deferred water by Mexico to evaluate possible impacts of this activity on flow and other resources for the Final EIS.[4] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

In general, the volumes of creation and delivery depend on the assumed annual delivery reductions to Mexico, and the storage credits are used to mitigate these delivery reductions. The assumptions from the Supply Driven Alternative were used for this modeling, with the results of those assumptions described below.

Creation

The Supply Driven Alternative assumed Mexico would create up to 250 kaf per year, depending on its total reduction volume. Specifically, Mexico's assumed creation equals 250 kaf minus Mexico's

[4] Assuming activity in Mexico maximizes the effects on river flows as it occurs at the most downstream point in CRSS.

reduction. Because Mexico's reductions are assumed to be 250 kaf in both years of the 2027-2028 Operating Guidelines, no annual creation occurs.

Delivery

In the Supply Driven Alternative Mexico is assumed to convert storage credits to meet assumed delivery reductions that exceed 250 kaf. Because Mexico's reductions are assumed to be 250 kaf in both years of the 2027-2028 Operating Guidelines, no delivery occurs.

T1.4.3 Lake Mead Mechanism – Federally Managed Water Resources Pool

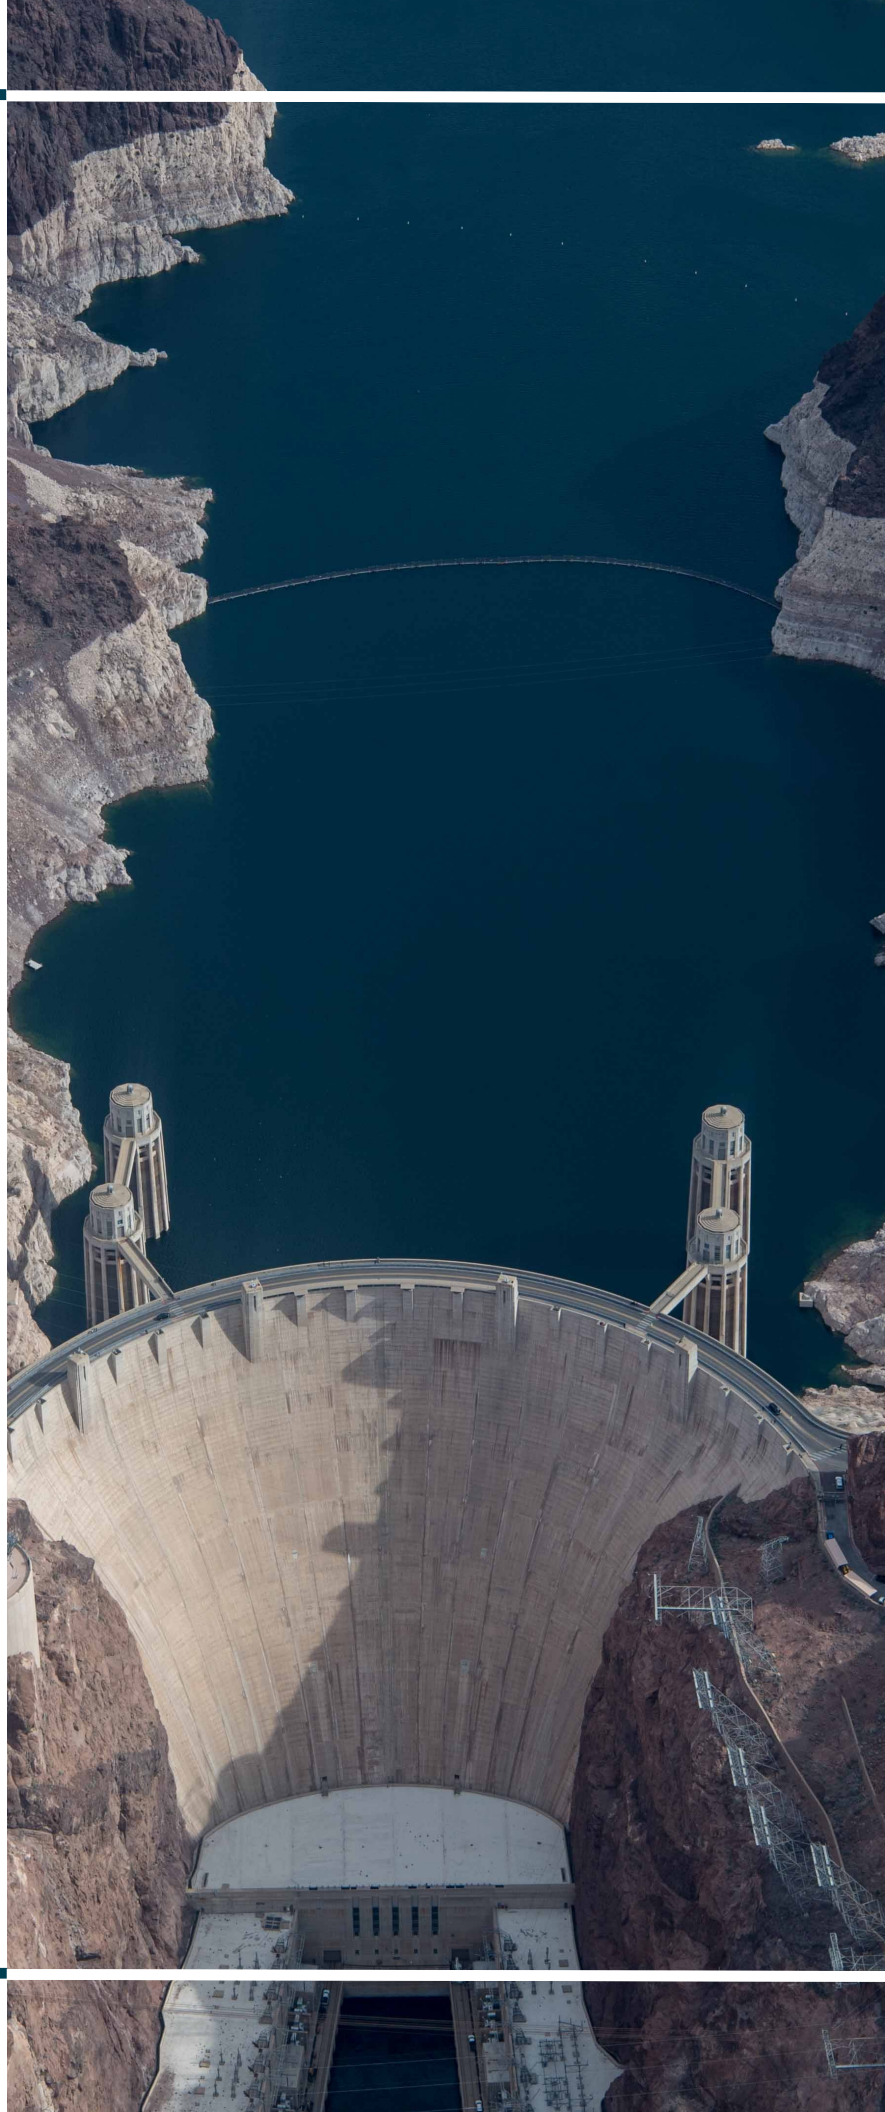
There are no model assumptions for the Federally Managed Water Resources Pool included in this analysis; however, the 2027-2028 Operating Guidelines are anticipated to include a Federally Managed Water Resources Pool. For more information on the Federally Managed Water Resources Pool, see **Chapter 2, Section 2.4.3.3.3**. The modeling of the Representative Preferred Alternative includes representative modeling of this pool.

T1.4.4 System Conservation: 700+ Plan

As described in the Lower Division States' May 1 proposal, the Lower Division States intend to contribute a cumulative minimum of 700 kaf of system conservation through 2028. Each state's contribution is assumed to be split equally between 2027 and 2028. These volumes are separate from ICS, not stored in individual state pools, and in addition to the previously described shortage volumes (**Section T1.3.2**).

Table T1-7 shows the annual system conservation volumes assumed for modeling purposes only for each state, totaling 700 kaf through 2028. The table also identifies the water user for which system conservation is modeled to occur, based on available demand and maximum downstream reach impacts.

Table T1-7
Assumed Annual System Conservation Volumes by State, 2027-2028 Operating Guidelines



State	Water User that System Conservation is Modeled On	Annual Conservation (kaf)	Cumulative 2027-2028 Conservation (kaf)
Arizona	Wellton Mohawk Irrigation and Drainage District (IDD)	150	300
California	Imperial Irrigation District (IID)	150	300
Nevada	Southern Nevada Water Authority (SNWA)	50	100
Total		**350**	**700**

TA 3. Hydrologic Resources

TA 3.1 Affected Environment

This section presents an overview of the hydrology of the Colorado River Basin (Basin) beginning with the full pool elevation of Lake Powell and extending downstream along the Colorado River to the Southerly International Boundary (SIB) with the United Mexican States (Mexico). It also includes groundwater that is under the direct influence of the Colorado River and the Lower Colorado River Basin (Lower Basin) reservoirs, starting with Lake Powell on the upstream end. The geography and connectivity of the hydrologic resources analysis area are the same as what was analyzed in the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead Final Environmental Impact Statement (EIS; 2007 Final EIS; Reclamation 2007a).

The Colorado River has been divided into nine distinct reaches along the study area. These reaches include the full pool Lake Powell to Glen Canyon Dam, from Glen Canyon Dam to Lake Mead at Separation Canyon (which includes the Grand Canyon National Park [GCNP]), the full pool Lake Mead (downstream of Separation Canyon) to Hoover Dam, from Hoover Dam to Davis Dam (including Lake Mohave), Davis Dam to Parker Dam (including Lake Havasu), from Parker Dam to Cibola Gage, from Cibola Gage to Imperial Dam, from Imperial Dam to the Northerly International Boundary (NIB), and from the NIB to the SIB. Refer to **Table 3-1**, Colorado River Reaches and Reach Limits in the Geographic Scope, for a description of the nine Colorado River reaches and their associated river miles and **Map 3-1**, Colorado River Reaches and Geographic Scope, for a map of the Colorado River reaches. Not included in the study area are reservoirs upstream of Lake Powell, the Salton Sea, and portions of northwestern Mexico that are operated independently.

Hydrologic resources within the study area that could potentially be affected by the implementation of any given alternative include:

- Reservoir storage, total system storage, reservoir releases, and corresponding changes in Colorado River flows downstream of the reservoirs
- Groundwater in areas adjacent to and connected to the Colorado River corridor

The overall characteristics and connectivity of the Basin remain unchanged from when the 2007 Final EIS was issued. However, since 2007, several factors have affected hydrologic resources in the Basin. These factors can be divided into two categories: operational changes in the Basin since 2007 and key environmental drivers. Refer to **Chapter 1**, Purpose and Need, **Section 1.8.2.1**, The Law of the River, for a summary of operational changes since 2007.

Worsening drought conditions have been a major driver for changes to hydrologic resources in the Basin. Since 2000, the Basin has experienced persistent drought conditions, exacerbated by a

warming climate resulting in increased evapotranspiration, reduced soil moisture, and ultimately reduced runoff. Runoff conditions in the Basin are below what was contemplated in the Record of Decision for Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead (2007 ROD) resulting in reduced reservoir storage, reservoir releases, and river flows.

TA 3.1.1 Hydrologic Overview

The Colorado River originates at the Continental Divide in Rocky Mountain National Park in Colorado and flows downstream through Utah, Nevada, Arizona, and California to Mexico, where it historically flowed into the Sea of Cortez. Major tributaries to the Colorado River include the Green, San Juan, Yampa, Gunnison, and Gila Rivers. While 85 percent of the Basin is desert and semi-arid rangelands, the remaining 15 percent is comprised of mountainous areas in Wyoming, Colorado, Utah, and New Mexico. These mountainous areas receive snow throughout the winter months, which makes up the majority, approximately 92 percent, of the Colorado River's streamflow. Mountain snowmelt in the Upper Colorado River Basin (Upper Basin) typically results in high river flows in the late spring that diminish quickly by mid-summer. The rest of the arid and semi-arid Basin historically receives fewer than 10 inches of precipitation per year. Flow in the Colorado River is highly variable from year to year because of variations in precipitation in the Basin. However, the Basin is currently experiencing a prolonged dry period resulting in extended periods of drought and record low runoff conditions.

The Colorado River Basin Climate and Hydrology: *State of the Science* report provided a comprehensive assessment of Basin hydroclimate conditions and trends through 2019 (Lukas and Payton 2020). According to the report, the Basin has experienced persistent drought conditions since 2000, exacerbated by increasing temperatures. This drought has led to a 20 percent decrease in average annual Upper Basin (at Lees Ferry Gaging Station) natural flows (Reclamation 2025a). 2000 to 2024 was the driest 25-year period in more than a century. A paleo reconstruction of Colorado River streamflow at Lee Ferry Compact Point, Arizona back to 762 current era (CE) indicates that this 24-year period is lower than any other period in the last 1,200 years (Meko et al. 2007).

These conditions have led to a cumulative streamflow deficit of about 70.0 million acre-feet (maf) relative to twentieth-century conditions (Reclamation 2025a). Historically, the primary driver for the hydrologic drought in the Basin has been below normal precipitation over the winter, resulting in reduced snowmelt in the spring, but warming temperatures are playing an increasing role as evaporative losses and soil moisture deficits increase.

Annual water use in the Basin has exceeded the annual inflows in most years since 2000. This resulted in a depletion of storage to a historic low of 24 percent of the total combined capacity of Lake Powell and Lake Mead (equivalent to approximately 12.68 maf) between March and April of 2023 (Reclamation 2025b). Since publication of the 2007 Final EIS, changes in the Basin have included further increases in temperature, ongoing years of below-normal precipitation, declining snowpack water volume and annual streamflow, and earlier snowmelt runoff. Since 2000, the average temperature across the Lower Basin has been 2.2 degrees Fahrenheit warmer than the twentieth-century average. Since 2007, the average temperature of the Lower Basin has trended upward, with the warmest 10-year period on record occurring from 2012 to 2022 (NOAA 2025).

Multidecadal trends are most informative when describing Basin precipitation due to the high interannual variability of weather events. For example, short term trends like the El Niño-Southern Oscillation can impact Lower Basin precipitation trends on a year-to-year basis. For both the Upper Basin and Lower Basin, a declining (but statistically non-significant) trend was noted over the period from 1980 to 2019. During the 1980 to 2019 period, precipitation over the cold season (October through March), which typically falls as snow, showed a greater declining trend than precipitation over the warm-season months. Because of naturally colder temperatures, snowpack at higher elevations in the Upper Basin has not been affected as much as snowpack at lower elevations; however, studies summarized in the *State of the Science* report indicate that snowmelt runoff is occurring 1–3 weeks earlier than the average timing prior to 2000.

TA 3.1.2 Upper Basin

Congress passed the Colorado River Storage Project Act in 1956, which authorized the construction of the Colorado River Storage Project (CRSP) reservoirs "to initiate the comprehensive development of the water resources of the Upper Basin, for the purposes, among others, of regulating flow of the Colorado River, storing water for beneficial consumptive use, making it possible for the States of the Upper Basin to utilize, consistently with the provisions of the Colorado River Compact, the apportionments made to and among them in the Colorado River Compact and the Upper Colorado River Basin Compact, respectively, providing for the reclamation of arid and semiarid land, for the control of floods, and for the generation of hydroelectric power, as an incident of the foregoing purposes…"

In addition to Lake Powell, the CRSP reservoirs include the Upper Basin reservoirs, known as CRSP Upper Initial Units (UIU). The CRSP UIU are Flaming Gorge in Utah, Navajo in New Mexico, and Blue Mesa in Colorado. These four CRSP reservoirs were constructed in the 1960s and took several years to begin filling. Excluding surcharge space, the total storage volume of the four CRSP reservoirs is 29.5 maf.

Flaming Gorge Reservoir has a total storage capacity of 3.79 maf and from 1980 to the implementation of the 2007 ROD, the average storage capacity (as a percentage of the total capacity) of Flaming Gorge Reservoir was approximately 82 percent. From 2007 through 2024, the average storage capacity of Flaming Gorge Reservoir was 83 percent. Flaming Gorge Reservoir experienced the two lowest storage capacities from 2002 to 2004 and spring 2023 of 68 percent and 65 percent of the total capacity, respectively.

Navajo Reservoir has a total storage capacity of 1.71 maf and from 1980 to the implementation of the 2007 ROD, the average storage capacity (as a percentage of the total capacity) of Navajo Reservoir was approximately 80 percent. From 2007 through 2024, the average storage capacity of Navajo Reservoir was 71 percent. Navajo Reservoir experienced the two lowest storage capacities from 2002 to 2004 and spring 2023 of 41 percent and 49 percent of the total capacity, respectively.

Blue Mesa Reservoir is part of the Aspinall Unit in Colorado, which also includes Crystal Reservoir and Morrow Point Reservoir. Blue Mesa has the largest capacity of the Aspinall Unit reservoirs with a total capacity of 941.0 thousand acre-feet (kaf). Crystal Reservoir has a total capacity of 26.0 kaf and Morrow Point has a total capacity of 117.0 kaf. From 1980 to the implementation of the 2007

ROD, the average storage capacity (as a percentage of the total capacity) of Blue Mesa Reservoir was approximately 61 percent. From 2007 through 2024, the average storage capacity of Blue Mesa Reservoir was 56 percent. Blue Mesa Reservoir experienced the two lowest storage capacities in the winters of 2018 and 2021 of 21 percent and 22 percent of the total capacity, respectively.

Release operations under the 2019 Drought Response Operations Agreement (DROA) began in 2021 and included releases from Flaming Gorge, Navajo, and Blue Mesa. In 2022, DROA operations included releases from Flaming Gorge. In 2023, DROA operations included recovery of storage at Flaming Gorge, Navajo, and Blue Mesa (Reclamation 2024a).

While the alternatives analyzed may include the operation of reservoirs upstream of Lake Powell (CRSP UIUs) to protect Glen Canyon Dam infrastructure, these Operations are intended to remain within the scope of the existing Records of Decision (RODs) for the respective facilities. Accordingly, the Final EIS does not expand the geographic scope of analysis upstream of Lake Powell.[1]

TA 3.1.3 Lake Powell and Glen Canyon Dam

Lake Powell is a reservoir that is located primarily in southern Utah with a portion extending into northern Arizona. Inflows into Lake Powell originate from the mainstream Colorado River which is dammed near Page, Arizona by Glen Canyon Dam. The concrete arch dam was constructed from 1956 to 1964, and rises 710 feet above the bedrock of Glen Canyon. Lake Powell is relatively narrow and when it is full, stretches over 180 miles in length along the mainstream Colorado River in Glen Canyon. When full, it also includes approximately 25 miles of Cataract Canyon and 50 miles of the San Juan River. The water surface operating range of Lake Powell runs between 3,490 feet (corresponding to the minimum power pool) and 3,700 feet (corresponding to the top of Glen Canyon Dam spillway). The total live storage capacity of Lake Powell at the full pool elevation of 3,700 feet is 23.31 maf (excluding approximately 1.9 maf of Flood Control space).

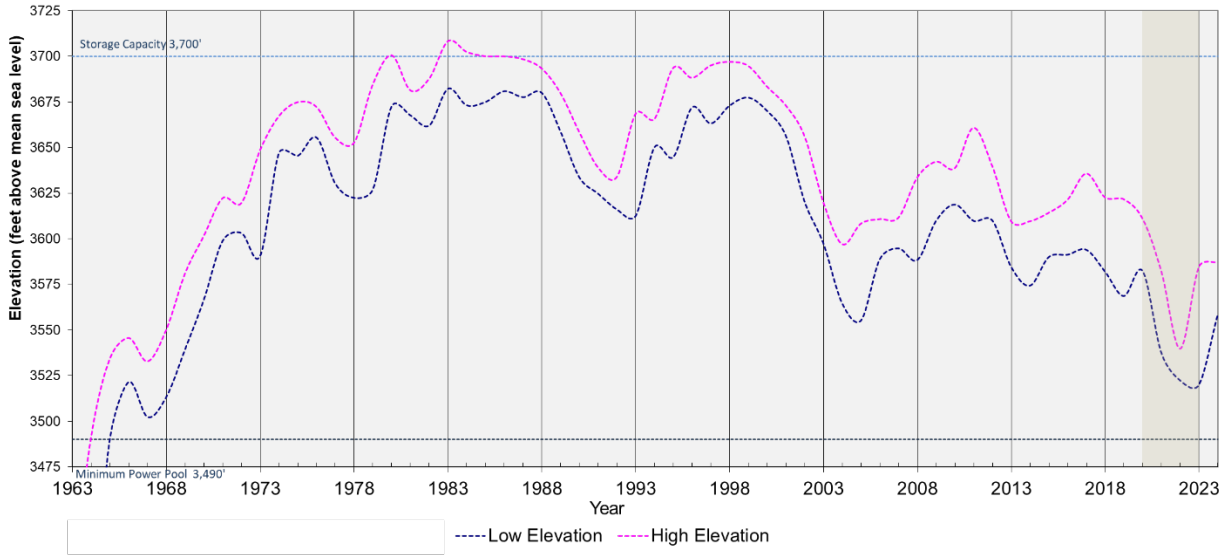
The 2007 Final EIS and 2024 Final Supplemental EIS (SEIS) noted that groundwater adjacent to Lake Powell may increase or decrease in correlation with corresponding changes in pool elevations. This EIS will consider qualitative impacts on groundwater elevations adjacent to the reservoirs, including Lake Powell. The Arizona Department of Water Resources Groundwater Site Inventory website (ADWR 2025) tracks depth to water measurements for three active groundwater monitoring wells located adjacent to Lake Powell near Glen Canyon Dam. All three groundwater monitoring wells show a decreasing groundwater elevation trend beginning in the early 2000s, with the lowest groundwater elevations occurring in 2022.

Releases are typically made through the penstock intakes which are eight 15-foot diameter steel pipes that deliver water to the Glen Canyon Powerplant turbines. Releases can be made from Glen Canyon Dam from 3,490 feet down to 3,370 feet (corresponding to dead pool) through the four 8-

[1] While the Secretary will consider and prioritize operations at these facilities that are consistent with existing RODs, the Secretary retains the authority to operate outside those RODs if necessary. The modeling assumptions regarding operation of the Upper Initial CRSP Units presented in this Final EIS are not intended to, and do not, limit the Secretary's ability to operate these facilities as necessary to respond to hydrologic conditions in accordance with applicable federal law, including operations for the authorized purposes as stated in the 1956 Colorado River Storage Project Act.

foot diameter river outlet works, however, according to the 2024 Establishment of Interim Operating Guidance for Glen Canyon Dam during Low Reservoir Levels at Lake Powell Technical Memorandum, the river outlet works were not intended for long-term use at low reservoir levels (Reclamation 2024b). The cutoff elevation for routine operations of Glen Canyon Dam is considered 3,490 feet. Lake Powell also services direct water delivery to the City of Page, Arizona and the LeChee Chapter of the Navajo Nation through three different intakes, one of which can access water as low as 3,362 feet through the outlet works (Reclamation 2023a).

In 1968, the Colorado River Basin Project Act directed the Secretary to establish the Long-Range Operating Criteria (LROC) which was developed in 1970 to establish operating criteria for Colorado River reservoirs that were compliant with the Law of the River. According to the LROC "the objective shall be to maintain a minimum release of water from Lake Powell of 8.23 million acre-feet for that year." Releases above this amount only occurred if Upper Basin storage exceeded the requirements listed in Section 602(a) of the Colorado River Basin Project Act, storage in Lake Powell exceeded storage in Lake Mead, and if a spill was anticipated. Lake Powell and Glen Canyon Dam are operated consistent with the Colorado River Storage Project Act.



Unregulated inflows to Lake Powell from the Upper Basin vary year to year based on hydrologic conditions. According to a study that reconstructed historic conditions as far back as 600 CE, the current drought is the driest to occur since 800 CE (Wahl 2022). During the current 24-year drought period, unregulated water year (WY) inflows (the Colorado River WY refers to the period from October 1 to September 30 of the following calendar year [CY]) to Lake Powell ranged from 2.64 maf in 2002 to 15.97 maf in 2011 with an average of 8.29 maf (Reclamation 2025c). From 2020 to 2022, the Basin experienced three of the lowest consecutive inflow WYs on record, with inflows for those three years totaling around 15.5 maf (with 2021 having the lowest inflow of 3.5 maf). This continued period of drying and decrease in inflows in recent years has resulted in critically low elevations at Lake Powell.

Lake Powell began filling in 1963. The lake reached its highest elevation of 3,708.34 feet in 1983. Since Lake Powell is fed by inflows from the Upper Basin, water surface elevations are variable due to hydrologic conditions. To capture conditions since the implementation of the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead (2007 Interim Guidelines), water surface elevation data were analyzed for the years 2008 through 2025 from the Bureau of Reclamation's (Reclamation's) Upper Basin Hydrologic dataset (Reclamation 2025b). The operating range during this period was between a low of 3,519.92 feet (occurring in 2023) and a high of 3,660.9 feet (occurring in 2011). The average operating elevation since the implementation of the 2007 Interim Guidelines was 3,602.3 feet, which is well below the average elevations in the 1980s and late 1990s, which were 3,683 feet and 3,679 feet, respectively. Since 2017, the annual average water surface elevation at Lake Powell has declined by approximately 87 feet, with the two largest year-over-year declines occurring in 2021 and 2022.

Lake Powell's annual high-water elevation and annual low-water elevation for 1963 through 2024 are shown in **Figure TA 3-1**. Note that these data include changes to elevations associated with operation of Lake Powell in accordance with the 2007 ROD, the Drought Contingency Plans (DCP; Reclamation 2019; implemented starting in 2020), and the Glen Canyon Dam Long-Term

Experimental and Management Plan Record of Decision (2016 LTEMP ROD; Reclamation 2016). The shaded box indicates four consecutive low elevation years (2020-2023), including the historical minimum of 3,520 feet (excluding the 1960s when Lake Powell was filling for the first time).

Figure TA 3-1
Lake Powell Annual High and Low Elevations (1963-2024)

Source: Reclamation 2025b

As mentioned previously, 2000 to 2024 is the driest 25-year period in more than a century. The start of these drought conditions in the 2000s triggered the need to outline specific operations to provide a greater degree of certainty to Colorado River water users about timing and volumes of potential water delivery reductions during low reservoir elevations. The result was the 2007 ROD, which adopted the 2007 Interim Guidelines (in effect through 2026) for the operation of Lake Powell and Lake Mead to manage potential water delivery reductions and provide flexibility to conserve and store water in the system.

The 2007 Interim Guidelines governed annual releases from Glen Canyon Dam based on the end of water year (EOWY) surface elevations of Lake Powell and Lake Mead. Different release volumes from Glen Canyon Dam were categorized by the following assigned Operational Tiers for Lake Powell[2]:

- Equalization Tier: releases are 8.23 maf or greater (to the extent necessary) to avoid spills or equalize storage in the two reservoirs as nearly as practicable. The "Equalization Volume" is the amount of water released above 8.23 maf in this Tier
- Upper Elevation Balancing Tier: releases depend on the elevation of Lake Powell and Lake Mead at the EOWY and are either 8.23 maf, or between 7.0 maf and 9.0 maf to balance contents

[2] The operational tiers are described in more detail in Sections 6.A through 6.D of the 2007 Interim Guidelines (Reclamation 2007b).

- Mid-Elevation Release Tier: releases depend on the elevation of Lake Powell and Lake Mead at the EOWY and are either 8.23 maf or 7.48 maf
- Lower Elevation Balancing Tier: releases between 7.0 maf and 9.5 maf as needed to balance contents

Since 2008, the most common Operational Tier has been the Upper Elevation Balancing Tier, which allowed releases from 7.0 maf to 9.0 maf (see **Table TA 3-1**). Glen Canyon Dam releases since 2007 have been between 7.0 maf to 12.52 maf (averaging 8.62 maf). This annual average of 8.62 maf is 1.13 maf lower than the average annual release from 1996 to 2007 of 9.75 maf, which can be attributed to hydrologic conditions in the Basin and operations under the 2007 Interim Guidelines.

Table TA 3-1
Summary of Lake Powell and Lake Mead Coordinated Operations 2008-2024

Year	Lake Powell Operations					Lake Mead Operations
	Operational Tier	Adjustment	Operating Year Unregulated Inflow (% Average) [6]	Release Volume (maf)	Equalization Volume (maf)	Operating Condition
2008	Upper Elevation Balancing	Equalization	126	8.98	0.75	Normal/Intentionally Created Surplus (ICS) Surplus
2009	Upper Elevation Balancing	None	106	8.24 [1]		Normal/ICS Surplus
2010	Upper Elevation Balancing	None	88	8.23		Normal/ICS Surplus
2011	Upper Elevation Balancing	Equalization	166	12.52	4.29 [2]	Normal/ICS Surplus
2012	Equalization	N/A	51	9.47	1.23 [3]	Normal/ICS Surplus
2013	Upper Elevation Balancing	None	53	8.23		Normal/ICS Surplus
2014	Mid-Elevation Release	N/A	108	7.48		Normal/ICS Surplus
2015	Upper Elevation Balancing	Balancing	106	9.00		Normal/ICS Surplus
2016	Upper Elevation Balancing	Balancing	100	9.00		Normal/ICS Surplus
2017	Upper Elevation Balancing	Balancing	124	9.00		Normal/ICS Surplus
2018	Upper Elevation Balancing	Balancing	48	9.00		Normal/ICS Surplus
2019	Upper Elevation Balancing	Balancing	135	9.00		Normal/ICS Surplus
2020 [4]	Upper Elevation Balancing	None	61	8.23		Normal/ICS Surplus and DCP Contributions

Year	Lake Powell Operations					Lake Mead Operations
	Operational Tier	Adjustment	Operating Year Unregulated Inflow (% Average) [6]	Release Volume (maf)	Equalization Volume (maf)	Operating Condition
2021 [4]	Upper Elevation Balancing	None	36	8.23		Normal/ICS Surplus and DCP Contributions
2022 [4]	Mid-Elevation Release	Adjusted in May 2022	63	7.00 [5]		Level 1 Shortage and DCP Contributions
2023 [4]	Lower Elevation Balancing	Balancing	140	8.58		Level 2 Shortage and DCP Contributions
2024 [4]	Mid-Elevation Release	None	83	7.48		Level 1 Shortage and DCP Contributions
2025 [4]	Mid-Elevation Release	None	50	7.48		Level 1 Shortage and DCP Contributions

Source: Adapted from Reclamation 2024c

[1] In 2009, while the scheduled release volume was 8.23 maf, the actual release was 8.24 maf due to rounding and a release of 5,702 acre-feet (af) above 8.23. Balancing did not occur in 2009.

[2] The total 2011 equalization volume was 5.52 maf, with 4.29 maf released in operating year 2011. The remaining equalization volume was released as soon as practicable and was released fully by December 31, 2011.

[3] Although Lake Powell operated in the Equalization Tier in 2011, 8.23 maf was released in operating year 2012 due to dry conditions. The additional release of 1.23 maf was operating year 2011 equalization water released during operating year 2012. The difference between 9.47 maf and 8.23 maf is due to rounding.

[4] Supplemental data for 2020 - 2024 provided by Annual Operating Plan (Reclamation 2020, 2021, 2022a, 2023b, 2024d, 2025d, 2025e).

[5] Lake Powell's release was reduced by 480,000 af during WY 2022 in May 2022 (Reclamation 2022b).

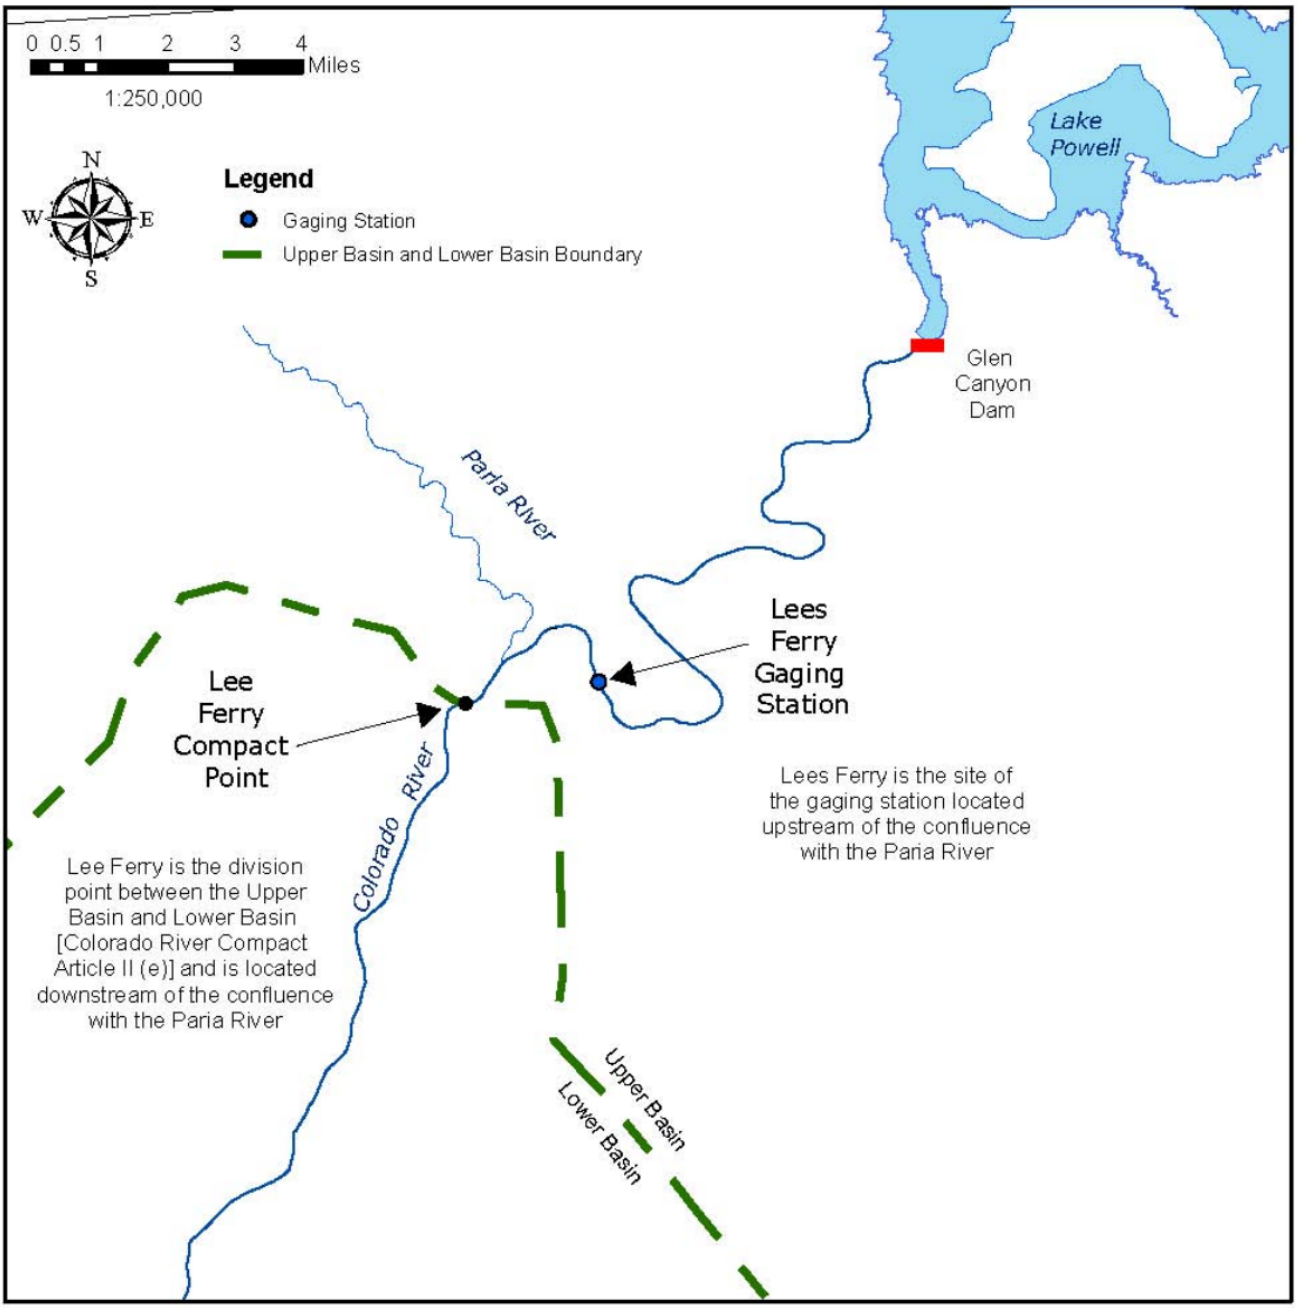
[6] The unregulated inflow statistics (percent average) are based on a mean of the 30-year period 1991-2020 for all years (9.6 maf).

Drought conditions from 2020 to 2022 triggered the need to supplement the 2007 Interim Guidelines with near-term provisions for addressing extremely low reservoir levels. The result was the 2024 Near-term Colorado River Operations Record of Decision (2024 ROD; Reclamation 2024e), which adopted modified operations to stabilize the declining reservoir elevations while still allowing for water releases and delivery to downstream water users. Beginning in 2024, releases from Lake Powell were based on the following modified Operational Tiers:

- Equalization Tier: remains the same as the 2007 ROD (Reclamation 2007b)
- Upper Elevation Balancing Tier: remains the same as the 2007 ROD (Reclamation 2007b)
- Mid-Elevation Release Tier: remains the same as the 2007 ROD (Reclamation 2007b) except that Reclamation may reduce releases to a minimum of 6.0 maf, if needed
- Lower Elevation Balancing Tier: remains the same as the 2007 ROD (Reclamation 2007b) except that Reclamation may reduce releases to a minimum of 6.0 maf, if needed
- If Lake Powell elevations are projected to drop below 3,500 feet, Reclamation facilities may be operated in a manner that protects the Colorado River system if hydrologic conditions require such action.

Releases from Glen Canyon Dam are scheduled on an annual, monthly, and hourly basis. Any sub annual releases comply with the 2016 LTEMP ROD and Supplemental Glen Canyon Dam Long-Term Experimental and Management Plan ROD (2024 LTEMP ROD) minimum daily and hourly flows of 5,000 cubic feet per second (cfs) at night and 8,000 cfs during the day through Glen Canyon Dam (Reclamation 2016).

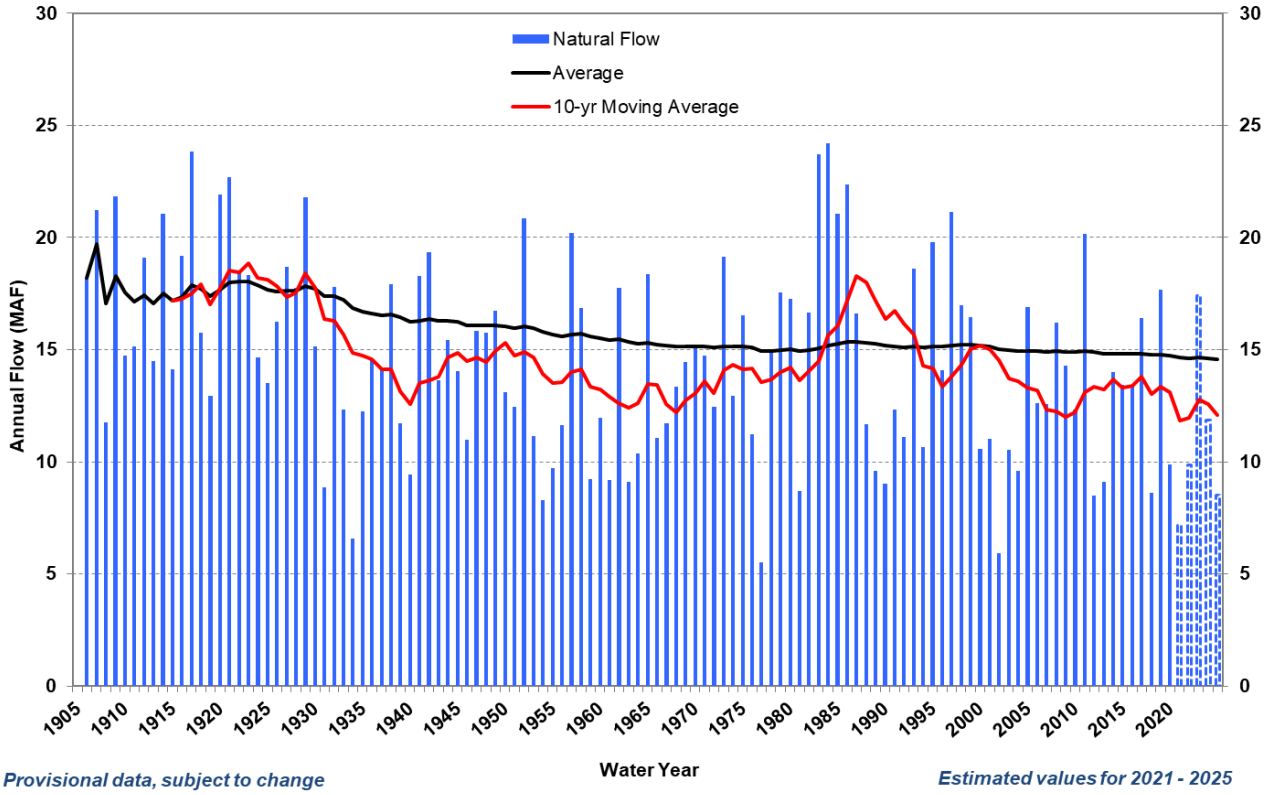
TA 3.1.4 Lees Ferry Gaging Station



The Lees Ferry Gaging Station is located in Arizona, approximately 15.9 river miles (RMs) downstream of Glen Canyon Dam, but upstream of the confluence with the Paria River. The Lees Ferry Gaging Station differs from the Lee Ferry Compact Point, which is the division point between the Upper Basin and Lower Basin as established by the 1922 Colorado River Compact. The Lee Ferry Compact Point is located a few miles downstream of the Lees Ferry Gaging Station and is downstream of the confluence with the Paria River. **Figure TA 3-2** shows the difference between the Lees Ferry Gaging Station location and the Lee Ferry Compact Point Location.

Natural flows at Lees Ferry are calculated based on observed (gage) flow and corrected by Reclamation for upstream reservoir changes in storage and release, losses including evaporation, and depletions due to agriculture and domestic uses. The calculated natural flow record for Lees Ferry begins in 1922. Natural flows at Lees Ferry for 1906 to 1921 are also available from reconstructions using gage records in the Upper Basin.

From 1906 to 2007, the average annual natural flow at the Lees Ferry was calculated to be 14.9 maf and ranged from 5.4 maf to 24.4 maf. Since the implementation of the 2007 ROD (2008 to 2025), the annual natural flow at the Lees Ferry averaged 12.7 maf and has ranged from a low of 6.7 maf (2021) to 20.3 maf (2011). **Figure TA 3-3** shows the WY natural flows calculated at the Lees Ferry for 1906 through 2025.



According to the 2020 *State of the Science* report, a 2-year average natural flow of less than 15.0 maf at Lees Ferry is considered a streamflow deficit (Lukas and Payton 2020). During the 1963–2007 period, the maximum 2-year average natural Lees Ferry flow was 24.0 maf in 1984. For comparison, since implementation of the 2007 ROD, the maximum 2-year average natural Lees Ferry flow was 16.27 maf in 2011. Other than the high flows in 2011, the 2-year average natural Lees Ferry flows since 2007 have been below 15.0 maf. Based on the 2020 *State of the Science* report's definition of a streamflow deficit, and the natural flow at Lees Ferry data, the system has been in a streamflow deficit since 2011 (Lukas and Payton 2020).

Figure TA 3-2
Lees Ferry Gaging Station and Lee Ferry Compact Point

Source: Reclamation 2007a

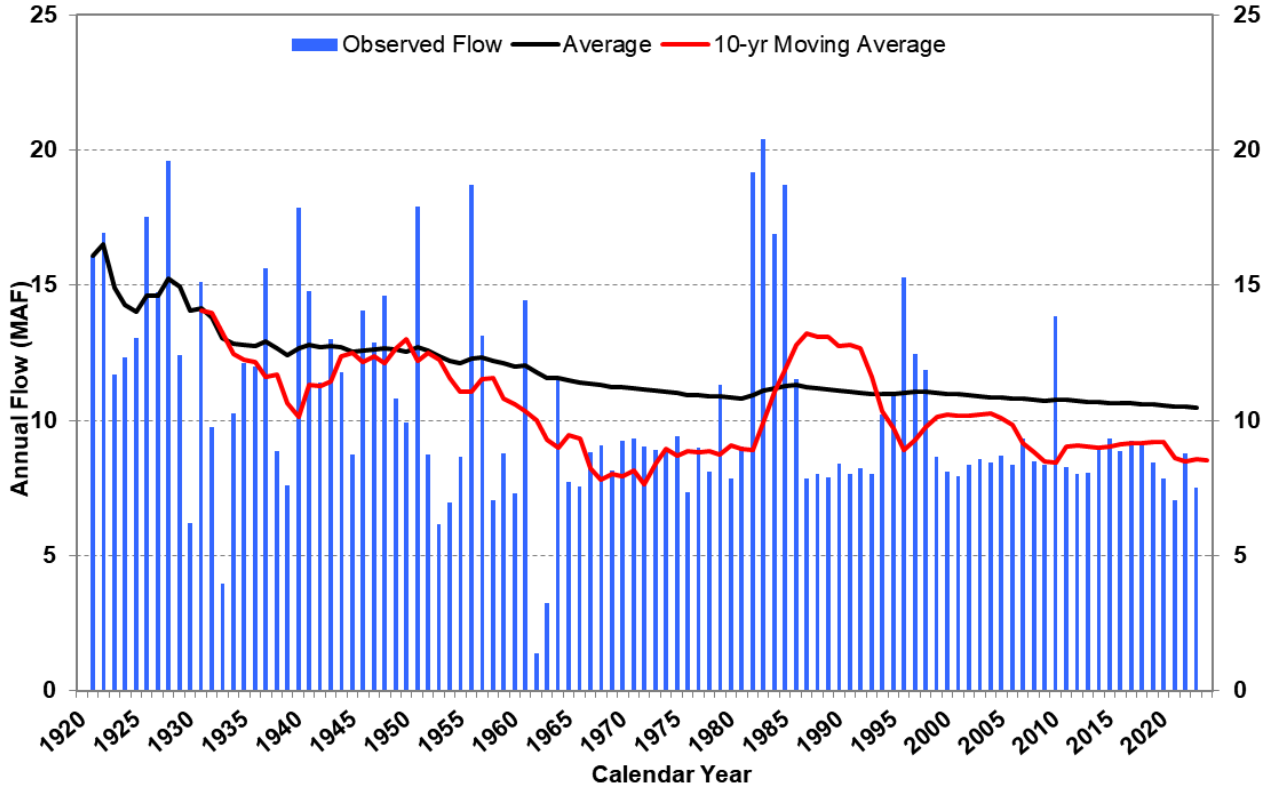


Figure TA 3-3
WY Colorado River Calculated Natural Flow at Lees Ferry Gaging Station, Arizona (1906-2025)

Source: Reclamation 2025f

The annual observed flow at Lees Ferry differs from natural flow in that it does not account for the above-mentioned factors and is simply the recorded gage data with infrastructure in place. The annual observed flow at Lees Ferry since Glen Canyon Dam was built (1963) until the 2007 ROD was implemented ranged from 1.4 maf (following when the dam was built in 1963) to 20.4 maf (1984) with an average of 9.8 maf. Since the implementation of the 2007 ROD (2008 to 2024), the annual observed flows at the Lees Ferry Gaging Station have generally decreased, ranging from 7.0 maf (in 2022) to 13.9 maf (in 2011) and averaging 8.8 maf. This average annual observed flow is approximately 1.0 maf less than the average observed flow from 1962-2007. **Figure TA 3-4** shows the observed flows recorded at the Lees Ferry for 1922 through 2024.

Figure TA 3-4
Colorado River Observed Flow at Lees Ferry Gaging Station, Arizona (1922-2024)

Source: Reclamation 2025f

TA 3.1.5 Glen Canyon Dam to Lake Mead

The narrow 292-mile reach between Glen Canyon Dam and Lake Mead flows through Marble Canyon, Glen Canyon, and GCNP. The reach through Glen Canyon is 15 miles long and the reach through the Grand Canyon reach is 277 miles long. Flows within this reach primarily consist of flow from Glen Canyon Dam releases but include contributions from perennial tributaries located between Glen Canyon Dam and Lake Mead. The two largest tributaries are the Paria River and Little Colorado River. The 95-mile long Paria River starts in the Grand Staircase-Escalante National Monument and joins the Colorado River approximately five miles downstream from Glen Canyon Dam. The 340-mile long Little Colorado River drains a region of the Colorado River watershed to the southeast of Lake Powell, including the Painted Desert. The smaller creeks entering the GCNP from side canyons include Bright Angel Creek, Shinumo Creek, Tapeats Creek, Kanab Creek, Havasu Creek, and Diamond Creek.

Based on historical United States Geological Survey (USGS) gage data, inflows from the Paria River and Little Colorado River make up approximately three percent of the total flow in this reach of the Colorado River (USGS 2025a). From 1906 to 2005, the annual inflow of the Paria River averaged 21 thousand acre-feet per year (kafy) and the Little Colorado River averaged 180.0 kafy. Since 2007, the annual inflows from the Paria River averaged 17.0 kafy and the Little Colorado River averaged 274.0

kaf. Just below the confluence of the Little Colorado River (USGS gage 09402500), the flows in Colorado River ranged from 7.56 maf to 14.24 maf (averaging 9.31 maf; USGS 2024).

The Stream Flow and Losses of the Colorado River in the Southern Colorado Plateau White Paper 5 (White Paper 5; Wang et al. 2020) stated that there is approximately 150.0 kaf a year of seepage loss around Glen Canyon Dam and this volume has remained consistent.

Downstream of Glen Canyon Dam is the incised Grand Canyon, which limits hydraulic connection to groundwater to sandbars. Debris flows from side canyons result in deposits into the Grand Canyon of boulders and sand to replenish sandbars during elevated flows. Refer to **TA 5**, Geomorphology and Sediment, for more details regarding physical geotechnical characteristics of the Grand Canyon. Effects on groundwater elevations through the Grand Canyon were not considered in the 2007 Final EIS or the 2024 Near-term Colorado River Operations Final SEIS (2024 Final SEIS). While the flows in the Colorado River would not affect groundwater in the region, changes to the groundwater systems in the Grand Canyon due to climate trends may be an additional environmental factor that affects flows in the Colorado River.

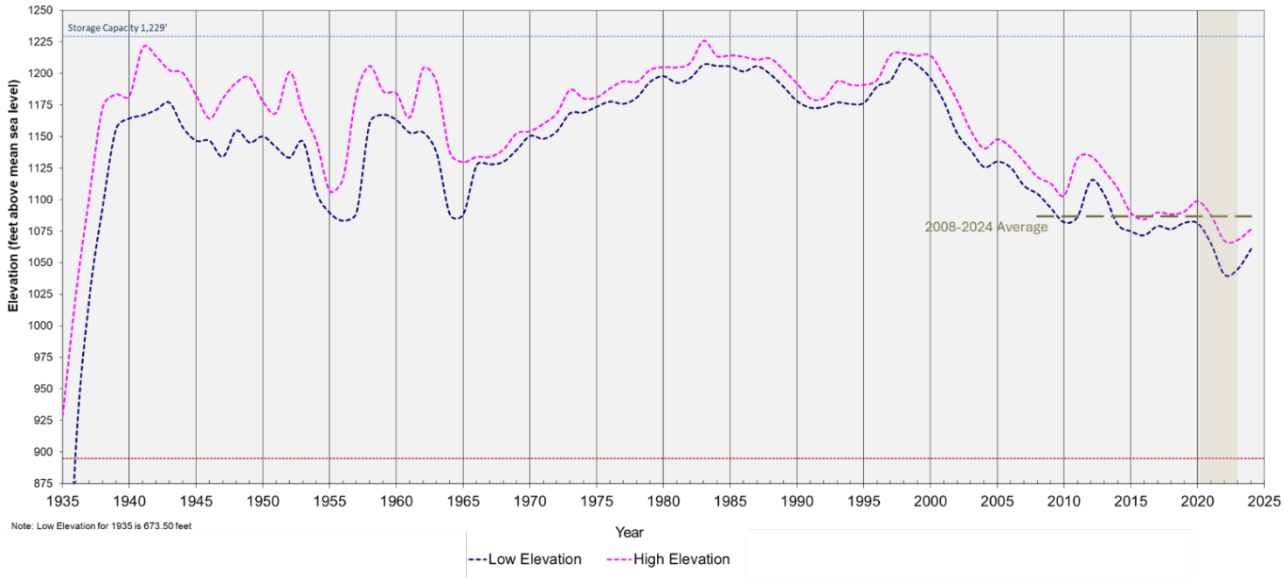
TA 3.1.6 Lake Mead and Hoover Dam

Lake Mead is a reservoir that is located on both sides of the Arizona-Nevada state line. Inflows into Lake Mead are from the Colorado River through Black Canyon, which is dammed by Hoover Dam and also from the Virgin River and Muddy River tributaries to the north of the reservoir. The concrete, thick arch dam was constructed from 1931 to 1936 and rises 726 feet as the highest concrete dam in the United States (U.S). When full, Lake Mead is 112 miles long.

The water surface elevation operating range of Lake Mead is set between 895 feet and 1,219.6 feet, with a maximum elevation of 1,229 feet. The total live storage capacity of Lake Mead at the full pool elevation of 1,219.6 feet is 26.12 maf (excluding 1.5 maf of Flood Control space).[3]

Groundwater basins adjacent to Lake Mead are generally small in size and are bound by zones of non-water bearing rock. Previous efforts in the 2007 Final EIS and 2024 Final SEIS noted that groundwater adjacent to Lake Mead may increase or decrease in correlation with changes in pool elevations. The Arizona Department of Water Resources Groundwater Site Inventory website (ADWR 2025) tracks depth to water measurements for one active groundwater monitoring well located to the south of Lake Mead, near the Detrital Wash. Groundwater elevations have remained steady since the groundwater monitoring well was installed in 1984 with the exception of two low groundwater elevation measurements in 2021 and 2022.

Beginning in 2011 and continuing for several years, Hoover Dam underwent improvements consisting of the installation of five new wide-head turbines to improve hydropower operations at lower water levels resulting in the lowering of the minimum power pool elevation from 1,050 feet to 950 feet. Low water level releases (below elevation 950 feet to elevation 895 feet) would continue through the four intake towers and penstocks but would no longer be able to be released through



[3] Exclusive flood control space of 1.5 maf at elevation 1,219.6 feet as defined in the Field Working Agreement Between Department of the Interior, Bureau of Reclamation and Department of the Army, Corps of Engineers for Flood Control of Hoover Dam and Lake Mead, Colorado River, Nevada-Arizona, February 8, 1984.

the hydropower turbines; instead, below 950 feet, water would only be released through the river outlet works. When elevations drop below 895 feet (referred to as dead pool), water is no longer able to be delivered downstream from Hoover Dam.

Lake Mead took approximately four years to fill to an average annual water surface elevation of 1,172 feet following the construction of Hoover Dam in 1936, but levels were highly variable. From 1939 to 1963, until Glen Canyon Dam and Lake Powell came online, the reservoir's water surface elevation fluctuated from 1,098 feet to 1,195 feet. Average annual peak elevation steadied in 1983 at 1,215 feet, then decreased through the late 1980s and early 1990s. In 1998, the average annual elevation peaked again at 1,214 feet before sharply declining to a new low of 1,118 feet in 2007. From 1939 to 2007, the average annual water surface elevation of Lake Mead was 1,170 feet.

Since 2007, water surface elevations at Lake Mead have generally declined. Reclamation's hydrologic database collected water surface elevation data from 2008 through 2024 which showed that the average annual operating range was between 1,040.6 feet (2022) and 1,134.5 feet (2011). The average annual operating elevation was 1,086.8 feet, approximately 83.2 feet lower than the historical average annual from 1939 to 2007. **Figure TA 3-5** shows the annual high-water elevation and annual low-water elevation of Lake Mead from 1935 to 2024 with the average elevation of 1,086.8 feet from 2007 to 2024 shown as a dashed line, for reference.

Figure TA 3-5
Lake Mead Annual High and Low Elevations (1935-2024)

Source: Reclamation 2025b

The Compact apportioned 7.5 maf of water per year for beneficial consumptive use to the Lower Division States. The LROC established operating criteria for Colorado River reservoirs including criteria for Normal, Surplus, and Shortage operating conditions at Lake Mead pursuant to Section II(B) of the Supreme Court Decree in *Arizona v. California* 1964 and the 2006 Consolidated Decree.

Prior to the 2007 ROD, there were no objective criteria to reduce deliveries to Lower Basin water users below normal apportionment.

The 2007 ROD also adopted criteria for storing and delivering conserved Colorado River system and non-system water in Lake Mead. Water conserved under this program is called Intentionally Created Surplus (ICS). The program allowed for additional flexibility in meeting water needs during drought and bolstered Lake Mead during low reservoir conditions. The 2019 DCP modified and expanded the original ICS program. Since the 2007 ROD, Lake Mead has operated on a normal/ICS condition each year from 2008 through 2021 (refer to **Table TA 3-1**, Summary of Lake Powell and Lake Mead Coordinated Operations 2008-2024, above for Lake Mead's operating condition). In 2022, Reclamation declared the first ever Level 1 Shortage Condition for Lake Mead. Hydrologic conditions worsened and Lake Mead operated at a Level 2 Shortage Condition in 2023. In 2024 and 2025, Lake Mead operated in a Level 1 Shortage Condition. From 2020 through 2025, contributions from the Lower Basin DCP were required when the elevation of Lake Mead was below elevation 1,090 feet.

2007 Interim Guidelines shortage, DCP contributions, and ICS activity since the 2007 ROD have contributed to decreases in Hoover Dam releases. Annual Hoover Dam releases from Lake Mead ranged from 8.275 maf to 12.781 maf (averaging 10.199 maf) from 1996 through 2007 but have since ranged from 8.515 maf to 9.615 maf (averaging 9.185 maf) from 2008 through 2024.

Hoover Dam releases are managed on an hourly basis to maximize the value of generated power by providing peaks during high-demand periods. Releases from Hoover Dam are also based on Flood Control regulations are directed by the U.S. Army Corps of Engineers (USACE). Approximately 1.5 maf of space must be reserved within Lake Mead at all times exclusively for Flood Control purposes.

TA 3.1.7 Hoover Dam to Lake Mohave

The 67-mile reach from Hoover Dam (Lake Mead) to Davis Dam forms Lake Mohave. The upper part of this reach consists of Pyramid Canyon, El Dorado Canyon, and Black Canyon. The steep walls of these canyons bound most of this reach. The narrow Lake Mohave is less than four miles across its widest point. The lake creates some minor side washes but flow within this reach is almost entirely comprised of releases from Hoover Dam (Reclamation 2007a).

Since the issuance of the 2007 ROD, releases from Hoover Dam have decreased to meet monthly elevation targets, resulting in lower river flows through this reach. The 2007 Interim Guidelines have reduced average annual releases from Hoover Dam by approximately 1.014 maf (annually averaging 9.185 maf).

The target water surface elevation range of Lake Mohave and Davis Dam were not affected by the 2007 Interim Guidelines, with target water surface elevation levels between elevation 633 feet to 645 feet. Lake Mohave generally reaches its lowest elevations in the fall as Reclamation aims to provide Flood Control capacity for runoff that results from hurricane-type storms from Baja California, Mexico. Lake Mohave generally reaches its highest elevations in the spring. The average storage in Lake Mohave has remained constant at approximately 1.6 maf over the past few decades, with an

average annual water surface elevation of approximately 640.8 feet from 1996 to 2007 and 640.9 feet since 2008.

With Black Canyon located directly downstream of Hoover Dam, the bedrock canyon limits the connection to groundwater with a few small sandbars. The 2007 Final EIS identified no anticipated impacts on the groundwater basins from the 2007 Interim Guidelines.

TA 3.1.8 Davis Dam to Lake Havasu

The 84-mile reach from Davis Dam to Parker Dam forms Lake Havasu, which provides a forebay and desilting basin that pumps water for delivery to the Metropolitan Water District of Southern California and Central Arizona Project service areas. Minor tributaries are located above the reservoir, but flow in this reach primarily consists of releases from Davis Dam.

Bill Williams River, the largest of the tributaries in this reach, flows directly into Lake Havasu. The small inflows (on the order of 50 cfs) from this tributary flow and are regulated by the USACE operations of Alamo Dam. Based on historical USGS gage data, from 1906 to 2007, the annual inflow ranged from 1,300 af to 702,000 af and averaged 102,000 af (USGS 2025b). Flood Control operations at the Alamo Dam occasionally contribute to increased flows to Lake Havasu. The 2007 Interim Guidelines did not affect these operations. Annual Alamo Dam releases from 2008 to 2022 have ranged from 15.4 af to 501,900 af and averaged 105,000 af. Bill Williams River flow contributions to the reach have remained unchanged.

Parker Dam is operated under the same rule curve that sets end-of-month target elevations as prior to the 2007 Interim Guidelines, maintaining Lake Havasu's water surface elevation between 445 and 450 feet. Seasonal adjustments to the reservoir's water surface elevation allow for Flood Control in the fall and higher water levels in the spring. The average annual elevation was 447.5 feet from 1996 to 2007, and approximately 447.7 feet from 2008 to 2022, remaining consistent for the last several decades.

This reach flows through two separate groundwater basins separated by the bedrock Topock Narrows: the Mohave Valley (north) and Chemehuevi Valley (south). Based on the 2007 Final EIS hydrologic and hydraulic models, the Mohave Valley aquifer, which is mostly alluvial fill, groundwater elevations were assumed to have decreased by approximately 0.25 feet since 2007. Water levels in the Chemehuevi Valley groundwater basin are assumed to have remained relatively consistent since 2007.

TA 3.1.9 Parker Dam to Cibola Gage

The 105-mile reach starting at Lake Havasu's Parker Dam is bounded on the downstream end by Reclamation's Cibola Gage. This reach primarily consists of releases from Parker Dam, which is considered the last major storage facility on the Colorado River.

Parker Dam releases are scheduled on a daily and hourly basis to meet demand for power while supplementing water supply downstream. The 2007 Interim Guidelines did not explicitly target Parker Dam operations but have resulted in decreased annual release rates since implementation. Current minimum releases of the dam are 1,600 cfs daily, 1,400 cfs hourly, releasing 95,000 af during

a 30-day month. The 2007 Final EIS stated Parker Dam releases from Lake Havasu ranged from 6.19 maf to 10.3 maf (averaged 7.4 maf) from 1996 to 2007. Since 2008, annual dam releases ranged from 6.2 maf to 6.7 maf (averaged 6.4 maf) through 2022. The average annual Parker Dam releases decreased by 1.0 maf post-implementation of the 2007 Interim Guidelines.

Two major diversion dams located in this reach are Headgate Rock Dam and Palo Verde Diversion Dam. The impoundments of these dams are used to facilitate the diversion of water for the Colorado River Indian Tribes and the Palo Verde Irrigation District. Current reservoir operations keep these reservoir levels at constant elevations.

The only large groundwater basin (mostly alluvial fill) within this reach is referred to by separate valley names: Parker Vally, Cibola Valley, and Palo Verde Valley. The 2007 Final EIS determined that groundwater elevations would decrease by approximately 0.15 feet to 0.30 feet in these areas based on hydrologic and hydraulic models and corresponding reductions in river flow. Therefore, groundwater levels have been assumed to have decreased since 2007 due to a decreasing trend in river flows.

TA 3.1.10 Cibola Gage to Imperial Dam

The 38-mile reach from Cibola Gage is bounded on the downstream end by Imperial Dam. Flows in this reach are primarily comprised of releases from Parker Dam. Imperial Dam is located approximately 18 miles northeast of Yuma, Arizona and provides enough increase in water surface elevation for gravity flow diversions to the All-American Canal (AAC) and the Gila Main Canal. The 2007 Interim Guidelines did not affect these diversions.

The Imperial Dam impoundment operates at a nearly constant elevation to meet water delivery requirements. The 2007 Interim Guidelines did not change operations of Parker Dam, but annual releases have decreased since 2008 due to decreased upstream releases from Lake Powell and Lake Mead, which translated to decreased inflows into Lake Havasu. Average flow rates in this reach ranged from 1,488 cfs to 18,168 cfs (averaged 8,931 cfs) from 1996 to 2007, and from 2,224 cfs to 18,751 cfs (averaged 7,632 cfs) since 2008. The reach has seen an average decrease of 1,299 cfs.

This reach is located in a narrow alluvial fill valley without irrigated agriculture, and many backwaters are located in the southern half of the reach. Groundwater elevations are assumed to have decreased in this reach since 2007.

TA 3.1.11 Imperial Dam to NIB

The 26-mile reach extends from Imperial Dam to the NIB between the U.S. and Mexico. The channel of the Colorado River through this reach is bounded by a system of levees. Flow through this reach is comprised of water released from Imperial Dam to make downstream deliveries, water leaked from the California sluiceway gates and return flow from Imperial Dam diversions.

Imperial Dam was constructed to raise the water surface elevation enough to provide gravity-controlled flow into the AAC on the California side and the Gila Gravity Main Canal on the Arizona side to meet water deliveries. The AAC diverts water for the Imperial Irrigation District, the

Coachella Valley Water District, the Yuma Project, and the City of Yuma. The AAC also has a desilting works used to remove sediment from the Colorado River prior to diversion into the AAC. The Gila Gravity Main Canal diverts water for Gila Valley, Yuma Mesa, and the Wellton-Mohawk area. Imperial Dam also regulates deliveries to Mexico.

Downstream of Imperial Dam, in the upper portion of the reach, flows are typically around 250 cfs to 350 cfs. Laguna Dam is located approximately 5 miles downstream from Imperial Dam and was initially constructed to divert water to the Yuma Project area. However, since the AAC was built, Laguna Dam has been used as a regulating structure to manage sluicing flows from Imperial Dam and to protect the toe of Imperial Dam. Approximately 9 miles downstream from Laguna Dam is the confluence with Gila River, which is a major tributary to the Colorado River.

The 2007 ROD did not affect the operations and flows in the upper portion of this reach. The Yuma Valley groundwater basin and the South Gila Valley groundwater basin were also not anticipated to be affected from the 2007 Interim Guidelines. Reclamation assumed that groundwater levels have remained essentially the same since 2007.

TA 3.1.12 NIB to SIB

The Morelos Diversion Dam, located 1.1 miles downstream of the NIB, impounds the majority of the water supply that is diverted by Mexico into the Reforma Canal. The dam is owned, operated, and maintained by Mexico per the 1944 United States-Mexico Treaty on Utilization of Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Water Treaty). The dam's flow in the limitrophe to the SIB consists of water in excess of Mexico's scheduled delivery due to Flood Control operations at Hoover Dam, seepage from Morelos Diversion Dam, irrigation return flows, groundwater inflow, and any water released for environmental purposes in the Colorado River Delta.

To ensure the annual 1.5 maf water delivery under Normal Conditions per the 1944 Water Treaty, the Morelos Diversion Dam operations have not changed as a result of the 2007 ROD or the 2024 ROD. In Minute 323 to the 1944 Water Treaty, Mexico agreed to reductions and savings under low elevation reservoir conditions. Refer to **Appendix N**, International Border Region of the Colorado River, for more details related to an overview of previous binational coordination efforts.

The Flood Control releases from Lake Mead and Hoover Dam upstream are largely dependent on hydrologic conditions and therefore have potential impacts. The average flows to Mexico in excess of the required delivery volume were approximately 114,081 af from 1974 to 2012, until Warren H. Brock Reservoir was built to reduce excess flows at the NIB. Prior to completion, the 10-year annual average flow from 2003 to 2012 was 82,853 af. Since completion of the reservoir, flows in excess of the required delivery volume have decreased by approximately two thirds, or by 56,000 af, per year. Additionally, considerations for hydrologic conditions, rainfall events, and other operational variables are relevant to the volume of flows in excess of the required delivery volume.

This reach is in the Colorado River Delta groundwater basin and is referred to as the limitrophe. It is characterized as a dry or minimally flowing streambed with an annual rainfall of less than three inches. Flows in this reach can be from releases from Morelos Diversion Dam, various wasteway

discharges from the Yuma area irrigation system, or from nearby agricultural fields percolating into the hyporheic zone and subsurface alluvium.

Due to high groundwater levels in adjacent irrigated fields, the upper portion of the limitrophe is a gaining reach that receives perennial inflow from the groundwater basin. Depths to groundwater increase in the southern portions of the limitrophe reach, towards the SIB, which is considered a losing reach. Groundwater elevations in this reach dropped around 27 feet between 1960 and 2009 (refer to **Appendix N**, International Border Region of the Colorado River, for more details related to the affected environment description for the border region).

TA 3.2 Environmental Consequences

This section provides an analysis of the extent and magnitude of potential impacts on hydrologic resources under the No Action Alternative, four action alternatives (as described in **Appendix S**), the Continued Current Strategies (CCS) Comparative Baseline (as described in **Chapter 3 , Section 3.2.3**), and the Representative Preferred Alternative (as described in **Chapter 2**).

As discussed in **Chapter 2**, the Preferred Alternative is a multi-year decision framework that establishes the process and criteria that would govern development and adoption of operating guidelines through 2036. The decision framework is anticipated to be implemented in two-year operating intervals. Unlike other alternatives, the operating guidelines for each interval are not specified in this Final EIS. The sideboards provide a basis for assumptions included in the Representative Preferred Alternative which captures the range of operating guidelines that may be adopted during each interval, but exact operations would be subject to the guidelines in place during each interval.

Methodology

Reclamation uses the Colorado River Simulation System (CRSS) model for long-term planning studies. CRSS simulates Basin conditions decades into the future (the full analysis period is through 2060) and can be used to account for hydrological uncertainty. CRSS is a monthly time-step model that produces reservoir elevations, releases and river flows as outputs. Refer to **Appendix A**, CRSS Model Documentation, for more details related to model documentation. Analysis in this appendix uses output from CRSS.

Decision Making under Deep Uncertainty (DMDU) is the approach used for quantitative analysis. It is a non-probabilistic evaluation framework that compares alternatives based on their ability to meet specific performance criteria in many potential future conditions and analyzes how the alternatives respond to specific hydrologic conditions. Additional background and technical details about the DMDU framework are provided in **Appendix E**, DMDU Overview and Approach.

Throughout the analysis there are three standard figures: conditional boxplots, robustness heatmaps, and vulnerability bar plots. Each type of figure explains key information regarding performance. When taken together, the figures provide a full picture of how the alternatives compare and whether significant negative impacts are reasonably foreseeable under each alternative. The conditional

boxplot figures show how the alternatives respond to different categories of preceding hydrology and enable a comparison of alternatives in specific hydrologic conditions (e.g., average conditions or dry conditions). To create these figures, all 34 years (2027–2060) from all 400 simulated futures (13,600 data points per alternative) are separated into five categories based on their preceding 3-year average Lees Ferry natural flow. Robustness heatmaps show the alternatives' ability to meet different levels of performance over one or more decades in the wide range of potential future conditions used in the analysis. Vulnerability bar plots provide complementary analysis to the robustness heatmaps by identifying the specific hydrologic conditions in which each alternative is likely to succeed or fail the preferred minimum performance level. For more information about these figures and detailed interpretation guidance, see **Chapter 3**, **Section 3.2.6**

Impact Analysis Area

The geographic scope of the hydrologic resources analysis is the Colorado River corridor from the upstream limits of full pool elevation of Lake Powell to the downstream limits of the SIB. Reservoirs upstream of Lake Powell are operated pursuant to their own RODs, which are not altered by the proposed alternatives.

Assumptions

The hydrologic resources results are direct outputs from CRSS. Refer to **Appendix A**, CRSS Model Documentation, for more details related to model assumptions and documentation. All action alternatives except for the Basic Coordination Alternative incorporate mechanisms related to the storage and delivery of conserved water in Lake Powell and/or Lake Mead (see **Appendix S**, Additional Description of Alternatives). Unless otherwise specified, impacts reflect modeling assumptions about voluntary conservation behavior.

Impact Indicators

The following indicators were used to assess impacts on hydrologic resources:

- **Reservoir elevations**: impacts on reservoir elevations due to operational activities
- **System storage**: impacts on system storage due to operational activities
- **Reservoir releases:** impacts on reservoir releases due to operational activities
- **River flows:** impacts on river flows due to operational activities
- **Groundwater**: qualitative impacts on groundwater adjacent to reservoirs and river reaches due to operational activities

TA 3.2.1 Issue 1: Reservoir Elevations

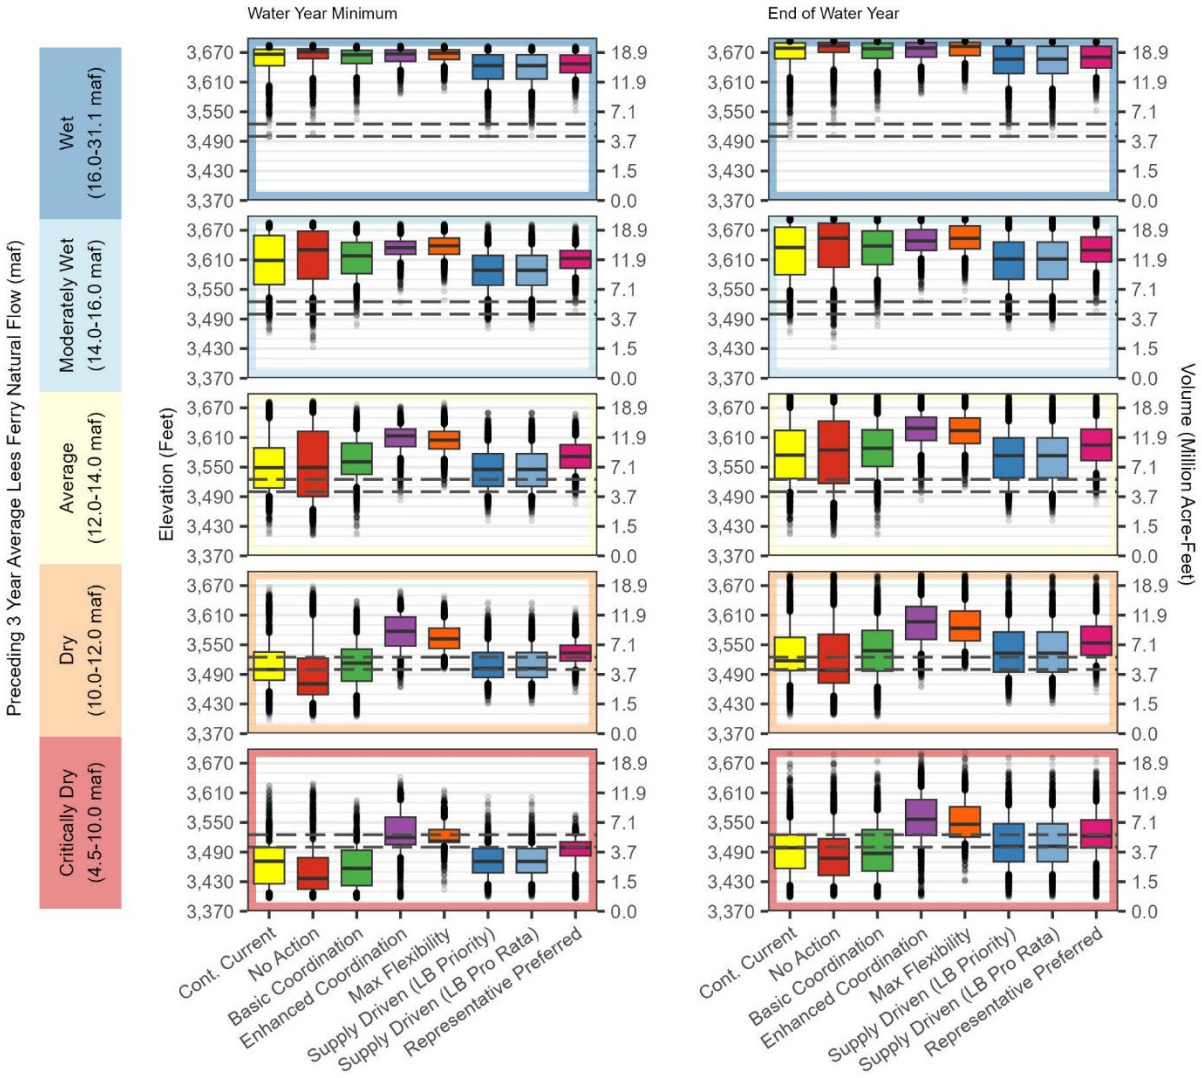
Issue 1 addresses how operational activities for the various alternatives would affect reservoir elevations. This includes comparing the various action alternatives to the No Action Alternative and the CCS Comparative Baseline for the following metrics:

- Lake Powell pool elevations
- Lake Mead pool elevations
- Impacts of modeling assumptions for Upper Basin and Lower Basin conservation activity on Lake Powell and Lake Mead storage

Lake Powell

This section presents a comparison of the No Action Alternative, CCS Comparative Baseline, and action alternatives with respect to EOWY and minimum water year elevations at Lake Powell. Note that the performance of the Lower Basin Priority (LB Priority) approach and the Lower Basin Pro Rata (LB Pro Rata) approach under the Supply Driven Alternative will not differ in Lake Powell elevations because they use the same operation of Lake Powell. Critical Lake Powell elevations are listed in **Table TA 3-2** below. The total live storage capacity of Lake Powell at the full pool elevation of 3,700 feet is 23.31 maf (excluding approximately 1.9 maf of Flood Control space).

Table TA 3-2
Critical Elevations at Lake Powell



Critical Condition	Associated Elevation	Description of Critical Elevation
Spillway	3,700 feet	Top of Glen Canyon Dam spillway
Spill Avoidance	3,680 feet	At high elevations, releases deviate from the planned release for spill avoidance and infrastructure protection. Capacity between this elevation and the top of the spillway allows for 1.9 maf of Flood Control storage
Buffer Elevation	3,525 feet	35-foot buffer elevation above 3,490 feet; may trigger additional (within Record of Decision) releases from CRSP UIUs (Flaming Gorge, Navajo, and Blue Mesa Reservoirs) for certain alternatives
Buffer Elevation	3,500 feet	10-foot buffer elevation above 3,490 feet
Minimum Power Pool	3,490 feet	Water can only be released through the river outlet works below this elevation; no longer able to produce hydropower at Glen Canyon Dam; releases below this elevation are constrained; extended operations through the river outlet works may cause cavitation damage, tailrace scour and sediment deposition, and could compromise the reliability and operational flexibility of Glen Canyon Dam and affect the ability to meet critical downstream water supply needs
Dead Pool	3,370 feet	No longer able to release water downstream through Glen Canyon Dam

Figure TA 3-6 presents conditional boxplots of the minimum WY elevations and EOWY elevations at Lake Powell (feet) under varying hydrologic conditions, defined by the preceding three-year average of Lees Ferry natural flow. The figure shows how the alternatives perform across these flow categories. See **Table TA 3-3** and **Table TA 3-4** at the end of this TA for the full statistical summaries, including the maximum, 90th percentile, 75th percentile, median, 25th percentile, 10th percentile, and minimum elevations (feet). **Figure TA 3-6** visualizes the same data as **Table TA 3-3** (left column) and **Table TA 3-4** (right column) using two side-by-side conditional box plot panels. The bold center line of each box represents the median value. The bottom and top of each box captures the 25th to 75th percentile of the modeled results, respectively. The lines extend to the 10th and 90th percentiles, and outliers are shown as dots.

In each flow category shown in the box plots, the critical elevation thresholds of 3,525 feet and 3,500 feet are identified with dashed lines. These elevations are important because they provide a 10-foot and a 35-foot buffer above 3,490 feet - the elevation below which water can only be released through the river outlet works. Operating below 3,490 feet limits the volume of water that can be

released, since water can only pass through the river outlet works. As described in **Chapter 1**, Purpose and Need, **Section 1.8.4.1**, there are infrastructure concerns associated with the uncertainty of extended operations through the river outlet works as the sole means of sustained water releases from Glen Canyon Dam that could compromise the reliability and operational flexibility of Glen Canyon Dam and affect the ability to meet critical downstream water supply needs. There are additional impacts to hydropower associated with operating below 3,490 feet as this is minimum power pool.

Figure TA 3-6
Water Year Minimum and End of Water Year (EOWY) Elevations and Storage Volumes of Lake Powell

In the Average Flow Category for EOWY elevations, the 25th, 50th, and 75th percentiles (hereafter, 25th-75th percentiles) for all alternatives and the CCS Comparative Baseline remains above 3,500 feet. Similarly, all alternatives and the CCS Comparative Baseline have 25th-75th percentiles that

remain above 3,525 feet except for the No Action Alternative, which has a 25th percentile elevation of 3,517 feet. The Enhanced Coordination and Maximum Operational Flexibility Alternatives have higher, less variable results centered around 3,625 feet, while the CCS Comparative Baseline and the No Action, Basic Coordination, Supply Driven (both LB Priority and LB Pro Rata approaches), and Representative Preferred Alternatives have median elevations around 3,580 feet.

In drier flow categories, the median EOWY elevations for the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives shift notably toward and below 3,500 feet, with the 25th-75th percentiles for the CCS Comparative Baseline and the No Action Alternative falling below 3,525 feet in the Critically Dry Flow Category (4.5-10.0 maf). The Enhanced Coordination and Maximum Operational Flexibility Alternatives show less of a decline across all flow categories; even in the Critically Dry Flow Category the 25th-75th percentiles for both remain above the critical threshold of 3,500 feet, with median reservoir elevations of 3,557 feet and 3,546 feet, respectively. In the Critically Dry Flow Category, median EOWY elevations shift below 3,500 feet for the Basic Coordination Alternative (3,487 feet), the No Action Alternative (3,478 feet), and the CCS Comparative Baseline (3,499 feet).

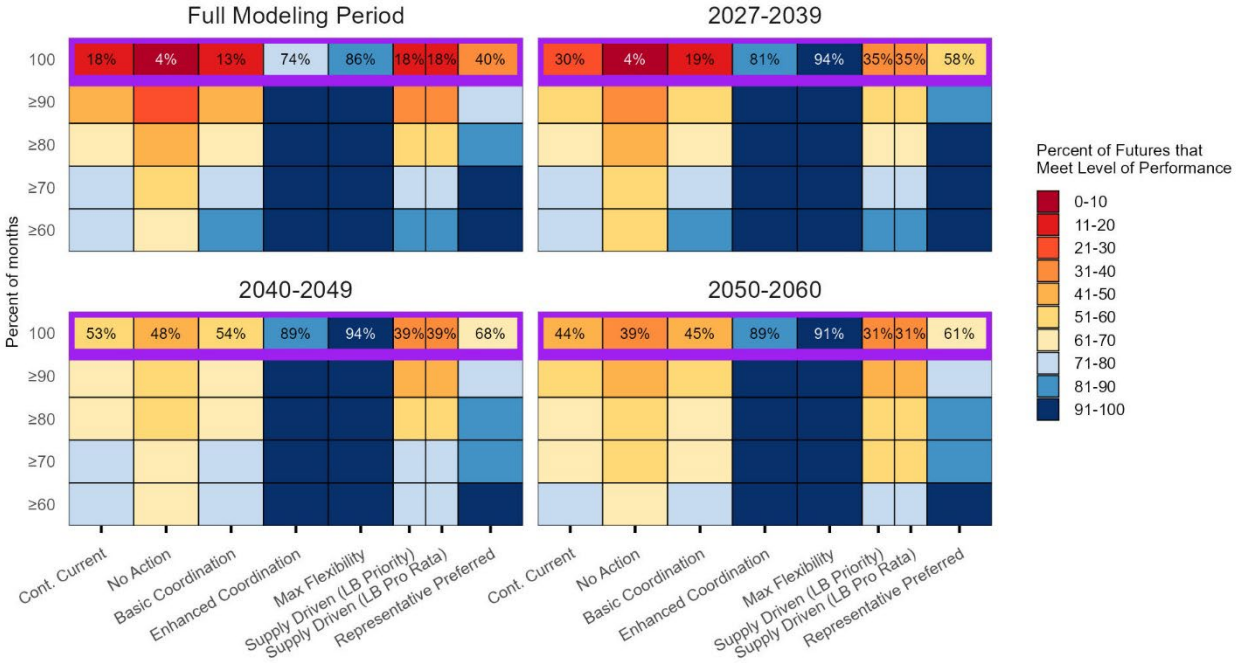
In the Dry Flow Category (10.0-12.0 maf) for EOWY elevations, the Representative Preferred Alternative has a median elevation of 3,554 feet with 25th and 75th percentiles of 3,529 feet and 3,588 feet, respectively. In the Critically Dry Flow Category for EOWY elevations, the Representative Preferred Alternative has a median elevation of 3,523 feet and decreasing variability, with 25th-75th percentiles spanning from 3,498 feet to 3,555 feet. With respect to the buffer elevation of 3,500 feet, the Representative Preferred Alternative remains above this threshold in more than 90 percent of years in the Dry Flow Category and in nearly 75 percent of years in the Critically Dry Flow Category; with respect to the buffer elevation of 3,525 feet, the Representative Preferred Alternative remains above this threshold in about 75 percent of years in the Dry Flow Category and nearly 50 percent of years in the Critically Dry Flow Category.

For the WY minimum panel, the comparisons across alternatives and flow categories are the same as in the EOWY elevations panel, but the distributions of elevations shift lower since Lake Powell generally reaches its minimum elevation in March before spring runoff begins and elevations increase by EOWY.

The alternatives and CCS Comparative Baseline generally perform similarly under Wet and Moderately Wet Flow Categories (16.0-31.1 maf and 14.0-16.0 maf), except for the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) which has a lower median reservoir elevation. Performance deviations increase under drier conditions because operations at lower elevations vary widely across alternatives.

In the Dry Category for WY minimums, the Representative Preferred Alternative has a median elevation of 3,534 feet and an interquartile range (32 feet, calculated as 75th percentile minus 25th percentile) which is the smallest of any alternative. In the Critically Dry Flow Category for WY minimums, the Representative Preferred Alternative has a median elevation of 3,499 feet. With respect to the buffer elevation of 3,500 feet, the Representative Preferred Alternative remains above this threshold in 90 percent of years in the Dry Flow Category and about 50 percent of years in the

Critically Dry Flow Category; with respect to the buffer elevation of 3,525 feet, the Representative Preferred Alternative remains above this threshold in about 50 percent of years in the Dry Flow Category and about 10 percent of years in the Critically Dry Flow Category.



Lake Powell 3,500 Feet Robustness and Vulnerability

Figure TA 3-7 compares alternatives with respect to keeping Lake Powell above an elevation of 3,500 feet. As described above, this elevation is important because it provides a 10-foot buffer to protect critical infrastructure, water supply, and hydropower, which are critically impacted at an elevation of 3,490 feet.

The rows of the heat map reflect the percent of months in which Lake Powell elevation stays above 3,500 feet. Higher percentages of years are preferable and harder to achieve.

The purple highlighted row represents the preferred minimum level of performance and captures the percentage of futures that an alternative keeps Lake Powell above 3,500 feet in 100 percent of the months. 100 percent of months was chosen as the preferred minimum level of performance because of the importance of avoiding critical impacts on water deliveries and hydropower.

Figure TA 3-7
Lake Powell 3,500 Feet: Robustness.
Percent of futures in which Lake Powell elevation stays above 3,500 feet in the percent of months specified by each row

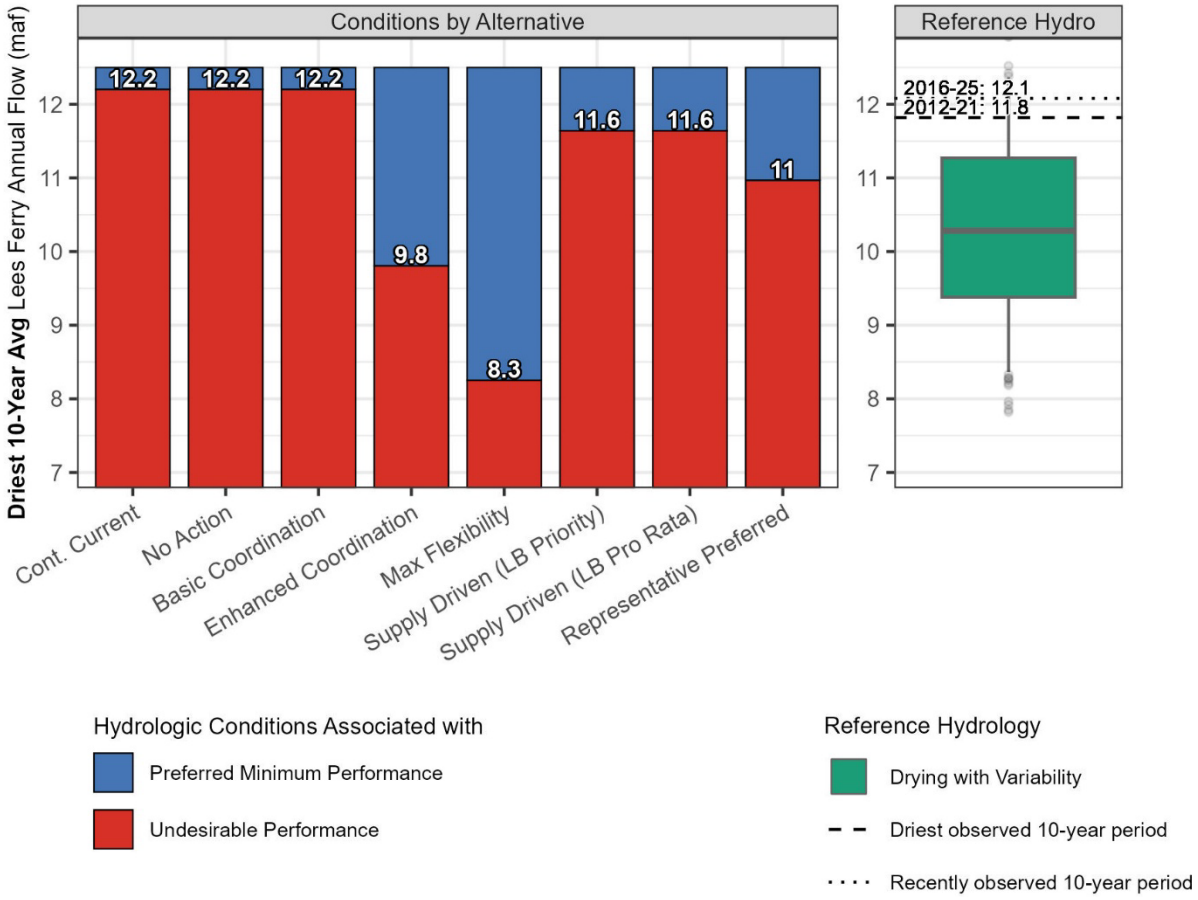
In the Full Modeling Period, the Enhanced Coordination and Maximum Operational Flexibility Alternatives can meet the preferred level of performance in 74 percent and 86 percent of the modeled futures, respectively, which is considerably more robust than the other alternatives. The CCS Comparative Baseline and the No Action, Basic Coordination, and Supply Driven (both LB

Priority and LB Pro Rata approaches) Alternatives are the least robust and are only able to meet the preferred minimum performance in 18 percent, 4 percent, 13 percent, and 18 percent of futures, respectively.

Based on the planned length of this decision, it is important to note that in the first modeling period (2027-2039) the Enhanced Coordination and Maximum Operational Flexibility Alternatives are most robust, achieving the preferred minimum level of performance in 81 percent and 94 percent of futures respectively. The Supply Driven Alternative (both LB Priority and Pro Rata approaches) and the CCS Comparative Baseline are less robust meeting the preferred minimum performance in 35 percent and 30 percent of futures respectively. The No Action and Basic Coordination Alternatives are least robust in the first modeling period meeting the preferred minimum performance in only 4 percent and 19 percent of futures respectively.

In the three subperiods, the alternatives meet the preferred minimum level of performance in greater percentages of futures because the preferred standard is easier to meet over shorter timespans than over the full 34 years. Additionally, the observed data prior to modeling and the initial system state (2027 begins with relatively low reservoir elevations) cause worse performance in the first decade.

In the lower rows of the heat maps, which reflect lower percentages of months where Lake Powell elevation stays above 3,500 feet, all alternatives improve.



The Representative Preferred Alternative meets preferred level of performance in 40 percent of modeled futures in the Full Modeling Period. Based on the planned length of this decision, it is important to note that the Representative Preferred Alternative meets the preferred minimum performance level in 58 percent of futures in the first modeling period (2027-2039).

Figure TA 3-7 highlights the preferred minimum performance level of keeping Lake Powell above an elevation of 3,500 feet because this elevation provides a 10-foot buffer to protect critical infrastructure, water supply, and hydropower, which are critically impacted at an elevation of 3,490 feet. To identify the hydrologic conditions that could cause undesirable performance, the incidence of Lake Powell elevations dropping below 3,500 feet for at least one month in any year across the 34-year modeling period was analyzed in **Figure TA 3-8**.

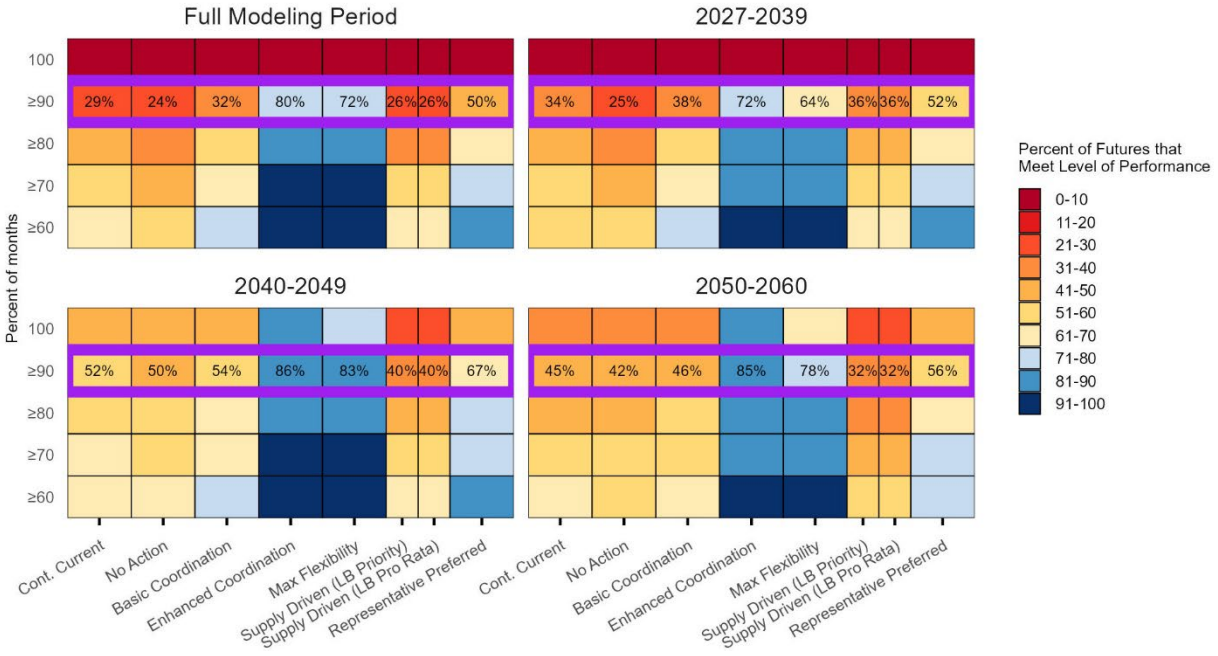
The driest 10-year average Lees Ferry annual flow was identified as a good predictor of undesirable performance. The reference hydrology panel shows the range of driest 10-year average flows represented along with the most recent and driest observed 10-year periods.

The CCS Comparative Baseline and the No Action, Basic Coordination, and the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are likely to result in undesirable performance under a wide range of hydrologic conditions, ranging between driest 10-year averages of 11.6 maf to 12.2 maf or lower (more than 75 percent of the reference hydrology traces). The Enhanced Coordination Alternative is vulnerable to undesirable performance if 10-year average flows are 9.8 maf or lower (fewer than 50 percent of the reference hydrology traces), and the Maximum Operational Flexibility Alternative is vulnerable to undesirable performance if 10-year average flows are 8.3 maf or lower (about 10 percent of the reference hydrology traces).

Figure TA 3-8
Lake Powell 3,500 Feet: Vulnerability.
Conditions that could cause Lake Powell elevation to fall below 3,500 feet in one or more months

The driest 10-year period in the observed record had an average of 11.8 maf and the most recent 10-year period had an average of 12.1 maf; the CCS Comparative Baseline, No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are vulnerable to conditions near what has already occurred, both in the observed record and the most recent 10-year period.

Modeling indicates that the Representative Preferred Alternative would likely be vulnerable to at least one occurrence of Lake Powell elevation below 3,500 feet under a 10-year average flow of 11 maf. While these conditions have not yet been observed, absent additional action, this alternative is reasonably likely to be vulnerable in the next 10 years because these conditions occur in nearly 75 percent of the traces in the Drying with Variability Ensemble, which represents a drier future.



Lake Powell 3,525 Feet Robustness and Vulnerability

Figure TA 3-9 compares alternatives with respect to keeping Lake Powell above elevation 3,525 feet. This elevation is important because it provides a 35-foot buffer to protect critical infrastructure, water supply, and hydropower, which are critically impacted at an elevation of 3,490 feet.

The rows of the heat map reflect the percent of months in which Lake Powell elevation stays above 3,525 feet. Higher percentages of years are preferable and harder to achieve.

The purple highlighted row captures the preferred minimum level of performance of keeping Lake Powell above 3,525 feet in at least 90 percent of months. Greater than or equal to 90 percent of months was chosen as the preferred minimum level of performance because it provides a reasonable amount of flexibility to go below 3,525 feet occasionally in very dry hydrology while avoiding critical impacts on water deliveries.

Figure TA 3-9
Lake Powell 3,525 Feet: Robustness.
Percent of futures in which Lake Powell stays above 3,525 feet in the percent of months specified by each row

In the Full Modeling Period, the Enhanced Coordination and the Maximum Operational Flexibility Alternatives can meet the preferred minimum level of performance in 80 percent and 72 percent of the modeled futures, respectively, which is considerably more robust than the other alternatives. The CCS Comparative Baseline and No Action Alternative are only able to meet the preferred minimum performance in 29 percent and 24 percent of futures, respectively. The Representative Preferred Alternative meets preferred level of performance in 50 percent of modeled futures in the Full Modeling Period. For the more stringent performance standard of keeping Lake Powell above 3,525 feet in 100 percent of months, all alternatives and the CCS Comparative Baseline show poor levels of performance and can only meet the more stringent standard in 0-10 percent of futures.

Based on the planned length of this decision it is important to note that in the first subperiod (2027-2039) the Enhanced Coordination and Maximum Operational Flexibility Alternatives meet the preferred minimum performance in 72 percent and 64 percent of futures respectively. The CCS

Comparative Baseline and Basic Coordination and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are similarly less robust meeting the preferred minimum performance in 34 percent, 38 percent, and 36 percent of futures respectively. The No Action Alternative is least robust meeting the preferred minimum performance in only 25 percent of futures in the first subperiod.

The Representative Preferred Alternative meets the preferred minimum performance level in 52 percent of futures in the first modeling period (2027-2039).

The alternatives meet the preferred minimum level of performance in greater percentages of futures in subperiods than the Full Modeling Period because the preferred standard is easier to meet over shorter timespans than over the full 34 years. Additionally, the observed data prior to modeling and the initial system state (2027 begins with relatively low reservoir elevations) cause worse performance in the first decade than the following two decades. The robustness ranking across the three alternatives in each subperiod is consistent with the ranking in the Full Modeling Period.

With respect to lower rows in the heatmap, which reflect lower percentages of years where Lake Powell elevation is above 3,525 feet, all alternatives improve.

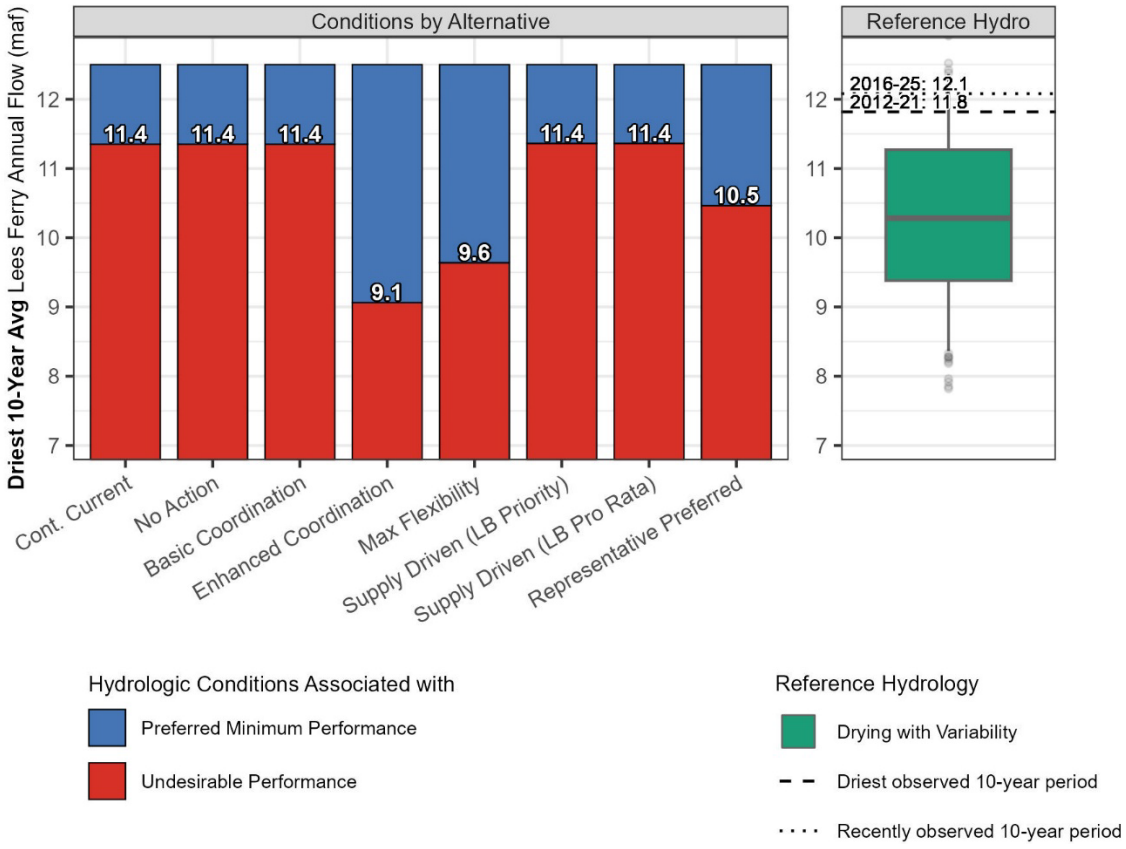


Figure TA 3-9 highlights the preferred minimum performance level of keeping Lake Powell elevation above 3,525 feet in more than 10 percent of months. To identify the hydrologic conditions that could cause undesirable performance, the incidence of Lake Powell elevations dropping below 3,525 feet in more than 10 percent of months across the 34-year modeling period was analyzed in **Figure TA 3-10**.

The driest 10-year average Lees Ferry annual flow was identified as a good predictor of undesirable performance. The reference hydrology panel shows the range of driest 10-year average flows represented along with the most recent and driest observed 10-year periods.

The CCS Comparative Baseline and the No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are vulnerable to undesirable performance at 11.4 maf or lower. Vulnerabilities for the Enhanced Coordination and Maximum Operational Flexibility Alternatives occur at much lower driest 10-year average flows: 9.1 maf or lower and 9.6 maf or lower, respectively.

Modeling indicates that the Representative Preferred Alternative would likely be vulnerable to Lake Powell elevation falling below 3,525 feet more than 10 percent of the time under a 10-year average flow of 10.5 maf. While these conditions have not yet been observed, absent additional action, this alternative is reasonably likely to be vulnerable in the next 10 years because these conditions occur in more than 50 percent of the traces in the Drying with Variability Ensemble, which represents a drier future.

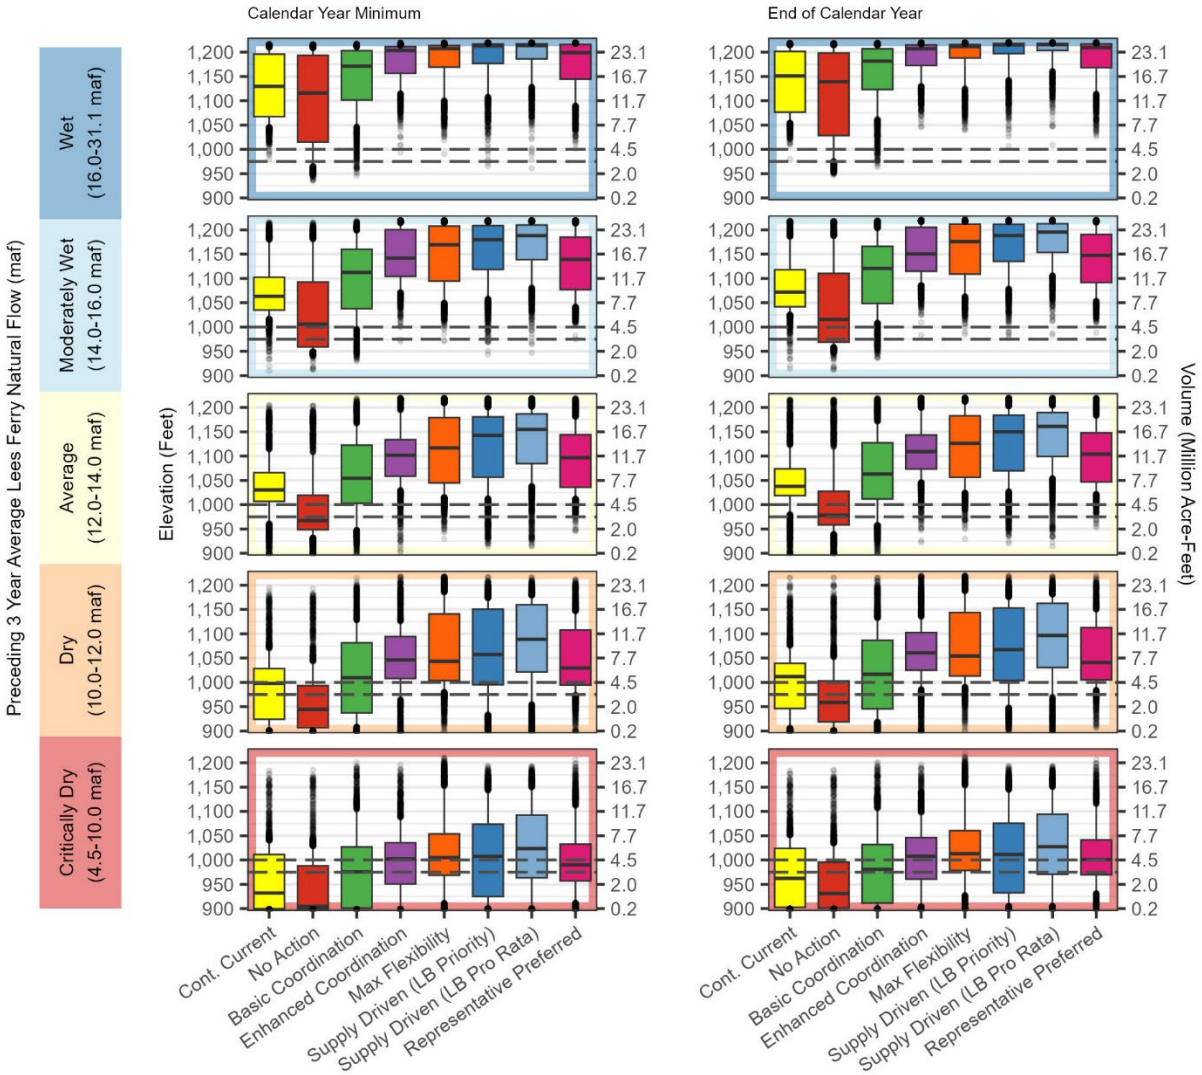
Figure TA 3-10
Lake Powell 3,525 Feet: Vulnerability.
Conditions that could cause Lake Powell elevation to fall below 3,525 feet in more than 10% of months

Lake Mead

This section presents a comparison of the No Action Alternative, CCS Comparative Baseline, and action alternatives with respect to minimum calendar year and end of calendar year (EOCY) elevations at Lake Mead. Critical elevations at Lake Mead listed in **Table TA 3-5** below preserve infrastructure and ensure Hoover Dam continues to operate under its intended design for purposes of downstream water releases. The total live storage capacity of Lake Mead at the full pool elevation of 1,219.6 feet is 26.12 maf (excluding approximately 1.5 maf of Flood Control storage available above the maximum operating elevation).

Figure TA 3-11 presents conditional boxplots of Lake Mead minimum CY and EOCY elevations (feet) and storage volumes under varying hydrologic conditions. The figure shows how the alternatives perform across these flow categories. See **Table TA 3-6** and **Table TA 3-7** at the end of this TA for the full statistical summaries. **Figure TA 3-11** visualizes the same data as **Table TA 3-6** (right column) and **Table TA 3-7** (left column) using two side-by-side conditional box plot panels. In each flow category, the critical thresholds of 1,000 feet and 975 feet are identified with dashed lines.

Table TA 3-5
Critical Elevations at Lake Mead



Critical Condition	Associated Elevation	Description of Critical Elevation
Spillway	1,221 feet	Top of Hoover Dam spillway.
Maximum Operating Elevation	1,219.6 feet	Allows for 1.5 maf of exclusive Flood Control space between elevations 1,219.6 feet and 1,229 feet (full pool).
Hydropower Critical Elevation	1,035 feet	Elevation at which 12 of the 17 turbines are no longer able to be used
Buffer Elevation	1,000 feet	Elevation of historical water supply significance that provides analysis continuity
Buffer Elevation	975 feet	25-foot buffer elevation[4] above minimum power pool (950 feet) for critical infrastructure and hydropower
Minimum Power Pool	950 feet	No longer able to produce hydropower at Hoover Dam; releases below this elevation are constrained.
Dead Pool	895 feet	No longer able to deliver water downstream through Hoover Dam.

In the Average Flow Category (12.0-14.0 maf) for EOCY elevations, the 25th-75th percentiles for all action alternatives and the CCS Comparative Baseline remain above the critical thresholds of 1,000 feet and 975 feet, while the median for the No Action Alternative (978 feet) falls between these critical elevations and the 25th percentile for the No Action Alternative drops below 975 feet. The Maximum Operational Flexibility and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives have the highest medians and similar 75th percentile elevations, but the Maximum Operational Flexibility Alternative is more variable with a lower 25th percentile elevation. The CCS Comparative Baseline falls between the No Action and Basic Coordination Alternatives in terms of median elevation.

As flow categories get drier, the EOCY elevations for all alternatives and the CCS Comparative Baseline shift notably toward and below 1,000 feet and 975 feet in the Critically Dry Flow Category, with exception of the Maximum Operational Flexibility Alternative, which maintains a 25th percentile elevation of 979 feet. The Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives all have median elevations above the critical threshold of 1,000 feet even in the Critically Dry Flow Category. For the Basic Coordination Alternative in the Critically Dry Flow Category, the median elevation of 981 feet falls between the two critical thresholds. In the Critically Dry Flow Category, the CCS Comparative Baseline and the No Action Alternative have median elevations of 962 feet and 931 feet, respectively, and fall below both critical thresholds.

[4] A larger buffer above the hydropower and critical infrastructure elevation is used at Lake Mead (25 feet) than at Lake Powell (10 feet) because Reclamation is required to deliver water orders that have already been approved and therefore does not have as much flexibility to adjust releases from Hoover Dam as from Glen Canyon Dam.

Figure TA 3-11
Calendar Year Minimum and End of Calendar Year Elevations and Storage Volumes of Lake Mead

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

In the Dry Flow Category for EOCY elevations, the Representative Preferred Alternative has a median elevation of 1,041 feet and average variability compared to other alternatives and the CCS Comparative Baseline, with 25th and 75th percentiles of 1,005 feet and 1,113 feet. In the Critically Dry Flow Category for EOCY elevations, the Representative Preferred Alternative has a median elevation of 1,001 feet and decreasing variability, with 25th and 75th percentiles of 970 feet and 1,041 feet. With respect to the critical threshold of 975 feet, the Representative Preferred Alternative remains above this elevation in more than 90 percent of years in the Dry Flow Category and in close to 75 percent of years in the Critically Dry Flow Category; with respect to the critical threshold of 1,000 feet, the Representative Preferred Alternative remains above this elevation in more than 75

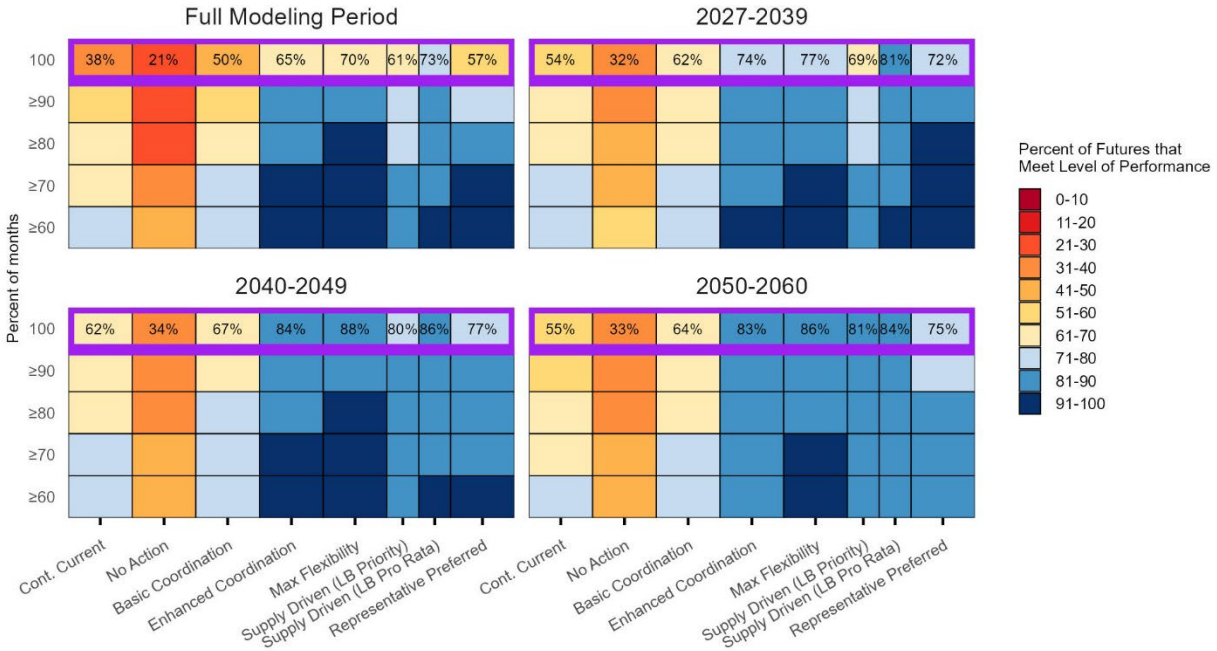
percent of years in the Dry Flow Category and in 50 percent of years in the Critically Dry Flow Category.

For the CY minimums panel, distributions of elevations shift lower since Lake Mead generally reaches its minimum elevation in July. The comparisons across alternatives and flow categories are similar to the EOCY elevations panel, but with the 25th-75th percentiles shifted slightly lower as well as some median elevations. In the Critically Dry Flow Category, the CY minimum elevation of Lake Mead falls below the critical threshold of 975 feet in more than 25 percent of years for all alternatives and the CCS Comparative Baseline. The CCS Comparative Baseline and No Action Alternative performed the worst with CY minimum elevations falling below 975 feet in more than 50 percent of years and almost 75 percent of years respectively.

In the Dry Category for CY minimums, the Representative Preferred Alternative has a median elevation of 1,030 feet and average variability compared to the other alternatives and the CCS Comparative Baseline, with 25th and 75th percentiles of 995 feet and 1,108 feet, respectively. In the Critically Dry Flow Category for CY minimums, the Representative Preferred Alternative has a median elevation of 990 feet and the least variability compared to the other alternatives and the CCS Comparative Baseline, with 25th and 75th percentiles ranging from 957 feet to 1,033 feet. With respect to the critical threshold of 975 feet, the Representative Preferred Alternative remains above this threshold in almost 90 percent of years in the Dry Flow Category and in more than 50 percent of years in the Critically Dry Flow Category; with respect to the critical threshold of 1,000 feet, the Representative Preferred Alternative remains above this threshold in about 75 percent of years in the Dry Flow Category and in nearly 50 percent of years in the Critically Dry Flow Category.

Lake Mead 975 Feet Robustness and Vulnerability

Figure TA 3-12 compares alternatives with respect to keeping Lake Mead above elevation 975 feet. Elevation 975 feet is important because it provides a 25-foot buffer to protect critical infrastructure and hydropower, which can no longer be produced at elevation 950 feet.



The rows of the heat map reflect the percent of months in which Lake Mead elevation stays above 975 feet. Higher percentages of years are preferable and harder to achieve.

The purple highlighted row represents the preferred minimum level of performance of keeping Lake Mead above 975 feet in 100 percent of months. 100 percent of months was chosen as the preferred minimum performance because of the importance of avoiding impacts on critical infrastructure and hydropower that occur if elevations dropped to 950 feet.

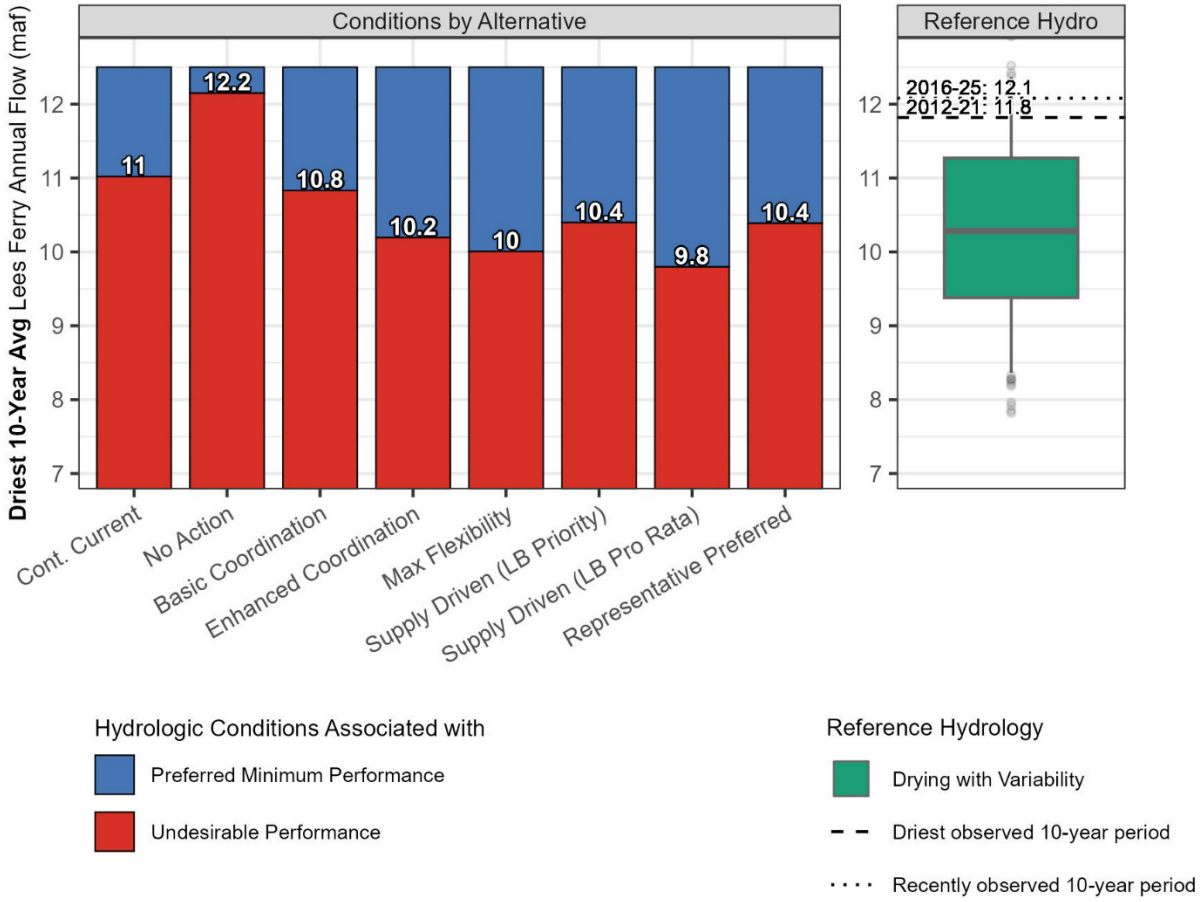
In the Full Modeling Period, the CCS Comparative Baseline and No Action Alternative meet the preferred minimum performance in 38 percent and 21 percent of futures, respectively. All action alternatives are more robust than the CCS Comparative Baseline and the No Action Alternative. The Basic Coordination Alternative meets the preferred minimum performance in 50 percent of futures. The Enhanced Coordination, Supply Driven (LB Priority approach) and Representative Preferred Alternatives are similarly robust, meeting the preferred minimum performance in 65 percent, 61 percent, and 57 percent of futures, respectively. The Maximum Operational Flexibility and Supply

Driven (LB Pro Rata approach) Alternatives are also similarly robust, meeting the preferred minimum performance in 70 and 73 percent of futures, respectively.

Figure TA 3-12
Lake Mead 975 Feet: Robustness.
Percent of futures in which Lake Mead elevation stays above 975 feet in the percent of months specified by each row

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

The action alternatives and the CCS Comparative Baseline show increasing robustness with darker shades of blue, as the specified frequency is relaxed in lower rows. Even when the frequency is relaxed to keeping Lake Mead above 975 feet only 60 percent of the time, the No Action Alternative only achieves the preferred minimum performance in 41-50 percent of futures.



In the first subperiod (2027-2039) the Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (LB Pro Rata approach) Alternatives are most robust meeting the preferred minimum performance in 74 percent, 77 percent, and 81 percent of futures respectively. The CCS Comparative Baseline, and the Basic Coordination and Supply Driven (LB Priority approach) Alternatives are somewhat less robust meeting the preferred minimum performance in 54 percent, 62 percent and 69 percent of futures respectively. The No Action Alternative is least robust in the first modeling period meeting the preferred minimum performance in only 32 percent of futures.

Based on the planned length of this decision, it is important to note that the Representative Preferred Alternative meets the preferred minimum performance level in 72 percent of futures in the first modeling period.

In the three subperiods, the alternatives meet the preferred minimum level of performance in greater percentages of futures because the preferred standard is easier to meet over shorter timespans than over the full 34 years. The robustness ranking across the three alternatives in each subperiod is generally consistent with the ranking in the Full Modeling Period.

Figure TA 3-12 highlights the preferred minimum performance level of keeping Lake Mead elevation above 975 feet in one or more months because this provides a 25-foot buffer for critical infrastructure and hydropower, which are critically impacted at an elevation of 950 feet. To identify the hydrologic conditions that could cause undesirable performance, the incidence of Lake Mead elevations dropping below 975 feet for at least one month in any year across the 34-year modeling period was analyzed in **Figure TA 3-13**.

Figure TA 3-13
Lake Mead 975 Feet: Vulnerability.
Conditions that could cause Lake Mead elevation to fall below 975 feet in one or more months

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

The driest 10-year average Lees Ferry annual flow was identified as a good predictor of undesirable performance. The reference hydrology panel shows the range of driest 10-year average flows represented along with the most recent and driest observed 10-year periods.

The Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (LB Pro Rata approach) Alternatives are vulnerable to undesirable performance at 10-year average flows of 10.2 maf or lower, 10.0 maf or lower, and 9.8 maf or lower, respectively. About 50 percent of the reference hydrology traces include averages this low or lower. The Supply Driven Alternative (LB Priority approach) is vulnerable to undesirable performance at a 10-year average flow of 10.4 maf or lower, which falls between the 50th and 75th percentiles of the reference hydrology ensemble. The CCS Comparative Baseline and the Basic Coordination Alternative are vulnerable to undesirable performance at 10-year average flows of 11.0 maf or lower and 10.8 maf or lower, respectively; about 75 percent of the reference hydrology traces include averages this low or lower.

The No Action Alternative is the most vulnerable, with a 10-year average flow of 12.2 maf or lower leading to undesirable performance. The driest 10-year period in the observed record had an average Lees Ferry flow of 11.8 maf and the most recent 10-year period had an average Lees Ferry flow of 12.1 maf; the No Action Alternative is vulnerable to conditions that are wetter than what has already occurred, both in the most recent and driest observed 10-year periods.

Modeling indicates that the Representative Preferred Alternative would likely be vulnerable to at least one occurrence of Lake Mead elevation falling below 975 feet under a 10-year average flow of 10.4 maf. While these conditions have not yet been observed, absent additional action, this alternative is reasonably likely to be vulnerable in the next 10 years because these conditions occur in about 50 percent of the traces in the Drying with Variability Ensemble, which represents a drier future.

Lake Mead 1,000 Feet Robustness and Vulnerability

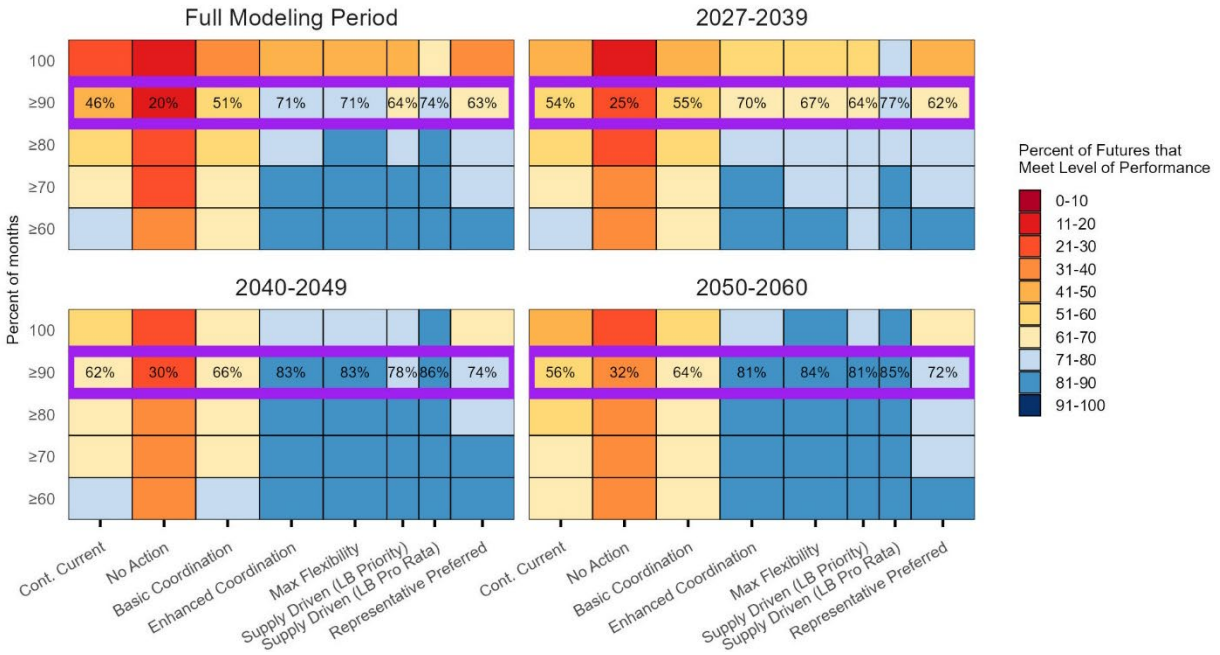


Figure TA 3-14 compares alternatives with respect to keeping Lake Mead's elevation above 1,000 feet, which is an elevation of historical significance to water supply that provides analysis continuity.

The rows of the heat map reflect the percent of months in which Lake Mead elevation stays above 1,000 feet. Higher percentages of years are preferable and harder to achieve.

The purple highlighted row represents the preferred minimum level of performance and captures the percentage of futures that an alternative keeps Lake Mead above 1,000 feet in 90 percent or more of the months. This threshold was chosen as the preferred minimum level of performance because it provides a reasonable amount of flexibility to go below 1,000 feet occasionally in very dry hydrology.

In the Full Modeling Period, the Enhanced Coordination, Maximum Operational Flexibility, Supply Driven (LB Priority approach), and Supply Driven (LB Pro Rata approach) Alternatives are similarly robust, meeting the preferred minimum level of performance in 71 percent, 71 percent, 64 percent, and 74 percent of futures, respectively. The CCS Comparative Baseline and No Action Alternative are the least robust, meeting the preferred minimum performance in 46 percent and 20 percent of futures, respectively.

Figure TA 3-14
Lake Mead 1,000 Feet: Robustness.
Percent of futures in which Lake Mead elevation stays above 1,000 feet in the percent of months specified by each row

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

Based on the planned length of decision, it is important to note that in the first decade (2027-2039) Enhanced Coordination, Maximum Operational Flexibility, Supply Driven (LB Priority approach), and Supply Driven (LB Pro Rata approach) Alternatives are similarly robust, meeting the preferred minimum level of performance in 70 percent, 67 percent, 64 percent, and 77 percent of futures respectively. The CCS Comparative Baseline and Basic Coordination Alternatives are somewhat less robust, meeting the preferred minimum performance in 54 percent and 55 percent of futures respectively. In the first modeling period, the No Action Alternative is the least robust, meeting the preferred minimum performance in 25 percent of modeled futures.

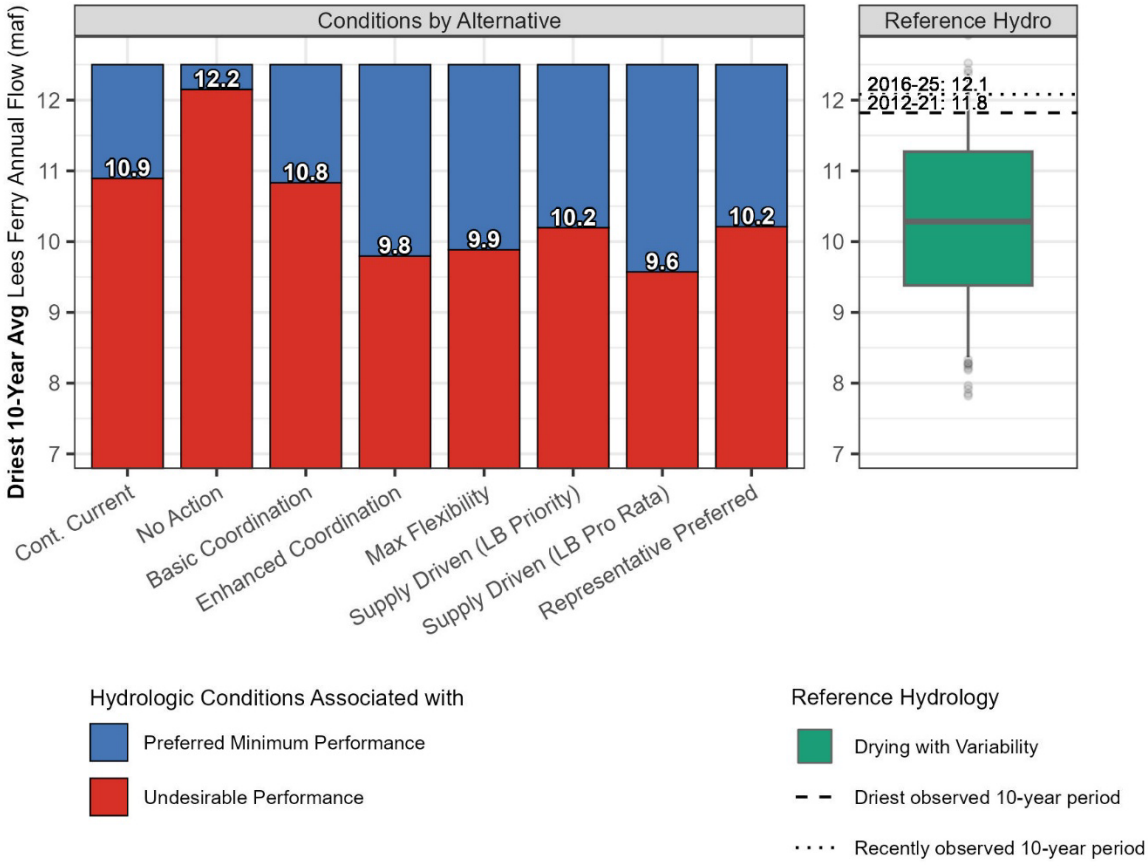
The Representative Preferred Alternative meets the preferred minimum level of performance in 63 percent of modeled futures in the full modeling period. Based on the planned length of this decision, it is important to note that the Representative Preferred Alternative meets the preferred minimum performance level in 62 percent of futures in the first modeling period (2027-2039).

In the three subperiods, the alternatives meet the preferred minimum level of performance in greater percentages of futures because the preferred standard is easier to meet over shorter timespans than over the full 34 years. Additionally, the observed data prior to modeling and the initial system state

(2027 begins with relatively low reservoir elevations) cause worse performance in the first decade. The robustness ranking across the three alternatives in each subperiod is consistent with the ranking in the Full Modeling Period.

With respect to lower rows in the heatmap which reflect lower percentages of years where Lake Mead elevation is above 1,000 feet, all alternatives improve, although the No Action Alternative is only able to meet the most relaxed performance standard (e.g., greater than or equal to 60 percent of months) in 31-40 percent of modeled futures.

Figure TA 3-14 highlights the preferred minimum performance level of keeping Lake Mead elevation above 1,000 feet in more than 90 percent of months because this represents an elevation of historical significance to water supply that provides analysis continuity. To identify the hydrologic conditions that could cause undesirable performance, the incidence of Lake Mead elevations dropping below 1,000 feet in more than 10 percent of months across the 34-year modeling period was analyzed in **Figure TA 3-15**.



The driest 10-year average Lees Ferry annual flow was identified as a good predictor of undesirable performance. The reference hydrology panel shows the range of driest 10-year average flows represented along with the most recent and driest observed 10-year periods.

The Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (LB Pro Rata approach) Alternatives are vulnerable to undesirable performance at 10-year average Lees Ferry flows of 9.8 maf or lower, 9.9 maf or lower, and 9.6 maf or lower, respectively. These conditions are slightly below the 50th percentile of the reference hydrology ensemble, meaning that about 50 percent of the traces in the reference hydrology ensemble are wetter than these values. The Supply Driven Alternative (LB Priority approach) is vulnerable to undesirable performance at 10-year average flows of 10.2 maf or lower, which is near the 50th percentile of the reference hydrology ensemble. The Basic Coordination Alternative and the CCS Comparative Baseline are vulnerable to undesirable performance at 10-year average flows of 10.8 maf or lower and 10.9 maf or lower, respectively, which are slightly below the 75th percentile of the reference hydrology ensemble.

The No Action Alternative is the most vulnerable, with a 10-year average flow of 12.2 maf or lower leading to undesirable performance in the modeling results. The driest 10-year period in the observed record had an average Lees Ferry flow of 11.8 maf and the most recent 10-year period had an average Lees Ferry flow of 12.1 maf; the No Action Alternative is vulnerable to conditions wetter than what has already occurred, both in the most recent and driest observed 10-year periods.

Modeling indicates that the Representative Preferred Alternative would likely be vulnerable to Lake Mead elevation falling below 1,000 feet more than 10 percent of the time under a 10-year average flow of 10.2 maf. While these conditions have not yet been observed, absent additional action, this alternative is reasonably likely to be vulnerable in the next 10 years because these conditions occur in about 50 percent of the traces in the Drying with Variability Ensemble, which represents a drier future.

Figure TA 3-15
Lake Mead 1,000 Feet: Vulnerability.
Conditions that could cause Lake Mead elevation to fall below 1,000 feet in more than 10% of months

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

Impacts of Modeling Assumptions for Upper Basin and Lower Basin Conservation Activity on Lake Powell and Lake Mead Storage

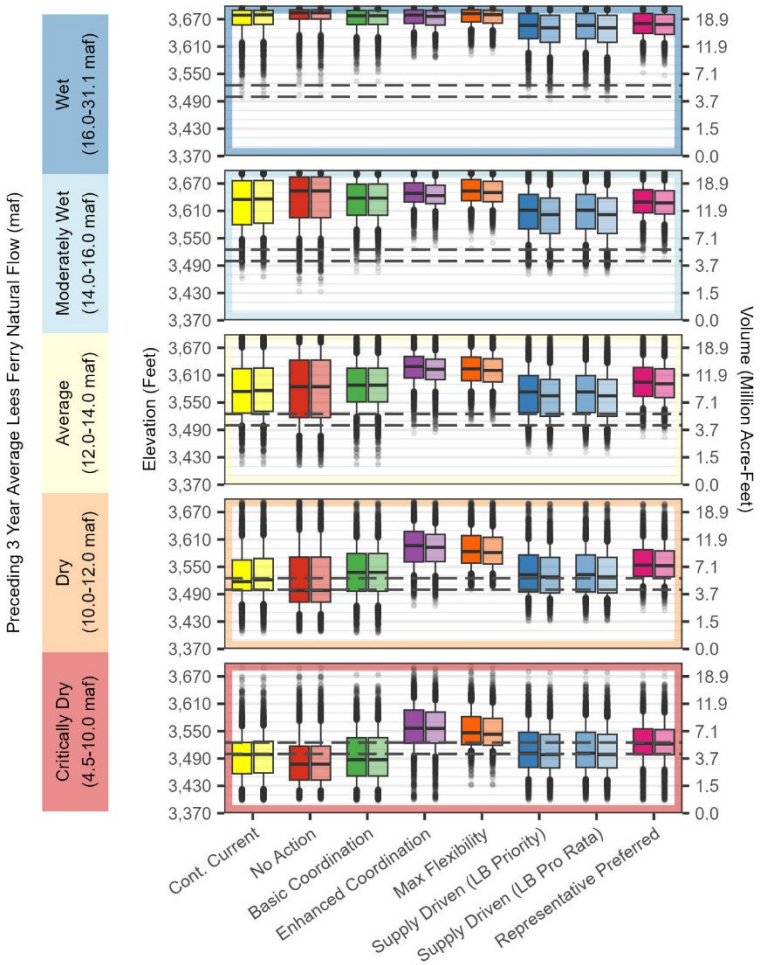
The following section describes the impacts of modeling assumptions for conservation activities for the various alternatives by showing how removing all conservation activity results in differences to reservoir elevations at Lake Powell and Lake Mead.

Table TA 3-8 below summarizes the various conservation mechanisms for each action alternative. All action alternatives, except for the Basic Coordination Alternative, incorporate mechanisms related to the storage and delivery of newly conserved water in Lake Powell and Lake Mead. Refer to **Appendix S,** Addtional Description of Alternatives, for specifics related to each alternative's conservation mechanisms. While the No Action and Basic Coordination Alternatives do not include mechanisms to conserve and store water in Lake Powell or Lake Mead, the alternatives include assumptions for the delivery of existing ICS that was conserved prior to

2027. For modeling purposes only, assumptions about storage and delivery of previously conserved water were developed to show the maximum impacts of the conservation pools on reservoir elevations and downstream flows; they are not intended to represent specific activities or constrain individual users. Refer to **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water, for more details related to the conservation assumptions for each alternative. The modeling results that incorporate the assumptions in this paragraph are labeled 'conservation-on'.

Table TA 3-8
Summary of Conservation Mechanisms by Alternative

Alternative	Conservation Pool Volume	Conservation Pool Mechanism
Continued Current Strategies Comparative Baseline	0.5 maf	Upper Basin pool in Lake Powell
	4.2 maf	Lower Basin pool in Lake Mead
No Action		No new mechanism; delivery of pre-2027 conservation only
Basic Coordination		No new mechanism; delivery of pre-2027 conservation only
Enhanced Coordination	2 maf	Upper Basin pool in Lake Powell
	5 maf	Lower Basin pool in Lake Mead
	2 maf	Protection Pool in Lake Mead
Maximum Operational Flexibility	5 maf	Upper Basin pool (distributed strategically across Lake Powell and Lake Mead)
	3 maf	Lower Basin pool (distributed strategically across Lake Powell and Lake Mead)
Supply Driven (both approaches)	3 maf	Upper Basin pool in Lake Powell
	8 maf	Lower Basin pool in Lake Mead
Representative Preferred	3 maf	Upper Basin pool in Lake Powell
	7 maf	Lower Basin pool in Lake Mead
	1 maf	Federally Managed Water Resources Pool in Lake Mead



In the 'conservation-off' results, there are no mechanisms for the storage or delivery of newly conserved water. Furthermore, delivery of pre-2027 conservation is turned off for all the alternatives and the CCS Comparative Baseline.

Figure TA 3-16 presents conditional boxplots of how conservation activity affects Lake Powell EOWY elevations (feet). In each boxplot pair, conservation activity is on in the left box (black outline with darker shading) and off in the right box (gray outline with lighter shading). See **Table TA 3-9** at the end of this TA for the full statistical summary.

Across all hydrologic flow categories, the Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives have higher median Lake Powell elevations when conservation is on (left box) compared to when it is off (right box), with

differences ranging from 0.5 to 9.8 feet. Additionally, across all flow categories, the 25th-75th percentiles for these alternatives shift upward when conservation is on compared to when it is off.

Figure TA 3-16
Impacts of Modeling Assumptions for Conservation Activity on End of Water Year Elevations (Feet) at Lake Powell

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

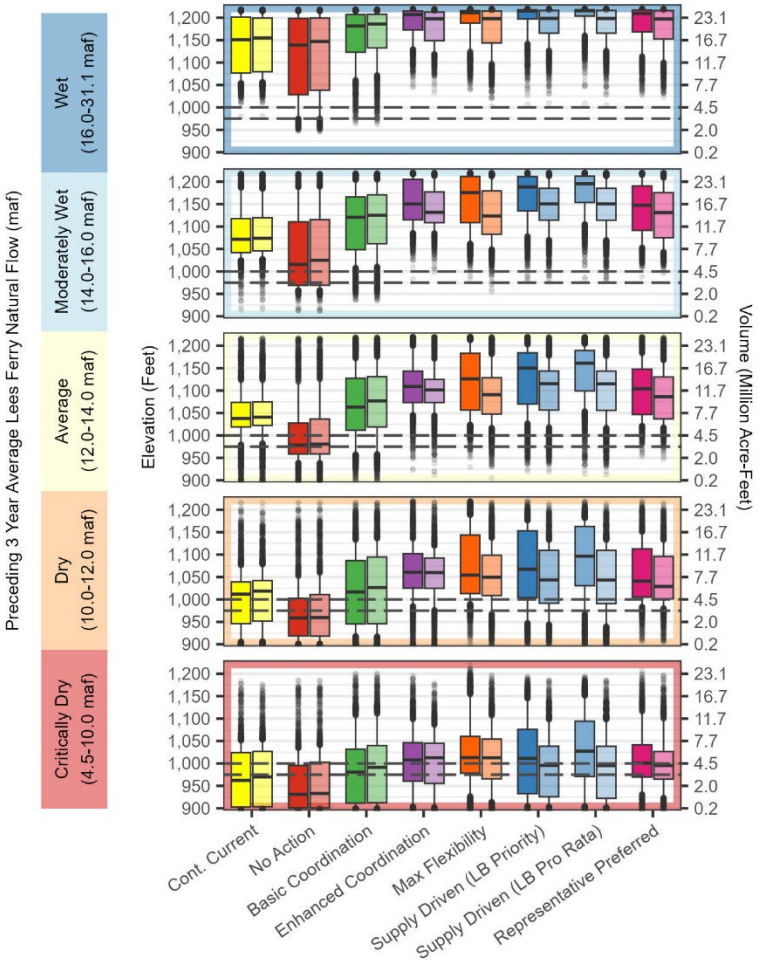
For the No Action and Basic Coordination Alternatives, the 25th-75th percentile elevations are very similar when comparing conservation activity on and conservation activity off across all flow categories.

The CCS Comparative Baseline has lower 25th-75th percentile elevations across all flow categories when conservation is on compared to when it is off, which differs from all alternatives. In the Average Flow Category and the Dry Flow Category, the CCS Comparative Baseline has lower median elevations in Lake Powell when conservation activity is on by 2.1 feet and 4.0 feet,

respectively; for the other flow categories, the CCS Comparative Baseline has very similar medians for both conservation activity on and conservation activity off.

In the Dry Flow Category, with conservation activity on, the median Lake Powell elevation for the Representative Preferred Alternative is 3,554 feet (1.2 feet higher than with conservation activity off). In the Critically Dry Flow Category, with conservation activity on, the median Lake Powell elevation for the Representative Preferred Alternative is 3,523 feet (0.8 feet higher than with conservation activity off). The variability is similar with conservation on and off in both the Dry and Critically Dry Flow Categories.

Figure TA 3-17 presents conditional boxplots of how conservation activity affects Lake Mead EOCY elevations (feet) and storage volumes. In each boxplot pair, conservation activity is on in the left box (black outline with darker shading) and off in the right box (gray outline with lighter shading). See **Table TA 3-10** at the end of this TA for the full statistical summary.



The Enhanced Coordination, Maximum Operational Flexibility, and the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives have higher median Lake Mead elevations when conservation activity is on across all flow categories except the Critically Dry Flow Category. Within the Critically Dry Flow Category, only the Maximum Operational Flexibility and the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives show higher median Lake Mead elevations when conservation is on. For these alternatives, the 25th-75th percentile elevations also shift upward when conservation is on across all hydrologic conditions, following the same general pattern as the median elevations. The CCS Comparative Baseline, the No Action Alternative and the Basic Coordination Alternative all have lower 25th-75th percentile elevations that shift downward when conservation is on, across all flow categories.

With respect to the critical elevation of 975 feet, the No Action Alternative falls below the critical threshold in almost 50 percent of years in the Average Flow Category for both conservation activity on and conservation activity off, while the CCS Comparative Baseline only falls below the threshold in more than 50 percent of years in the Critically Dry Flow Category for both conservation activity on and conservation activity off. With respect to the critical elevation of 1,000 feet, the No Action Alternative falls below the critical threshold between 25 and 50 percent of years in the Average Flow Category for both conservation activity on and conservation activity off and in about 75 percent of years in the Critically Dry Flow Category for both conservation activity on and conservation activity off. With respect to the critical elevation of 1,000 feet, the CCS Comparative Baseline falls below the critical threshold in fewer than 25 percent of years in the Average Flow Category for both conservation activity on and conservation activity off and in fewer than 75 percent of years in the Critically Dry Flow Category for both conservation activity on and conservation activity off.

In the Dry Flow Category, under the Representative Preferred Alternative the median Lake Mead elevation with conservation activity on is 1,041 feet (11.8 feet higher than with conservation activity off). Performance of the Representative Preferred Alternative in this category is most similar to the Basic Coordination Alternative but with 25th percentile values that are closer to the median (reduced variability) for both conservation activity on and off. In the Critically Dry Flow Category, under the Representative Preferred Alternative, the median Lake Mead elevation with conservation activity on

is 1,001 feet (5.6 feet higher than with conservation activity off). Performance of the Representative Preferred Alternative is again similar to the Basic Coordination Alternative, but with reduced variability for both conservation activity on and off.

Figure TA 3-17
Impacts of Modeling Assumptions for Conservation Activity on EOCY Elevations and Storage Volumes for Lake Mead

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

With respect to the critical elevation of 975 feet, the Representative Preferred Alternative falls below the critical threshold in less than 10 percent of years in the Dry Flow Category and more than 25 percent of years in the Critically Dry Flow Category, for both conservation activity on and conservation activity off. With respect to the critical elevation of 1,000 feet, the Representative Preferred Alternative falls below the critical threshold in about 25 percent of years in the Dry Flow Category and around 50 percent of years in the Critically Dry Flow Category for both conservation activity on and conservation activity off.

Lake Mohave and Lake Havasu

Lake Mohave and Lake Havasu are operated under an existing rule curve that determines specific target elevations at the end of each month (refer to **TA 6**, Water Quality). The existing rule curves were used in CRSS and applied to operations for all alternatives and the CCS Comparative Baseline.

Although inflows into Lake Mohave vary across alternatives due to differences in releases from Lake Mead, target elevations are maintained within the rule curve bounds. As a result, lake elevations are not affected by the different upstream operations occurring in the alternatives or the CCS Comparative Baseline.

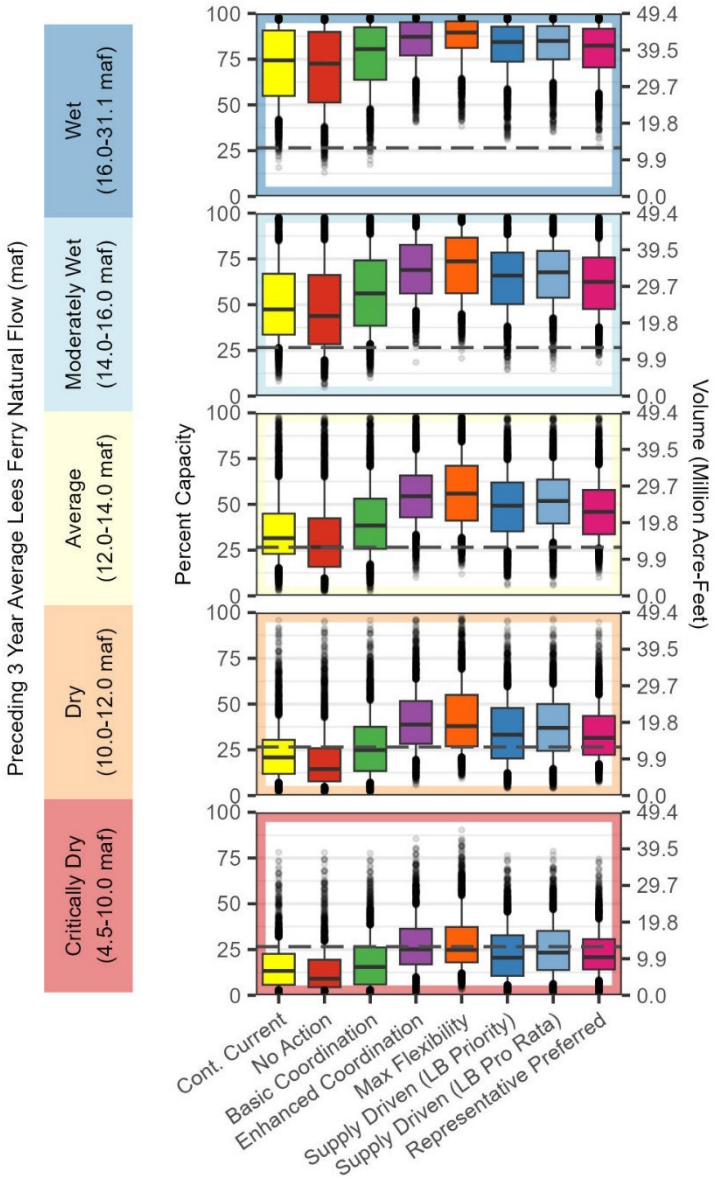
Similarly, although inflows into Lake Havasu from upstream operations (Davis Dam releases) vary across alternatives, target elevations are maintained within the rule curve bounds. As a result, lake elevations are not affected by the different upstream operations occurring in the alternatives or the CCS Comparative Baseline.

TA 3.2.2 Issue 2: System Storage

Issue 2 addresses how operational activities would affect system storage. This was evaluated by comparing the various action alternatives to the No Action Alternative and the CCS Comparative Baseline for the following metrics:

- Combined System Storage at Lake Powell and Lake Mead
- Combined System Storage at CRSP reservoirs
- Combined System Storage at all seven reservoirs

Combined System Storage at Lake Powell and Lake Mead



This section compares all alternatives and the CCS Comparative Baseline with respect to EOWY combined storage of Lake Powell and Lake Mead. Analysis of the combined storage of these two reservoirs provides insight into overall system conditions because their combined volume makes up about 85 percent of the volume in the major system reservoirs.[5] Excluding space allocated for surcharge and Flood Control, the live storage capacity at Lake Powell is 23.31 maf and 26.12 maf at Lake Mead, resulting in a maximum combined live storage of 49.43 maf.

Figure TA 3-18 presents conditional boxplots of EOWY combined storage in Lake Powell and Lake Mead, expressed as a percentage of total storage capacity. The vertical axis shows combined percent full on the left and volume of storage on the right. A threshold line indicates the lowest observed EOWY combined storage, which occurred in September 2022, at 26.55 percent full (equivalent to 13.1 maf). See **Table TA 3-11** at the end of this TA for the full statistical summary.

In the Average Flow Category, the Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (LB Pro Rata approach) Alternatives all have median Lake Powell and Lake Mead combined storage volumes above 50 percent of the total combined storage capacity. Fewer than 10 percent of modeled years (corresponding to the 10th percentile) for these action alternatives fall below the lowest observed EOWY storage reference of 26.55 percent. In terms of interquartile

[5] Specifically, Lake Powell and Lake Mead account for 85 percent of the live storage capacity of the seven largest reservoirs in the system (Flaming Gorge, Blue Mesa, Navajo, Powell, Mead, Mohave, and Havasu).

Figure TA 3-18
EOWY Powell and Mead Combined Storage[6]

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

range, the Maximum Operational Flexibility Alternative shows the greatest variability, with the highest 75th percentile storage volume; the Enhanced Coordination Alternative has the least variability; and the Supply Driven Alternative (LB Pro Rata approach) has the lowest 25th percentile storage volume. By comparison, the CCS Comparative Baseline and the Basic Coordination and No

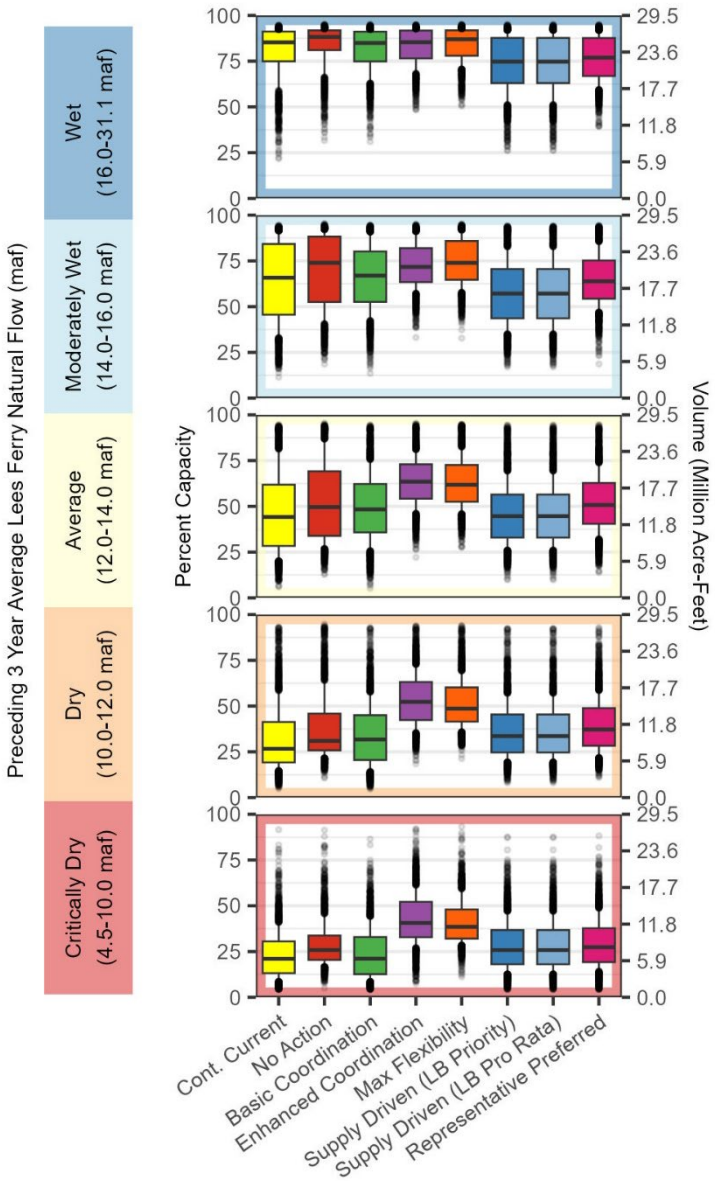
[6] Dashed reference line is historical EOWY minimum 26.55 percent in September 2022.

Action Alternatives have lower median storage volumes, at 32, 38, and 27 percent of total capacity, respectively. Under the CCS Comparative Baseline, more than 25 percent of years (corresponding to the 25th percentile), fall below the lowest observed EOWY storage reference of 26.55 percent. Under the No Action Alternative, almost 50 percent of years (corresponding to the 50th percentile) fall below the lowest observed EOWY storage reference of 26.55 percent.

In the Critically Dry Flow Category, the same general trends are observed. For the Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (LB Pro Rata approach) Alternatives, about 50 percent of modeled years (corresponding to the 50th percentile) fall below the lowest observed EOWY storage reference of 26.55 percent. For the CCS Comparative Baseline and No Action and Basic Coordination Alternatives, more than 75 percent of years (corresponding to the 75th percentile) fall below this reference.

In the Dry Flow Category, the Representative Preferred Alternative has a median of 32 percent combined storage, with 25th and 75th percentiles of 22 and 44 percent combined storage, respectively. In the Critically Dry Flow Category, the Representative Preferred Alternative has a median of 21 percent combined storage, with 25th and 75th percentiles of 14 and 31 percent combined storage. Under the Representative Preferred Alternative, more than 25 percent of years in the Dry Flow Category and nearly 75 percent of years in the Critically Dry Flow Category have combined storage below the lowest observed historical value of 26.55 percent.

Combined System Storage at CRSP Reservoirs



This section compares all alternatives and the CCS Comparative Baseline with respect to EOWY combined storage of the CRSP reservoirs, including Lake Powell and the CRSP UIUs—Flaming Gorge, Navajo, and Blue Mesa. Analysis of the combined storage provides insight into the system conditions at Lake Powell and the CRSP UIUs, and this volume is the criteria for Lake Powell releases in the Maximum Operational Flexibility Alternative. The CRSP UIU reservoirs can be operated in accordance with their respective RODs, subject to hydrologic conditions, to help protect infrastructure at Glen Canyon Dam.

Specifically, the CCS Comparative Baseline, along with the Basic Coordination and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives, assume additional releases from the CRSP UIUs when Lake Powell is projected to, or physically falls below, elevation 3,525 feet. The CCS Comparative Baseline and Basic Coordination Alternative include additional releases from Flaming Gorge, Blue Mesa, and Navajo Reservoirs, while the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) assumes additional releases only from Flaming Gorge.

Excluding surcharge space, the total storage volume of the four CRSP reservoirs is approximately 29.5 maf, with Lake Powell accounting for approximately 80 percent. Because storage at the CRSP UIUs varies minimally across alternatives, most differences in performance are attributable to Lake Powell operations. Additionally, because transfers within the CRSP reservoirs, from the UIUs downstream to Lake Powell, do not change total combined storage, these intra-system balancing operations are not visible in the conditional box plots. Differences across alternatives are therefore driven primarily by Lake Powell operations, as described in Issue 1 above.

Figure TA 3-19 presents conditional boxplots of EOWY CRSP combined system storage, expressed as a percentage of total storage capacity. See **Table TA 3-12** at the end of this TA for the full statistical summary.

Figure TA 3-19
EOWY CRSP Combined Storage

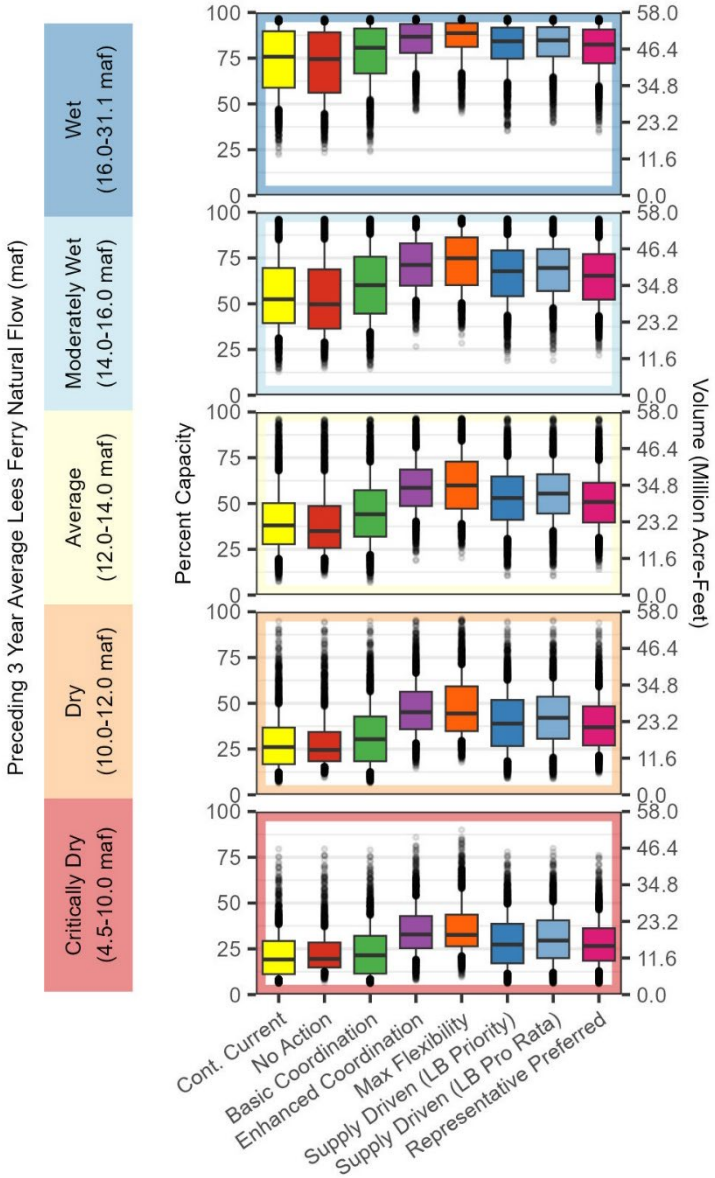
The alternatives and the CCS Comparative Baseline generally perform similarly under the Wet Flow Category, except for the Supply Driven (both LB Priority and LB Pro Rata approaches) and the Representative Preferred Alternatives, which have the lowest median combined CRSP reservoir storage (as a percent of the total capacity). As flow categories become drier, combined CRSP reservoir storage decreases and differences between alternatives become more apparent.

In the Average Flow Category, the median EOWY CRSP combined storage values for the CCS Comparative Baseline, No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are near 50 percent of the total capacity, while the Enhanced Coordination and Maximum Operational Flexibility Alternatives have higher median storage values, at 63 percent and 62 percent, respectively. Among these alternatives, the Enhanced Coordination Alternative has the highest 75th percentile storage but the smallest interquartile range, reflecting higher upper-end storage with relatively lower variability. By comparison, the No Action Alternative has a similar 75th percentile and the largest interquartile range, indicating greater variability in combined CRSP storage.

In the Critically Dry Flow Category, median and interquartile range patterns shift as hydrologic conditions worsen. The Enhanced Coordination and Maximum Operational Flexibility Alternatives have the highest median storage values (41 and 38 percent, respectively). The remainder of the alternatives and the CCS Comparative Baseline have similar medians (21 to 26 percent). Considering the 10th through 90th percentile values, the CCS Comparative Baseline and Basic Coordination Alternative result in the least CRSP combined storage. The No Action Alternative exhibits the least variability (interquartile range of 13 percent) followed by the Maximum Operational Flexibility Alternative (16 percent), while the Basic Coordination Alternative exhibits the most variability (20 percent).

In the Dry Flow Category for EOWY CRSP combined storage, the Representative Preferred Alternative has a median of 37 percent combined storage, with 25th and 75th percentiles ranging from 28 to 49 percent combined storage. In the Critically Dry Flow Category, the Representative Preferred Alternative has a median of 27 percent combined storage, with 25th and 75th percentiles of 19 and 38 percent combined storage, respectively.

Combined System Storage at Seven-Reservoirs



This section compares all alternatives and the CCS Comparative Baseline with respect to EOWY combined storage of Lake Powell, the three CRSP UIUs (Flaming Gorge, Navajo, and Blue Mesa), Lake Mead, Lake Mohave, and Lake Havasu (referred to herein as the seven-reservoir storage). Excluding space allocated for surcharge and Flood Control, the live storage capacity of these seven reservoirs is 58.01 maf, with Lake Powell and Lake Mead accounting for approximately 90 percent of the total system storage capacity.

Figure TA 3-20 presents conditional boxplots of EOWY combined storage for the seven reservoirs, expressed as a percentage of the total storage capacity. See **Table TA 3-13** at the end of this TA for the full statistical summary.

In the Average Flow Category, the Maximum Operational Flexibility Alternative exhibits the greatest median seven-reservoir storage (60 percent), followed closely by Enhanced Coordination (59 percent). The Maximum Operational Flexibility, Enhanced Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives all have median EOWY seven-reservoir storage above 50 percent of the total storage capacity. The Enhanced Coordination Alternative exhibits the least variability (interquartile range of 20 percent) while the Maximum Operational Flexibility exhibits the greatest variability (interquartile range of 26 percent). The Basic Coordination

and No Action Alternatives and the CCS Comparative Baseline have the lowest median seven-reservoir storage of 44 percent, 35 percent, and 38 percent, respectively. Likewise, they have the lowest 10th and 25th percentile seven-reservoir storage.

Figure TA 3-20
EOWY Seven-Reservoir Combined Storage

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

In the Critically Dry Flow Category, the order of medians and relationships across the alternatives and the CCS Comparative Baseline are generally similar to those in the Average Flow Category, but with notable reductions to storage volumes. The CCS Comparative Baseline and No Action

Alternative have the lowest median seven-reservoir storage (both with 19 percent), followed by the Basic Coordination Alternative (21 percent).

In the Dry Flow Category, the Representative Preferred Alternative has a median seven-reservoir storage of 37 percent, with 25th and 75th percentiles of 27 and 48 percent. In the Critically Dry Flow Category, the Representative Preferred Alternative has a median of 27 percent combined storage, with 25th and 75th percentiles of 18 and 36 percent.

TA 3.2.3 Issue 3: Reservoir Releases

Issue 3 addresses how operational activities would affect reservoir releases. This was evaluated by comparing the various action alternatives to the No Action Alternative and the CCS Comparative Baseline for the following metrics:

- WY Releases from Glen Canyon Dam
- 10-Year Releases from Glen Canyon Dam
- 10-Year Flows at Lee Ferry Compact Point
- CY Releases from Hoover Dam
- CY Releases from Davis Dam
- CY Releases from Parker Dam

Glen Canyon Dam

This section compares all alternatives and the CCS Comparative Baseline with respect to WY releases from Glen Canyon Dam at Lake Powell. Note that the performance of the LB Priority approach and the LB Pro Rata approach under the Supply Driven Alternative will not differ in Glen Canyon Dam releases because they use the same operation of Lake Powell.

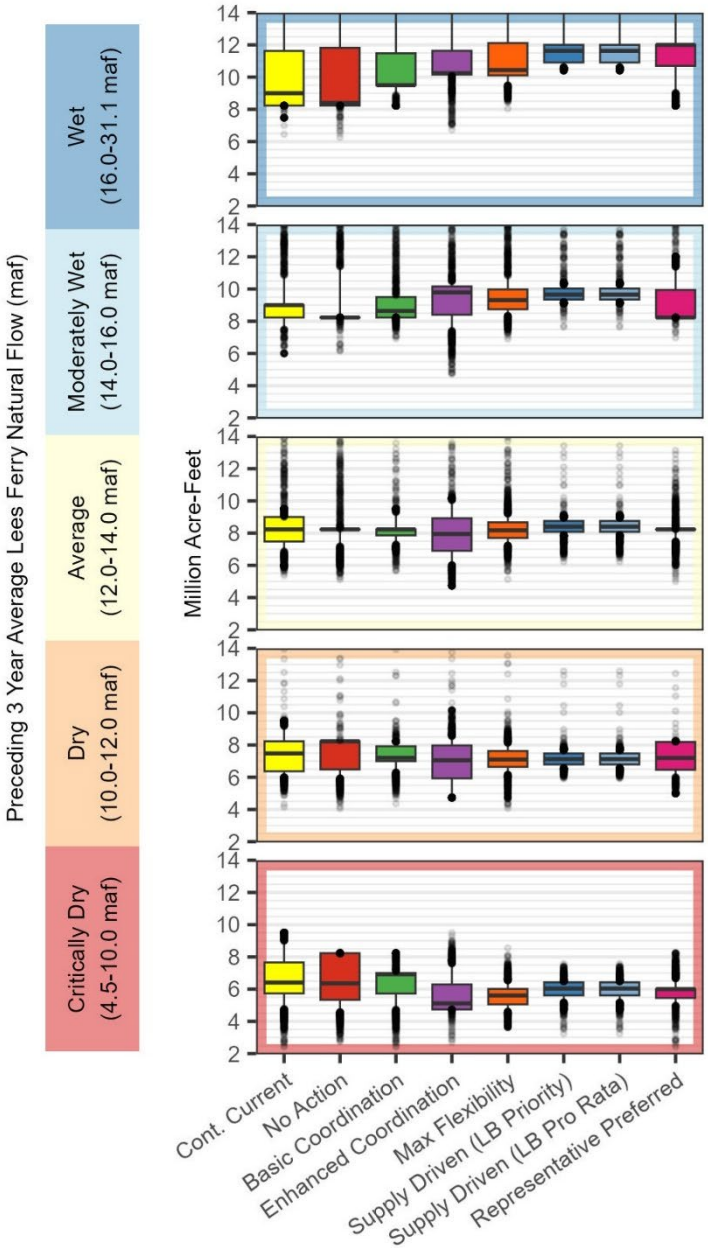


Figure TA 3-21 presents conditional boxplots of WY releases (maf) from Glen Canyon Dam. The y-axis has been truncated to facilitate easier comparison of the alternatives, see **Table TA 3-14** at the end of this TA for the full statistical summary.

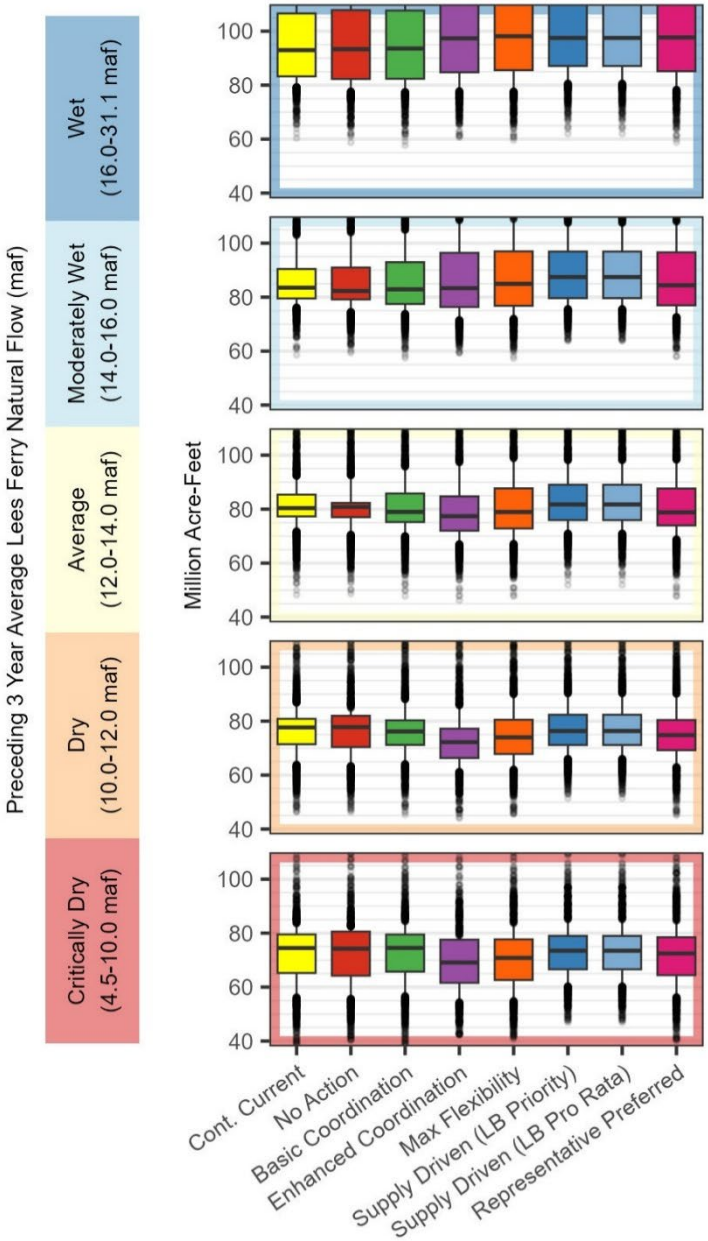
In the Average Flow Category, the median annual Glen Canyon Dam releases for all alternatives and the CCS Comparative Baseline are between 7.95 maf (Enhanced Coordination) and 8.41 maf (Supply Driven [both LB Priority and LB Pro Rata approaches]). The Enhanced Coordination Alternative has the most variable release (interquartile range of 2.02 maf), followed by the CCS Comparative Baseline (interquartile range of 1.52 maf). The No Action and Representative Preferred Alternatives have the least variable release (interquartile range of 0 maf).

In the Critically Dry Flow Category, the No Action Alternative (6.36 maf), CCS Comparative Baseline (6.41 maf), and Basic Coordination Alternative (6.92 maf) have the largest median releases while the Enhanced Coordination (5.11 maf) and Maximum Operational Flexibility (5.61 maf) Alternatives have the lowest median releases. The No Action Alternative has the most variable releases (interquartile range of 2.90 maf) due to a large difference between the intended release (8.23 maf) and what is physically capable of being released due to infrastructure limitations below 3,490 feet.

In the Dry Flow Category for annual Glen Canyon Dam releases, the Representative Preferred Alternative has a median annual release of 7.20 maf, with 25th and 75th percentiles of 6.47 and 8.19 maf, respectively. In the Critically Dry Flow Category, the Representative Preferred Alternative has a median annual release of 6.0 maf. The 25th and 75th percentiles are 5.45 and 6.0 maf. Representative Preferred releases under Critically Dry Hydrology are the least variable of all alternatives.

Figure TA 3-21
WY Releases from Glen Canyon Dam[7]



[7] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-14** for the full range of the data.

Glen Canyon Dam 10-Year Releases

Figure TA 3-22 presents conditional boxplots of cumulative 10-year releases from Glen Canyon Dam. The y-axis is truncated to enable easier comparison of alternatives. See **Table TA 3-15** at the end of this TA for the full statistical summary and full range of values.

Figure TA 3-22
10-Year Cumulative Releases from Glen Canyon Dam[8]

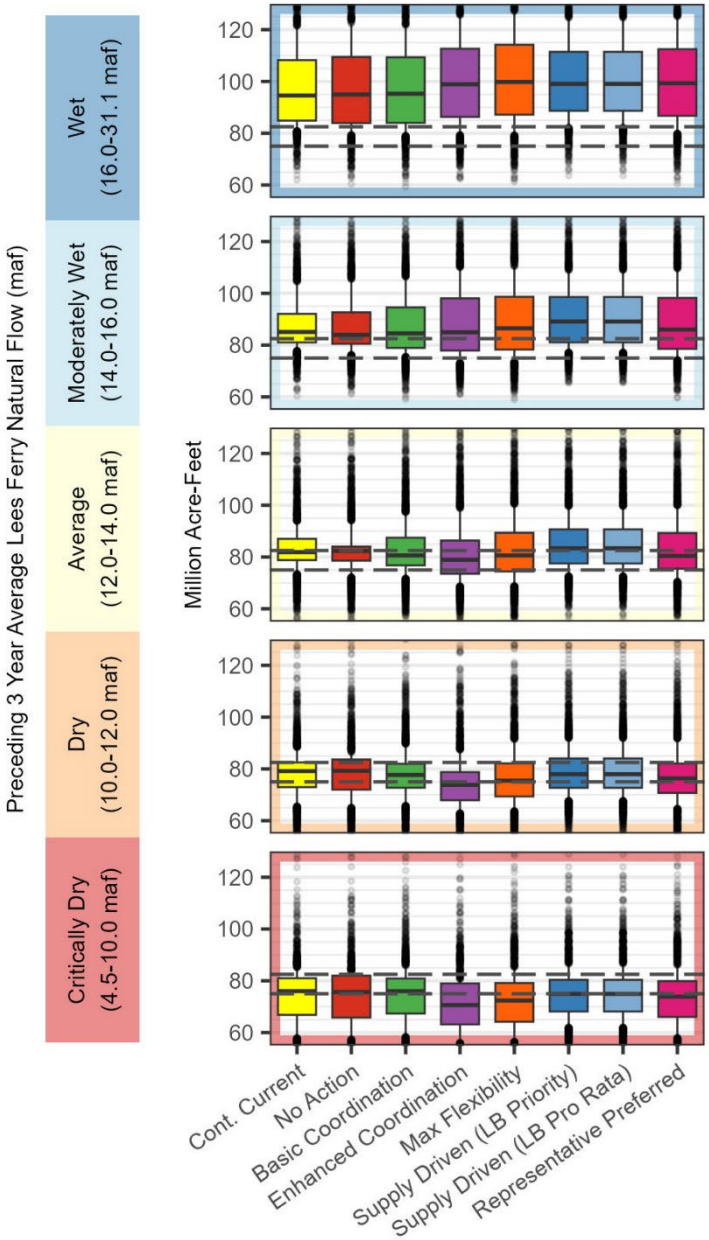
[8] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-15** for the full range of the data.

In the Average Flow Category, the median 10-year cumulative release ranges from 77.4 maf (Enhanced Coordination Alternative) to 81.7 maf (Supply Driven Alternative [both LB Priority and LB Pro Rata approaches]). Considering the 25th percentile, the Enhanced Coordination Alternative still exhibits the smallest 10-year release (72.0 maf), but the CCS Comparative Baseline has the greatest 10-year release of 77.3 maf. All action alternatives display significant variability, with the Maximum Operational Flexibility Alternative having the largest interquartile range of 14.8 maf (25th and 75th percentiles of 72.8 and 87.7 maf, respectively). In contrast, the No Action Alternative and CCS Comparative Baseline are the least variable with interquartile ranges of 5.3 and 8.1 maf, respectively.

In the Critically Dry Flow Category, the Basic Coordination Alternative and CCS Comparative Baseline have the highest median release (both 74.5 maf), followed closely by the No Action Alternative (74.2 maf). The Enhanced Coordination Alternative has the lowest median release (69.1 maf). The No Action Alternative has the greatest variability in 10-year releases (interquartile range of 16.4 maf) followed by the Enhanced Coordination (16.0 maf) and Maximum Operational Flexibility Alternatives (15.1 maf). However, for the No Action Alternative, this variability is driven by infrastructure-constrained releases (Lake Powell elevations below 3,490 feet) while it is driven by annual releases that are highly responsive to hydrologic conditions in the Enhanced Coordination and Maximum Operation Flexibility Alternatives.

In the Dry Flow Category for 10-year cumulative releases from Glen Canyon Dam, the Representative Preferred Alternative has a median 10-year release of 74.8 maf, with 25th and 75th percentiles of 69.2 maf and 80.4 maf, respectively. In the Critically Dry Flow Category, the Representative Preferred Alternative has a median 10-year release of 72.4 maf, with 25th and 75th percentiles of 64.4 maf and 78.5 maf, respectively.

Cumulative 10-Year Lee Ferry Flows



The Lee Ferry is the division point between the Upper Basin and the Lower Basin, as established by the 1922 Colorado River Compact. The Lee Ferry is located in Arizona, approximately 17 miles downstream of Glen Canyon Dam and approximately 1 mile downstream of the confluence with the Paria River. Refer to **Figure TA 3-2** in the Affected Environment Section for a map of the Lee Ferry.

Figure TA 3-23 presents conditional boxplots of cumulative 10-year Lee Ferry flow volumes (maf), with **Table TA 3-16** at the end of this TA providing the full statistical summary. In each flow category, 75.0 maf and 82.5 maf are shown with dashed lines; however, comparison of modeled output to these thresholds is discussed under the description of **Table TA 3-17** and **Table TA 3-18** and **Figure TA 3-24.** To facilitate easier comparison of alternatives, the y-axis is truncated.

In the Average Flow Category, the median Compact Point 10-year volume ranges from 78.9 maf (Enhanced Coordination Alternative) to 83.4 maf (Supply Driven Alternative [both LB Priority and LB Pro Rata approaches]). Considering the 25th percentile, the Enhanced Coordination Alternative also exhibits the smallest Compact Point 10-year volume (73.5 maf), but the CCS Comparative Baseline has the greatest volume of 78.8 maf. All action alternatives display significant variability, with the Maximum Operational Flexibility Alternative having the largest interquartile range of 14.9

maf (25th and 75th percentiles of 74.4 and 89.4 maf, respectively). In contrast, the No Action Alternative and CCS Comparative Baseline are the least variable with interquartile ranges of 5.4 and 8.2 maf, respectively.

Figure TA 3-23
Compact Point 10-Year Volume[9]

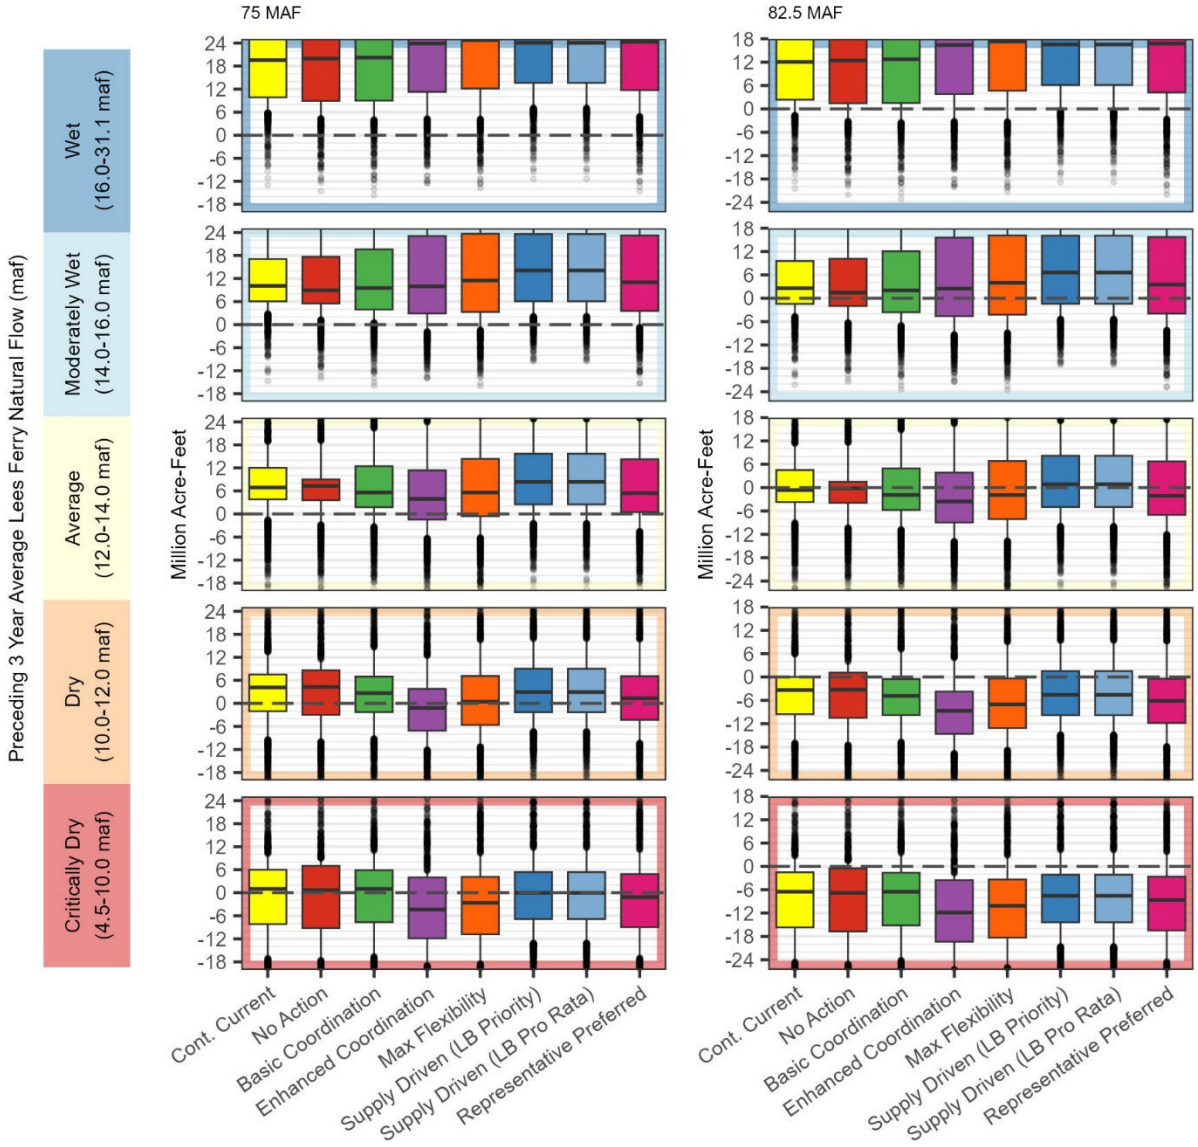
In the Critically Dry Flow Category, the CCS Comparative Baseline and Basic Coordination Alternative have the highest median Compact Point 10-year volume (both 76.0 maf), followed

[9] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-16** for the full range of the data.

closely by the No Action Alternative (75.7 maf). The Enhanced Coordination Alternative has the lowest median 10-year Compact Point volume (70.6 maf). The No Action Alternative has the greatest variability in Compact Point 10-year volumes (interquartile range of 16.2 maf) followed by the Enhanced Coordination (15.8 maf) and Maximum Operational Flexibility Alternatives (15.0 maf). However, for the No Action Alternative, this variability is driven by infrastructure-constrained releases (Lake Powell elevations below 3,490 feet) while it is driven by annual releases that are highly responsive to hydrologic conditions in the Enhanced Coordination and Maximum Operation Flexibility Alternatives.

In the Dry Flow Category, the Representative Preferred Alternative has a median Compact Point 10-year volume of 76.4 maf, with 25th and 75th percentiles of 70.7 maf and 82.1 maf, respectively. In the Critically Dry Flow Category, the Representative Preferred Alternative has a median Compact Point 10-year volume of 73.9 maf, with 25th and 75th percentiles of 66.0 maf and 79.9 maf, respectively.

Figure TA 3-24 presents the cumulative 10-year flow volume at the Compact Point relative to two different thresholds using two side-by-side conditional box plot panels. In each panel, the dashed line denotes the zero-difference threshold between the modeled Compact Point 10-year volume and the applicable threshold (75.0 maf in the left panel and 82.5 maf in the right panel). Positive values indicate Compact Point 10-year volumes greater than the threshold. The y-axis is truncated to facilitate easier comparison of the alternatives. Consult **Table TA 3-17** and **Table TA 3-18** for the full range of data.



Under Average hydrology, considering the Compact Point 10-year volume **relative to 75.0 maf** (left column), the median values for all alternatives and the CCS Comparative Baseline are greater than zero, ranging from 3.9 maf (Enhanced Coordination Alternative) to 8.4 maf (Supply Driven Alternative [both LB Priority and LB Pro Rata approaches]). Considering the 25th percentile, Enhanced Coordination (-1.5 maf) and Maximum Operational Flexibility (-0.6 maf) are the only alternatives with 10-year volumes less than 75.0 maf.

Under Average hydrology, considering the Compact Point 10-year volume **relative to 82.5 maf** (right column), the only alternative with a median value greater than zero is Supply Driven (both LB Priority and LB Pro Rata approaches) (0.9 maf). After Supply Driven (both LB Priority and LB Pro Rata approaches), the median values for the No Action Alternative and CCS Comparative Baseline are the least negative (i.e. have 10-year volumes closest to 82.5 maf), with values of -0.2 and -0.6 maf, respectively.

In Critically Dry hydrology, considering the Compact Point 10-year volume relative to 75.0 maf, only the CCS Comparative Baseline (1.0 maf), Basic Coordination Alternative (1.0 maf), and No Action Alternative (0.7 maf) have positive median values (i.e. 10-year volumes greater than 75.0 maf). The median for the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) is slightly negative (-0.06 maf). Relative to 82.5 maf, greater than 75 percent of years are negative (i.e. 10-year volumes less than 82.5 maf) for all alternatives and the CCS Comparative Baseline.

The variability across alternatives and under different hydrologic conditions are the same as discussed in **Figure TA 3-23**.

Figure TA 3-24[10]
Compact Point 10-Year Volume Relative to 75.0 maf and 82.5 maf

In the Dry Flow Category, the Representative Preferred Alternative has a median 10-year volume relative to 75.0 maf of 1.4 maf, indicating that over 50 percent of years under Dry conditions result in 10-year volumes above 75.0 maf. However, less than 25 percent of years exhibit 10-year volumes greater than 82.5 maf (i.e. the 75th percentile relative to 82.5 maf is negative). Under the Critically Dry Flow Category, fewer than 50 percent of years have 10-year volumes greater than 75.0 maf, while slightly more than 10 percent of years result in 10-year volumes greater than 82.5 maf.

[10] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-17** and **Table TA 3-18** for the full range of the data.

Hoover Dam

This section compares all the alternatives and the CCS Comparative Baseline with respect to CY releases from Hoover Dam at Lake Mead.

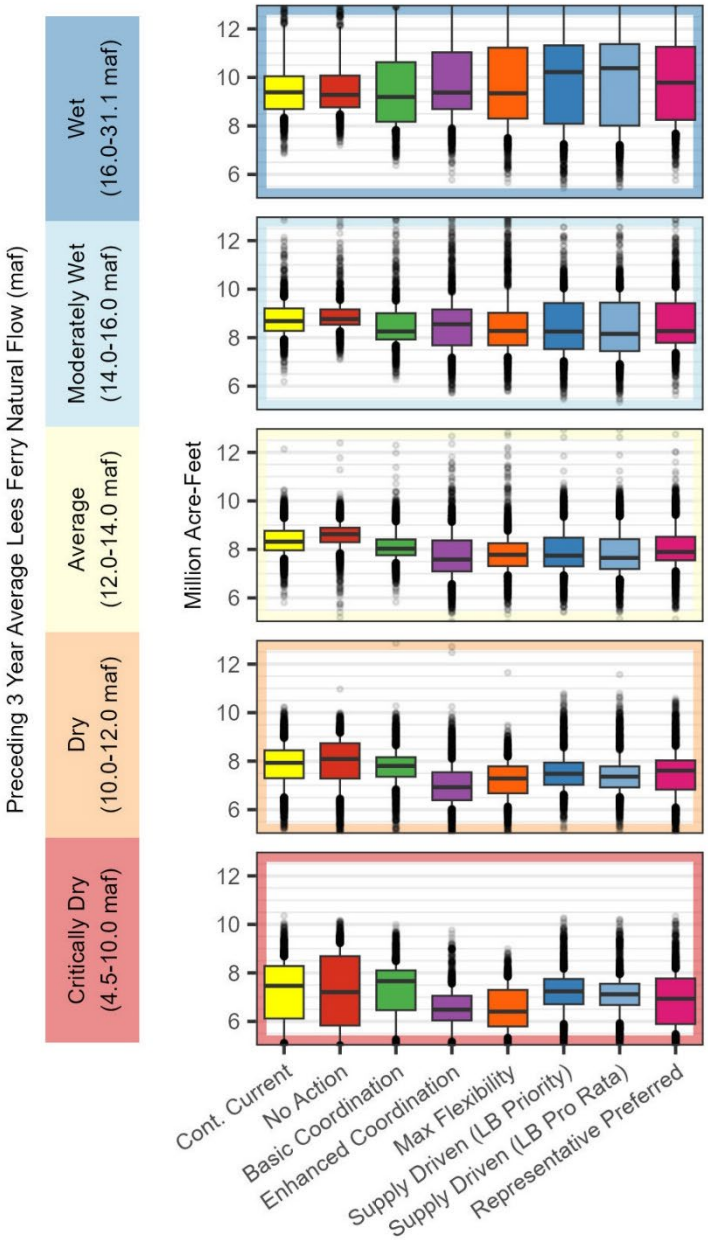


Figure TA 3-25 presents conditional boxplots of CY releases (maf) from Hoover Dam. The range of releases has been truncated to facilitate comparison of the alternatives, see **Table TA 3-19** at the end of this TA for the full range of data.

In the Average Flow Category, the median CY releases from Hoover Dam range from 7.58 maf, under the Enhanced Coordination Alternative, to 8.63 maf, under the No Action Alternative. The median releases for the No Action and Basic Coordination Alternatives and the CCS Comparative Baseline are all above 8.0 maf, while the median releases for other alternatives are all less than 8.0 maf. The No Action and Basic Coordination Alternatives have the least variable releases, with interquartile ranges of 0.60 and 0.65 maf, respectively. The Supply Driven (LB Priority approach), Supply Driven (LB Pro Rata approach), and Enhanced Coordination Alternatives have the greatest variability, with interquartile ranges of 1.18, 1.23 and 1.27 maf, respectively.

In the Critically Dry Flow Category, all alternatives except Enhanced Coordination and Maximum Operational Flexibility Alternatives have median releases between 7.12 maf (Supply Driven [LB Pro Rata approach]) and 7.66 maf (Basic Coordination). Maximum Operational Flexibility and Enhanced Coordination have median releases of 6.40 and 6.48 maf, respectively. All alternatives except Enhanced Coordination and Supply Driven (both LB Priority and LB Pro Rata approaches) have increased variability in Critically Dry conditions compared to Average conditions, with interquartile ranges between 1.51 maf (Maximum Operational Flexibility) and 2.86 maf (No Action Alternative). The Enhanced Coordination (1.02 maf), Supply Driven (LB Priority approach) (1.04 maf), and Supply Driven (LB Pro Rata approach) (0.88 maf) Alternatives have less variable releases (i.e. smaller interquartile ranges).

The Representative Preferred Alternative is roughly in the middle of the other alternatives and CCS Comparative Baseline, in terms of both median releases and variability in releases (except in Critically Dry where it is more variable). In the Dry Flow Category, the median release is 7.61 maf with an interquartile range of 1.20 maf (25th and 75th percentiles of 6.83 and 8.03 maf). In the Critically Dry Flow Category, the median release is 6.94 maf with an interquartile range of 1.88 maf (25th and 75th percentiles of 5.89 and 7.77 maf).

Figure TA 3-25
CY Releases from Hoover Dam[11]

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

[11] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-19** for the full range of the data.

Davis Dam

Releases from Davis Dam, at Lake Mohave, are based on target elevations defined by the existing rule curve (refer to **TA 6**, Water Quality). Inflows into Lake Mohave vary across alternatives, and because elevations are kept to the range determined by the rule curve, releases from Davis Dam subsequently vary across alternatives.

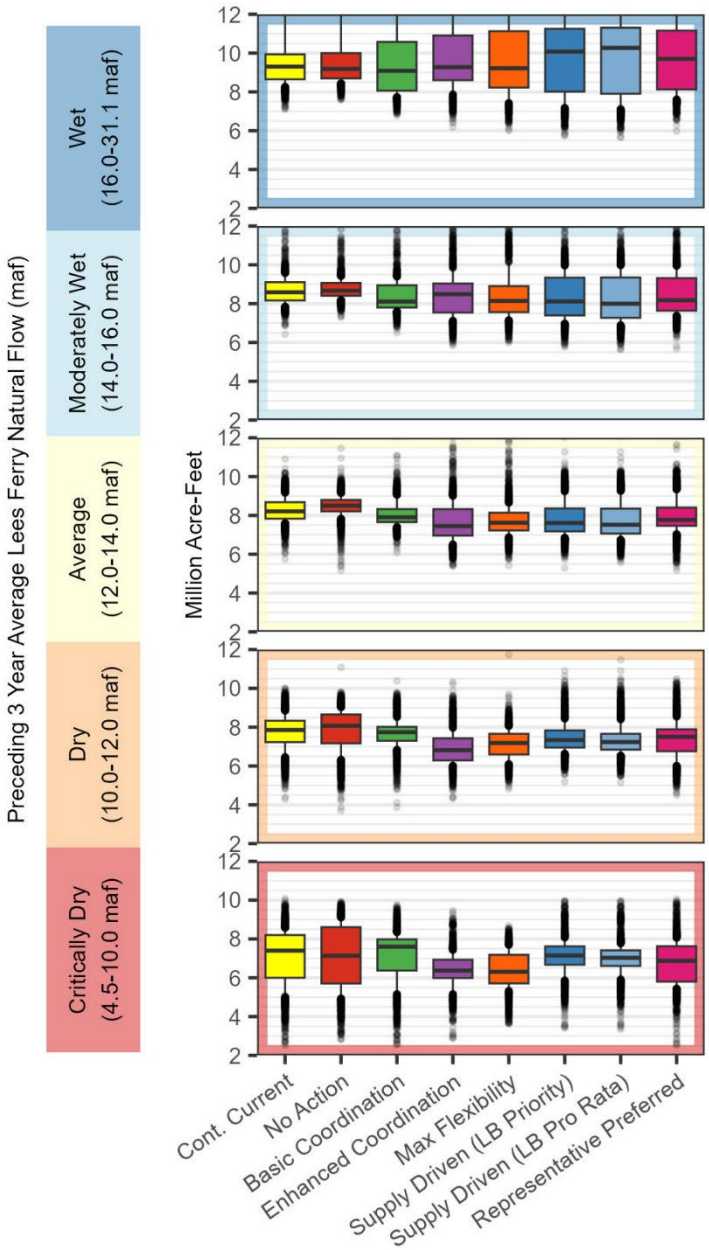

Figure TA 3-26 presents conditional boxplots of CY releases from Davis Dam. The range of releases has been truncated to facilitate comparisons of alternatives, see **Table TA 3-20** at the end of this TA for the full statistical summary and full range of values.

In the Average Flow Category, the median CY releases from Davis Dam range from 7.4 maf (Enhanced Coordination) to 8.5 maf (No Action Alternative). The median release for the CCS Comparative Baseline is 8.2 maf and for the Basic Coordination Alternative is 7.9 maf. Meanwhile, the median releases for the Maximum Operational Flexibility and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are closer to the median release under Enhanced Coordination (at 7.6 maf, 7.6 maf, and 7.5 maf, respectively). The No Action and Basic Coordination Alternatives have the least variability (interquartile ranges of 0.6 and 0.7 maf) while the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives have the most (interquartile ranges of 1.4 and 1.3 maf).

In the Critically Dry Flow Category, the median CY releases from Davis Dam range from 6.3 maf (Maximum Operational Flexibility Alternative) to 7.6 maf (Basic Coordination Alternative). The median for the Enhanced Coordination Alternative (6.4 maf) is similar to the Maximum Operational Flexibility Alternative, although the Maximum Operational Flexibility Alternative exhibits greater variability. The Supply Driven (both LB Priority and LB Pro Rata approaches) and the Representative Preferred Alternatives have median releases greater than the Maximum Operational Flexibility and Enhanced Coordination Alternatives but less than the Basic Coordination Alternative and the CCS Comparative Baseline. The Supply Driven (LB Pro Rata approach), Enhanced Coordination, and Supply Driven (LB Priority approach) Alternatives exhibit the least variability (interquartile ranges of 0.8, 0.9, and 0.9 maf) while the CCS Comparative Baseline and No Action Alternative exhibit the greatest variability (interquartile ranges of 2.2 and 2.9 maf).

In the Dry Flow Category, the Representative Preferred Alternative has a median release of 7.5 maf, which is roughly in the middle compared to the other alternatives. However, it has the third greatest variability (interquartile range of 1.1 maf), behind only the No Action and Basic Coordination Alternatives. In the Critically Dry Flow Category, the median release is 6.9 maf and the interquartile range is 1.8 maf, both of which are roughly in the middle compared to other alternatives.

Figure TA 3-26
CY Releases from Davis Dam[12]

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

[12] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-20** for the full range of the data.

Parker Dam

Releases from Parker Dam, at Lake Havasu, are based on target elevations defined by the existing rule curve (refer to **TA 6**, Water Quality). Inflows into Lake Havasu vary across alternatives, and because elevations are kept to the range determined by the rule curve, releases from Parker Dam subsequently vary across alternatives.

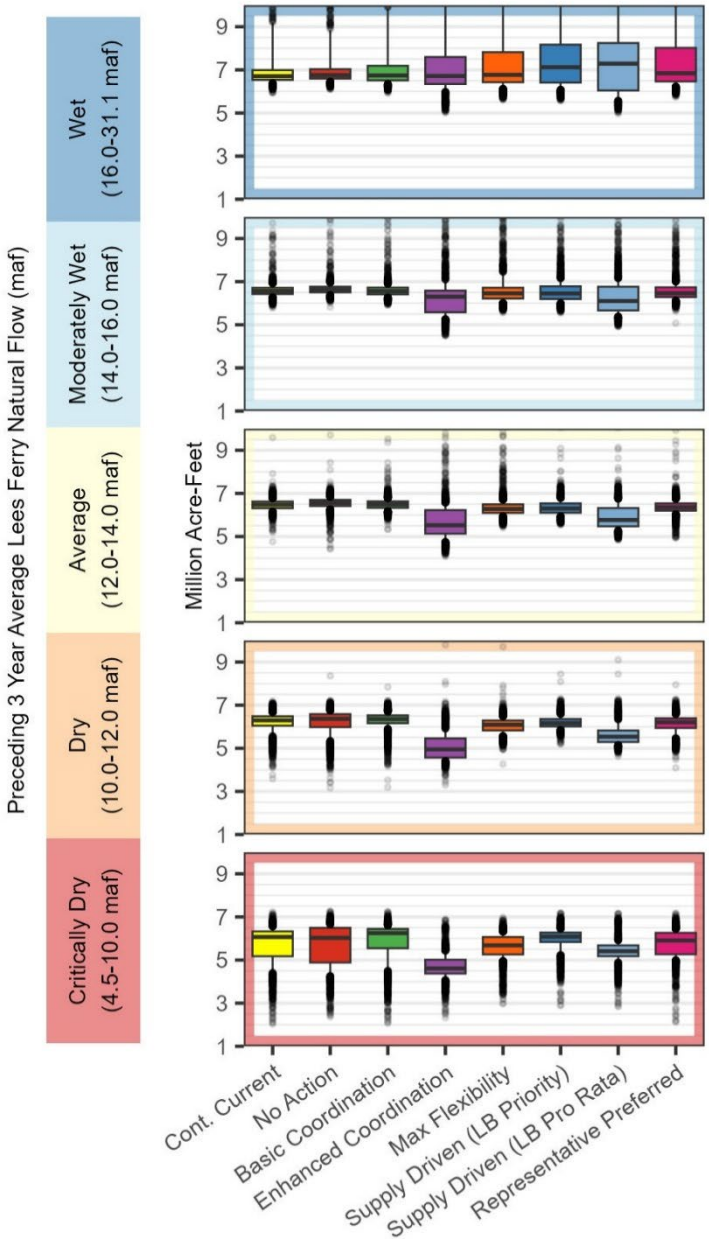

Figure TA 3-27 presents conditional boxplots of CY releases from Parker Dam. The range of releases is truncated to facilitate comparisons between the alternatives, see **Table TA 3-21** at the end of this TA for the full statistical summary and full range of values.

In the Average Flow Category, all alternatives except the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives have median releases between 6.3 and 6.6 maf. The Enhanced Coordination (5.5 maf) and Supply Driven (LB Pro Rata approach) (5.8 maf) Alternatives have notably lower median releases due to pro rata-based distribution of shortages. The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives also have the greatest variability (interquartile ranges of 1.1 and 0.8 maf, respectively), whereas the other alternatives have interquartile ranges between 0.3 and 0.4 maf.

As conditions become drier, median releases decrease for all alternatives and variability increases for all alternatives except the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives. In the Critically Dry Flow Category, the Enhanced Coordination (4.6 maf), Supply Driven (LB Pro Rata approach) (5.4 maf), and Maximum Operational Flexibility (5.7 maf) Alternatives have the lowest median releases. The remaining alternatives and the CCS Comparative Baseline have higher and similar releases between 6.0 and 6.3 maf. When comparing the Critically Dry to Average Flow Category, most alternatives have greater variability in releases except for the Enhanced Coordination (interquartile range decreases from 1.1 maf to 0.6 maf), Supply Driven (LB Pro Rata approach) (decreases from 0.8 to 0.5 maf), and Supply Driven (LB Priority approach) Alternatives (remains 0.4 maf).

The Representative Preferred Alternative exhibits median releases and release variability similar to most alternatives. In the Dry Flow Category, the median release is 6.2 maf with 25th and 75th percentiles of 5.9 and 6.4 maf (interquartile range of 0.5 maf). Under the Critically Dry Flow Category, the median release is 5.9 maf with 25th and 75th percentiles of 5.3 and 6.3 maf (interquartile range of 1.0 maf).

Figure TA 3-27
CY Releases from Parker Dam[13]

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

[13] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-21** for the full range of the data.

TA 3.2.4 Issue 4: River Flows

Issue 4 addresses how operational activities would affect river flows. This was evaluated by comparing the various action alternatives to the No Action Alternative and the CCS Comparative Baseline for the following metrics:

- Annual Colorado River flows below Glen Canyon Dam
- Annual Colorado River flows below Hoover Dam
- Annual Colorado River flows below Davis Dam
- Annual Colorado River flows below Parker Dam
- Annual Colorado River flows at Imperial Dam
- Annual Colorado River flow below Imperial Dam
- Annual Colorado River flow below Morelos Diversion Dam

The conclusions in this section are drawn from three-year average natural flow model outputs and are framed using five flow categories. The conditional box plots show the distribution of river flows (y-axis) over the full analysis period relative to each alternative (x-axis).

Reach 1: Glen Canyon Dam to Lake Mead

This reach of the river (between Glen Canyon Dam and Lake Mead) extends for 292 miles through narrow canyons, including GCNP. River flows in this reach primarily consist of controlled releases from Glen Canyon Dam at Lake Powell. Refer to Issue 3 for the analysis of WY releases and the 10-year cumulative releases from Glen Canyon Dam for the No Action Alternative, CCS Comparative Baseline, and action alternatives. While the results of CRSS analysis are on an annual basis, monthly releases from Lake Powell at Glen Canyon Dam meet the 2016 LTEMP ROD (Reclamation 2016) minimum flows. Reclamation has the option to conduct high flow experiment releases from Glen Canyon Dam under certain conditions to reduce sediment deposition, which usually occurs in durations ranging from 60 hours to 10 days. Refer to **TA 5**, Geomorphology and Sediment, and **TA 8**, Biological Resources – Fish and Other Aquatic Species, for the analysis of high flow experiment flows from Glen Canyon Dam.

This reach also includes contributions from the Paria River and Little Colorado River, two perennial tributaries that discharge to the Colorado River between Glen Canyon Dam and Lake Mead. Based on historical USGS gage data, inflows from the Paria River and Little Colorado River make up approximately three percent of the total flow in this reach of the Colorado River (USGS 2025a). From 1906 to 2005, the annual inflow of the Paria River averaged 21.0 kafy and the Little Colorado River inflow averaged 180.0 kafy. Since 2007, the annual inflow from the Paria River averaged 17.0 kafy, and the Little Colorado River inflow averaged 274.0 kafy. Inflows from the Paria River and Little Colorado River were modeled in CRSS as the same across alternatives.

Relating back to the Issue 3 analysis for Glen Canyon Dam, in the Average Flow Category, the median WY releases from Glen Canyon Dam are: 8.41 maf under the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), 8.23 maf under the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives, 8.17 maf under the Maximum Operational Flexibility Alternative, 7.95 maf under the Enhanced Coordination Alternative, and 8.23 maf under

the Representative Preferred Alternative. The historic combined inflows from the Paria River and the Little Colorado River (291.0 kaf combined) are approximately 3.5 percent to 3.7 percent of these modeled Average Flow Category median Glen Canyon Dam releases.

Reach 2: Hoover Dam to Lake Mohave

This reach of the river (starting from the Hoover Dam at Lake Mead) is 67 miles long and flows through Pyramid Canyon, El Dorado Canyon, and Black Canyon. Lake Mohave is on the downstream end of the reach, and it acts hydraulically like a tailwater to Hoover Dam. River flows in this reach primarily consist of releases from Hoover Dam with small contribution from tributary inflows. According to the 2007 Final EIS, tributary inflows, mostly from side washes, comprise less than 1 percent of the total annual flow (Reclamation 2007a). CRSS modeling of flows in this reach do not account for tributary inflows and reflect only releases from Hoover Dam.

Below is brief summary of the modeling results presented in Issue 3 based on CY releases from Hoover Dam. For modeling results and an in-depth discussion, refer to **Table TA 3-19** and **Figure TA 3-25**.

In the Average Flow Category, the median annual flow volumes for the No Action Alternative, Basic Coordination Alternative, and the CCS Comparative Baseline range from 8.03 to 8.63 maf. The remaining alternatives range from 7.58 maf (Enhanced Coordination) to 7.89 maf (Representative Preferred). In the Critically Dry Flow Category, median values decrease, with the smallest values being 6.40 maf (Maximum Operational Flexibility) and 6.48 maf (Enhanced Coordination) and the largest values being 7.47 maf (CCS Comparative Baseline) and 7.66 maf (Basic Coordination). The Representative Preferred Alternative generally results in annual volumes in the middle compared to other alternatives and the CCS Comparative Baseline.

Reach 3: Davis Dam to Lake Havasu

This reach of the Colorado River (starting from Davis Dam at Lake Mohave) is 84 miles long and forms Lake Havasu. River flows in this reach are mostly comprised of releases from Davis Dam and tributary inflow from the Bill Williams River.

Inflows from the Bill Williams River discharge directly into Lake Havasu and are regulated by the USACE operations of Alamo Dam. From 1906 to 2007, the annual inflow averaged 102,000 af. From 2008 to 2022 the annual inflow averaged 105,000 af (USGS 2025b).

Releases from Davis Dam are the variable that would differ between alternatives, so they have been used for comparison. Below, a brief summary of CY releases from Davis Dam are provided. For modeling results and in-depth discussion, refer to **Table TA 3-20** and **Figure TA 3-26**.

In the Average Flow Category, the Basic Coordination Alternative, CCS Comparative Baseline, and No Action Alternative have the largest annual volumes of 7.9, 8.2, and 8.5 maf. The remaining alternatives range from 7.4 maf (Enhanced Coordination) to 7.8 maf (Representative Preferred). In the Critically Dry Flow Category, median values decrease, with the smallest values being 6.3 maf (Maximum Operational Flexibility) and 6.4 maf (Enhanced Coordination) and the largest values being 7.4 maf (CCS Comparative Baseline) and 7.6 maf (Basic Coordination). The Representative

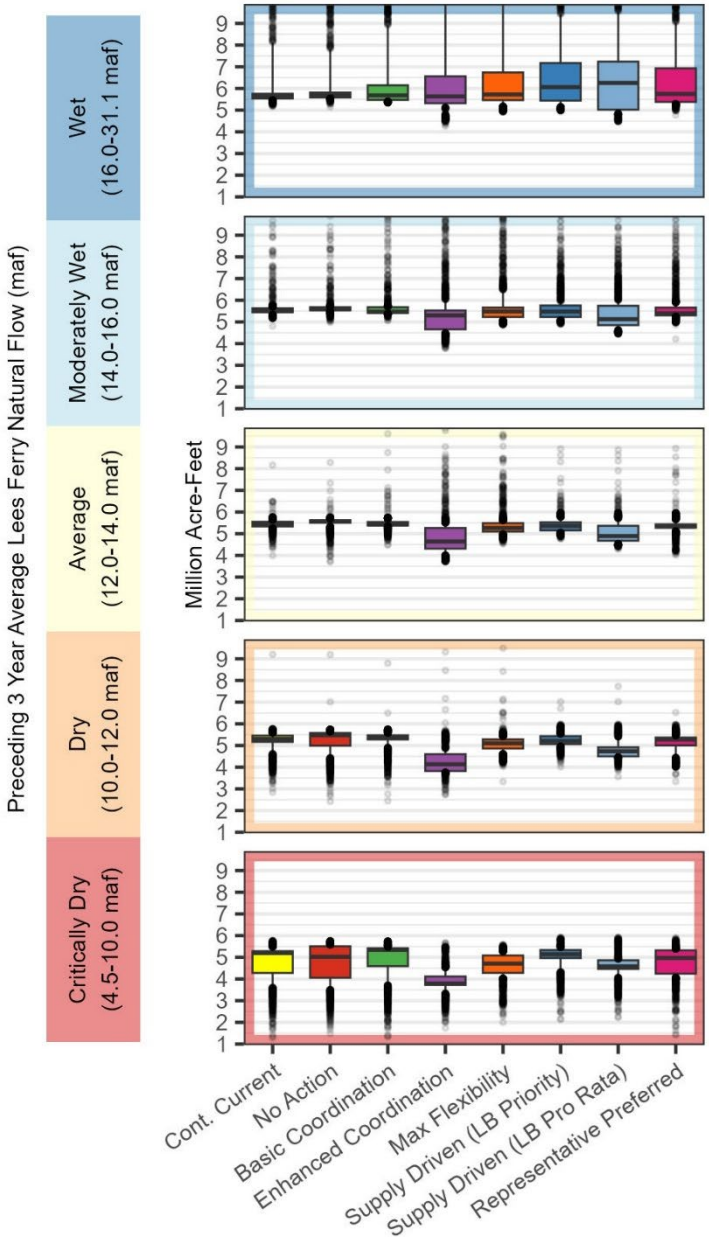
Preferred Alternative generally results in annual volumes in the middle compared to other alternatives and the CCS Comparative Baseline.

Reach 4: Parker Dam to Cibola Gage

This reach of the river (starting from Parker Dam at Lake Havasu) is 105 miles long and goes to Reclamation's Cibola Gage. Flows in this reach primarily consist of releases from Parker Dam. Two major diversion dams are located in this reach of the river: Headgate Rock Dam and Palo Verde Diversion Dam. The impoundments of these dams are used to facilitate the diversion of water for the Colorado River Indian Tribes and Palo Verde Irrigation District.

The analysis of flows for this reach is based on CY release volumes from Parker Dam. A brief summary is provided below. For modeling results and in-depth discussion, refer to Issue 3, **Table TA 3-21** and **Figure TA 3-27**.

In the Average Flow Category, all alternatives except Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives have median releases between 6.3 and 6.6 maf. The Enhanced Coordination (5.5 maf) and Supply Driven (LB Pro Rata approach) (5.8 maf) Alternatives have notably lower median releases due to pro rata-based distribution of shortages. As conditions become drier, median releases decrease for all alternatives. In the Critically Dry Flow Category, the Enhanced Coordination (4.6 maf), Supply Driven (LB Pro Rata approach) (5.4 maf), and Maximum Operational Flexibility (5.7 maf) Alternatives have the lowest median releases. The remaining alternatives and the CCS Comparative Baseline have higher and similar releases between 5.9 and 6.3 maf. The Representative Preferred Alternative has annual volumes similar to other alternatives besides the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives, which are notably lower.



Reach 5: Cibola Gage to Imperial Dam

This reach of the river (starting from the Cibola Gage) is 38 miles long and is bounded on the downstream end by Imperial Dam at Imperial Reservoir. Flows in this reach consist primarily of releases from Parker Dam but are impacted by diversions and return flows. The Imperial Dam impoundment in this reach operates at a nearly constant elevation to meet water delivery requirements.

Figure TA 3-28 presents conditional boxplots of annual flow volume at Imperial Dam. The range of volumes is truncated at the high end to facilitate comparisons between alternatives, see **Table TA 3-22** at the end of this TA for the full statistical summary and full range of values.

In the Average Flow Category, most alternatives and the CCS Comparative Baseline have a median volume between 5.3 and 5.6 maf. The exceptions are the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives, which have smaller median volumes of 4.6 and 4.9 maf, respectively. The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives are also distinct in that they have greater variability (interquartile ranges of 1.0 maf and 0.7 maf) compared to other alternatives and the CCS Comparative Baseline (interquartile ranges between 0.1 and 0.4 maf). These differences are due to the pro rata-based shortage distributions in the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives.

Figure TA 3-28
Annual Flow Volume at Imperial Dam[14]

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

As hydrology becomes drier, all alternatives and the CCS Comparative Baseline show smaller annual flow volumes. In the Critically Dry Flow Category, most alternatives and the CCS Comparative Baseline have a median volume between 5.0 and 5.3 maf. However, the Enhanced Coordination (3.8

[14] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-22** for the full range of the data.

maf), Supply Driven (LB Pro Rata approach) (4.6 maf), and Maximum Operational Flexibility (4.7 maf) Alternatives have noticeably smaller annual volumes. The CCS Comparative Baseline, No Action Alternative, and Basic Coordination Alternative show greater variability (i.e. larger interquartile ranges) in the Critically Dry Flow Category compared to the Average Flow Category, likely due to dead pool-related delivery reductions (see **Figures TA 4-1** and **TA 4-2** in **TA 4**, Water Deliveries). The Maximum Operational Flexibility and Representative Preferred Alternatives also show greater variability, but likely due to increased shortages (not dead pool-related delivery reductions - see **Figures TA 4-1** and **TA 4-2** in **TA 4**, Water Deliveries). Variability decreases for the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives and remains about the same for the Supply Driven Alternative (LB Priority approach).

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: a median value of 5.3 maf (tied with CCS Comparative Baseline and third largest behind No Action and Basic Coordination Alternatives) and an interquartile range of 0.4 maf (third largest variability after the Enhanced Coordination and No Action Alternatives). In the Critically Dry Flow Category, the Representative Preferred Alternative exhibits the following outcomes: a median value of 5.0 maf (in the middle of the range of medians) and an interquartile range of 1.1 maf (second largest variability after the No Action Alternative).

Reach 6: Imperial Dam to NIB

This reach of the river (starting from the Imperial Dam) is 26 miles long and is bounded on the downstream end by NIB between the U.S. and Mexico. Flows in this reach primarily consist of releases from Imperial Dam to make delivery requirements. Flows in this reach also include water leaked from the AAC's sluiceway gates and return flow from Imperial Dam diversions.

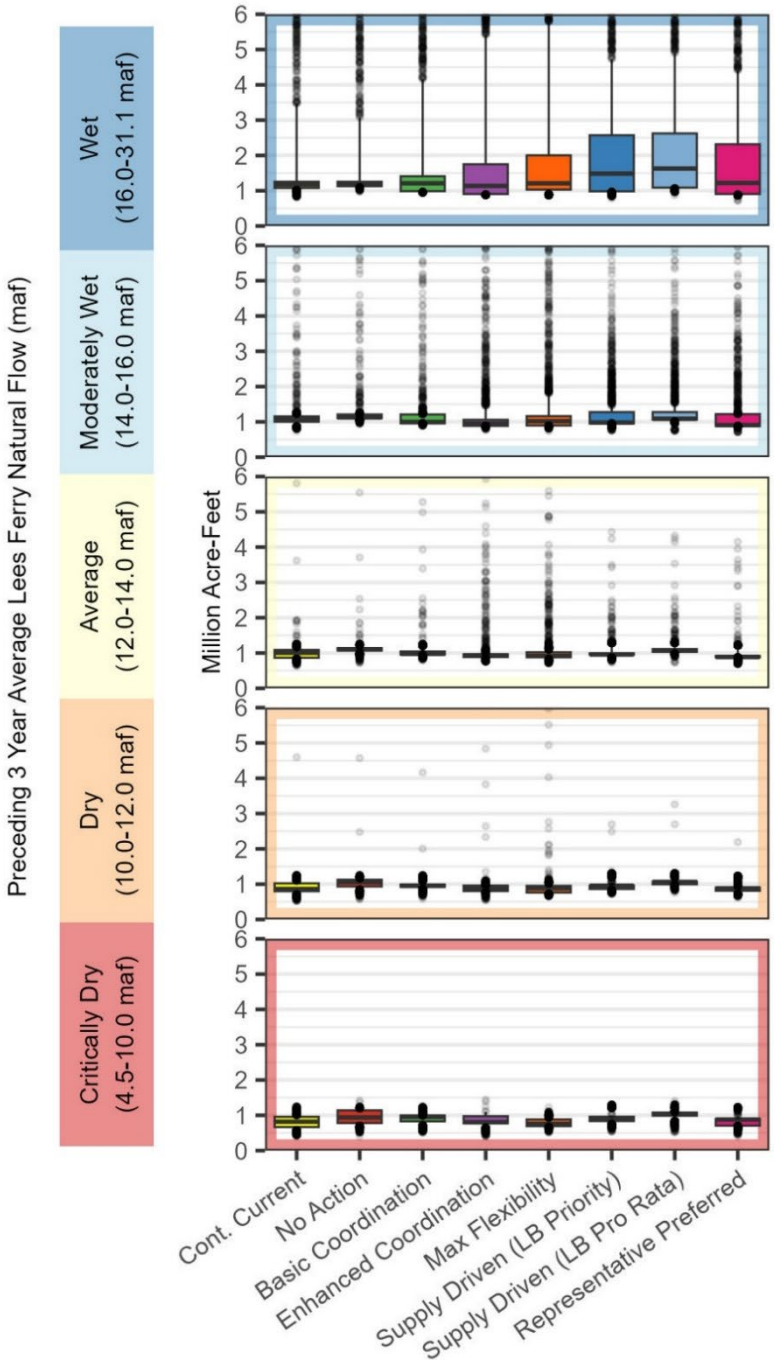


Figure TA 3-29 presents conditional boxplots of annual flow volume below Imperial Dam. The range of volumes is truncated at the high end to facilitate comparisons between alternatives, see **Table TA 3-23** at the end of this TA for the full statistical summary and full range of values.

In the Average Flow Category, the median annual flow volumes below Imperial Dam range from 0.9 maf (Maximum Operational Flexibility and Enhanced Coordination Alternatives) to 1.1 maf (No Action and Supply Driven [LB Pro Rata] Alternatives, and CCS Comparative Baseline). The CCS Comparative Baseline and all action alternatives have low variability in the Average Flow Category, with interquartile ranges between 34 and 221 kaf. Although rare, less than 10 percent of years have large volumes with maximums between 8.5 and 15.6 maf due to Flood Control operations.

In the Critically Dry Flow Category, the median annual flow volumes range from 0.8 maf (CCS Comparative Baseline, Enhanced Coordination Alternative, and Maximum Operational Flexibility Alternatives), to 1.0 maf (Supply Driven Alternative [LB Pro Rata approach] and Basic Coordination Alternatives). Variability in terms of interquartile range and outliers is low.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median volume is 0.9 maf and the interquartile range is 88 kaf. In the Critically Dry Flow Category, the median volume is 0.9 maf and the interquartile range is 192 kaf. Overall, the Representative Preferred Alternative has annual volumes on the low end of all alternatives.

Figure TA 3-29
Annual Flow Volume Below Imperial Dam[15]

Note: Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

[15] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-23** for the full range of the data.

Reach 7: NIB in the Limitrophe to SIB

This reach of the river (starting from the NIB) is split into two sub reaches. Approximately 1.1 miles downstream from the NIB is Morelos Diversion Dam where, under normal operations, the entirety of the remaining Colorado River is diverted by Mexico for water supply into the Reforma Canal.

Downstream of Morelos Diversion Dam, the reach continues to the SIB and the Colorado River Delta. Flows through this reach, referred to as the limitrophe, consist of water in excess of Mexico's scheduled delivery. Flows in excess could be due to Flood Control operations at Hoover Dam, seepage from Morelos Diversion Dam, irrigation return flows, groundwater inflow, and any water released for environmental purposes in the Colorado River Delta.

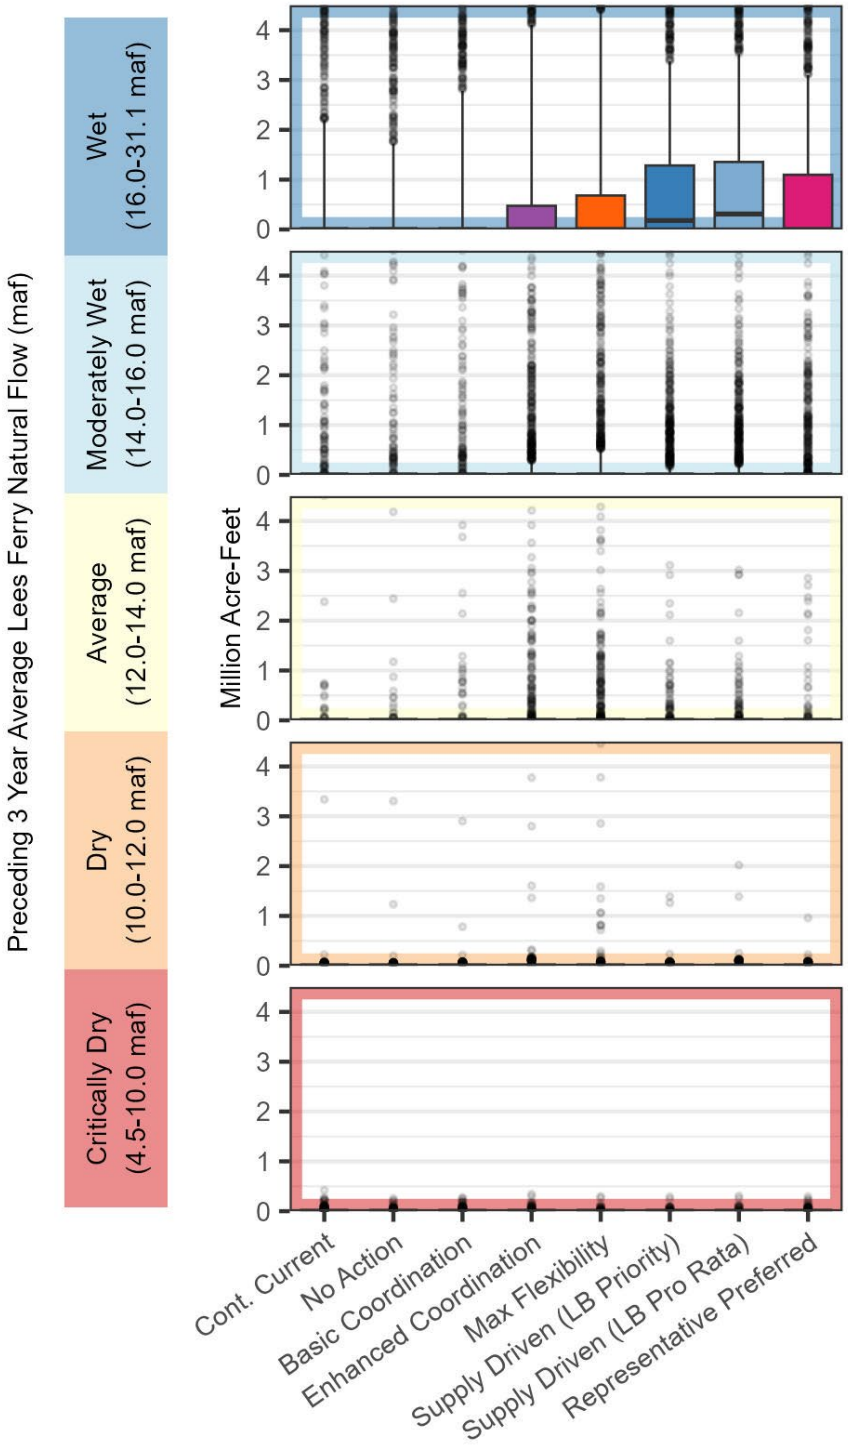

Figure TA 3-30 presents conditional boxplots of annual flow volume below Morelos Diversion Dam. The range of volumes is truncated to facilitate comparisons between alternatives, see **Table TA 3-24** at the end of this TA for the full statistical summary and full range of values.

In the Wet Flow Category, flows in the Colorado River below Morelos Diversion Dam occur in 50 percent of years for the Supply Driven Alternative (both LB Priority and Pro Rata approaches), greater than 25 percent of years for the Enhanced Coordination, Maximum Operational Flexibility and Representative Preferred Alternatives, and fewer than 25 percent of years for other alternatives and the CCS Comparative Baseline (i.e., the 75th percentile is 0).

As natural flow decreases, flows in the Colorado River below Morelos Diversion Dam become even less frequent. In the Average, Dry, and Critically Dry Flow Categories, flows occur in 10 percent or fewer years for all alternatives and the CCS Comparative Baseline (i.e. the 90th percentile is zero).

Although infrequent, there is the possibility of large volume flows in the limitrophe (e.g. greater than 1.0 maf in one calendar year) in all but the Critically Dry Flow Category. These are the result of exceptionally high flows that occur in some of the hydrologic futures considered in the modeling analysis.

Figure TA 3-30
Annual Flow Volume Below Morelos Diversion Dam[16]

[16] The plotting range has been truncated to facilitate comparison of the alternatives. Consult **Table TA 3-24** for the full range of the data.

TA 3.2.5 Issue 5: Groundwater

Issue 5 addresses how operational activities for the various alternatives would affect groundwater adjacent to reservoirs and within specific reaches along the Colorado River. This was evaluated by comparing the various action alternatives to the No Action Alternative and the CCS Comparative Baseline for the following metrics:

- Qualitative discussion of possible groundwater impacts based on relative changes to Colorado River flows for each reach, and relative changes to reservoir elevations where applicable.
- Hydraulic connectivity between groundwater and the reservoirs and river reaches of the Colorado River vary depending on a number of factors, including physical geotechnical characteristics, vegetative groundcover, whether irrigation is occurring nearby, and distance from the river.

Regional scale changes to groundwater are complex and hard to quantify without extensive data records and groundwater models. Current data on groundwater at a regional scale is limited in scope and historical duration.

There are no legal requirements to not deplete groundwater for nearby wells, although decreasing reservoir elevations may contribute to decreased groundwater elevations depending on hydraulic connectivity. Secondary impacts on groundwater are not considered in this analysis (e.g., if actions under the various alternatives would result in more groundwater pumping occurring in order to supplement decreased supply).

Reach 1: Lake Powell to Lake Mead

Fluctuations in elevations at Lake Powell may be reflected in groundwater elevations adjacent to the reservoir, depending on the hydraulic connectivity between the reservoir and nearby groundwater wells. Relating back to the Issue 1 analysis, the water surface elevations at Lake Powell vary by alternative with the Maximum Operational Flexibility Alternative and the Enhanced Coordination Alternative being the most robust at keeping elevations above 3,500 feet in 100 percent of months over the full modeling period (86 percent and 74 percent, respectively). Since these two alternatives are the most robust for reservoir elevations, groundwater elevations adjacent to Lake Powell are anticipated to be slightly higher under these alternatives compared to the others. The Representative Preferred Alternative is the third most robust (40 percent) followed by the CCS Comparative Baseline and Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) (all 18 percent), and the Basic Coordination Alternative (13 percent). The No Action Alternative is the least robust at keeping Lake Powell elevations above 3,500 feet and is therefore anticipated to result in lower groundwater elevations adjacent to the reservoir.

Reach 1 of the Colorado River extends from downstream of Glen Canyon Dam, through the GCNP, to Lake Mead. The Grand Canyon restricts hydraulic connection to groundwater to sandbars. Due to physical geotechnical characteristics, changes to groundwater levels in this reach are not anticipated to be affected by the various alternatives.

Black Canyon, which is dammed by Hoover Dam, is made of bedrock that limits the connection to groundwater with a few small sandbars. As such, groundwater basins adjacent to Lake Mead are generally small in size and are bounded by zones of non-water bearing rock. Changes in water surface elevations at Lake Mead are not anticipated to be affected by the various alternatives.

Reach 2: Hoover Dam to Davis Dam

Reach 2 of the Colorado River extends from downstream of Hoover Dam to Lake Mohave (formed by Davis Dam) and runs through a bedrock canyon that limits the connection to groundwater. Due to physical geotechnical characteristics of the bedrock canyon, changes to groundwater levels in this reach are not anticipated to be affected by the various alternatives.

Groundwater elevations adjacent to Lake Mohave are not anticipated to be affected by the various alternatives because the release rule curve that Lake Mohave operates under is the same for all alternatives in this analysis. The rule curve keeps water surface elevations of Lake Mohave within a tight range and Reclamation will continue to operate releases from Davis Dam in this manner.

Reach 3: Davis Dam to Parker Dam

Reach 3 of the Colorado River extends from downstream of Davis Dam to Lake Havasu (formed by Parker Dam) and flows through two different groundwater basins. The upper portion of this reach is within the Mohave Valley groundwater basin, which is alluvial fill, and fluctuations in river flows through this section may affect groundwater in the alluvial basin.

Relating back to the Issue 4 analysis, the river flows in this reach are mostly comprised of releases from Davis Dam and tributary inflow from the Bill Williams River. Releases from Davis Dam vary by alternative, with the Basic Coordination Alternative having the highest flows in the reach under the Critically Dry Flow Category. Therefore, groundwater elevations through the Mohave Valley groundwater basin are anticipated to be higher under this alternative during dry conditions, compared to the others. Following this connection between river flows and adjacent groundwater elevations, the CCS Comparative Baseline is anticipated to have the second highest groundwater elevations in the Critically Dry Flow Category, closely followed by the No Action Alternative, Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), and the Representative Preferred Alternative. The Enhanced Coordination and the Maximum Operational Flexibility Alternatives are anticipated to result in lower groundwater elevations in dry conditions compared to the other alternatives.

The lower portion of this reach is within the Chemehuevi Valley and is dominated by Lake Havasu. Similar to Lake Mohave, the groundwater elevations adjacent to Lake Havasu are not anticipated to be affected by the various alternatives because of the strict release rule curve is the same for all alternatives within this analysis. The rule curve keeps water surface elevations of Lake Havasu within a tight range and Reclamation will continue to operate releases from Parker Dam in this manner.

Reach 4: Parker Dam to Cibola Gage

Reach 4 of the Colorado River extends from downstream of Parker Dam to the USGS gage station known as Cibola Gage. This reach flows through one large alluvial fill groundwater basin and fluctuations in river flows through this section may affect groundwater in this alluvial basin.

Relating back to the Issue 4 analysis, the river flows in this reach are mostly comprised of releases from Parker Dam which vary by alternative. In the Critically Dry Flow Category, the Basic Coordination Alternatives has the highest flows in the reach, therefore, groundwater elevations through this reach of the river are anticipated to be higher under this alternative compared to others. The Supply Driven Alternative (LB Priority approach) is anticipated to have the next highest groundwater elevations in the Critically Dry Flow Category, followed by the CCS Comparative Baseline, and the No Action, Representative Preferred, and Maximum Operational Flexibility Alternatives. The Supply Driven Alternative (LB Pro Rata approach) is anticipated to have the second lowest groundwater elevations in the Critically Dry Flow Category and the Enhanced Coordination Alternative is anticipated to have the lowest groundwater elevations.

Reach 5: Cibola Gage to Imperial Dam

Reach 5 of the Colorado River extends from the USGS gage station known as Cibola Gage down to Imperial Dam and runs through a narrow alluvial fill valley. Fluctuations in river flows through this section may affect groundwater.

Flows in this reach primarily consist of releases from Parker Dam and mirror trends in reach 4. As such, groundwater elevations in this reach of the river also mirror trends for relative groundwater elevations in Reach 4. In the Critically Dry Flow Category, The Basic Coordination Alternative is anticipated to have the highest groundwater elevations compared to the other alternatives. The CCS Comparative Baseline is anticipated to have the second highest groundwater elevations during in the Critically Dry Flow Category, closely followed by the Supply Driven (LB Priority approach), No Action, Representative Preferred, and Maximum Operational Flexibility Alternatives. The Supply Driven Alternative (LB Pro Rata approach) is anticipated to have the second lowest groundwater elevations in the Critically Dry Flow Category and the Enhanced Coordination Alternative is anticipated to have the lowest groundwater elevations.

Reach 6: Imperial Dam to NIB

Reach 6 of the Colorado River extends from downstream of Imperial Dam to the NIB and bypasses most of the river channel as it runs through a series of lined canals and sluiceways. Therefore, the proposed alternatives are not anticipated to affect groundwater basins adjacent to this reach.

Reach 7: NIB in the Limitrophe to SIB

Reach 7, referred to as the limitrophe, of the Colorado River extends from the NIB to the SIB and consists of the deep Colorado River Delta groundwater basin. Infrequent flows in this reach may occur due to releases at Morelos Diversion Dam under exceptionally wet hydrologic conditions.

The upstream portion of this reach is considered a gaining reach because high groundwater elevations from nearby irrigated fields results in flow to the surface. The proposed alternatives would not affect irrigation to nearby fields, therefore, there are no anticipated impacts on the groundwater in this section of the reach.

The downstream portion of this reach is considered a losing reach because groundwater is recharged from the river. Groundwater elevations in this section of the reach have historically declined and are likely to continue to decline under dry conditions.

TA 3.2.6 Summary Comparison of Alternatives

Issue 1: Reservoir Elevations

Issue 1 evaluates how operational activities under the CCS Comparative Baseline, No Action Alternative, and action alternatives would affect reservoir elevations at Lake Powell and Lake Mead. The analysis compares Lake Powell EOWY and WY minimum elevations, Lake Mead EOCY and CY minimum elevations, and the effects of Upper Basin and Lower Basin conservation assumptions on reservoir storage. Modeling shows fewer performance deviations under wetter flow categories, while differences among alternatives increase under dry and critically dry conditions because operations at lower elevations vary widely across alternatives.

Performance patterns vary by reservoir, alternative, flow category, and metric. At Lake Powell, differences among alternatives become more pronounced under drier hydrologic conditions, with some alternatives maintaining higher elevations and greater robustness above key thresholds, while others shift closer to or below those thresholds. At Lake Mead, the action alternatives perform better than the No Action Alternative for maintaining elevations above key thresholds, although results vary across alternatives and flow categories. Conservation activity increases median elevations for several action alternatives, but effects vary by reservoir, alternative, and flow category. Lake Mohave and Lake Havasu elevations are not affected because existing rule curves maintain target elevations within operational bounds.

Under the Representative Preferred Alternative, modeled results show reduced low-elevation outcomes compared to more vulnerable alternatives, but vulnerability remains under drier future hydrologic conditions. In the Dry and Critically Dry Flow Categories with conservation activity on, median EOWY elevations at Lake Powell are 3,554 feet and 3,523 feet, respectively, and median EOCY elevations at Lake Mead are 1,041 feet and 1,001 feet, respectively. Lake Powell robustness results for the key thresholds indicate that the Representative Preferred Alternative meets preferred minimum performance levels in about 40 to 50 percent of modeled futures over the full modeling period and about 52 to 58 percent of futures during 2027-2039. For Lake Mead, robustness results indicate that the alternative meets preferred minimum performance levels in about 57 to 63 percent of modeled futures over the full modeling period and about 62 to 72 percent of futures during 2027-2039. Vulnerability analyses indicate that, absent additional action, the Representative Preferred Alternative would be reasonably likely to be vulnerable in the next 10 years to elevations below key Lake Powell and Lake Mead thresholds under the 10-year average annual flow conditions identified in the modeling.

Issue 2: System Storage

Issue 2 evaluates how operational activities under the action alternatives would affect EOWY system storage compared to the No Action Alternative and CCS Comparative Baseline. The analysis considers combined storage at Lake Powell and Lake Mead, the CRSP reservoirs, and the seven-reservoir system. Across the alternatives, storage outcomes generally decline as hydrologic conditions become drier, with the Enhanced Coordination and Maximum Operational Flexibility Alternatives often maintaining higher median storage than the No Action Alternative, Basic Coordination Alternative, and CCS Comparative Baseline. For Lake Powell and Lake Mead, alternatives with higher combined storage generally reduce the frequency of modeled years falling

below the lowest observed historical EOWY combined storage value. For CRSP reservoirs, differences are driven primarily by Lake Powell operations because storage at the CRSP UIU reservoirs varies minimally across alternatives. For the seven-reservoir system, alternatives capable of implementing larger Lower Basin shortages tend to result in greater seven-reservoir storage.

Overall, the results show differences among alternatives in their ability to maintain system storage under drier hydrologic conditions. The CCS Comparative Baseline and the No Action and Basic Coordination Alternatives generally show lower median storage than the Enhanced Coordination and Maximum Operational Flexibility Alternatives, and for Lake Powell and Lake Mead they also show a greater frequency of modeled years below lowest observed historical EOWY combined storage value. Under the Representative Preferred Alternative, modeled storage is lower under drier conditions: in the Dry Flow Category, median combined storage is 32 percent for Lake Powell and Lake Mead, 37 percent for CRSP reservoirs, and 37 percent for the seven-reservoir system. In the Critically Dry Flow Category, median storage declines to 21 percent for Lake Powell and Lake Mead, 27 percent for CRSP reservoirs, and 27 percent for the seven-reservoir system. For Lake Powell and Lake Mead specifically, more than 25 percent of modeled years in the Dry Flow Category and nearly 75 percent of modeled years in the Critically Dry Flow Category fall below the lowest observed historical EOWY combined storage value.

Issue 3: Reservoir Releases

Issue 3 evaluates how operational activities under the action alternatives would affect reservoir releases compared to the No Action Alternative and CCS Comparative Baseline, focusing on annual water year releases from Glen Canyon Dam, cumulative 10-year Glen Canyon Dam releases and Lee Ferry flows, and calendar year releases from Hoover, Davis, and Parker Dams. Across alternatives, modeled releases vary by hydrologic condition and by how operations respond to hydrologic and reservoir conditions, with drier conditions generally associated with lower median releases and, for many alternatives and locations, greater variability.

The Enhanced Coordination and Maximum Operational Flexibility Alternatives generally show greater responsiveness to hydrologic conditions at Glen Canyon Dam and the Lee Ferry, while the No Action Alternative shows high variability under critically dry conditions due to infrastructure-constrained releases when Lake Powell falls below about 3,490 feet. At Hoover Dam, releases reflect modeled Lake Mead operations and conserved-water storage and delivery assumptions. At Davis and Parker Dams, releases also reflect inflows and target elevations defined by existing rule curves. Differences between the Supply Driven Alternative (LB Priority approach) and the Supply Driven Alternative (LB Pro Rata approach) at Lower Basin dams arise from how each shortage-distribution approach interacts with modeled conserved-water storage and delivery assumptions.

Under the Representative Preferred Alternative, Glen Canyon Dam releases are comparatively less variable under critically dry conditions, while modeled releases at Hoover, Davis, and Parker Dams are generally within the range of the other alternatives, with some variation by dam and hydrologic condition. Median annual Glen Canyon Dam releases decline from 7.20 maf in the Dry Flow Category to 6.0 maf in the Critically Dry Flow Category, reflecting reduced supply while remaining the least variable among alternatives under critically dry hydrology. At Lee Ferry, the Representative Preferred Alternative has median 10-year volumes of 76.4 maf under Dry conditions and 73.9 maf

under Critically Dry conditions. Under Dry conditions, more than half of modeled 10-year periods exceed 75.0 maf, but fewer than 25 percent exceed 82.5 maf. Under Critically Dry conditions, fewer than half of modeled 10-year periods exceed 75.0 maf, and slightly more than 10 percent exceed 82.5 maf. Downstream, the Representative Preferred Alternative releases at Hoover, Davis, and Parker Dams generally decrease as hydrologic conditions become drier. These releases are generally within the middle of the modeled alternatives or similar to most alternatives, with the main differences related to variability. Hoover releases are more variable under Critically Dry conditions, and Davis Dam releases show relatively higher variability under Dry conditions.

Issue 4: River Flows

Issue 4 evaluates how operational activities under the action alternatives would affect Colorado River flows compared to the No Action Alternative and CCS Comparative Baseline. The analysis considers annual flow volumes below Hoover Dam, below Davis Dam, below Parker Dam, at Imperial Dam, below Imperial Dam, and below Morelos Diversion Dam using three-year average natural flow model outputs across five flow categories. Across these reaches, modeled river flows generally decrease, or become less frequent below Morelos Diversion Dam, as hydrologic conditions become drier.

In the reaches from Glen Canyon Dam through Parker Dam, modeled comparisons generally focus on dam releases because those releases are the primary source of flow or the operational variable that differs among alternatives. Differences among alternatives are particularly apparent in drier hydrologic conditions and in reaches downstream of Parker Dam, where shortage distribution, conserved water assumptions, diversions, flows, and delivery requirements affect annual flow volumes and variability. Below Morelos Diversion Dam, flows are infrequent under all alternatives except during some wetter hydrologic conditions. In the Average, Dry, and Critically Dry Flow Categories, flows occur in 10 percent or fewer years for all alternatives and the CCS Comparative Baseline.

Under the Representative Preferred Alternative, annual flow volumes are generally in the middle of the range of alternatives and the CCS Comparative Baseline below Hoover Dam and Davis Dam. Below Parker Dam, annual volumes are similar to most alternatives, except for the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives, which are notably lower. Farther downstream, the Representative Preferred Alternative reflects the effects of diversions, return flows, delivery requirements, and increased shortages under drier conditions. At Imperial Dam, median annual flow under the Representative Preferred Alternative is 5.3 maf in the Dry Flow Category and 5.0 maf in the Critically Dry Flow Category. Below Imperial Dam, median annual flow is 0.9 maf in both the Dry and Critically Dry Flow Categories, which is on the low end of the alternatives. Below Morelos Diversion Dam, flows remain infrequent in the Average, Dry, and Critically Dry Flow Categories, occurring in 10 percent or fewer modeled years across all alternatives and the CCS Comparative Baseline.

Issue 5: Groundwater Elevations

Issue 5 evaluates how operational activities under the action alternatives could affect groundwater adjacent to reservoirs and along specific reaches of the Colorado River compared to the No Action Alternative and CCS Comparative Baseline. The analysis is qualitative because groundwater

responses are complex, available regional data are limited, and hydraulic connectivity varies by location. Groundwater effects are expected to be limited in many areas because some reaches are constrained by bedrock, lined canals, or reservoir operations that do not meaningfully vary across alternatives. Potential effects are most likely near Lake Powell, where reservoir elevations may influence adjacent groundwater, and in alluvial portions of the river where flow changes may affect groundwater elevations.

Overall, potential groundwater effects vary by reach and are most closely tied to Lake Powell elevations and relative river flows through connected groundwater basins. Alternatives that maintain higher Lake Powell elevations or higher flows in hydraulically connected alluvial reaches would generally be expected to support higher nearby groundwater elevations. Under the Representative Preferred Alternative, groundwater elevations near Lake Powell are anticipated to be lower than under the Maximum Operational Flexibility and Enhanced Coordination Alternatives but higher than under the CCS Comparative Baseline, No Action Alternative, Basic Coordination Alternative, and the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches). Across the river reaches, the Representative Preferred Alternative is expected to have little or no groundwater effect where hydraulic connectivity is limited or operations are similar across alternatives. Where flow-related groundwater effects are possible, it is generally not identified as producing either the highest or lowest anticipated groundwater elevations.

Statistical Summary Tables

Table TA 3-3
Minimum Water Year Elevation (Feet) at Lake Powell

Alternative	Flow Category	Max (feet)	90% (feet)	75% (feet)	50% (feet)	25% (feet)	10% (feet)	Min (feet)
CCS Comparative Baseline	16.0-31.1	3,686	3,680	3,676	3,667	3,643	3,604	3,499
CCS Comparative Baseline	14.0-16.0	3,686	3,675	3,659	3,609	3,560	3,534	3,462
CCS Comparative Baseline	12.0-14.0	3,683	3,649	3,589	3,549	3,508	3,492	3,414
CCS Comparative Baseline	10.0-12.0	3,667	3,573	3,535	3,500	3,478	3,456	3,398

TA 4. Water Deliveries

TA 4.1 Affected Environment

Water from the Colorado River is delivered to entities in the Lower Division States and the United Mexican States (Mexico) for domestic and agricultural use, in accordance with the Law of the River. Colorado River water is also used to serve many purposes in the Upper Colorado River Basin (Upper Basin). The geographic scope of this Environmental Impact Statement (EIS) does not extend above Lake Powell and accordingly does not include an analysis of the impact on Upper Basin water users. With respect to Upper Basin conservation, the nexus to the proposed federal action is the storage and delivery of that conserved water in Lake Powell. The effects of this storage in and delivery from Lake Powell are within the scope of the EIS (see EIS **Chapter 3**, **Section 3.3**, Hydrologic Resources, and **TA 3**, Hydrologic Resources), while specific activities that may be undertaken in the Upper Basin to generate the conserved water are not within the scope of this EIS. Any such activities are unknown at this time and will not necessarily require federal decision making. Any federal decisions associated with these conservation activities will be assessed outside of this EIS.

The Law of the River is an umbrella term for the collection of laws, compacts, decrees, court decisions, contracts, and regulatory guidelines that govern management and operation of the Colorado River. Most notable among these documents are the Colorado River Compact of 1922, the Boulder Canyon Project Act (BCPA), the 1944 United States-Mexico Treaty on Utilization of Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Water Treaty), the 1968 Colorado River Basin Project Act, and the 2006 Consolidated Decree (Reclamation 2016a). Several additions to this collection of documents include the: Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead Final EIS (2007 Final EIS; Reclamation 2007a) and Record of Decision (2007 ROD; Reclamation 2007b), which established the 2007 Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead (2007 Interim Guidelines); Minute 323, Extension of Cooperative Measures and Adoption of a Binational Water Scarcity Contingency Plan in the Colorado River Basin in 2017 (International Boundary and Water Commission 2017); the 2019 Lower Basin Drought Contingency Plan (DCP; Reclamation 2019), the 2024 Glen Canyon Long-Term Experimental and Management Plan Final Supplemental EIS (Reclamation 2016a) and Record of Decision (Reclamation 2016b); and the 2024 Near-term Colorado River Operations Final Supplemental EIS (Reclamation 2024a) and Record of Decision (2024 ROD, Reclamation 2024b). Specific to the Upper Basin, changes include implementation of the 2019 Upper Basin DCP's Drought Response Operating Agreement, which seeks to prevent reaching critically low elevations in Lake Powell while maintaining compliance with the Colorado River Compact. The 2007 Interim Guidelines and 2019 DCP are set to expire at the end of 2026, necessitating the development of new guidelines that are proposed and analyzed in this EIS.

The Colorado River Compact apportions 7.5 million acre-feet (maf) of water per year to the Upper Basin, and 7.5 maf to the Lower Colorado River Basin (Lower Basin), with division of the two basins occurring at Lees Ferry, Arizona. Within each basin, further apportionments are made to individual states and entities. The 2007 Interim Guidelines as modified by the 2024 ROD provide, among other things, guidelines for Normal, Surplus, and Shortage Conditions in the Lower Basin during the interim period through 2026.

This section describes historic water deliveries to entities within the Colorado River Basin (Basin), including apportionments to the Upper and Lower Division States, entitlements, depletion schedules, allotments to Mexico, and distribution of shortages to the Lower Division States. See EIS **Chapter 1**, **Section 1.8** for a description of historical water use across the Upper and Lower Basins.

TA 4.1.1 Apportionments to the Upper Division States

Water is distributed among the Upper Division States by the 1948 Upper Colorado River Basin Compact as a percentage of the total amount available for consumptive use each year after the deduction of Arizona's 50 thousand acre-feet (kaf) apportionment of Upper Basin water. These apportionment percentages are provided in **Table TA 4-1**. The Upper Division State apportionments have not yet been fully developed.

Table TA 4-1
Upper Division States Apportionment

State	Annual Apportionment (Percent)
Colorado	51.75
New Mexico	11.25
Utah	23.00
Wyoming	14.00

Source: Upper Colorado River Basin Compact 1948

TA 4.1.2 Apportionments to the Lower Division States

Water apportionments to the Lower Division States were established by the BCPA and are summarized in **Table TA 4-2**.

Table TA 4-2
Lower Division States Apportionment

State	Annual Apportionment (maf)
Arizona	2.8
California	4.4
Nevada	0.3
Total	**7.5**

Source: U.S. Congress 1928

TA 4.1.3 Water Delivery Entitlements to Entities in the Lower Division States

Rights to use Colorado River water within the Lower Division States, known as entitlements, are established in accordance with the BCPA and the Consolidated Decree. All of the water apportioned to the Lower Division States is allocated in accordance with these documents. For users in the Lower Division States, entitlements arise through (i) a decreed right, (ii) a Section 5 water delivery contract, or (iii) a Secretarial reservation.

According to Section 5 of the BCPA, the Secretary of the Interior (Secretary) is authorized as the contracting authority for the Lower Colorado River, and any user of Colorado River water in the Lower Basin is required to have a contract with the Secretary acting through the Bureau of Reclamation (Reclamation).

The Consolidated Decree lists and quantifies all Present Perfected Rights (PPRs) in the Lower Division States. PPRs are the highest priority Lower Basin mainstream Colorado River water entitlements that were perfected before June 25, 1929. The Consolidated Decree also lists federal reserved water rights for five Indian reservations. PPRs are satisfied first in order of priority in years when less than 7.5 maf of water is available from the Colorado River for consumptive use in the Lower Division States before other entitlements are fulfilled. A summary of the total amounts of water apportioned through PPRs for each of the Lower Division States is provided in **Table TA 4-3**. These entitlements are summarized in terms of both diversion and consumptive use. The return flows used to compute the consumptive use equivalent of diversion entitlements have been estimated from historical data.

Table TA 4-3
PPRs in the Lower Division States

State	Estimated Diversion Entitlement (acre-feet per year (afy))	Estimated Consumptive Use Entitlement (afy)
Arizona	1,077,971	597,811
California	3,019,573	2,801,326
Nevada	13,034	8,698
Total Lower Division States	**4,110,578**	**3,407,835**

Source: Reclamation 2023

The BCPA stipulates that all mainstream Colorado River water delivery contracts in the Lower Basin are for permanent use. Water delivery contracts may describe entitlements as an annual diversion, an annual consumptive use, or both.

A Secretarial reservation is an entitlement established by the Secretary for use at federal facilities or on federal lands. Secretarial reservations have been established for water use on Bureau of Land Management lands, on the Cibola, Imperial, and Havasu National Wildlife Refuges, at Hoover and Davis Dams, and at the Lake Mead National Recreation Area.

Storage & Delivery of Conserved and Non-System Water and Treatment of Pre-2027 Intentionally Created Surplus

As outlined in the 2007 Interim Guidelines, Lower Basin entitlement holders can store conserved water in Lake Mead, provided they have an Intentionally Created Surplus (ICS) exhibit and an approved ICS creation plan. ICS may only be created in a given year via approved conservation actions and a reduction in consumptive use. The ICS created is also subject to constraints as defined in the 2007 ROD (Reclamation 2007b) and the 2019 DCP agreement (Reclamation 2019).

Under the 2007 Interim Guidelines, ICS can be delivered to the Lower Division States when an ICS Surplus Condition is determined. The ICS Surplus Condition is enacted when (i) Lake Mead's January 1 elevation is projected to be above 1,075 feet, (ii) a Flood Control Surplus has not been determined, and (iii) delivery of ICS has been requested by one or multiple of the Lower Division States. The ICS Surplus Condition is enacted concurrent with the Normal operating condition in a given year and differs from other surplus conditions under the 2007 Interim Guidelines as discussed below. The Lower Basin DCP modified ICS delivery provisions, allowing for delivery of ICS below elevation 1,075 feet to elevation 1,025 feet. Beginning in 2027, guidelines regarding the delivery and creation of ICS will change in accordance with the 2007 ROD and Lower Basin DCP to incorporate additional thresholds and repayment timelines.

TA 4.1.4 Lower Division States' Water Supply Determination

As outlined in the Consolidated Decree and Article III of the 1968 Long-Range Operating Criteria, the Secretary determines the water supply condition for the Lower Division on an annual basis. The water supply conditions are:

- Normal Condition: sufficient water is available to satisfy 7.5 maf of consumptive use in the Lower Division States;
- Surplus Condition: sufficient water is available to satisfy an excess of 7.5 maf of consumptive use in the Lower Division States; and
- Shortage Condition: insufficient water is available to satisfy 7.5 maf of consumptive use in the Lower Division States.

The 2007 ROD provides objective criteria used to make annual water supply determinations. The supply condition is annually determined based on the projected elevation of Lake Mead on January 1, as modeled by the prior year's August 24-Month Study (Reclamation 2024c). The guidance provides supply thresholds under which the consumptive use from Lake Mead would be Normal, Surplus, or Shortage Conditions, as well as outlining coordinated reservoir management strategies between Lake Powell and Lake Mead.

Under a Surplus Condition, 46 percent of the surplus water is to be apportioned to Arizona, 50 percent to California, and 4 percent to Nevada, as outlined in the Consolidated Decree. In addition to the Consolidated Decree, the 2007 Interim Guidelines provide guidance regarding when a Surplus Condition should be declared, how surplus water should be distributed by use (e.g., agriculture, domestic, etc.), and recognition of modifications to surplus distributions amongst the states via forbearance agreements. Lake Mead has not operated in a Surplus Condition since the publication of the 2007 ROD.

Table TA 4-4 summarizes historical ICS deliveries for the Lower Division States. Note that states may elect not to request ICS deliveries during an ICS Surplus year, and may also create ICS during that year, hence some of the years under this condition display zero volume delivered.

Table TA 4-4
Lower Basin Annual Historical ICS Deliveries by State

Calendar Year	Operating Condition	ICS Delivered (acre-feet (af))			
		AZ	CA	NV	Total
2008	Normal/ICS Surplus	0	46,976	9,638	56,614
2009	Normal/ICS Surplus	0	0	0	0
2010	Normal/ICS Surplus	0	5,191	0	5,191
2011	Normal/ICS Surplus	0	0	0	0
2012	Normal/ICS Surplus	0	0	1,000	1,000
2013	Normal/ICS Surplus	0	93,857	0	93,857
2014	Normal/ICS Surplus	0	320,992	0	320,992
2015	Normal/ICS Surplus	0	70,756	75,000	145,756
2016	Normal/ICS Surplus	0	0	0	0
2017	Normal/ICS Surplus	0	0	0	0
2018	Normal/ICS Surplus	0	0	0	0
2019	Normal/ICS Surplus	0	0	0	0
2020	Normal/ICS Surplus and DCP Contributions	4,606	0	0	4,606
2021	Normal/ICS Surplus and DCP Contributions	0	18,786	0	18,786
2022	Level 1 Shortage and DCP Contributions	52,841	111,392	0	164,233
2023	Level 2 Shortage and DCP Contributions	1,318	0	0	1,318
2024	Level 1 Shortage and DCP Contributions	8,180	0	0	8,180
2025	Level 1 Shortage and DCP Contributions	0	0	0	0

Source: Reclamation 2024d

Under a Shortage Condition, the Consolidated Decree stipulates that all PPRs must be satisfied first in order of their priority dates before the remaining available water can be allocated consistent with the BCPA and other applicable federal statutes. In total, the annual water supply condition is currently governed by Section 2 of the 2007 Interim Guidelines, Articles III(3)(c) of the Operating Criteria and Article II(B)(3) of the Consolidated Decree, the 2019 Lower Basin DCP, and the 2024 ROD.

Each year, Reclamation develops an Annual Operating Plan for management of reservoirs on the Colorado River. The Annual Operating Plan reports on rules, guidelines, and decisions made for operations in the previous year as well as projected operations for the upcoming year. From 2008 to 2021, Lake Mead operated in an ICS/Surplus Condition, before switching to a Shortage Condition

for the years 2022 through 2025. Additionally, DCP contributions were implemented from 2020 through 2025 (Reclamation 2024d).

TA 4.1.5 Depletion Schedules for Upper Division States

Projected depletions for the Upper Division States were updated in 2017 and adopted in 2022 by the Upper Colorado River Commission. This includes detailed depletion volumes on a decadal basis through 2070 for each of the Upper Division States. Tabular data for these projections through 2060[1] can be found in **Appendix L**, Upper Division States Depletion Schedules**.**

TA 4.1.6 Depletion Schedules for the Lower Division States

Projected mainstream depletions for the Lower Division States can be found in **Appendix M**, Lower Division States Depletion Schedules.

Historical lower Colorado River mainstream consumptive use by state is shown from 2008 to 2025 in **Table TA 4-5**. At the time of this report, the data was only available through 2025. Total annual lower Colorado River mainstream consumptive use has declined on average from 2008 to 2025.

Table TA 4-5
Consumptive Use of Lower Colorado River Mainstream Water by Lower Division States (Annual)

Calendar Year	Arizona (af)	California (af)	Nevada (af)	Lower Division States Total (af)
2008	2,752,497	4,498,810	269,654	7,520,961
2009	2,831,711	4,358,074	248,613	7,438,398

[1] While the UCRC depletion demand schedule is through 2070, the CRSS modeling was only performed through 2060.

TA 4.1.7 Mexico's Allotment

Mexico's allotment of Colorado River water is described under Article 10 of the 1944 Water Treaty. The 1944 Water Treaty guarantees that 1.5 maf will be delivered to Mexico annually. Additionally, it outlines Surplus Conditions such that no greater than 1.7 maf shall be delivered to Mexico in a given year, and Extraordinary Drought such that deliveries are reduced in proportion to reductions of United States (U.S.) consumptive uses. Minute 242 provides guidance for the geographic locations where deliveries from the U.S. will be made, specifically that approximately 1.36 maf will be delivered upstream of Morelos Diversion Dam, with the remainder being delivered downstream of the dam. Subsequent agreements included Minute 319 to the 1944 Water Treaty, which established four coordination mechanisms that affected flows in the International Border Region of the Colorado River. Upon Minute 319's expiration, Minute 323 built upon and extended these provisions by providing operational flexibility, storage options, and binational mechanisms for adjusting deliveries to Mexico under low and high elevation reservoir conditions.

Minute 323 does not change Mexico's allotment, but it does adjust how and under what conditions deliveries occur. Since 2019, the deliveries to Mexico were further adjusted for water savings contributions, as required under Minute 323, and since 2021 for reductions under low elevation reservoir conditions. Minute 323 additionally secures Mexico's ability to create water for or take delivery of Mexico's Water Reserve. Mexico's Water Reserve refers to the volume of Mexico's Colorado River allotment that is intentionally deferred (not taken for immediate use) and stored in Lake Mead for later delivery or recovery. This is in addition to the volumes of Mexico's Recoverable Water Savings, which are deferred during certain low reservoir elevations for recovery at a future time. Deliveries to Mexico were further adjusted in 2024, 2025, and 2026 through additional conserved water by Mexico under Minute 330.

Modeling assumptions have been made to project deliveries to Mexico. These projected deliveries are for analysis purposes only and are not intended to reflect an interpretation or application of the 1944 Water Treaty or to be misconstrued as U.S. policy regarding water deliveries to Mexico. For further information regarding Mexico's allotment and pertinent policy, please refer to **Appendix N**, International Border Region of the Colorado River.

TA 4.1.8 Distribution of Shortages and Reductions to and within the Lower Division States

The 2007 Interim Guidelines, the 2019 DCP and Minute 323 to the 1944 Water Treaty provide for a maximum of 1.375 maf of shortages and reductions (including DCP contributions and BWSCP savings). Beyond these required activities, Reservoir Protection Conservation implemented through the 2024 ROD resulted in additional Lower Basin conservation from 2023 to 2026. The Reservoir Protection Conservation may vary year to year, but is designed to achieve a collective total volume of 3.0 maf. A summary of the 2007 Interim Guidelines Shortages, 2019 DCP contributions, and 2024 ROD conservation is shown in **Table TA 4-6**.

Distribution of Shortages within Arizona

Arizona's 2.8 maf apportionment is allocated via the priority system outlined in **Table TA 4-7**, as presented and analyzed in the 2007 Final EIS. Arizona's priority system is divided into six priorities as displayed in **Table TA 4-7**.

Table TA 4-6
Lower Division States' Total 2007 ROD Shortages, 2019 DCP Contributions, and 2024 ROD Conservation

Lake Mead Elevation (feet)	2007 ROD Shortages + 2019 DCP Contributions (kaf)				2024 ROD Conservation (kaf)*				Total 2007 ROD Shortages + 2019 DCP Contributions + 2024 ROD Conservation (kaf)**			
	AZ	NV	CA	Total	AZ	NV	CA	Total	AZ	NV	CA	Total
1,090 – 1,075	192	8	0	200	280	70	400	750	472	78	400	950
1,075 – 1,050	512	21	0	533					792	91	400	1,283
1,050 – 1,045	592	25	0	617					872	95	400	1,367
1,045 – 1,040	640	27	200	867					920	97	600	1,617
1,040 – 1,035	640	27	250	917					920	97	650	1,667
1,035 – 1,030	640	27	300	967					920	97	700	1,717
1,030 – 1,025	640	27	350	1,017					920	97	750	1,767
<1,025	720	30	350	1,100					1,000	100	750	1,850

Source: Reclamation 2024a
* Actual 2024 ROD conservation by state may vary each year depending on the conservation agreements in place in that year. 2024 ROD conservation shown are approximations and only apply for years 2023 to 2026, such that collectively a total of 3.0 maf of 2024 ROD conservation would occur through 2026.
** The total of 2007 ROD shortages, DCP contributions, 2024 ROD conservation, and any other additional conservation would not exceed 2.083 maf in a given year. These total volumes only apply to 2023 through 2026.

Table TA 4-7
Arizona's Priority System for Mainstream Colorado River Water

Priority	Rights to Be Satisfied
First	PPRs established prior to June 25, 1929
Second[1]	Federal reservations and perfected rights established or effective prior to September 30, 1968
Third[1]	Entitlements pursuant to contracts executed on or before September 30, 1968
Fourth	(1) Entitlements pursuant to contracts, Secretarial reservations, and other arrangements between the U.S. and water users established subsequent to September 30, 1968 (2) Contract for Central Arizona Project
Fifth	Any unused Arizona entitlement
Sixth	Entitlements to surplus water

Source: Reclamation 2024a
[1] The Arizona second and third priorities are coequal in their priority.

Distribution of Shortages within California

California's 4.4 maf apportionment is allocated using a priority system based upon Secretarial regulations which incorporate provisions of the California Seven-Party Agreement of 1931. California's priority system is outlined below in **Table TA 4-8** from the 2007 Final EIS.

Table TA 4-8
California Seven-Party Agreement Priorities for Mainstream Colorado River Water

Priority	Rights to Be Satisfied
First	PPRs established prior to June 25, 1929: Palo Verde Irrigation District for beneficial use upon 104,500 acres
Second	Reclamation's Yuma Project for beneficial use on up to 25,000 acres
Third[1,2]	(a) Imperial Irrigation District and Coachella Valley Water District (b) Palo Verde Irrigation District for use on 16,000 acres on the Lower Palo Verde Mesa
Fourth[3]	Metropolitan Water District and/or the City of Los Angeles and/or others on the coastal plain of Southern California for 550 thousand acre-feet per year (kafy)
Fifth	(a) Metropolitan Water District and/or the City of Los Angeles and/or others on the coastal plain of Southern California for 550 kafy (b) City and/or County of San Diego for 112 kafy
Sixth[4]	(a) Imperial Irrigation District and Coachella Valley Water District (b) Palo Verde Irrigation District for use on Lower Palo Verde Mesa
Seventh	All remaining water available within California for agricultural use

Source: Reclamation 2024a

[1] The total beneficial use of priorities 1, 2, and 3 shall not exceed 3.85 mafy.

[2] Article 4.7 of the Quantification Settlement Agreement by and among Imperial Irrigation District, The Metropolitan Water District of Southern California, and Coachella Valley Water District, dated October 10, 2003, refers to provisions of the Acquisition Agreements and the Allocation Agreement regarding shortage sharing between these two agencies.

[3] The sum of priorities 1 through 4 is 4.4 mafy.

[4] The sum of priority 6 is 300,000 afy.

Distribution of Shortages within Nevada

Nevada's 0.3 maf apportionment is allocated as outlined in **Table TA 4-9** below. The priority system was designed and implemented in 1992 through the contracting of Southern Nevada Water Authority (SNWA) by Reclamation for the balance of Nevada's apportionment.

Table TA 4-9
Nevada's Priority System for Mainstream Colorado River Water

Priority	Rights to Be Satisfied
First	PPRs established prior to June 25, 1929: Fort Mojave Indian Reservation (12,534 afy) Lake Mead National Recreation Area (Diversion = 500 afy or Consumptive Use = 300 afy)
Second	Lake Mead National Recreation Area (1,500 afy, estimated)
Third	Boulder City (5,876 afy)
Fourth	City of Henderson (15,878 afy) Precision Castparts Corporation or Henderson Water Company, LLC (8,208 afy) SNWA (from Basic Water Company) (14,950 afy)
Fifth	Lakeview Company (0 afy) Pacific Coast Building Products (928 afy)
Sixth	Las Vegas Valley Water District (15,407 afy)

Priority	Rights to Be Satisfied
Seventh	U.S. Air Force (delivery from SNWA; 4,000 afy), Boy Scouts (annexed by SNWA; 10 afy), Reclamation (300 afy), and Nevada Department of Wildlife (formerly Nevada Department of Fish and Game; consumptive use 25 afy)
Eighth	Robert B. Griffith Project (308,000 afy) and Big Bend (10,000 afy) SNWA (balance of state apportionment, unused and surplus)

TA 4.2 Environmental Consequences

This section compares water deliveries from the mainstream Colorado River under the No Action Alternative, four action alternatives (as described in **Appendix S**), the Continued Current Strategies (CCS) Comparative Baseline (as described in **Chapter 3**, **Section 3.2.4**), and the Representative Preferred Alternative (as described in **Chapter 2**).

As discussed in **Chapter 2**, the Preferred Alternative is a multi-year decision framework that establishes the process and criteria that would govern development and adoption of operating guidelines through 2036. The decision framework is anticipated to be implemented in two-year operating intervals. Unlike other alternatives, the operating guidelines for each interval are not specified in this Final EIS. The sideboards provide a basis for assumptions included in the Representative Preferred Alternative, which captures the range of operating guidelines that may be adopted during each interval, but exact operations would be subject to the guidelines in place during each interval.

TA 4.2.1 Methodology

This section examines potential effects on water deliveries under the action alternatives as compared to the No Action Alternative and the CCS Comparative Baseline. Potential impacts are considered for the following water delivery resources: shortage volumes, dead pool–related reductions, depletion volumes, and surplus volumes. Also provided is a comparison of Upper Basin conservation across the alternatives.

Reclamation uses the Colorado River Simulation System (CRSS) model for long-term planning studies. CRSS simulates Basin conditions decades into the future (the full analysis period is through 2060) and can be used to account for hydrologic and operational uncertainty. CRSS is a monthly time-step model that produces reservoir elevations, releases, and river flows as outputs. Refer to **Appendix A**, CRSS Model Documentation, for more details related to model documentation.

Additionally, the Shortage Allocation Model(s) (SAM) and Alternative Distribution Model(s) (ADM) were used to analyze potential impacts of the alternatives on individual water users within each Lower Division State under varying levels of shortage. Modeling assumptions for the SAMs and ADMs are summarized in **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation.

Decision Making under Deep Uncertainty (DMDU) is the approach used for quantitative analysis. It is a non-probabilistic evaluation framework that compares alternatives based on their ability to meet

specific performance criteria in many potential future conditions and analyzes how the alternatives respond to specific hydrologic conditions. Additional background and technical details about the DMDU framework are provided in **Appendix E**, DMDU Overview and Approach.

Throughout the analysis, there are three standard figures: conditional boxplots, robustness heatmaps, and vulnerability bar plots. Each type of figure explains key information regarding performance. When taken together, the figures provide a full picture of how the alternatives compare and whether significant negative impacts are reasonably foreseeable under each alternative. The conditional boxplot figures show how the alternatives respond to different categories of preceding hydrology and enable a comparison of alternatives in specific hydrologic conditions (e.g., average conditions or dry conditions). To create these figures, all 34 years (2027–2060) from all 400 simulated futures (13,600 data points per alternative) are separated into five categories based on their preceding 3-year average Lees Ferry natural flow. Robustness heatmaps show the alternatives' ability to meet different levels of performance over one or more decades in the wide range of potential future conditions used in the analysis. Vulnerability bar plots provide complementary analysis to the robustness heatmaps by identifying the specific hydrologic conditions in which each alternative is likely to succeed or fail the preferred minimum performance level. For more information about these figures and detailed interpretation guidance, see **Chapter 3**, **Section 3.2.6**, Decision Making under Deep Uncertainty.

Impact Analysis Area

The geographic scope of the water deliveries analysis is the Colorado River corridor from the upstream limit of full pool elevation of Lake Powell to the downstream limit of the Southerly International Boundary. The geographic scope of this EIS does not extend above Lake Powell and accordingly does not include an analysis of the impact on Upper Basin water users. Although assumptions about Upper Basin conservation are included in various alternatives, no assumptions are made with respect to where conserved water is generated nor about the specific activities that produce it (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water, for more information).

Assumptions

CRSS was used to analyze shortage volumes and Lower Basin water deliveries, and the SAMs and ADMs were used to analyze shortage impacts on specific groups of water users. CRSS also includes assumptions regarding Upper Basin conservation activities but does not make assumptions with respect to conservation by different entities or via specific activities. Refer to their respective appendices for more details related to model assumptions and documentation. All action alternatives except for the Basic Coordination Alternative incorporate mechanisms related to the storage and delivery of conserved water in Lake Powell and/or Lake Mead (see **Chapter 2**, **Section 2.4;** see also **Appendix S**). Unless otherwise specified, impacts reflect modeling assumptions about voluntary conservation behavior.

Impact Indicators

This section discusses impacts on the Lower Division States' water deliveries, deliveries to Mexico, and the distribution of shortages within the Lower Division States. To quantify impacts, the following indicators are used:

- Magnitude of shortage volumes
- Distribution of shortages and depletions among and within the Lower Division States

TA 4.2.2 Issue 1: Apportionments to the Upper Division States

The alternatives would not affect apportionments to the Upper Division States. Therefore, no impact analysis is warranted.

TA 4.2.3 Issue 2: Lower Division States' Apportionments and Water Entitlements

The approaches to distributing shortages incorporated in all alternatives are designed to explore a wide range of potential concepts and impacts; they do not reflect an intention by Reclamation to alter apportionments or water entitlements. However, because the concepts would affect a range of users, impacts on deliveries to different entities are analyzed in Issues 3, 5, and 7, and addressed in **Appendix C,** Shortage Allocation Model and Alternative Distribution Model Documentation.

TA 4.2.4 Issue 3: Lower Division States' Water Supply Determinations

Issue 3 addresses how operational activities affect water deliveries for the Lower Division States and Mexico. It also presents total Basin conservation activity across different alternatives. Impacts will be analyzed through the comparison of the various action alternatives to the No Action Alternative and the CCS Comparative Baseline for the following metrics:

- Annual Lower Basin Reductions (Shortage and Lake Mead Dead Pool–Related Reductions)
- Effects of Modeling Assumptions for Upper Basin and Lower Basin Conservation Activity on Lower Basin Shortages and Deliveries
- Shortage
- Maximum Shortage
- 2027 Shortage Volumes Under Each Set of Initial Conditions
- Annual Lower Basin Shortage
- Annual Shortage by State (Arizona, California, Nevada) and water delivery reductions to Mexico
- Annual Depletions by State (Arizona, California, Nevada) and Mexico
- Surplus

Shortage vs Dead Pool–Related Reductions: Comparison for full Lower Basin

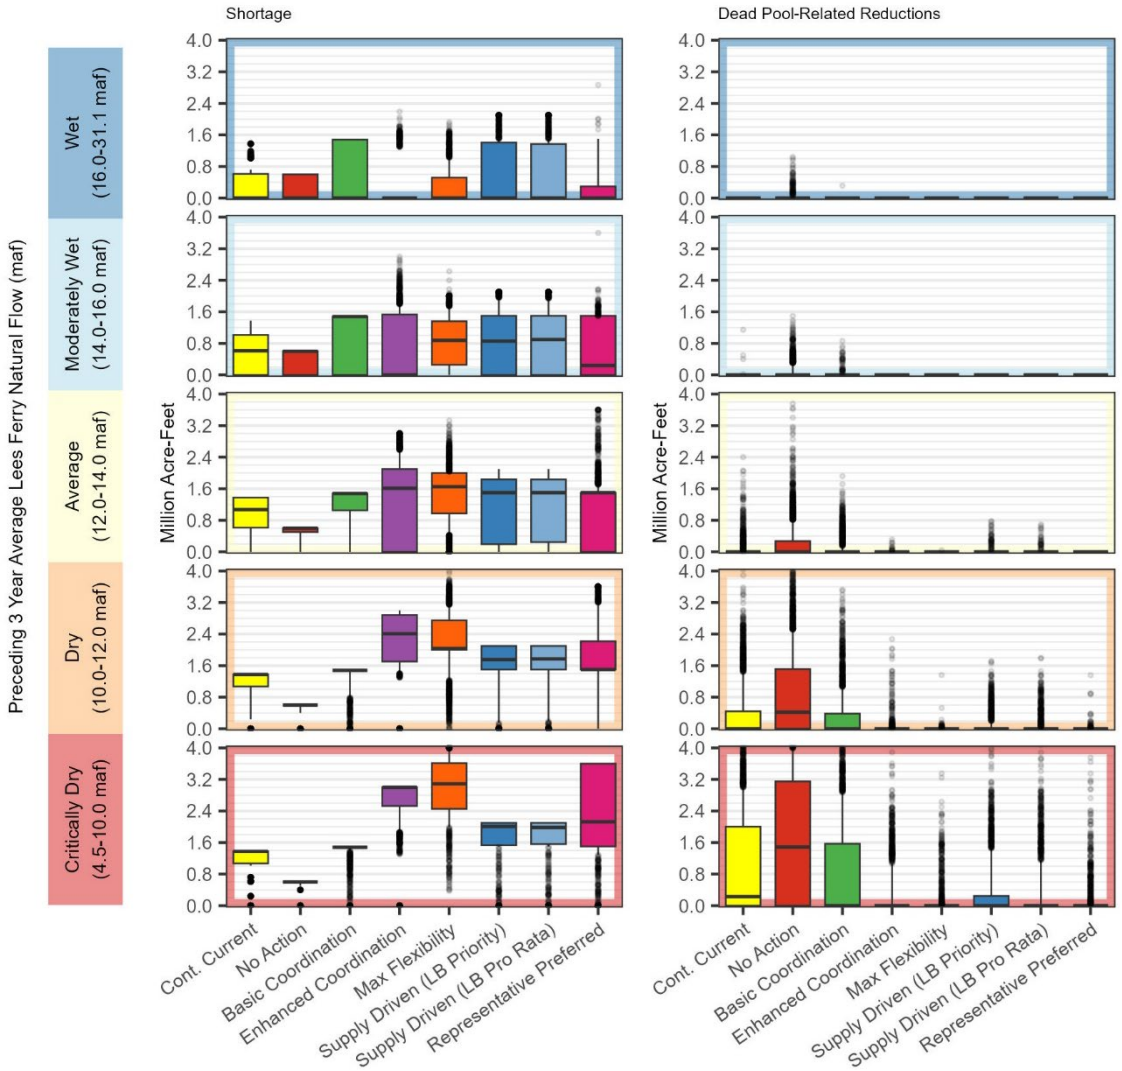
Shortage refers to delivery reductions at the Basin, state, or individual apportionment level that are defined and distributed as part of an alternative's shortage operations. Volumes and distributions of shortage are described in **Chapter 2**. Dead pool–related reductions occur when there is not enough water in Lake Mead to fully meet downstream demands and/or when Hoover Dam infrastructure constraints result in releases below the demand volume. In some cases, these unplanned reductions

occur because Lake Mead is approaching dead pool (elevation 895 feet), and in some cases they occur higher (up to elevation 950 feet).

Note that the approach to distributing unplanned reductions associated with dead pool is not a component of any alternative. It is important for the impact analysis to show that these volumes occur, but it is not appropriate to analyze how they may impact specific states or users. Therefore, shortage results beyond this section will focus on shortage only. Where impacts due to dead pool–related reductions are presented, they will be specifically noted.

Annual Lower Basin Reductions

Figure TA 4-1 shows annual Lower Basin shortages and dead pool–related reductions for each alternative using conditional boxplots. The box plots show how the alternatives perform under varying hydrologic conditions, defined by the preceding three-year average of Lees Ferry natural flow. The bottom and top of each box capture the 25th to 75th percentile of the modeled results, respectively. The lines extend to the 10th and 90th percentiles, and outliers are shown as dots. To enable easier comparison of all flow categories, the vertical axes have been truncated at the high end, and some outliers in the Critically Dry Flow Category have been omitted. Statistical summaries of the left and right columns are provided in **Table TA 4-10** and **Table TA 4-11** at the end of this technical appendix.



Generally, lower maximum volumes of shortages correspond to higher frequency and larger volumes of dead pool–related reductions, seen most prominently in the No Action Alternative. Dead pool–related reductions occur when there is not enough water in Lake Mead to fully meet downstream demands and/or when Hoover Dam infrastructure constraints result in releases below the demand volume. In the Average Flow Category, the medians and interquartile ranges for shortage involve reductions of 2.1 maf or less. The Maximum Operational Flexibility Alternative has the highest median shortage at 1.7 maf. The Enhanced Coordination Alternative has a median shortage of 1.6 maf and has the largest interquartile range of shortages. The remaining action alternatives have less variability (smaller interquartile ranges) but similar medians; all action alternative medians are higher than the CCS Comparative Baseline (1.1 maf) and the No Action Alternative (0.6 maf).

In the Average Flow Category, all action alternatives except for the Basic Coordination Alternative have infrequent dead pool–related reductions: only the outlier years, if any at all, and the largest volume is 0.8 maf. The Basic Coordination Alternative has greater maximum dead pool–related reductions of 1.9 maf, similar to the 2.4 maf for the CCS Comparative Baseline. The No Action Alternative has the most frequent and highest magnitude dead pool–related reductions, with a maximum value of 3.8 maf in the Average Flow Category.

The greatest contrast between alternatives occurs in the Critically Dry Flow Category. All action alternatives except for the Basic Coordination Alternative show increases in median shortage reductions compared to their respective medians in the Average Flow Category, with the Enhanced Coordination Alternative and Maximum Operational Flexibility Alternative reaching median shortages of 3.0 maf and 3.1 maf, respectively. The No Action Alternative has the lowest median shortage among all alternatives, and the Basic Coordination Alternative has the second lowest median shortage at 1.5 maf. These two alternatives have minimal variability because they are almost

always at their maximum shortages, but this leads to much larger medians and variability in dead pool-related reductions than other alternatives.

Figure TA 4-1
Annual Lower Basin Reductions

Note: Shortage and dead pool-related reduction volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the International Boundary and Water Commission (IBWC) in consultation with the Department of State.

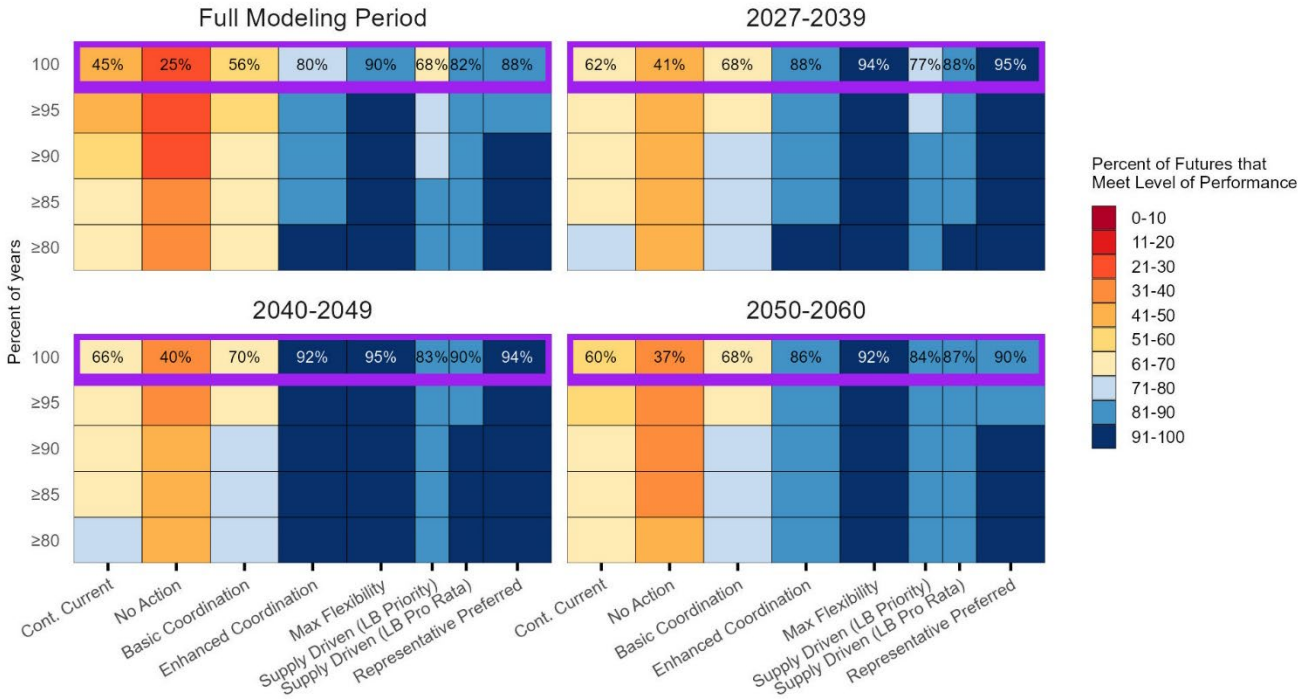
While dead pool–related reductions increase across all alternatives as the flow categories become drier, these reductions only occur above the 50th percentile (i.e., in less than 50 percent of years) for all action alternatives in the Critically Dry Flow Category. While shortages under the Basic Coordination Alternative remain low (not exceeding 1.5 maf), this alternative results in a larger percentage of futures with dead pool–related reductions from Lake Mead as it is compared to other

action alternatives. In the Critically Dry Flow Category, all action alternatives have lower dead pool–related reductions than the CCS Comparative Baseline and the No Action Alternative.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median shortage is 1.5 maf, and there is variability within the interquartile range, especially comparing the 75th percentile volume of 2.2 maf to the median. The median dead pool-related reduction is 0.0 maf, and only outlier years exhibit any dead pool-related reductions, with a maximum of 1.4 maf.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median shortage is 2.1 maf, and the interquartile range is large (25th and 75th percentile of 1.5 and 3.6 maf, respectively). The median dead pool-related reductions are 0.0 maf, and 10 percent of years exhibit dead pool-related reductions with a maximum of 3.8 maf. (Note that the 2027-2028 Operating Guidelines specify a maximum shortage of 1.5 maf, and consultations triggered by critical elevations at Lake Mead would be undertaken before larger volumes of shortage could occur during that term.)

Lake Mead Dead Pool-Related Reductions



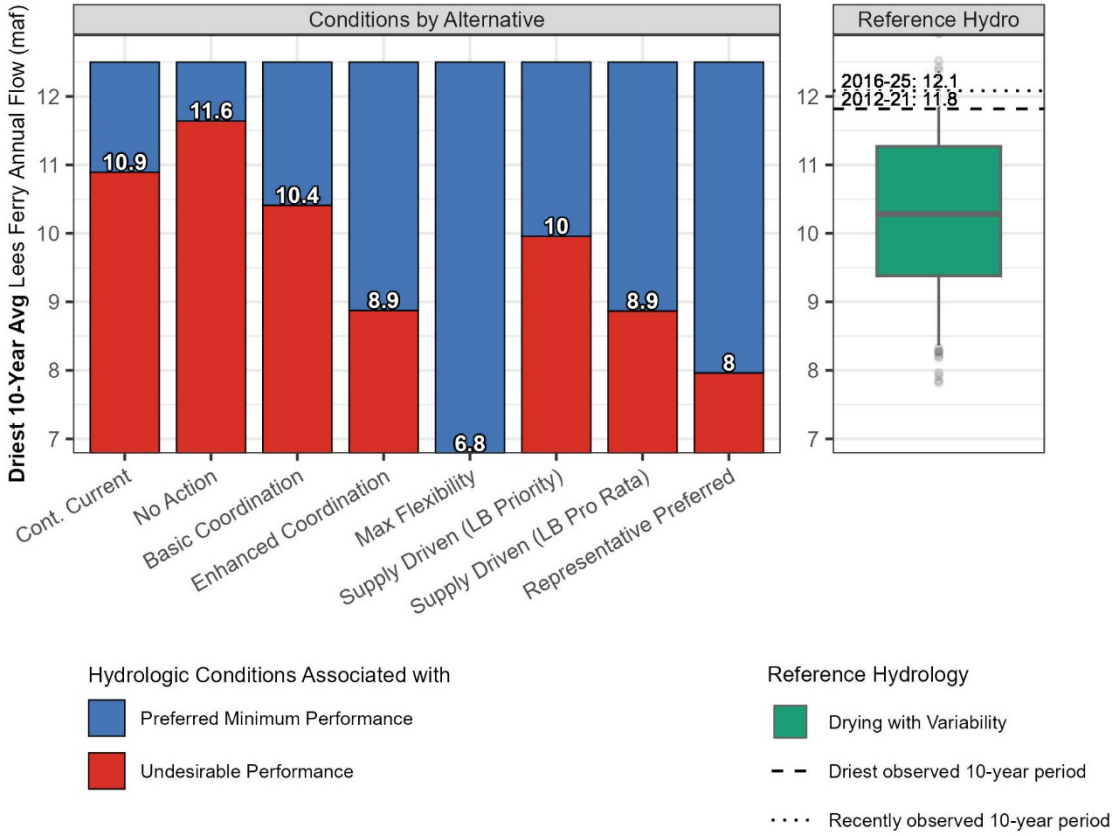
Lake Mead Dead Pool-Related Reductions Robustness

Figure TA 4-2 below depicts the ability of each alternative (columns) to avoid dead pool–related reductions at Lake Mead in the specified percent of years (rows). Four modeling periods are shown to capture the full modeling period, 2027-2039, 2040-2049, and 2050-2060. The preferred minimum performance is shown in the purple highlighted row, which represents the percentage of futures that an alternative avoids dead pool–related reductions in 100 percent of years.

Over the full modeling period, the Maximum Operational Flexibility Alternative is the most robust, avoiding any dead pool-related reductions in 90 percent of the futures, followed by the Representative Preferred Alternative and Supply Driven (Lower Basin Pro Rata [LB Pro Rata] approach) Alternatives, which avoid dead pool-related reductions in 88 and 82 percent of the futures, respectively. The Enhanced Coordination Alternative avoids dead pool-related reductions in 80 percent of modeled futures. All four of these action alternatives, as well as the Supply Driven Alternative (Lower Basin Priority [LB Priority] approach), are more robust than the Basic Coordination Alternative and the CCS Comparative Baseline, which avoid dead pool-related reductions in 56 percent and 45 percent of futures, respectively. The No Action Alternative is the least robust, avoiding dead pool-related reductions in only 25 percent of futures.

Based on the planned length of this decision, it is important to compare robustness in the 2027-2039 modeling period. The Representative Preferred and Maximum Operational Flexibility Alternatives are the most robust, meeting the preferred minimum performance level in 95 and 94 percent of futures, respectively. The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives both meet the preferred minimum performance level in 88 percent of futures, and the Supply Driven Alternative (LB Priority approach) meets this performance level in 77 percent of futures. The No Action and Basic Coordination Alternatives and the CCS Comparative Baseline are less robust, meeting the preferred minimum performance level in 41, 68, and 62 percent of futures, respectively.

Figure TA 4-2
Lake Mead Dead Pool-Related Reductions: Robustness
Percent of futures in which dead pool-related reductions are avoided in the percent of years specified by each row



Note: Dead pool-related reduction volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Lake Mead Dead Pool-Related Reductions Vulnerability

Figure TA 4-3 below shows what flow conditions are likely to cause dead pool–related reductions from Lake Mead in any year. This definition of undesirable performance is based on the highlighted row in **Figure TA 4-2** above, which defined a future as successful when an alternative avoided dead pool–related reductions 100 percent of the time.

For this vulnerability analysis, the driest 10-year average Lees Ferry annual flow was determined to be skillful at predicting undesirable performance. The vulnerability threshold for each alternative is described and compared to the observed record and the Drying with Variability Ensemble using this streamflow summary statistic. The driest observed 10-year average flow from 2012-2021 (11.8 maf) and the average flow from 2016-2025 (12.1 maf) are also provided as dashed and dotted lines, respectively, for comparison.

Figure TA 4-3
Lake Mead Dead Pool–Related Reductions: Vulnerability.
Conditions that could cause Lake Mead Dead Pool–Related Reductions in Any Year

Note: Dead pool-related reduction volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

The Basic Coordination Alternative would likely be vulnerable to dead pool-related reductions under a 10-year average Lees Ferry natural flow of 10.4 maf or drier, which is slightly less vulnerable than the CCS Comparative Baseline, which is likely to be vulnerable if the 10-year average is 10.9 maf or drier. The No Action Alternative is vulnerable to a 10-year average of 11.6 maf, which is similar to the driest observed 10-year average of 11.8 maf. The Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are not likely to be vulnerable to undesirable performance unless the 10-year average flow is much drier than any observed conditions, and fewer than 50 percent of the traces in the Drying with Variability ensemble include conditions that would be likely to cause vulnerability in these alternatives. Modeling indicates that the Representative Preferred Alternative would likely be vulnerable to at least one occurrence of dead pool-related reductions under a 10-year average flow of 8.0 maf. This alternative is not likely to be vulnerable in the next 10 years because these conditions

have not been observed and they occur in fewer than 10 percent of traces in the Drying with Variability Ensemble, which represents how hydrologic conditions may change in a warmer future.

Conservation Activity

All action alternatives except for the Basic Coordination Alternative incorporate mechanisms related to the storage and delivery of conserved water in Lake Powell and Lake Mead. **Table TA 4-12** below summarizes the various conservation mechanisms for each action alternative. Refer to **Chapter 2** and **Appendix S** for specifics related to each alternative's policy on conservation.

For modeling purposes, assumptions about conservation and delivery of pre-2027 conserved water were developed to show the maximum impacts of the conservation pools on reservoir elevations and downstream flows; they are not intended to represent specific activities or constraints on individual users. See **Chapter 2** and **Appendix S** of the EIS for more information about the assumptions for each alternative. Upper Basin conservation activity is discussed in Issue 6, below.

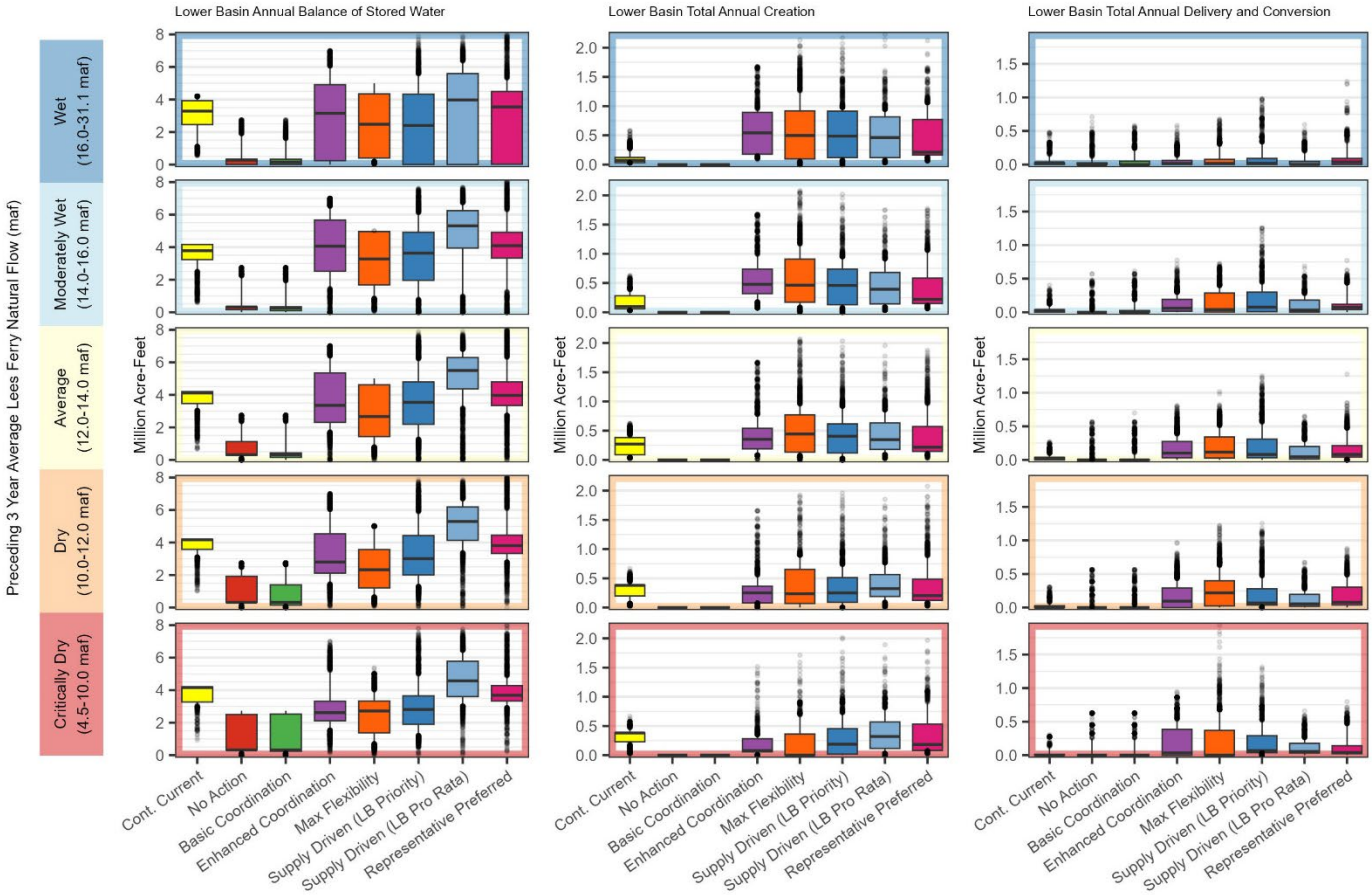


Table TA 4-12
Summary of Conservation Mechanisms by Alternative

Alternative	Conservation Pool Volume	Conservation Pool Mechanism
CCS Comparative Baseline	0.5 maf	Upper Basin pool in Lake Powell
	4.2 maf	Lower Basin pool in Lake Mead
No Action		No new mechanism; delivery of pre-2027 conservation only
Basic Coordination		No new mechanism; delivery of pre-2027 conservation only
Enhanced Coordination	2 maf	Upper Basin pool in Lake Powell
	5 maf	Lower Basin pool in Lake Mead
	2 maf	Protection Pool in Lake Mead
Maximum Operational Flexibility	5 maf	Upper Basin pool (distributed strategically across Lake Powell and Lake Mead)
	3 maf	Lower Basin pool (distributed strategically across Lake Powell and Lake Mead)
Supply Driven (both LB Priority and LB Pro Rata approaches)	3 maf	Upper Basin pool in Lake Powell
	8 maf	Lower Basin pool in Lake Mead
Representative Preferred	3 maf	Upper Basin pool in Lake Powell
	7 maf	Lower Basin pool in Lake Mead
	1 maf	Federally Managed Water Resources Pool in Lake Mead

Lower Basin Conservation Activity

Figure TA 4-4 shows three components of Lower Basin conservation activity for each alternative[2] using three columns of conditional boxplots. The first column shows the annual balance of stored water, which includes any conserved water retained in system reservoirs from prior years. The second column shows total annual creation, which represents new conservation generated each year. The third column shows total annual delivery and conversion, which represents the use of previously conserved water to meet authorized operational purposes. Statistical summaries of the data shown in **Figure TA 4-4** are provided in **Table TA 4-13** through **Table TA 4-15** at the end of this technical appendix.

Figure TA 4-4
Annual Lower Basin Conservation Activity

Note: Lower Basin conservation activity includes assumptions related to the storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

[2] For all alternatives except the Maximum Operational Flexibility Alternative, Lower Basin conserved water is only stored in Lake Mead. For the Maximum Operational Flexibility Alternative, this water can be stored in Lake Mead, Lake Powell, or both.

In the Average Flow Category, the Supply Driven (LB Pro Rata approach) Alternative has the highest median balance of stored water at 5.5 maf (left column). The Supply Driven Alternative (LB Priority approach) has the same size pool, but a lower median balance of 3.5 maf due to different assumptions about shortage distribution and conservation activity among Lower Basin water users. The CCS Comparative Baseline has a higher median balance than the Enhanced Coordination and Maximum Operational Flexibility Alternatives, but the ranges of the banks in those two action alternatives are larger because they have larger pools. The No Action and Basic Coordination Alternatives have small balances of stored water because they do not include new conservation mechanisms and the balances only reflect pre-2027 conservation. The Representative Preferred Alternative has a similar median to the CCS Comparative Baseline, 4.0 maf and 4.1 maf, respectively, but more variability due to a larger-sized bank.

In the Dry and Critically Dry Flow Categories, the relative rankings of median balances are similar to those in the Average Flow Category, but balances decrease because annual creation volumes (middle column) decrease as conditions get drier. Conversion and delivery volumes (right column) increase between the Average and Dry Flow Categories, but stay the same or decrease in the Critically Dry Flow Category due to lower available stored water and/or low Lake Mead elevations that preclude delivery or conversion.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median annual balance of stored water is 3.8 maf, and there is relatively low variability within the interquartile range: the 75th percentile balance is 4.5 maf, and the 25th percentile balance is 3.3 maf. The median volume of annual creation is 0.2 maf, and the median volume of annual delivery and conversion is 0.1 maf.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median annual balance of stored water is 3.7 maf, and there is relatively low variability within the interquartile range: the 75th percentile balance is 4.3 maf, and the 25th percentile balance is 3.3 maf. The median volume of annual creation is 0.2 maf, and the median volume of annual delivery and conversion is 0.0 maf.

Effects of Modeling Assumptions for Total Basin Conservation Activity on Lower Basin Shortages and Deliveries

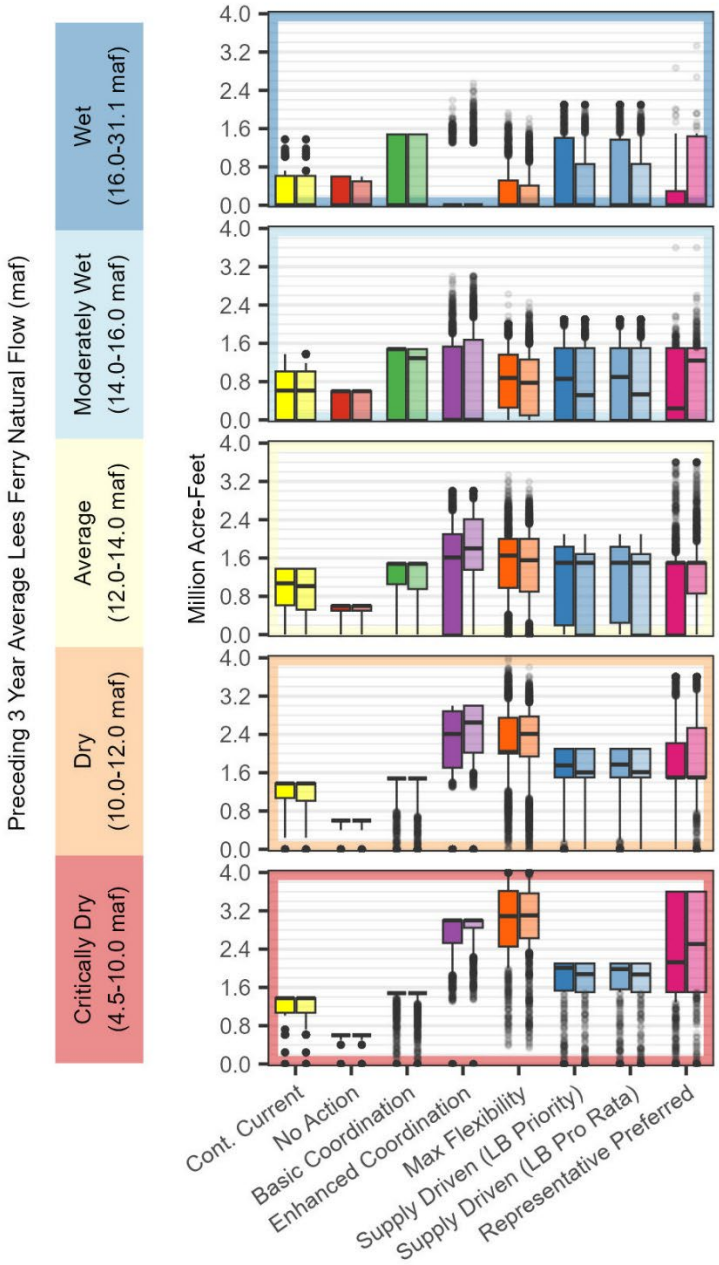
The following section evaluates how modeling assumptions about conservation activities (which are different for each alternative) affect Lower Basin shortages and depletions by comparing scenarios with all conservation activities removed to those that include conservation activities. While the No Action and Basic Coordination Alternatives do not include mechanisms to conserve and store water in Lake Powell or Lake Mead, the alternatives do include assumptions for the delivery of existing ICS that was conserved prior to 2027. In the conservation-off results, activity related to pre-2027 conservation is turned off for all the alternatives and the CCS Comparative Baseline.

For the purposes of this technical appendix, the analysis for each figure comparing the effects of conservation activities will provide context for the subsequent figures; it will not synthesize the implications of different conservation mechanisms across resources.

Shortage

Figure TA 4-5 shows the effects of conservation activity on annual Lower Basin shortages using paired boxplots. For each alternative, conservation activity is turned on for the left of each pair (darker color) and conservation activity is turned off for the right of each pair (lighter color). Unless otherwise specified, all analyses in this EIS have conservation activity turned on. A statistical summary of the data shown in **Figure TA 4-5** is provided in **Table TA 4-16** at the end of this technical appendix.

For all alternatives and the CCS Comparative Baseline, and across the Average, Dry, and Critically Dry Flow Categories, the median shortages are generally similar when comparing results with conservation activity on and conservation activity off. In other words, modeled conservation activity does not greatly impact the median shortage. However, conservation activity does have a variety of effects on overall variability of shortage for the different action alternatives that include conservation mechanisms. The analysis below is organized by alternative. The minimal differences in the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives are not described.



In the Enhanced Coordination Alternative, turning off conservation activity slightly increases shortage volumes in most percentiles in the Average, Dry, and Critically Dry Flow Categories. This is because conservation is not operationally neutral when determining shortages, so lower overall combined storage in Lake Powell and Lake Mead increases shortage volumes.

In the Average Flow Category, turning off conservation activity for the Maximum Operational Flexibility Alternative results in slightly lower shortages at the 25th and 10th percentiles. Similarly to the dynamics in the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), an operationally neutral conservation mechanism does not impact shortage determinations, but without conservation conversion or delivery to offset shortages, the shortages have a more positive impact on storage, which drives shortages along with hydrologic conditions. The relationship between conservation activity on versus off is different in the Dry and Critically Dry Flow Categories, with complex dynamics related to total system storage, hydrologic conditions, and changes in available conserved water impacting the comparisons of shortage with and without conservation activity. In the Critically Dry Flow Category, median shortage is nearly identical with slightly more variability if conservation activity is turned on.

The Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) shows the same impacts of conservation activity on versus off. In the Average Flow Category, shortage is slightly lower at the 75th, 25th, and 10th percentiles with conservation turned off because, without the operationally neutral conservation that can be used to partially offset shortages, shortage volumes are actual delivery reductions and therefore have a more positive impact on Lake Mead elevation, which is the driver of shortage. This also explains the small differences in median shortages in the Dry and Critically Dry Flow Categories.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median shortage with conservation on and off is 1.5 maf. The interquartile range is large whether conservation activity is on or off due to the differences between the median and 75th percentiles. This range is slightly smaller with conservation on: the 25th and 75th percentiles of shortage are 1.5 maf and 2.2 maf, respectively, with conservation on and 1.5 maf and 2.5 maf, respectively, with conservation off.

Figure TA 4-5
Effects of Conservation Activity Modeling Assumptions on Lower Basin Shortage
(Conservation On: Darker Shade, Left; Conservation Off: Lighter Shade, Right)

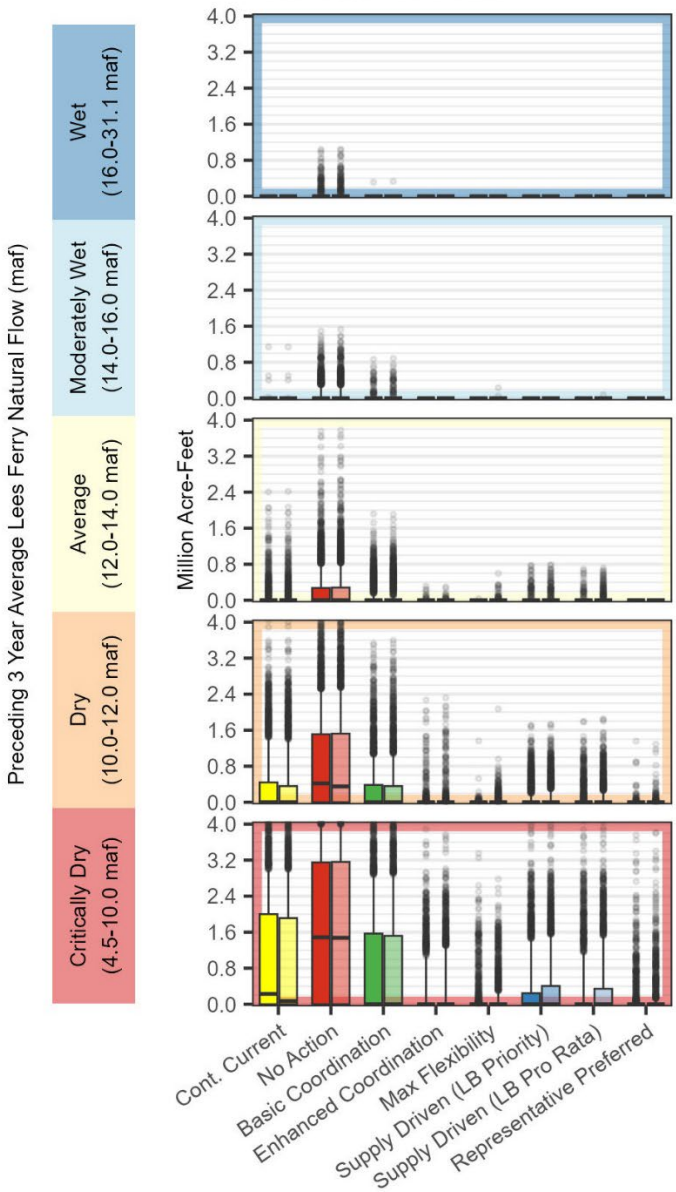
Note: Shortage volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median shortage with conservation on is 2.1 maf and 2.5 maf with conservation off. The interquartile range is large whether conservation activity is on or off: the 25th and 75th percentiles of shortage are 1.5 maf and 3.6 maf, respectively, with conservation on and 1.5 maf and 3.6 maf, respectively, with conservation off.

Dead Pool-Related Reductions

Figure TA 4-6 shows the effects of conservation activity on annual Lake Mead dead pool-related reductions using paired boxplots. For each alternative, conservation activity is turned on for the left of each pair (darker color) and conservation activity is turned off for the right of each pair (lighter color). Unless otherwise specified, all analyses in this EIS have conservation activity turned on. A statistical summary of the data shown in **Figure TA 4-6** is provided in **Table TA 4-17** at the end of this technical appendix.

Across flow categories, the CCS Comparative Baseline, No Action, Basic Coordination, Enhanced Coordination, and Representative Preferred Alternatives are minimally affected by conservation activity. The discussion for **Figure TA 4-6** will focus on the Maximum Operational Flexibility Alternative and the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches).



In the Average Flow Category, only the Maximum Operational Flexibility Alternative is notably affected by turning conservation activity off; instead of only one year having minimal dead pool-related reductions, turning off conservation activity results in a larger number of years with the reductions and a maximum volume of 0.6 maf. These outlier volumes are lower than the dead pool-related reductions seen in the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), which do not show significant impacts related to conservation activity assumptions.

In the Dry Flow Category, the Maximum Operational Flexibility Alternative shows a large increase in the number of years with dead pool-related reductions when conservation activity is removed, and the maximum volume is 2.1 maf compared to 1.4 maf with conservation activity turned on. The conservation activity does not make a significant impact on the Supply Driven Alternative (LB Priority approach), but there is some impact in the Supply Driven Alternative (LB Pro Rata approach): the median dead pool-related reductions in this alternative are 0.0 maf in both cases, but the 90th percentile of years with conservation activity removed is 0.3 maf, compared with 0.0 maf with conservation activity turned on.

The differences for all three alternatives are largest in the Critically Dry Flow Category. For the Maximum Operational Flexibility, while median dead pool-related reductions are 0.0 maf and there are many non-zero outlier years both with and without conservation activity, the 90th percentile of years with conservation activity turned off is 0.3 maf. The Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) both show significant effects when conservation activity is turned off, but the difference is larger in the Supply Driven Alternative (LB Pro Rata approach), especially comparing 75th percentiles: with conservation activity on, the 75th percentile is 0.0 maf and with conservation activity removed, the 75th percentile is 0.3 maf.

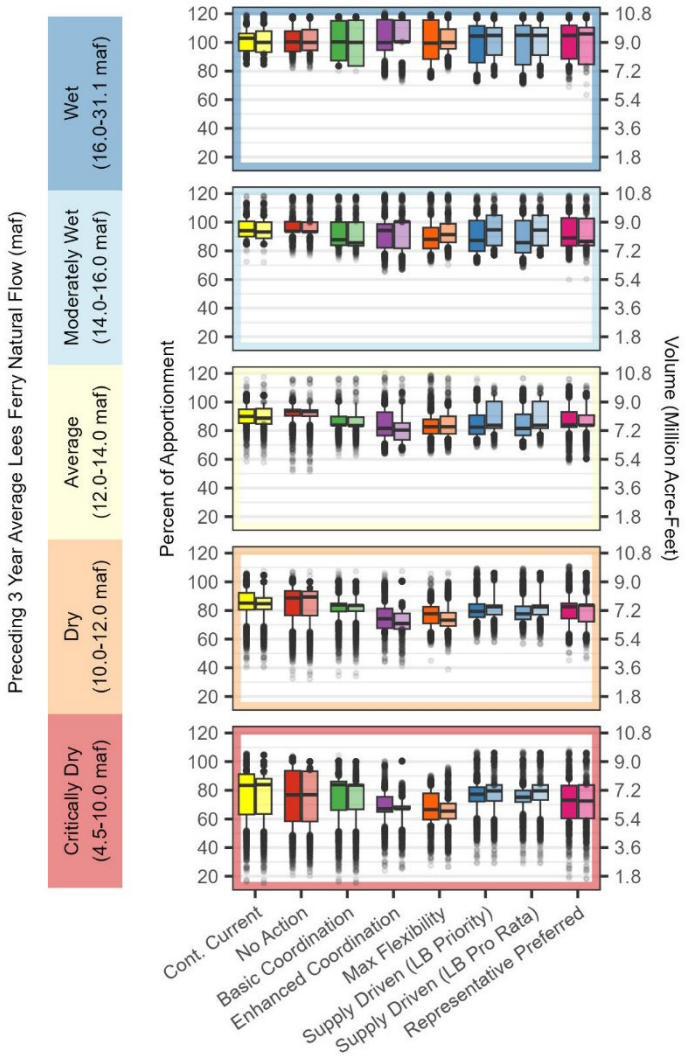
Figure TA 4-6
Effects of Conservation Activity Modeling Assumptions on Lake Mead Dead Pool-Related Reductions

(Conservation On: Darker Shade, Left; Conservation Off: Lighter Shade, Right)

Note: Lower Basin conservation activity includes assumptions related to the storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Depletions

Figure TA 4-7 shows the effects of conservation activity on annual Lower Basin depletions using paired boxplots. The right-hand vertical axis shows depletions as the percent of apportionment and the left-hand axis shows volume. Results will be described using percent of apportionment. For each alternative, conservation activity is turned on for the left of each pair (darker color) and conservation activity is turned off for the right of each pair (lighter color). Unless otherwise specified, all analyses in this EIS have conservation activity turned on. A statistical summary of the data shown in **Figure TA 4-7** is provided in **Table TA 4-18** at the end of this technical appendix.



For all alternatives and the CCS Comparative Baseline, and across the Average, Dry and Critically Dry Flow Categories, the median depletions are similar when comparing results with conservation activity on and conservation activity off (no changes greater than 5 percent of apportionment). In other words, conservation activity does not greatly impact the median depletions. However, conservation activity does have a variety of effects on overall variability of depletions for the different action alternatives that include conservation mechanisms. The analysis below is organized by alternative. The minimal differences in the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives are not described.

Under the Enhanced Coordination Alternative, in the Average Flow Category, the median depletions with conservation activity on are 81.6 percent of apportionment and with conservation activity off, they are 80.4 percent of apportionment. While median depletions are similar with and without conservation activity, depletions are moderately to significantly lower in the Average, Dry, and Critically Dry Flow Categories when conservation is turned off. This occurs because the conservation mechanism is not operationally neutral with respect to Lower Basin shortage determinations, and without conserved water to increase reservoir elevations, shortages are higher, and depletions are lower.

In the Average Flow Category, the median depletions under the Maximum Operational Flexibility Alternative are 82.8 percent of apportionment with conservation activity on and 82.7 percent of apportionment and with conservation activity off. Overall, depletions are slightly higher with conservation activity turned on, but depletions are moderately lower without conservation activity in the Dry and Critically Dry Flow Categories. In the two drier flow categories, the absence of the ability to offset shortages by delivering conserved water reduces overall depletions.

Depletions under the two Supply Driven Alternative approaches respond similarly to conservation activity on versus off: in the Average Flow Category, Supply Driven Alternative (LB Priority approach) median depletions with conservation activity on and off are 82.4 and 83.7 percent of apportionment and the median depletions for Supply Driven Alternative (LB Pro Rata approach) are 81.6 and 83.7 percent of apportionment, respectively, with conservation activity turned on and off. The 25th percentile of depletions is higher with no conservation activity and in the 75th percentile depletions are 10 percent higher in the Average Flow Category. In this flow category, shortages are similar with conservation on and off (see **Figure TA 4-5**) but without conservation, depletions are higher. In the Dry and Critically Dry Flow Categories, the differences in depletions with conservation on and off are smaller because of higher shortages and, in the conservation-on results, limited opportunity to conserve water while there is more delivery of previously conserved water.

Figure TA 4-7
Effects of Conservation Activity Modeling Assumptions on Lower Basin Depletions (Conservation On: Darker Shade, Left, Conservation Off: Lighter Shade, Right)

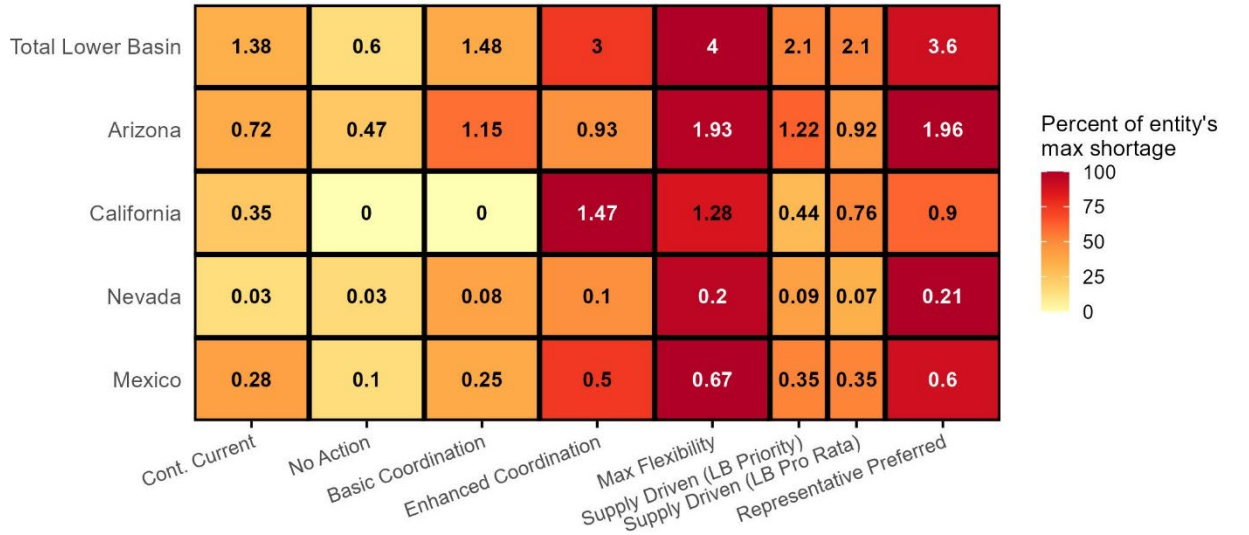
Note: The modeled annual Lower Basin depletions include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median depletion with conservation on is 82.6 percent of apportionment and 83.7 percent of apportionment with conservation off. The interquartile range is relatively large whether conservation activity is on or off due to the differences between the median and 25th percentiles; the 25th and 75th percentiles of depletions are 74.4 and 85.0 percent, respectively, with conservation on, and 72.2 and 83.7 percent, respectively, with conservation off.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median depletion with conservation on is 73.1 percent of apportionment and 72.5 percent of apportionment with conservation off. The interquartile range is relatively large whether conservation activity is on or off; the 25th and 75th percentiles of depletions are 60.4 and 83.3 percent, respectively, with conservation on, and 60.4 and 83.7 percent, respectively, with conservation off.

Shortage

This section compares all the alternatives and the CCS Comparative Baseline with respect to shortages to each of the Lower Division States and Mexico.



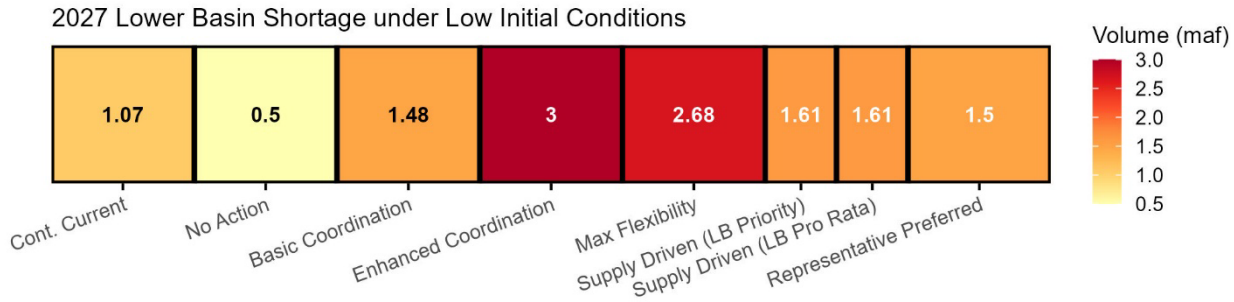
Maximum Shortage

Figure TA 4-8 compares alternatives based on the maximum shortage volume applied to the total Lower Basin and to each state and Mexico. The rows correspond to the entire Lower Basin (top row) and to different states or Mexico, and the columns correspond to different alternatives. Under each alternative, the shortages per state and Mexico sum to the total Lower Basin shortage shown in the top row[3]. Because the alternatives have different maximum volumes and also different distributions of shortage, each row has an independent color scale to facilitate identifying the maximum shortage to each entity: the darkest color in each row identifies the alternative that produces the maximum shortage for that entity. Under the CCS Comparative Baseline, DCP contributions and Binational Water Scarcity Contingency Plan savings are counted as shortages, though the required volumes are recoverable under certain conditions.

For all entities except California, either the Maximum Operational Flexibility Alternative or Representative Preferred Alternative imposes the largest maximum shortages. (Note that, as demonstrated by the 2027-2028 Operating Guidelines, the distribution of shortage under any specific operating guidelines adopted under the Preferred Alternative decision framework may differ from the priority distribution method reflected here for the Representative Preferred Alternative.) The Enhanced Coordination Alternative is highest for California. For all entities, the No Action Alternative imposes the lowest (or is tied for lowest in Nevada and California) maximum shortage. California takes its largest shortage under the Enhanced Coordination Alternative, due to its pro rata approach to shortage distribution and large total shortage volumes.

[3] The sum of individual entities' volumes is different than the Total Lower Basin volumes for the Maximum Operational Flexibility and Representative Preferred Alternatives due to rounding values to two decimal places. The Total Lower Basin volume is correct.

Figure TA 4-8
Maximum Shortage (maf)



Note: Lower Basin shortage volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

First Year Shortage

Figure TA 4-9 compares each alternative's 2027 Lower Basin shortage volume based on the modeled initial reservoir conditions. The color scale represents volume of shortage; darker colors correspond to the higher shortages.

Figure TA 4-9
Lower Basin Shortage in 2027

Note: Lower Basin shortage volumes include modeling assumptions for reductions in water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

In 2027, the largest Lower Basin shortages would be imposed by the Enhanced Coordination Alternative, while the No Action Alternative would impose the lowest shortages. The Representative Preferred Alternative would impose 1.5 maf of shortage.

Annual Lower Basin Shortage

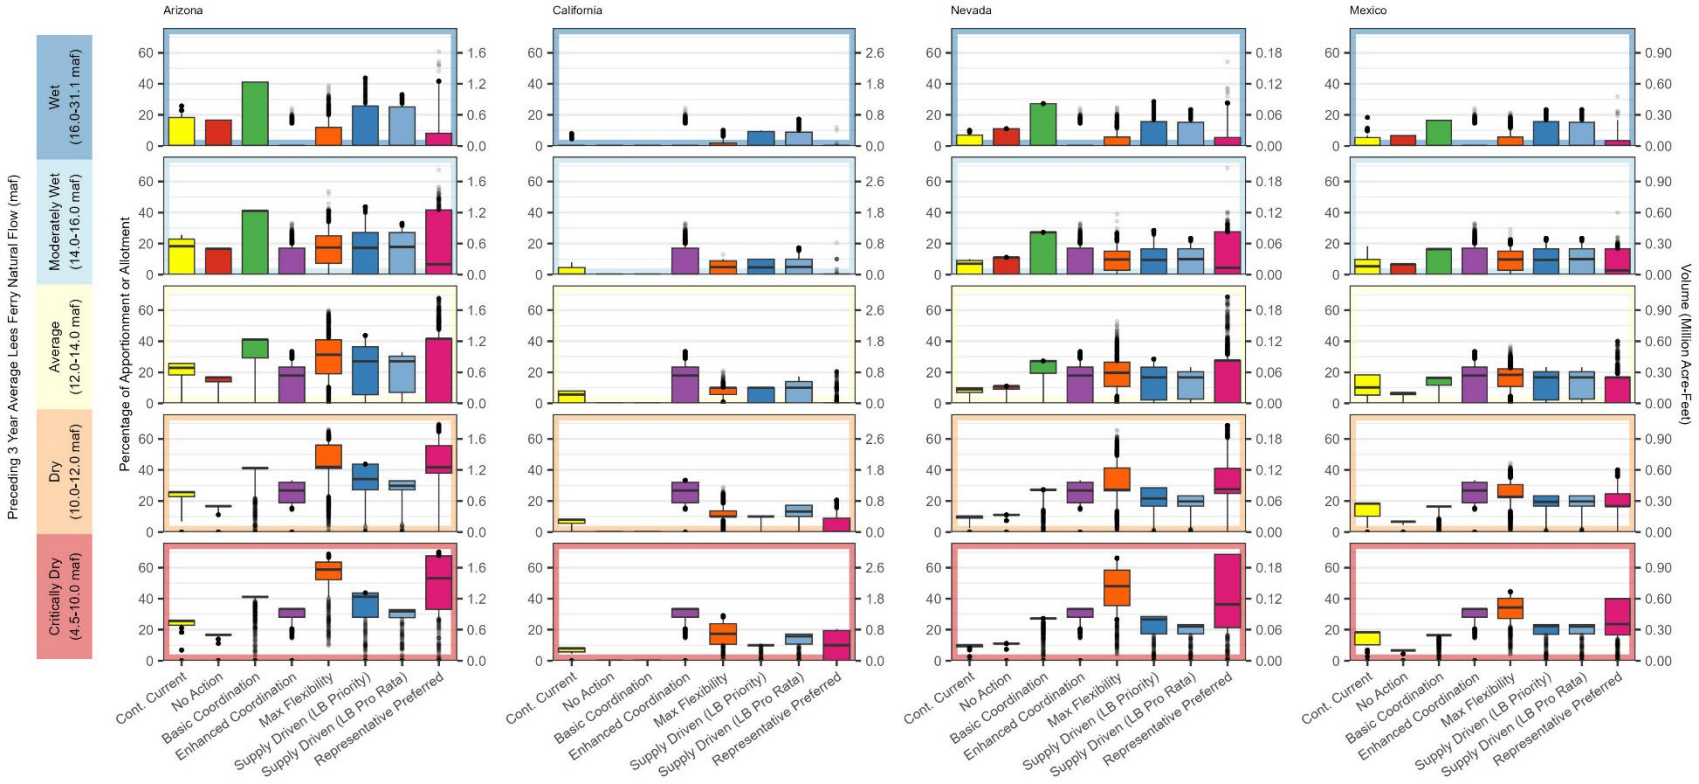


Figure TA 4-10 shows shortages to each Lower Division State and Mexico using four columns of conditional boxplots. The vertical axis for each state's column is scaled based on its respective volume of apportionment or allotment; the percent apportionment is shown on the left side of each column, and the absolute volume of shortage is shown on the right. Results will be described using percent of apportionment. Statistical summaries of the data shown in **Figure TA 4-10** are provided in **Table TA 4-19**, **Table TA 4-23**, **Table TA 4-29**, and **Table TA 4-37** at the end of this technical appendix.

Arizona, Nevada, and Mexico show similar relationships between alternatives across flow categories and are described together. In the Average Flow Category, the CCS Comparative Baseline and the No Action Alternative generally have the lowest median shortages, between 6.7 percent of allotment (Mexico, No Action Alternative) to 22.9 percent of apportionment (Arizona, CCS Comparative Baseline). These alternatives also show relatively low variability from the 25th to 75th percentiles, except for CCS Comparative Baseline for Mexico, which ranges from 5.3 percent to 18.3 percent of allotment. Recall that low shortages in **Figure TA 4-10** are associated with large and frequent dead pool–related reductions (see **Figure TA 4-1**, **Figure TA 4-2**, and **Figure TA 4-3**). Under the Basic Coordination Alternative, 50 percent of years have the maximum shortage volume in Arizona and Nevada and Mexico shortages of 41.1 percent, 27.2 percent and 16.4 percent of apportionment or allotment, respectively. The Maximum Operational Flexibility and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives have similar median shortage percentages in Mexico and Nevada, around 20 percent, but Arizona takes shortages at a higher percentage of apportionment in these alternatives, around 30 percent. The Enhanced Coordination Alternative has exactly the same median shortage (17.9 percent of apportionment) and variability (25th and 75th percentiles of 0.0 and 23.3 percent of apportionment, respectively) across all entities since shortages are distributed using a pro rata approach.

In the Dry Flow Category, median shortages for Arizona, Nevada, and Mexico generally increase, and variability generally decreases. The Critically Dry Flow Category continues this shift, with most alternatives showing median shortages at the maximum shortage possible and some lower end variability. The exception in this category is the Maximum Operational Flexibility Alternative, which only reaches its largest shortages in high outliers and has large variability.

Shortages in California exhibit different patterns from the other three entities due to the shortage distribution methods associated with each alternative. The No Action and Basic Coordination Alternatives apply a priority distribution scheme, but the total Lower Basin shortages are low enough that they do not impose any shortages on California. In the Average Flow Category, the Enhanced Coordination Alternative shows the highest median shortage (17.9 percent of apportionment) because it uses a pro rata distribution scheme and it also has the most variability among the alternatives. The Maximum Operational Flexibility and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives all have median shortages of 10.0 percent of apportionment.

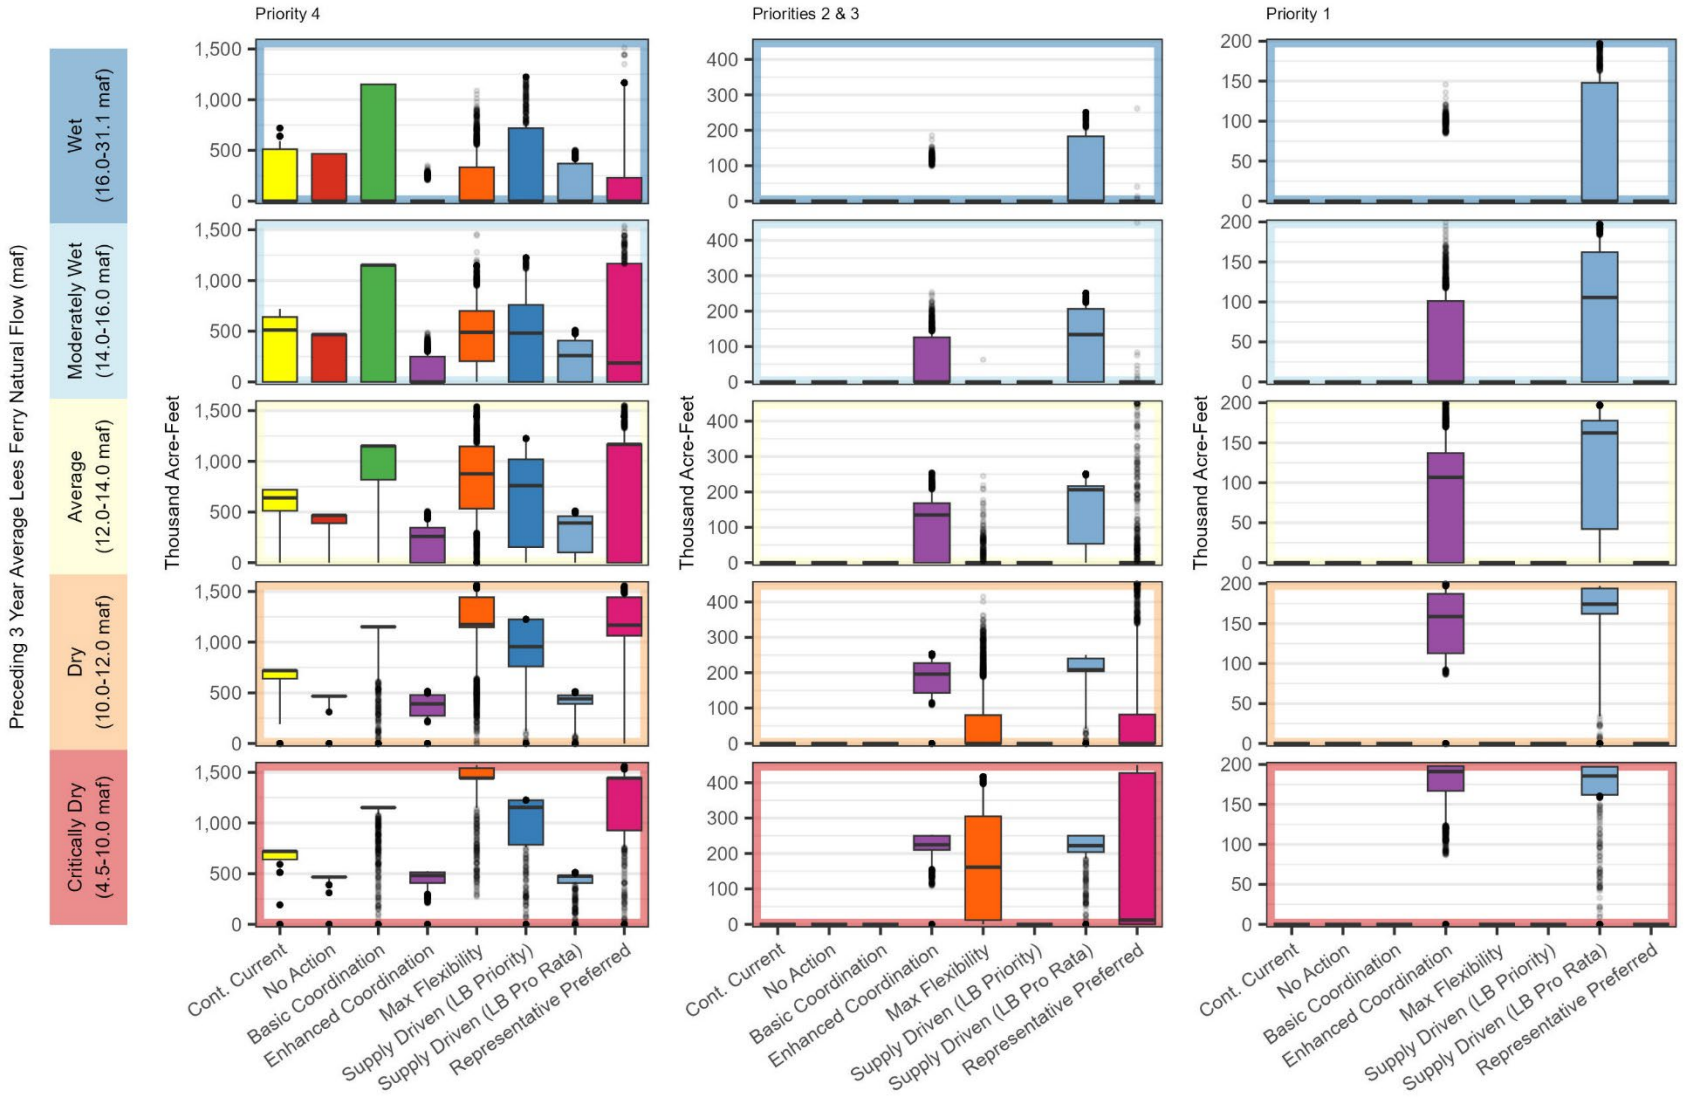
Figure TA 4-10
Calendar Year Shortage by State and Water Delivery Reductions to Mexico

Note: The modeled annual delivery reductions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

In the Critically Dry Flow Category, the CCS Comparative Baseline and Supply Driven Alternative (LB Priority approach) show median shortages of 8.0 and 10.0 percent of California's apportionment, respectively. The Supply Driven (LB Pro Rata approach) and Maximum Operational Flexibility Alternatives have median shortages of 15.8 and 17.3 percent of apportionment, respectively. The Enhanced Coordination Alternative has the highest median shortages of 33.3 percent of California's apportionment.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median calendar year shortage for Arizona is 41.7 percent, and the 25th to 75th percentiles range from 38.0 to 55.6 percent. For California, the median shortage is 0.0 percent with a 75th percentile of 8.9 percent. For Nevada, the median shortage is 27.6 percent, and the 25th to 75th percentiles range from 24.9 to 41.0 percent. For Mexico, the median water delivery reduction is 16.7 percent, and the 25th to 75th percentiles range from 16.7 to 24.6 percent.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median calendar year shortage for Arizona is 53.1 percent, and the 25th to 75th percentiles range from 33.1 to 67.6 percent. For California, the median shortage is 10.0 percent, and the 25th to 75th percentiles range from 0.0 to 19.5 percent. For Nevada, the median shortage is 36.3 percent, and the 25th to 75th percentiles range from 21.4 to 68.5 percent. For Mexico, the median water delivery reduction is 23.6 percent, and the 25th to 75th percentiles range from 16.7 to 40.0 percent.



Annual Shortage by State and Priority

Arizona

Figure TA 4-11 compares the shortages to different priority groups in Arizona using three columns of conditional boxplots, a column for each priority within the state; Priorities 2 and 3 are co-equal. The vertical axis for each column is scaled based on the volume of shortages applied to the priority group. The sum of the shortages across priority groups (i.e., the sum of the columns in **Figure TA 4-11**) is shown in the previous figure, **Figure TA 4-10**. Statistical summaries of the data shown in **Figure TA 4-11** are provided in **Table TA 4-20** through **Table TA 4-22** at the end of this technical appendix.

All alternatives apply shortages to Priority 4 users, the most junior users in Arizona. The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives impose shortages on Priorities 1, 2, and 3 users because they use pro rata-based approaches to distributing shortages, and the shortages under the Supply Driven Alternative (LB Pro Rata approach) are slightly higher because of how shortages are distributed across states. The Maximum Operational Flexibility and Representative Preferred Alternatives result in shortages to Priority 2 and 3 users because, while they use priority-based distribution methods, the total Lower Basin shortage volumes are large enough to extend to these users. The remaining discussion will focus primarily on Priority 4 users.

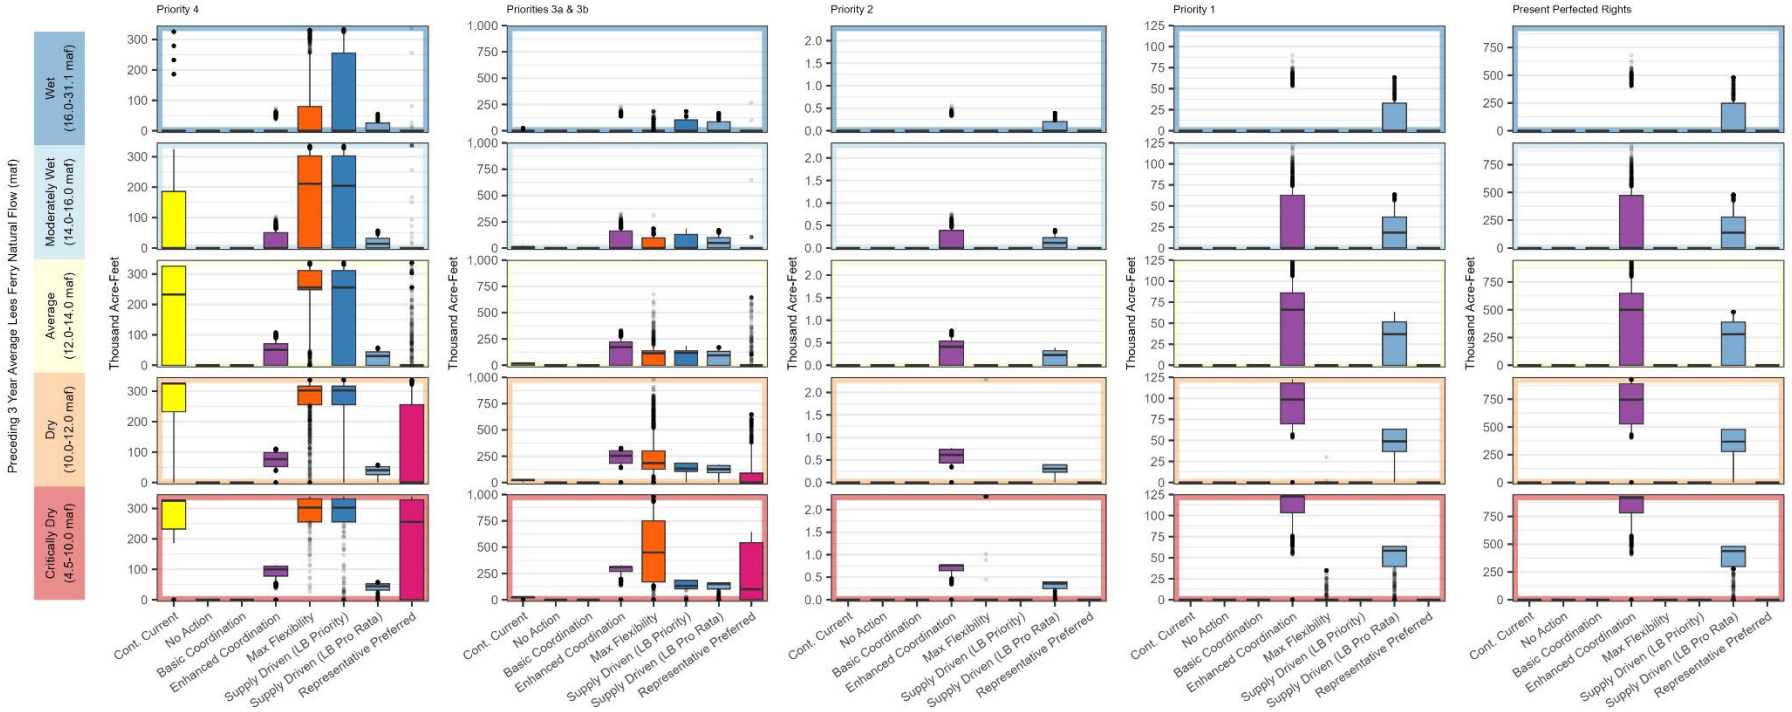
Figure TA 4-11
Annual Shortage for Arizona

In the Average Flow Category, the Maximum Operational Flexibility and Supply Driven (LB Priority approach) Alternatives have median Priority 4 shortages of 876.5 and 760.0 kaf, respectively, and both have wide variability between their 25th and 75th percentiles. The Basic Coordination, Supply Driven (LB Pro Rata approach) and Enhanced Coordination Alternatives have less variability, with median shortages of 1,151.6 kaf, 391.6 and 259.5 kaf, respectively. The No Action Alternative and CCS Comparative Baseline have low variability with medians of 466.8 and 640.0 kaf, respectively.

As conditions get drier, median shortages to Priority 4 users increase, and variability decreases. In the Critically Dry Flow Category, the Maximum Operational Flexibility, Basic Coordination, and Supply Driven (LB Priority approach) Alternatives show similar volumes of shortage to Arizona Priority 4 users at 1,442.6, 1,151.6 and 1,153.0 kaf, respectively. The No Action, Enhanced Coordination, and Supply Driven (LB Pro Rata approach) Alternatives have similar median shortages, with volumes between 466.9 and 480.9 kaf.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: For Priority 4 users, the median state shortage is 1,167.1 kaf, and the 25th to 75th percentiles range from 1,063.6 to 1,442.6 kaf, respectively. For Priority 2 and 3 (co-equal) users, the median is 0.0 kaf, and the 75th percentile is 82.0 kaf. Priority 1 users do not take shortage under this alternative.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: For Priority 4 users, the median state shortage is 1,442.6 kaf, and the 25th to 75th percentiles range from 926.3 to 1,442.6 kaf. For Priority 2 and 3 users, the median shortage is 12.0 kaf, and the 25th to 75th percentiles range from 0.0 to 427.5 kaf. Priority 1 users do not take shortage under this alternative.



California

Figure TA 4-12 compares the shortages to different priority groups in California using five columns of conditional boxplots, a column for each priority within the state. The vertical axis for each column is scaled based on the volume of shortages applied to the priority group. The sum of the shortages across priority groups (i.e., the sum of the columns in **Figure TA 4-12**) is shown in **Figure TA 4-10**. Statistical summaries of the data shown in **Figure TA 4-12** are provided in **Table TA 4-24** through **Table TA 4-28** at the end of this technical appendix.

The No Action and Basic Coordination Alternatives do not apply shortages to California water users due to their combinations of low maximum Lower Basin shortages and use of the priority system to distribute the shortages. However, recall that low maximum Lower Basin shortage volumes translate to higher volumes of dead pool-related reductions (see **Figure TA 4-12**).

The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives use pro rata-based distribution approaches, so these alternatives apply shortages to senior priority groups while other alternatives do not. In the Average, Dry, and Critically Dry Flow Categories, the Enhanced Coordination Alternative applies higher median shortages than the Supply Driven Alternative (LB Pro Rata approach) for Priorities 1 and 2 and PPRs. The Maximum Operational Flexibility Alternative also applies shortages to these groups in a small number of years in the Dry and Critically Dry Flow Categories. The remaining discussion will focus on Priority 4 and the co-equal Priorities 3a and 3b.

Figure TA 4-12
Annual Shortage for California

Priority 4 users are the most junior and experience the largest volumes of shortages relative to their total volume of rights. In the Average, Dry and Critically Dry flow categories, the Maximum Operational Flexibility and Supply Driven (LB Priority approach) Alternatives have the same median shortages of 255.7, 302.7 and 302.7 kaf, respectively, due to using the same distribution method. The Supply Driven Alternative (LB Priority approach) has a wider interquartile range in the Average Flow Category, but the interquartile ranges are the same for these two alternatives in the Dry and Critically Dry flow categories. The Supply Driven (LB Pro Rata approach) and Enhanced Coordination Alternatives both have lower medians and smaller ranges than the other alternatives that short these users due to their pro rata-based distribution methods, but the Enhanced Coordination Alternative has higher medians in all flow categories (50.8, 76.5, and 100.0 kaf in Average, Dry, and Critically Dry, respectively) than the Supply Driven Alternative (LB Pro Rata approach) (30.3, 40.1, and 44.0 kaf in Average, Dry, and Critically Dry, respectively).

The Representative Preferred Alternative exhibits the following shortages to Priority 4 users in the Dry Flow Category: the median shortage is 0.0 kaf, and there is large variability within the interquartile range, especially comparing the 75th percentile volume of 255.7 kaf to the median. The Representative Preferred Alternative exhibits the following shortages to Priority 4 users in the Critically Dry Flow Category: the median shortage is 255.7 kaf, and there is large variability within the interquartile range, with the 25th percentile of shortages being 0.0 kaf and the 75th percentile of shortages being 328.2 kaf.

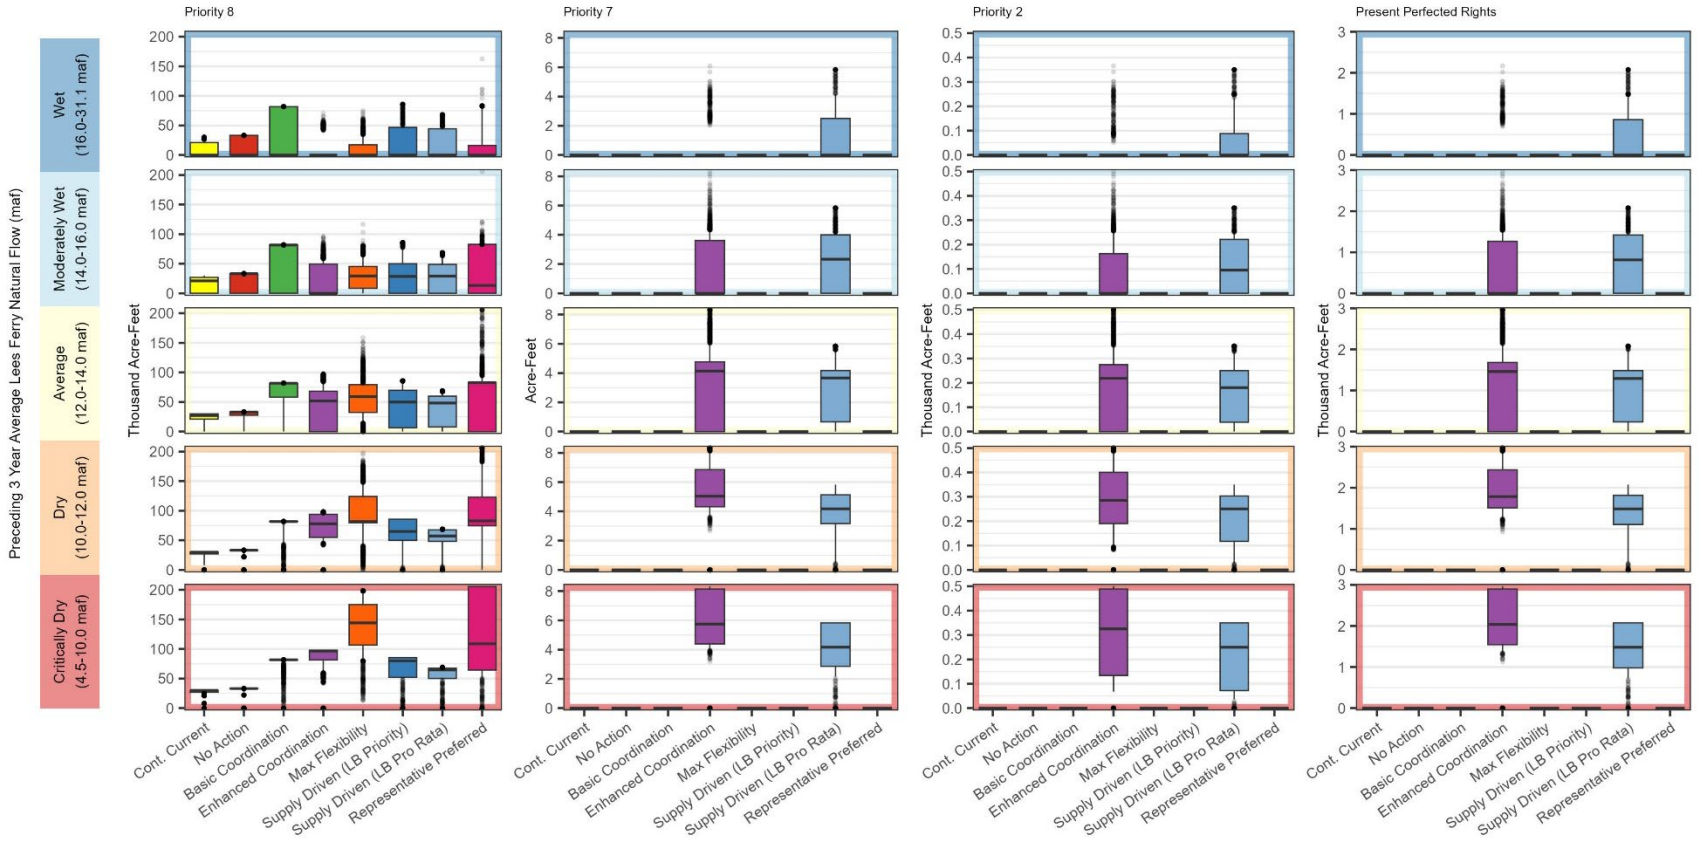
Priorities 3a and 3b (co-equal) users have relatively small differences in median shortages across alternatives that short these users in the Average and Dry flow categories; excluding the Representative Preferred Alternative (described later), the median shortages range from 172.3 kaf to 93.6 kaf in the Average Flow Category under Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives, respectively. The median shortages in the Dry Flow Category range from 254.1 kaf to 125.9 kaf under these same two respective alternatives. In the Critically Dry Flow Category, comparisons between alternatives are similar, but with higher medians and less variability, with the exception of the Maximum Operational Flexibility Alternative, which has the highest median shortage of 448.7 kaf and large variability, with 168.7 kaf of shortage at the 25th percentile and 749.7 kaf at the 75th percentile.

The Representative Preferred Alternative exhibits the following shortages to Priorities 3a and 3b users in the Dry Flow Category: the median shortage is 0.0 kaf, and with some variability within the interquartile range when comparing the 75th percentile volume of 89.0 kaf to the median. The Representative Preferred Alternative exhibits the following shortages to Priorities 3a and 3b users in the Critically Dry Flow Category: the median shortage is 100.4 kaf, and there is large variability within the interquartile range, with the 25th percentile of shortages being 0.0 kaf and the 75th percentile of shortages being 542.9 kaf.

Nevada

Figure TA 4-13 compares the shortages to different priority groups in Nevada using four columns of conditional boxplots, a column for each priority group within the state. The vertical axis for each column is scaled based on the volume of shortages applied to the priority group. The sum of the shortages across priority groups (i.e., the sum of the columns in **Figure TA 4-13**) is shown in **Figure TA 4-10**. Statistical summaries of the data shown in **Figure TA 4-13** are provided in **Table TA 4-30** through **Table TA 4-33** at the end of this technical appendix.

A comparison of the vertical axis units and ranges for each column shows that the Priority 8 group captures the vast majority of water rights in Nevada, so discussion will focus on the leftmost column. The other priority groups receive shortages under the Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives because of the pro rata-based shortage distribution methods.



In the Average Flow Category, median shortage volumes are clustered in three groups: the Basic Coordination and Representative Preferred Alternatives impose 81.7 and 82.8 kaf, respectively; the Maximum Operational Flexibility, Enhanced Coordination, Supply Driven (LB Priority approach) and Supply Driven (LB Pro Rata approach) Alternatives impose 58.9, 51.9, 50.0, and 48.3 kaf, respectively; the CCS Comparative Baseline and the No Action Alternative impose 27.0 and 33.1 kaf, respectively. The action alternatives besides the Basic Coordination Alternative show similar variability based on the differences between their respective 25th and 75th percentile shortages; the Basic Coordination Alternative has less variability.

As conditions get drier, median shortages for the action alternatives generally increase. Compared with the Average Flow Category, variability in the Critically Dry Flow Category increases for the Maximum Operational Flexibility and Representative Preferred Alternatives, while it decreases for the other alternatives. In the Critically Dry Flow Category, the Basic Coordination Alternative has the same median shortage of 81.7 kaf because the maximum shortage is low enough that it was being applied even in Average flow conditions. The Enhanced Coordination, Maximum Operational Flexibility, Supply Driven (LB Priority approach), and Supply Driven (LB Pro Rata approach) Alternatives have median shortages of 96.5, 144.1, 79.8, and 64.6 kaf, respectively.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: For Priority 8 users, the median state shortage is 82.8 kaf, and the 25th to 75th percentiles range from 74.7 to 122.9 kaf. No other priority groups take shortage under this alternative.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: For Priority 8 users, the median state shortage is 108.9 kaf, and the 25th to 75th percentiles range from 64.2 to 205.6 kaf. No other priority groups take shortage under this alternative.

Figure TA 4-13
Annual Shortage for Nevada

Annual Depletions

This section compares the annual depletions to the Lower Division States and Mexico across all alternatives and the CCS Comparative Baseline. Depletion (sometimes referred to as "total consumptive use") is the net amount of water used. It is calculated as the amount of water diverted from the river minus the return flow. Return flow is the portion of diverted water that is not consumed and returns to the river for subsequent downstream use. Depletions depend both on the total shortage volume as well as the approach used to distribute shortages among states, and also account for modeling assumptions related to voluntary conservation mechanisms.

In this section, dead pool-related reduction impacts are included in the figures and discussion.

Arizona

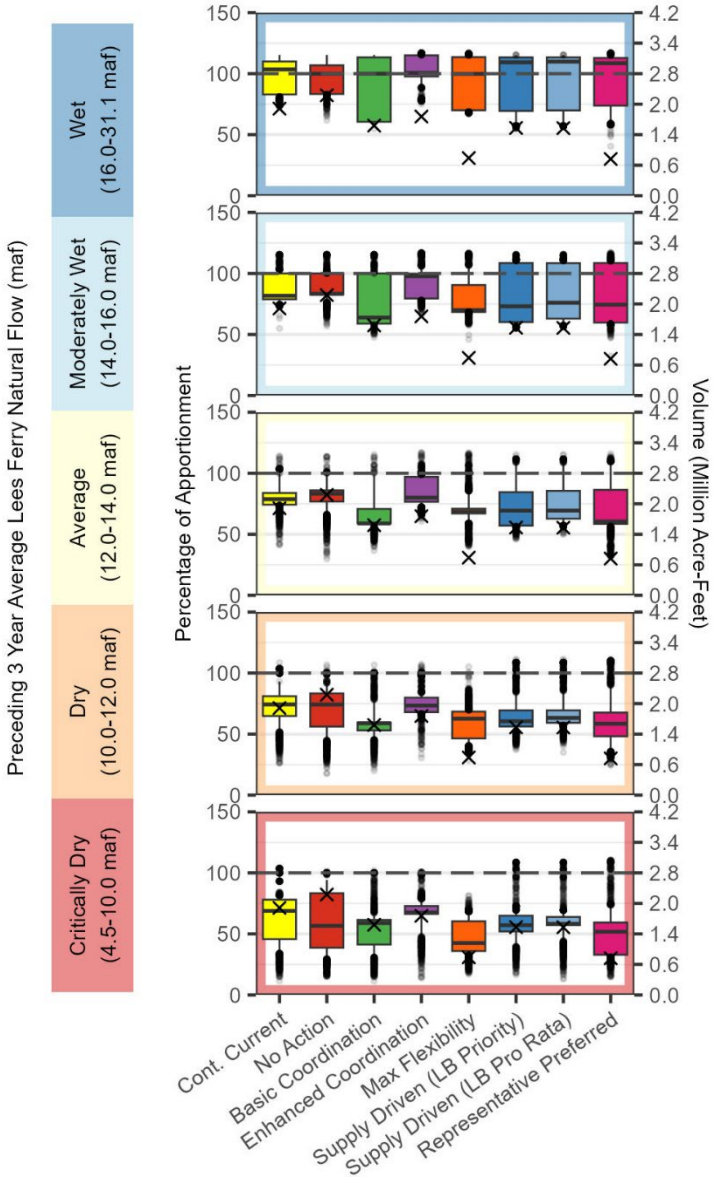


Figure TA 4-14 shows Arizona's depletions under each alternative using conditional boxplots. The results are plotted in terms of their percentage of the state's 2.8-maf apportionment (units shown on the left side of panels) and the volume of shortage (units shown on the right side of panels). A dashed line is included on each panel at 100 percent of apportionment. Results will be described using percent of apportionment. Each alternative includes an "X" marker indicating the smallest depletion volume that was *not* affected by dead pool–related reductions from Lake Mead; any data points below the marker were affected by infrastructure constraints at Lake Mead elevations near dead pool. The volume associated with the marker differs by alternative because shortage volumes vary among alternatives, which affects the occurrence and magnitude of dead pool-related reductions. A statistical summary of the data shown in **Figure TA 4-14** is provided in **Table TA 4-34** at the end of this technical appendix.

In the Average Flow Category, across the alternatives, Arizona's median depletions range from 83.3 percent of apportionment (No Action Alternative) to 58.9 percent (Basic Coordination Alternative). Generally, in this flow category, Arizona gets 100 percent of apportionment in only about 10 percent of years because the alternatives apply shortages in most of the years in this flow category (and conservation activity does not fully offset the shortages). The Enhanced Coordination Alternative has moderate variability and the highest 75th percentile of depletions due to the pro rata-based shortage distribution. In the No Action and Basic Coordination Alternatives, nearly 50 percent of years have depletions affected by dead pool-related reductions, while there are few or no years impacted by these reductions in the other alternatives. The Representative Preferred Alternative has similar variability to the Supply Driven Alternative (LB Priority approach) in the interquartile range because they distribute the use the same for the first 1.5 maf of shortage, but lower median depletions than that alternative due to having a larger maximum shortage volume.

Median depletions do not go down significantly from the Average Flow Category to the Dry Flow Category, but percentages of years affected by dead pool-related reductions increase. In the Critically Dry Flow Category, median and 25th percentiles of depletions decrease significantly compared to the Average Flow Category in most alternatives due to large shortage volumes and limited availability of or access to conserved water to offset them. Across alternatives, the median depletions range from 67.5 percent of apportionment (Enhanced Coordination Alternative) to 42.5 percent of apportionment (Maximum Operational Flexibility Alternative). The CCS Comparative Baseline and the No Action, Basic Coordination, and Maximum Operational Flexibility Alternatives

show the largest decreases in their median and 25th percentile depletions. Near or above 50 percent of years under the CCS Comparative Baseline and the Basic Coordination and Supply Driven (LB Priority approach) Alternatives are affected by dead pool-related reductions, and approximately 75 percent of years are affected by these reductions under the No Action Alternative.

Figure TA 4-14
Annual Depletions in Arizona

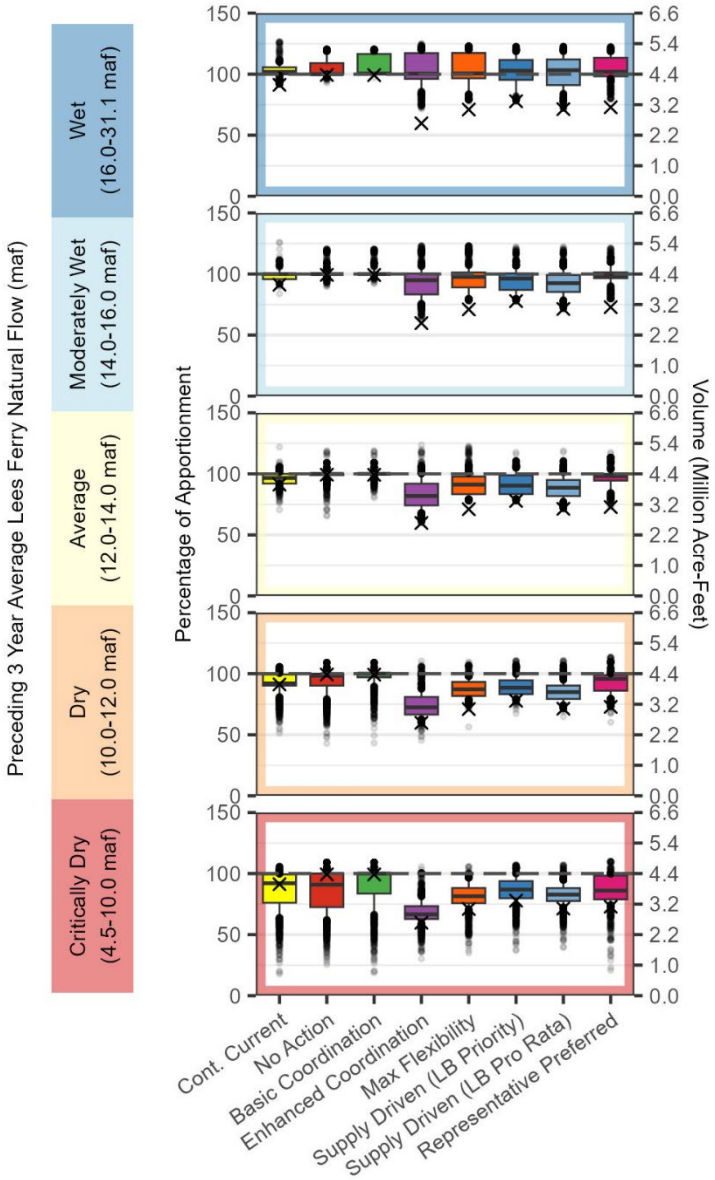
Note: Depletion volumes below the "X" marker were affected by infrastructure constraints at Lake Mead elevations near dead pool.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median depletion by Arizona is 58.5 percent of apportionment, and the 25th to 75th percentiles range from 48.2 to 67.7 percent. Depletions in some outlier years (below the 10th percentile) are affected by dead pool at Lake Mead.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median depletion by Arizona is 51.8 percent of apportionment, and the 25th to 75th percentiles range from 32.9 to 59.3 percent. Depletions in approximately 10 percent of years are affected by dead pool at Lake Mead.

California

Figure TA 4-15 shows California's depletions under each alternative using conditional boxplots. The results are plotted in terms of their percentage of the state's 4.4-maf apportionment (units shown on the left side of panels) and the volume of shortage (units shown on the right side of panels). A dashed line is included on each panel at 100 percent of apportionment. Each alternative includes an "X" marker indicating the smallest depletion volume that was *not* affected by dead pool–related reductions from Lake Mead; any data points below the marker were affected by infrastructure constraints at Lake Mead elevations near dead pool. The volume associated with the marker differs by alternative because shortage volumes vary among alternatives, which affects the occurrence and magnitude of dead pool-related reductions. A statistical summary of the data shown in **Figure TA 4-15** is provided in **Table TA 4-35** at the end of this technical appendix.



In the Average Flow Category, across the alternatives, California's median depletions range from 100.0 percent of apportionment (No Action and Basic Coordination Alternative) to 81.9 percent (Enhanced Coordination Alternative). In the No Action and Basic Coordination Alternatives, any depletions below 100 percent are associated with dead pool-related reductions. For the other alternatives, in this flow category, California gets at least 100 percent of apportionment in approximately 10 to 25 percent of years because the alternatives apply shortages in most of the years in this flow category (and conservation activity does not fully offset the shortages). The Enhanced Coordination Alternative has the highest variability and lowest median depletions due to the pro rata-based shortage distribution.

Except for the Enhanced Coordination Alternative, median depletions do not go down significantly from the Average Flow Category to the Critically Dry Flow Category because California takes a lower percentage of shortage than other entities, but percentages of years affected by dead pool-related reductions increase. Across alternatives, the median depletions in the Critically Dry Flow Category range from 100.0 percent of apportionment (Basic Coordination Alternative) to 66.6 percent of apportionment (Enhanced Coordination Alternative). Near or above 50 percent of years under the CCS Comparative Baseline and the Basic Coordination Alternative are affected by dead pool-related reductions, and approximately 75 percent of years are affected by these reductions under the No Action Alternative. Approximately 10 percent of years or fewer are affected by dead pool in the other alternatives.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median depletion by California is 95.8 percent of apportionment, and the 25th to

75th percentiles range from 86.1 to 98.9 percent. Depletions in some outlier years (below the 10th percentile) are affected by dead pool at Lake Mead.

Figure TA 4-15
Annual Depletions in California

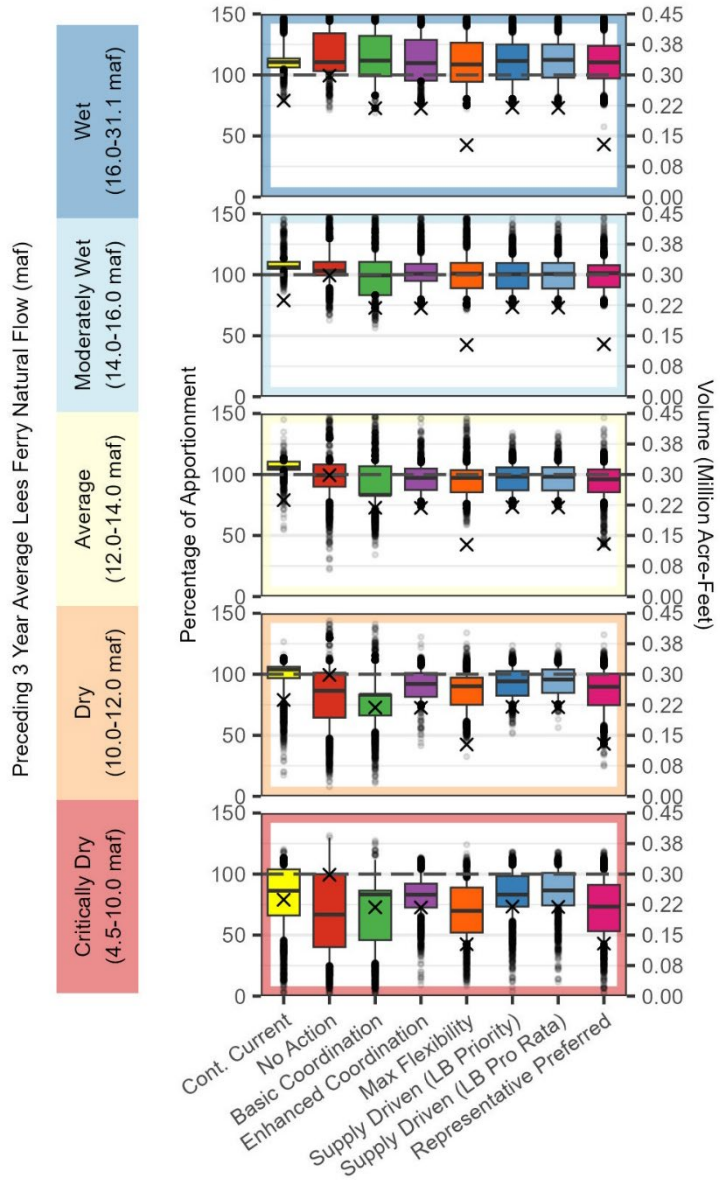
Note: Depletion volumes below the "X" marker were affected by infrastructure constraints at Lake Mead elevations near dead pool.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median depletion by California is 86.0 percent of apportionment, and the 25th to 75th percentiles range from 78.9 to 98.3 percent. Depletions in fewer than 10 percent of years are affected by dead pool at Lake Mead.

Nevada

Figure TA 4-16 shows Nevada's depletions under each alternative using conditional boxplots. The results are plotted in terms of their percentage of the state's 300-kaf apportionment (units shown on the left side of panels) and the volume of shortage (units shown on the right side of panels). A dashed line is included on each panel at 100 percent of apportionment. Each alternative includes an "X" marker indicating the smallest depletion volume that was *not* affected by dead pool–related reductions from Lake Mead; any data points below the marker were affected by infrastructure constraints at Lake Mead elevations near dead pool. The volume associated with the marker differs by alternative because shortage volumes vary among alternatives, which affects the occurrence and magnitude of dead pool-related reductions. A statistical summary of the data shown in **Figure TA 4-16** is provided in **Table TA 4-36** at the end of this technical appendix.

In the Average Flow Category, across the alternatives, Nevada's median depletions range from 105.8 percent of apportionment (CCS Comparative Baseline) to 83.3 percent (Basic Coordination Alternative). Except for the Basic Coordination Alternative, in this flow category, Nevada gets at least 100 percent of apportionment in approximately 40 to 50 percent of years. This is a higher percent of years than either Arizona or California because of modeling assumptions about conservation activity. The Basic Coordination Alternative shows the lowest median depletions because it distributed shortage to Arizona and Nevada only. Except for CCS Comparative Baseline, the alternatives have similar variability.



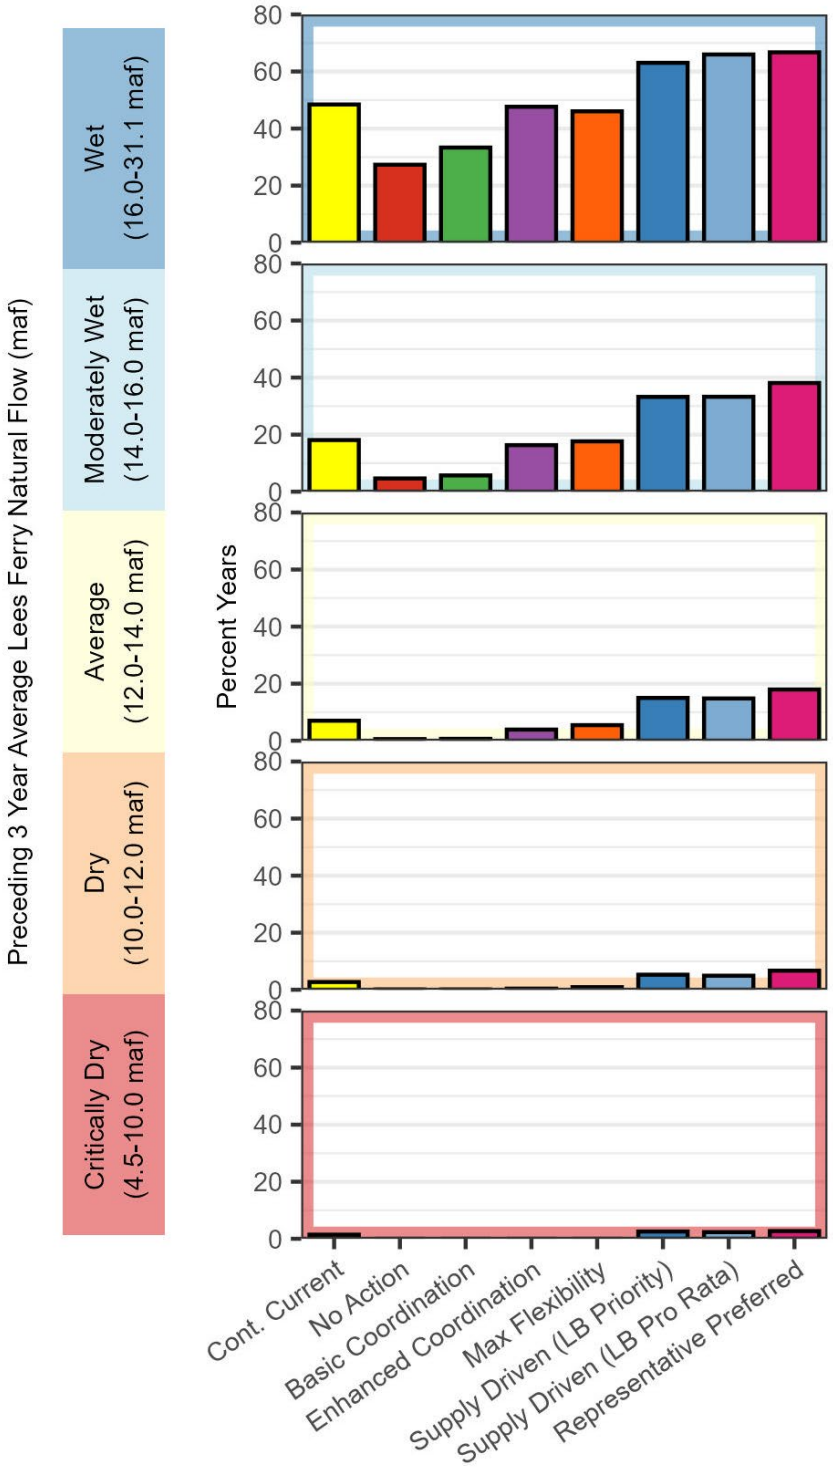
Median depletions do not go down significantly from the Average Flow Category to the Dry Flow Category, but percentages of years affected by dead pool-related reductions increase. In the Critically Dry Flow Category, median and 25th percentiles of depletions decrease significantly compared to the Average Flow Category in most alternatives due to large shortage volumes and limited availability of or access to conserved water to offset them. The CCS Comparative Baseline and the Basic Coordination, Enhanced Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives have similar median depletions around 85 percent of apportionment. The No Action, Maximum Operational Flexibility, and Representative Preferred Alternatives have similar median depletions, around 70 percent of apportionment. Near or above 50 percent of years under the CCS Comparative Baseline and the Basic Coordination Alternative are impacted by dead pool-related reductions, and 75 percent of years in the No Action Alternative are impacted by these reductions. The Enhanced Coordination and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives are impacted by dead pool in approximately 25 percent of years, and the Maximum Operational Flexibility Alternative is impacted by these reductions in approximately 10 percent of years.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median depletion by Nevada is 89.7 percent of apportionment, and the 25th to 75th percentiles range from 74.7 to 100.5 percent. Depletions in some outlier years (below the 10th percentile) are affected by dead pool at Lake Mead.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median depletion by Nevada is 73.3 percent of apportionment,

and the 25th to 75th percentiles range from 53.1 to 91.2 percent. Depletions in approximately 10 percent of years are affected by dead pool at Lake Mead.

Figure TA 4-16
Annual Depletions in Nevada



Note: Depletion volumes below the "X" marker were affected by infrastructure constraints at Lake Mead elevations near dead pool.

Surplus

Figure TA 4-17 below compares the alternatives with respect to frequency of surplus deliveries. Percents of years with surplus deliveries are broken out by different hydrologic conditions, categorized by preceding three-year average Lees Ferry natural flows. Because the frequency of surplus deliveries occurring in each flow category is shown and not the volume of surplus water

delivered, bars are used instead of boxplots. The height of the bar shows the percent of years when surplus deliveries occurred.

Figure TA 4-17
Percent of Years with Delivery Surplus

In the Average Flow Category, the Representative Preferred Alternative has the highest frequency of surplus deliveries at 18.0 percent of years, followed closely by the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), which resulted in surplus deliveries in about 15 percent of years. The CCS Comparative Baseline and the Enhanced Coordination and Maximum Operational Flexibility Alternatives resulted in surplus deliveries in fewer than 10 percent of years.

All alternatives resulted in surplus deliveries in fewer than 10 percent of the years in the Dry Flow Category, and only the CCS Comparative Baseline, Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) and the Representative Preferred Alternative had any incidence of surplus deliveries in the Critically Dry Flow Category (fewer than 3 percent of years).

TA 4.2.5 Issue 4: Deliveries to Mexico

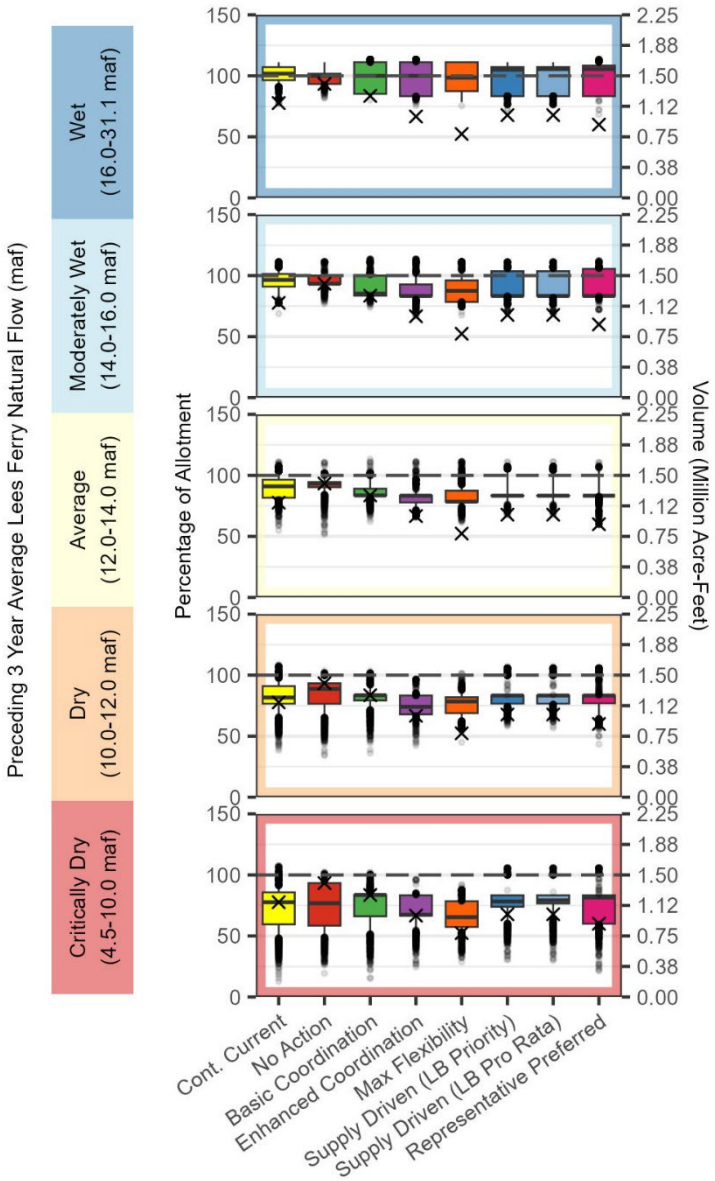
Issue 4 addresses how operational activities affect deliveries to Mexico. This will be achieved by comparison of the various action alternatives to the No Action Alternative and CCS Comparative Baseline for the following metrics:

- Annual water delivery reductions to Mexico
- Annual depletions in Mexico

Refer to **Appendix N**, International Border Region of the Colorado River, for additional information regarding water deliveries to the International Border Region.

Deliveries to Mexico under the CCS Comparative Baseline are established in Minute 319 and Minute 323, Extension of Cooperative Measures and Adoption of a Binational Water Scarcity Contingency Plan in the Colorado River Basin in 2017 (International Boundary and Water Commission 2017), which identify maximum reductions to Mexico's delivery to 275 kaf, including volumes of Mexico's recoverable water savings. All alternatives assume a 1.5 maf annual allotment to Mexico but differ in how reductions and surplus are determined. Under the No Action Alternative, determination of deliveries to Mexico is made in accordance with the 1944 Mexican Water Treaty.

Water delivery reductions to Mexico under all the alternatives, except for the CCS Comparative Baseline, are modeled in proportion to Lower Division States shortage. All alternatives assume that a consistent 16.67 percent of all Lower Basin shortages are applied to water deliveries to Mexico on an annual basis. Refer to **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation, and **Appendix N**, International Border Region of the Colorado River, for specifics.



Annual Water Delivery Reductions

Refer to **Figure TA 4-10** for the conditional boxplots showing reductions to Mexico. A statistical summary of the data shown in **Figure TA 4-10** is provided in **Table TA 4-37** at the end of this technical appendix.

Annual Depletions

Figure TA 4-18 shows Mexico's depletions under each alternative using conditional boxplots. The results are plotted in terms of their percentage of the 1.5-maf allotment (units shown on the left side of panels) and the volume of shortage (units shown on the right side of panels). A dashed line is included on each panel at 100 percent of allotment. Each alternative includes an "X" marker

Figure TA 4-18
Annual Depletions in Mexico

Note: The modeled annual depletions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.
Note: Depletion volumes below the "X" marker were affected by infrastructure constraints at Lake Mead elevations near dead pool.

indicating the smallest depletion volume that was *not* affected by dead pool–related reductions from Lake Mead; any data points below the marker were affected by infrastructure constraints at Lake Mead elevations near dead pool. The volume associated with the marker differs by alternative because shortage volumes vary among alternatives, which affects the occurrence and magnitude of dead pool-related reductions. A statistical summary of the data shown in **Figure TA 4-18** is provided in **Table TA 4-38** at the end of this technical appendix.

In the Average Flow Category, across the alternatives, Mexico's median depletions range from 93.3 percent of allotment (No Action Alternative) to 78.5 percent (Maximum Operational Flexibility Alternative). Generally, in this flow category, Mexico gets at least 100 percent of allotment in only about 10 percent of years or fewer because the alternatives apply delivery reductions in most of the years in this flow category (and conservation activity does not fully offset the reductions). In the No Action and Basic Coordination Alternatives, nearly 50 percent of years have depletions affected by dead pool-related reductions, while there are few or no years impacted by these reductions in the other alternatives.

Median depletions do not go down significantly from the Average Flow Category to the Dry Flow Category, but percentages of years affected by dead pool-related reductions increase. In the Critically Dry Flow Category, median and 25th percentiles of depletions decrease significantly compared to the Average Flow Category in most alternatives due to large shortage volumes and limited availability of or access to conserved water to offset them. The CCS Comparative Baseline, the No Action and Basic Coordination Alternatives, Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), and the Representative Preferred Alternative have similar median depletions around 80 percent of allotment. The Enhanced Coordination and Maximum Operational Flexibility Alternatives have similar median depletions, around 66 percent of allotment. Near or above 50 percent of years under the CCS Comparative Baseline and the Basic Coordination Alternative are impacted by dead pool-related reductions, and 75 percent of years in the No Action Alternative are impacted by these reductions. The Enhanced Coordination and Representative Preferred Alternatives are impacted by dead pool in approximately 25 percent of years, and the Maximum Operational Flexibility and Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) are impacted by these reductions in approximately 10 percent of years.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Dry Flow Category: the median depletion by Mexico is 83.3 percent of allotment, and the 25th to 75th percentiles range from 76.9 to 83.3 percent. Depletions in some outlier years (below the 10th percentile) are affected by dead pool at Lake Mead.

The Representative Preferred Alternative exhibits the following outcomes with respect to the Critically Dry Flow Category: the median depletion by Mexico is 81.5 percent of allotment, and the 25th to 75th percentiles range from 60.0 to 83.3 percent. Depletions in approximately 25 percent of years are affected by dead pool at Lake Mead.

TA 4.2.6 Issue 5: Lower Division States Combined Shortages

Issue 5 addresses how operational activities affect modeled distribution of combined shortages for the Lower Division States. This will be achieved through the comparison of the various action alternatives to the No Action Alternative and CCS Comparative Baseline for the following metrics:

- Volumes of Shortage by Water User Type (tribal, domestic, irrigation)

As discussed in **Chapter 2**, the alternatives considered evaluate a distribution of shortages via priority and pro rata. Lower Division States' shortage distributions discussed under this issue were modeled with the SAM and ADM to estimate the volume of available water to entitlement holders or water users under Shortage Conditions over a specified range of shortage volumes. There are three unique SAMs and five ADMs to capture the nuances of the alternatives and sensitivity analyses, which are further explained in **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation. The following analysis describes the distribution of shortages expected for a specified shortage volume.

Tribal Shortage Impacts

The following **Table TA 4-39** describes shortage impacts on tribal entitlements, broken out by SAM and ADM modeling approach and aligned by alternative. Each row corresponds to a modeling approach and EIS alternative or the CCS Comparative Baseline. Within the row, the color gradient is representative of conditional formatting for values ranging from zero to 1,103 kaf, the total of the entitlements modeled in the tribal category. The color gradient indicates the percentage reduction, with the darkest orange representing 100 percent reduction. The maximum values are a total of the Consumptive Use or equivalent entitlements modeled for tribal users. Each column of modeled total shortage was chosen based on points of interest in one or more models, or to provide granularity in the results over a range of volumes of interest. Total shortage volumes include an assumed component for Mexico, as described in the sections of this appendix pertaining to each model, and will not sum across panels.

As shown in the table, the shortage impacts of priority-based alternatives range from 209-582 kaf. The shortage impacts of pro rata-based alternatives range from 76-378 kaf. The pro rata-based alternatives display smaller shortage impacts compared to the priority-based alternatives at the same total shortage volume considered. For example, under a total shortage volume of 2,100 kaf, the Maximum Operational Flexibility and Supply Driven (LB Priority approach) Alternatives estimate a shortage impact of 510 kaf. The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives estimate a shortage impact of 264 and 357 kaf, respectively. Overall, for tribal users, priority-based alternatives result in greater shortage impacts compared to pro rata-based alternatives. These tradeoffs are further discussed in **TA 18**, Indian Trust Assets.

Assuming a maximum shortage volume of 1.5 maf distributed based on the Lower Division States' May 1, 2026 proposal, the Representative Preferred Alternative would impose a maximum shortage of 346 kaf to tribal users in 2027 and 2028,[4] Modeling assumptions for 2029-2060 show a maximum

[4] While the Representative Preferred Alternative models shortages above 1.5 maf in 2028, consistent with the sideboards, under the Preferred Alternative, Reclamation would consult with stakeholders if Lake Mead elevation is projected below 1,000 feet. (See **Chapter 2** for more details on the sideboards under the Preferred Alternative).

potential impact to tribal users of over 574 kaf, but as demonstrated by the 2027-2028 Operating Guidelines, the distribution of shortage under any specific operating guidelines adopted under the Preferred Alternative decision framework may differ from the priority distribution method reflected here for the Representative Preferred Alternative.

Domestic Shortage Impacts

The following **Table TA 4-39** describes shortage impacts on Domestic users, broken out by SAM and ADM modeling approach and aligned by alternative. Each row corresponds to a modeling approach and EIS alternative or the CCS Comparative Baseline. Within the row, the color gradient is representative of conditional formatting for values ranging from zero to 1,606 kaf, the total of the entitlements modeled in the domestic category. The color gradient indicates the percentage reduction, with the darkest orange representing 100 percent reduction. The maximum values are a total of the Consumptive Use or equivalent entitlements modeled for domestic users. Each column of modeled total shortage was chosen based on points of interest in one or more models, or to provide granularity in the results over a range of volumes of interest. Total shortage volumes include an assumed component for Mexico, as described in the sections of this appendix pertaining to each model, and will not sum across panels.

As shown in the table, the shortage impacts of priority-based alternatives range from 277-1,501 kaf. The shortage impacts of pro rata-based alternatives range from 109-546 kaf. The pro rata-based alternatives display smaller shortage impacts compared to the priority-based alternatives at the same total shortage volume considered. For example, under a total shortage volume of 2,100 kaf, the Maximum Operational Flexibility and Supply Driven (LB Priority approach) Alternatives estimate a shortage impact of 1,179 kaf. The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives estimate a shortage impact of 382 and 449 kaf, respectively. Overall, for domestic users, priority-based alternatives result in greater shortage impacts compared to pro rata-based alternatives. These tradeoffs are further discussed in **TA 17**, Population and Land Use.

Assuming a maximum shortage volume of 1.5 maf distributed based on the Lower Division States' May 1, 2026 proposal, the Representative Preferred Alternative would impose a maximum shortage of 858 kaf to domestic users in 2027 and 2028[5]. Modeling assumptions for 2029-2060 show a maximum potential impact to domestic users of over 1,472 kaf, but as demonstrated by the 2027-2028 Operating Guidelines, the distribution of shortage under any specific operating guidelines adopted under the Preferred Alternative decision framework may differ from the priority distribution method reflected here for the Representative Preferred Alternative.

Irrigation Shortage Impacts

The following **Table TA 4-39** describes shortage impacts on non-tribal irrigation users, broken out by SAM and ADM modeling approach and aligned by alternative. Each row corresponds to a modeling approach and EIS alternative or the CCS Comparative Baseline. Within the row, the color gradient is representative of conditional formatting for values ranging from zero to 4,749 kaf, the total of the entitlements modeled in the irrigation category. The color gradient indicates the

[5] While the Representative Preferred Alternative models shortages above 1.5 maf in 2028, consistent with the sideboards, under the Preferred Alternative, Reclamation would consult with stakeholders if Lake Mead elevation is projected below 1,000 feet. (See **Chapter 2** for more details on the sideboards under the Preferred Alternative).

Table TA 4-39
Total Shortage Impact Volumes (kaf)

Tribal Shortage Impacts

Modeling Approach	EIS Alternatives and Comparative Baseline	600	1,000	1,500	1,800	2,000	2,100	2,300	3,000	3,500	4,000

LB Pro Rata	Supply Driven (LB Pro Rata approach)	206	387	613	778	889	944				

Note:
Totals include Mexico and will not sum across panels.
*CCS Comparative Baseline strategies results are of limited comparability due to their fixed shortage volumes; shortages shown for 600 kafy and 1.0 maf per year in total shortage are associated with 613 kafy and 1,013 kafy of total shortage in the CCS Comparative Baseline SAM.

percentage reduction, with the darkest orange representing 100 percent reduction. The maximum values are a total of the Consumptive Use or equivalent entitlements assigned to irrigation users. Each column of total modeled shortage was chosen based on points of interest in one or more models, or to provide granularity in the results over a range of volumes of interest. Total shortage volumes include an assumed component for Mexico, as described in the sections of this appendix pertaining to each model, and will not sum across panels.

As shown in the table, the shortage impacts of priority-based alternatives range from 2-1,211 kaf. The shortage impacts of pro rata-based alternatives range from 206 to 1,578 kaf. The pro rata-based alternatives display larger shortage impacts compared to the priority-based alternatives at the same total shortage volume considered. For example, under a total shortage volume of 2,100 kaf, the Maximum Operational Flexibility and Supply Driven (LB Priority approach) Alternatives estimate a shortage impact of 88 kaf. The Enhanced Coordination and Supply Driven (LB Pro Rata approach) Alternatives estimate a shortage impact of 1,105 and 944 kaf, respectively. Overall, for non-tribal irrigation users, pro rata-based alternatives result in greater shortage impacts compared to priority-based alternatives. These tradeoffs are further discussed in **TA 17**, Population and Land Use.

Assuming a maximum shortage volume of 1.5 maf distributed based on the Lower Division States' May 1, 2026 proposal, the Representative Preferred Alternative would impose a maximum shortage of 70 kaf to non-tribal irrigation users in 2027 and 2028[6]. Modeling assumptions for 2029-2060 show a maximum potential impact to non-tribal irrigation users of over 829 kaf, but as demonstrated by the 2027-2028 Operating Guidelines, the distribution of shortage under any specific operating guidelines adopted under the Preferred Alternative decision framework may differ from the priority distribution method reflected here for the Representative Preferred Alternative.

Volumes of Shortage by State (Arizona, California, Nevada)

State specific distribution of shortages can be viewed in **Appendix C**, Shortage Allocation Model and Alternative Distribution Model Documentation.

TA 4.2.7 Issue 6: Upper Basin Conservation

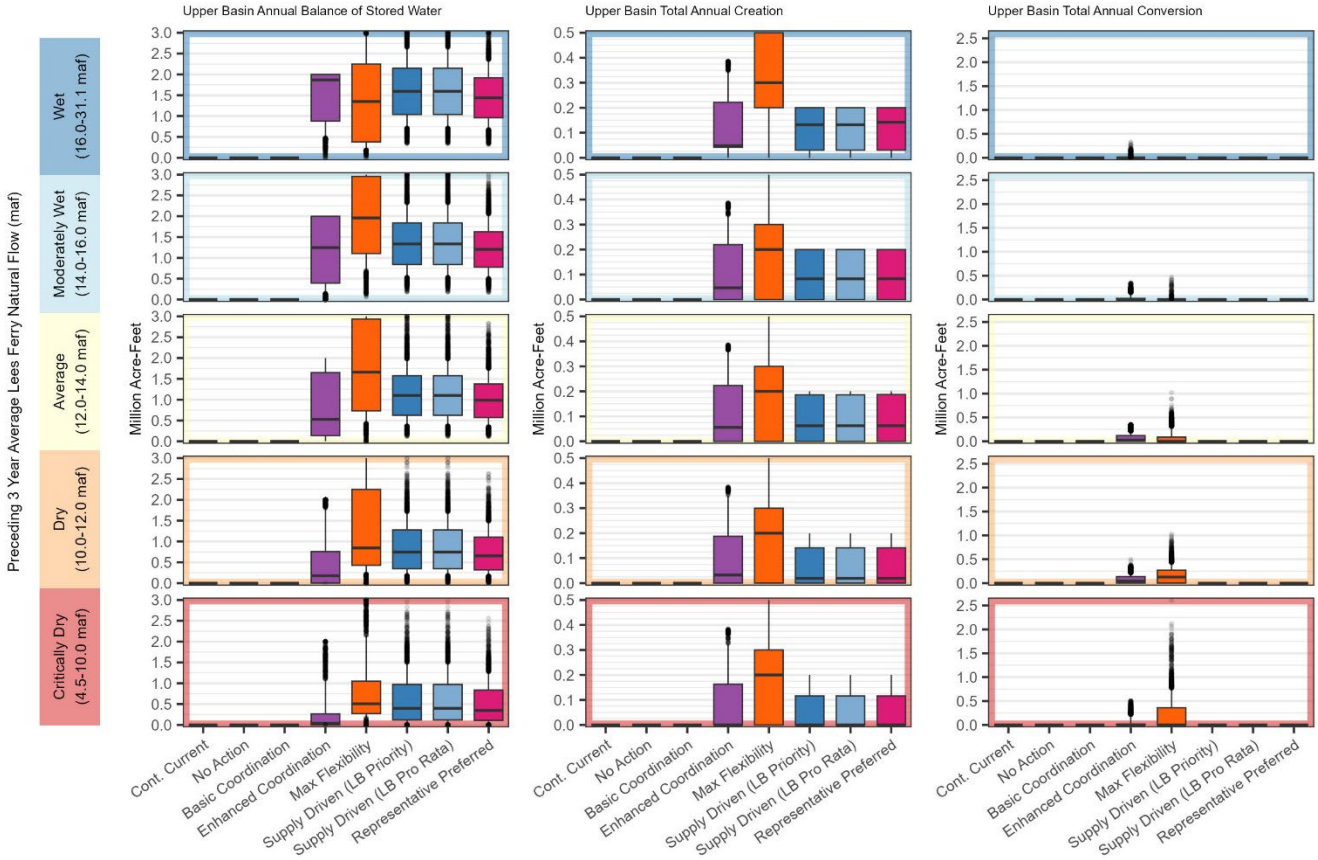

Figure TA 4-19 shows three components of Upper Basin Conservation activity.[7] The first column shows the annual, total volume of conserved water accumulated by the Upper Basin. The second column reports the annual volume of conserved water that is created. The third column reports the annual volume that is converted to system water. Statistical summaries of the data shown in **Figure TA 4-19** are provided in **Table TA 4-40** through **Table TA 4-42** at the end of this technical appendix.

There is zero accumulation, creation, or conversion under the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives, so the remainder of the discussion on **Figure TA**

[6] While the Representative Preferred Alternative models shortages above 1.5 maf in 2028, consistent with the sideboards, under the Preferred Alternative, Reclamation would consult with stakeholders if Lake Mead elevation is projected below 1,000 feet. (See **Chapter 2** for more details on the sideboards under the Preferred Alternative).
[7] For all alternatives except Maximum Operational Flexibility, Lower Basin conserved water is stored in Lake Powell. For Maximum Operational Flexibility, this water can be stored in Lake Mead, Lake Powell, or both.

4-19 focuses on Enhanced Coordination, Maximum Operational Flexibility, Representative Preferred, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives.[8]

Figure TA 4-19
Annual Upper Basin Conservation Activity

Note: In addition to the conservation volumes, the Supply Driven alternative also includes "gap water" (see EIS **Appendix S,** Additional Description of Alternatives, and **Appendix A,** CRSS Model Documentation). The modeled gap water volume increases with higher natural flow release percentages and drier hydrologic conditions. The median is 0.0 maf for the 60 and 65 percent natural flow release scenarios in the Average and Critically Dry flow categories, and increases to slightly over 0.1 maf and 0.8 maf, respectively, for the 70 percent scenario; the maximum gap water volume across all flow categories is approximately 1.1 maf. **Appendix D**, Sensitivity Analysis – Effects of Natural Flow Percentage Used for the Supply Driven Alternative, includes additional information on the modeled volumes of gap water.

Considering total annual accumulation (first column), in the Average Flow Category, the Maximum Operational Flexibility Alternative has the highest median (1.7 maf), followed by the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches; 1.1 maf) and the Representative Preferred and the Enhanced Coordination Alternatives (1.0 maf and 0.5 maf, respectively). The relative ranking is the same under the Critically Dry Flow Category, with medians of 0.5 maf

[8] UB conservation activity is the same for both the LB Priority and LB Pro Rata approaches under the Supply Driven Alternative.

(Maximum Operational Flexibility Alternative), 0.4 maf (Supply Driven Alternative [both LB Priority and LB Pro Rata approaches]), 0.3 maf (Representative Preferred Alternative), and 0.0 maf (Enhanced Coordination Alternative).

Considering total annual creation (second column), under the Average Flow Category, the Maximum Operational Flexibility Alternative has the largest median (0.2 maf), followed by the Representative Preferred, Supply Driven (both LB Priority and LB Pro Rata approaches), and Enhanced Coordination Alternatives at around 0.1 maf. Under the Critically Dry Flow Category, the median for the Maximum Operational Flexibility Alternative remains at 0.2 maf, but the median is 0.0 maf for the Enhanced Coordination, Representative Preferred, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives. However, the 75th percentiles are 0.3 maf (Maximum Operational Flexibility Alternative), 0.2 maf (Enhanced Coordination Alternative), and 0.1 maf (Representative Preferred and Supply Driven [both LB Priority and LB Pro Rata approaches] Alternatives).

Considering total annual conversion (third column), the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) does not convert any conserved water since conservation is created as system water (i.e., values of 0.0 maf for all flow categories and all percentiles). For the Maximum Operational Flexibility and Enhanced Coordination Alternatives, the largest conversion volumes occur in Dry to Critically Dry Flow Categories. Because conversion happens relatively infrequently and at small volumes, it is useful to compare the 75th percentile values. In the Dry Flow Category, 75th percentile conversion volumes are 0.3 maf (Maximum Operational Flexibility Alternative) and 0.1 maf (Enhanced Coordination Alternative). Under the Critically Dry Flow Category, the 75th percentile values are 0.4 maf (Maximum Operational Flexibility Alternative) and approximately 0.0 maf (Enhanced Coordination Alternative).

TA 4.2.8 Issue 7: Lower Division States' 2027-2028 Water Supply Determinations in the Representative Preferred Alternative

The Preferred Alternative is a decision framework under which specific operating guidelines will be periodically reviewed, developed, and updated. Within the framework, the specific shortage volumes and distributions within the operational sideboards will be determined for each set of guidelines. As described in **Chapter 2**, the Representative Preferred Alternative was designed to capture these operational sideboards, but the volume and distribution of shortage under any specific operating guidelines adopted under the Preferred Alternative decision framework may differ.

As of the date of this Final EIS, the first set of operating guidelines are anticipated to cover 2027-2028. To reflect the May 1, 2026 proposal by the Lower Division States, the Representative Preferred Alternative used the LB Priority distribution method for 2027 and 2028, up to 1.5 maf of shortage, as noted in the description of the alternative. The figures below show impacts in 2027 and 2028 of the Representative Preferred Alternative modeling.

While the Representative Preferred Alternative models shortages above 1.5 maf in 2028, consistent with the sideboards, under the Preferred Alternative Reclamation would consult with stakeholders if Lake Mead elevation is projected below 1,000 feet to determine potential additional reductions to Lower Basin water deliveries.

Figure TA 4-20, shows the occurrences of different volumes of total annual Lower Basin shortage volumes modeled in the Representative Preferred Alternative in the years 2027 and 2028 across the 400 modeled traces. In 2027, all 400 traces resulted in a 1.5-maf shortage. In 2028, only 148 traces resulted in a 1.5 maf shortage, while 252 traces resulted in larger shortage volumes, up to 3 maf occurring in 3 traces. Because shortages greater than 1.5 maf are subject to consultation, as is their distribution should they be deemed necessary, they will not be further analyzed.

Figure TA 4-20
Distribution of 2027-2028 Total Annual Lower Basin Shortage Volumes in the Representative Preferred Alternative

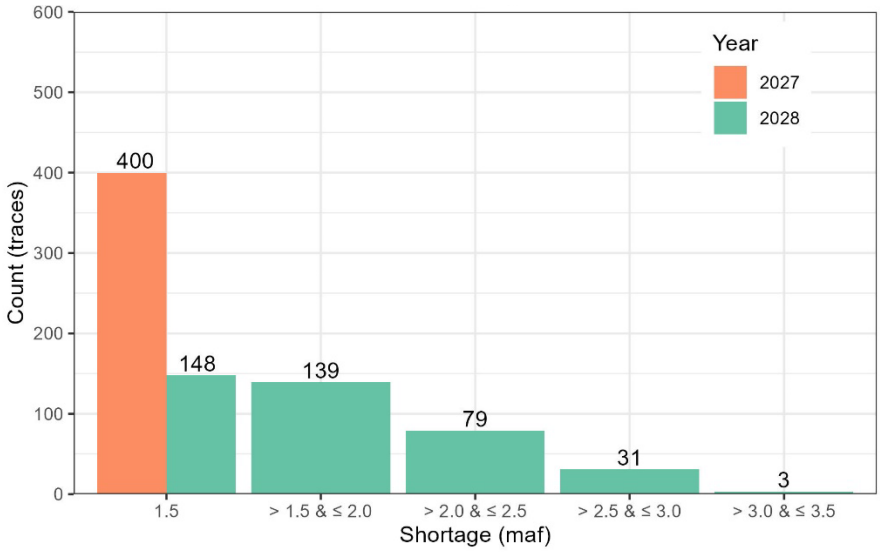

Figure TA 4-21, shows the distribution of annual depletions for each state in 2027 and 2028 in the Representative Preferred Alternative. The panel for each state is scaled by its apportionment; the left vertical axis for each panel shows depletions by percent of apportionment, and the right vertical axis shows absolute volumes of depletions. Arizona's median 2027-2028 depletion is 58.5 percent of apportionment, or 1.6 maf, with maximum and minimum depletions of 75.3 percent and 56.6 percent. California's median 2027-2028 depletion is 89.2 percent of apportionment, or 3.9 maf, with maximum and minimum depletions of 99.8 percent and 78.9 percent. Nevada's median 2027-2028 depletion is 73.3 percent of apportionment, or 0.2 maf, with maximum and minimum depletions of 86.0 percent and 73.3 percent. These modeled depletions reflect the assumed shortage distribution method, as well as the assumptions for the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water, for detailed assumptions). **Table TA 4-43** provides the statistical summary of data in **Figure TA 4-21**.

Figure TA 4-21
Distribution of 2027-2028 Annual Depletions by State in the Representative Preferred Alternative

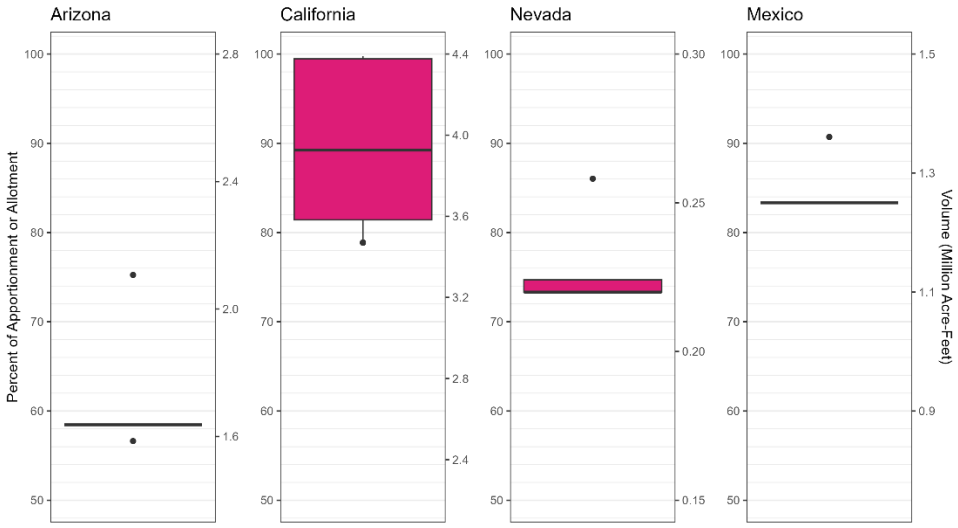

Table TA 4-43
Distribution of 2027-2028 Annual Depletions by State in the Representative Preferred Alternative

State	Max		90th Percentile		75th Percentile		50th Percentile		25th Percentile		10th Percentile		Min	
	%	maf	%	maf	%	maf	%	maf	%	maf	%	maf	%	maf
Arizona	75.3	2.1	58.5	1.6	58.5	1.6	58.5	1.6	58.5	1.6	58.5	1.6	56.6	1.6

TA 4.2.9 Summary Comparison of Alternatives

Summary of Issue 1: Apportionments to the Upper Division States

Issue 1 considered whether the alternatives could affect apportionments to the Upper Division States. Because no changes to those apportionments are expected, no further impact analysis was needed.

Summary of Issue 2: Lower Division States' Apportionments and Water Entitlements

Issue 2 considered whether the alternatives could affect the Lower Division States' apportionments or water entitlements. The shortage distribution approaches were evaluated to explore potential concepts and impacts and not to change existing apportionments or entitlements. Related delivery effects are addressed under Issues 3, 5 and 7, and further summarized below.

Summary of Issue 3: Lower Division States Water Supply Determinations

Issue 3 evaluates how the operational alternatives would affect water supplies for the Lower Division States and Mexico, including shortages, dead pool-related reductions, conservation activity, depletions, delivery reductions, and surplus deliveries. The results show a recurring tradeoff where alternatives with lower planned shortages tend to leave Lake Mead more vulnerable, increasing the risk of dead pool-related reductions. Alternatives with larger or more responsive shortages tend to provide stronger protection against dead pool-related reductions by increasing reservoir elevations and reducing the frequency and magnitude of unplanned cuts. This pattern is most apparent in the No Action and Basic Coordination Alternatives, which have lower planned shortages but show greater dead pool risk than the other action alternatives.

Differences among the operational alternatives become more pronounced as hydrology becomes drier. Most action alternatives include mechanisms for storing and delivering conserved water in Lake Powell and Lake Mead, with the Basic Coordination Alternative as the exception. Modeled conservation activity generally does not substantially change median Lower Basin shortages, dead pool-related reductions, or depletions in most cases, but it can significantly affect the ranges of these outcomes, especially in the Average Flow Category. As conditions become drier, annual conservation creation decreases, causing stored-water balances to decline. In Critically Dry conditions, delivery and conversion can also be limited by lower available stored water or low Lake Mead elevations.

Impacts also vary by how shortages are distributed. Arizona, Nevada, and Mexico tend to see median shortages increase as conditions become drier. California's outcomes depend more on how shortages are distributed, with priority-based approaches limiting or avoiding reductions and pro rata approaches spreading reductions to a broader set of users, including senior priority groups. Depletions reflect the combined effects of shortage volume, shortage distribution, conservation assumptions, and dead pool-related constraints. In the driest conditions, depletions tend to decline as shortages increase and access to conserved water becomes more limited. Overall, surplus deliveries occur infrequently and are concentrated in less severe hydrologic categories.

The Representative Preferred Alternative uses planned shortages to provide stronger protection against dead pool-related reductions. Under both Dry and Critically Dry conditions, the median Lower Basin shortage increases from 1.5 maf in Dry conditions to 2.1 maf in Critically Dry conditions, while median dead pool-related reductions remain 0.0 maf. Dead pool-related reductions are limited to outlier years in the Dry Flow Category, with a maximum of 1.4 maf, whereas in the Critically Dry category they occur in about 10 percent of years and reach a maximum of 3.8 maf. The vulnerability analysis shows that the Representative Preferred Alternative would likely become vulnerable to at least one dead pool-related reduction only under a 10-year average Lees Ferry annual flow of 8.0 maf, a condition much drier than the observed record and present in fewer than 10 percent of Drying with Variability traces. At the state and Mexico level, shortages and delivery reductions under the Representative Preferred Alternative increase for Arizona, Nevada, and Mexico as conditions become Dry and Critically Dry, while California has a median shortage of 0.0 percent in Dry conditions and 10.0 percent in Critically Dry conditions. Depletions under the Representative Preferred Alternative generally decline in Critically Dry conditions as shortage volumes increase and dead pool-related reductions are implemented in some years.

Summary of Issue 4: Deliveries to Mexico

Issue 4 evaluates how the alternatives would affect Colorado River deliveries to Mexico, using two metrics: annual water delivery reductions to Mexico and annual depletions in Mexico. In the Average Flow Category, Mexico's median depletions range from 93.3 percent of allotment under the No Action Alternative to 78.5 percent under the Maximum Operational Flexibility Alternative, and Mexico generally receives its full allotment in about 10 percent of years or fewer. In this same flow category, dead pool-related reductions at Lake Mead occur frequently under the No Action and Basic Coordination Alternatives, but are limited or absent under several other alternatives.

For the Representative Preferred Alternative, Mexico's median depletions are relatively similar between the Dry and Critically Dry flow categories, but variability and dead pool effects increase under the driest conditions. In the Dry Flow Category, Mexico's median depletion is 83.3 percent of allotment, while the median depletion is 81.5 percent in the Critically Dry Flow Category. Under this alternative, dead pool-related reductions affect approximately 25 percent of Critically Dry years, which is less frequent than under No Action but more common than under Maximum Operational Flexibility and the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives.

Summary of Issue 5: Lower Division States' Combined Shortages

Issue 5 evaluates how operational activities under the action alternatives would affect the modeled distribution of combined shortages among Lower Division States water users, compared to the No Action Alternative and CCS Comparative Baseline. The analysis focuses on shortage volumes by water user type (tribal, domestic, and non-tribal irrigation) and uses the SAM and ADM to estimate how available water could be reduced under a range of shortage conditions. Across the alternatives, shortage outcomes vary depending on whether reductions are distributed primarily by priority or on a pro rata basis, with the modeling results illustrating how these different distribution approaches shift impacts among user groups.

In general, priority-based approaches tend to result in greater modeled shortages for tribal and domestic users, while pro rata-based approaches tend to distribute larger shortage impacts to non-tribal irrigation users. This reflects a tradeoff among alternatives, where approaches that protect certain users based on priority may concentrate shortages among other entitlement holders, while broader pro rata approaches spread reductions more evenly but can increase impacts to irrigation users. Under the Representative Preferred Alternative, maximum modeled shortages in 2027 and 2028 would be 346 kaf for tribal users, 858 kaf for domestic users, and 70 kaf for non-tribal irrigation users, unless critical Lake Mead elevations prompt consultation and consideration of additional volumes. For 2029 through 2060, modeling shows the potential for larger impacts, but the actual distribution of shortages would depend on the specific operating guidelines adopted under the Preferred Alternative decision framework.

Summary of Issue 6: Upper Basin Conservation

Upper Basin conservation activity occurs only under the Enhanced Coordination, Maximum Operational Flexibility, Supply Driven (both LB Priority and LB Pro Rata approaches), and Representative Preferred Alternatives. There is no accumulation, creation, or conversion under the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives. In general, annual accumulation is highest under Maximum Operational Flexibility, followed by the Supply

Driven (both LB Priority and LB Pro Rata approaches) and Representative Preferred Alternatives. Annual creation is also highest under Maximum Operational Flexibility, while the other alternatives generally create smaller volumes and show more limited creation, particularly in the Critically Dry Flow Category. Conversion of conserved water is more limited overall, and the Supply Driven (both LB Priority and LB Pro Rata approaches) and Representative Preferred Alternatives do not show conversion because, for the former, conserved water is created directly as system water, and for the latter, there is no conversion mechanism assumed in the modeling.

Summary of Issue 7: Lower Division States' 2027-2028 Water Supply Determinations in the Representative Preferred Alternative

The Preferred Alternative establishes a decision framework rather than a single fixed set of operating rules. Under that framework, specific operating guidelines will be developed and adopted periodically, and the actual shortage volumes and distributions may differ from those modeled in the Representative Preferred Alternative. The Lower Division States' proposal for distributing shortages up to 1.5 maf on May 1, 2026 was incorporated in the Representative Preferred Alternative for 2027 and 2028.

In the Representative Preferred Alternative modeling, all 400 traces show a 1.5-maf Lower Basin shortage in 2027. In 2028, 148 traces remain at 1.5 maf, while 252 traces show larger shortages, with up to 3.0 maf in 3 traces. It is anticipated that volumes and distribution of shortages above 1.5 maf, should they be deemed necessary, would be developed based on consultation and are not analyzed in this Issue. Modeled 2027-2028 depletions reflect the assumed shortage distribution method and conserved-water assumptions, with median depletions of about 1.6 maf for Arizona, 3.9 maf for California, 0.2 maf for Nevada, and 1.3 maf for Mexico.

TA 4.3 Statistical Summary Tables

Table TA 4-10
Lower Basin Shortage (maf)

Alternative	Flow Category	Max (maf)	90% (maf)	75% (maf)	50% (maf)	25% (maf)	10% (maf)	Min (maf)

Note: Lower Basin conservation activity includes assumptions related to the storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Note: Lower Basin conservation activity includes assumptions related to the storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Note: Lower Basin conservation activity includes assumptions related to the storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

Note: The modeled annual delivery reductions in Mexico include modeling assumptions for reductions in water deliveries to Mexico and storage available to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Water Treaty or to represent current U.S. policy or a determination of future U.S. policy regarding deliveries to Mexico. The U.S. will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Water Treaty with Mexico through the IBWC in consultation with the Department of State.

TA 5. Geomorphology and Sediment

TA 5.1 Affected Environment

This section presents an overview of sediment and geomorphic features in the Colorado River study area. The influx and efflux of sediment result in spatial and temporal variations in sandbars and channel-margin deposits throughout the Colorado River (Grams et al. 2013). Sandbar formation is a complex process that depends on:

- Flow Conditions
- Sediment Supply
- Sediment Transport
- Geomorphic Features

TA 5.1.1 Flow Conditions

Prior to the construction of the dams, the Colorado River conveyed high suspended sediment concentrations throughout most seasons during base flows and with larger flood flows (USGS 2011). The construction of Glen Canyon Dam effectively cut off approximately 95 percent of the historical sediment supply from the upper watershed (Topping et al. 2000). As a result, the Colorado River now typically transports sand downstream faster than tributaries can resupply sand on a seasonal to annual basis. This sediment deficit has resulted in progressive erosion of channel and sandbar deposits from Marble and Grand Canyons since 1963. From 1964 to 2017, net erosion occurred for approximately 69 percent of all years in Marble Canyon and for approximately 52 percent of all years in Grand Canyon (Topping et al. 2021).

Maximum releases from the dam are substantially less than historical annual peak flows, and the high-water zone has been lowered compared with the historical level. Under pre-dam conditions, sand would accumulate in Marble Canyon and upper Grand Canyon from July through March when flows were largely below 7,000 to 11,000 cubic feet per second (cfs), then erode from April to June when flows were typically higher (Topping et al. 2000). Current dam operations, under which most flows are greater than 7,000 to 11,000 cfs, do not allow for substantial sand accumulation. In conjunction with reduced sand supply, post-dam discharges have reduced the zone of annual deposition, increased the rate of sediment erosion, and contributed to the loss of beaches and sandbars (USGS 2011).

Since 1996, the Bureau of Reclamation (Reclamation) has conducted high-flow experiment (HFE) releases, managing limited sediment resources to maintain or increase sandbar size. HFE releases, which are designed to improve sediment deposition, provide the only mechanism available for sandbar building and are the most important tool for sediment resources. These water releases from Glen Canyon Dam are much larger than the base flow that is typically released. HFE releases may be

as low as 31,500 cfs, though releases of 37,000 cfs or greater are necessary for sandbar deposition (increased sandbar size) at higher elevations (Hazel et al. 2022; Salter et al. 2025). Sandbars erode between HFE releases (Hazel et al. 2022), with the highest rates immediately after a flood (when bars have the most sediment available for erosion) and decreasing with time (Grams et al. 2010). Steadier flows erode bars at a lower rate than fluctuating flows, under which high flow pulses increase velocity and shear stress (Wright et al. 2008).

Long-term rehabilitation of eddy sandbars can occur only if increases in sandbar volume caused by high flows exceed the erosion that occurs during intervening periods. HFE releases are the only existing mechanism for producing river stages high enough to contribute to significant sandbar building. More frequent HFE releases result in net increases of sandbar size given sufficiently great sand enrichment (Grams et al. 2025). Smaller amounts of deposition combined with large volumes of erosion during intervening periods result in a long-term decrease in sandbar size.

TA 5.1.2 Sediment Supply

The Paria and Little Colorado Rivers, tributaries to the Colorado River, are the major sources of sediment replenishment downstream of the dam. These tributaries affect the mechanisms that control sandbars in Marble and Grand Canyons. No major sediment source exists upstream of the Paria River, effectively making sediment a nonrenewable resource in modern-day Glen Canyon (Grams et al. 2007). Sand supplied by tributaries remains in storage for typically a few months to a year in Marble Canyon before much of it is transported downstream unless flows are below approximately 9,000 cfs (Topping et al. 2000, 2021; Rubin et al. 2002; USGS 2011).

TA 5.1.3 Sediment Transport

The Colorado River in the Grand Canyon is a sediment-supply-limited bedrock river. Releases from Glen Canyon Dam are clear, sediment-free water (Salter et al. 2025). Sediment supplied to the Colorado River comes from tributaries. Sediments are typically classified by particle size and include the following classes:

- Silt and clay (less than 0.0625 millimeters)
- Sand (0.0625 to 2.0 millimeters)
- Gravel and cobbles (2.0 to 256 millimeters)
- Boulders (greater than 256 millimeters)

In general, the term "fine sediment" refers to sediments that are sand-sized or smaller. This group makes up most of the transported sediment in the river and is carried in suspension by most dam releases. Therefore, in this analysis, unless otherwise noted as "coarse sediment," sediment and fine sediment are used interchangeably. Sand contributes the most to sediment storage, deposition rates, and downstream sand export (Topping et al. 2021). The quantity of silt and clay transported depends mainly on the tributary supply. Sandbars contain some silt and clay, but their existence primarily depends on the transport of sand. Sand sediments in the Colorado River are delivered by tributary streams, arroyos, and ephemeral[1] washes. As described above, the Paria and Little Colorado Rivers are the dominant sources. The smaller tributaries in Marble Canyon upstream from river mile (RM)

[1] A wash that flows part of the time, usually after a rainstorm, during wet weather, or for only part of the year.

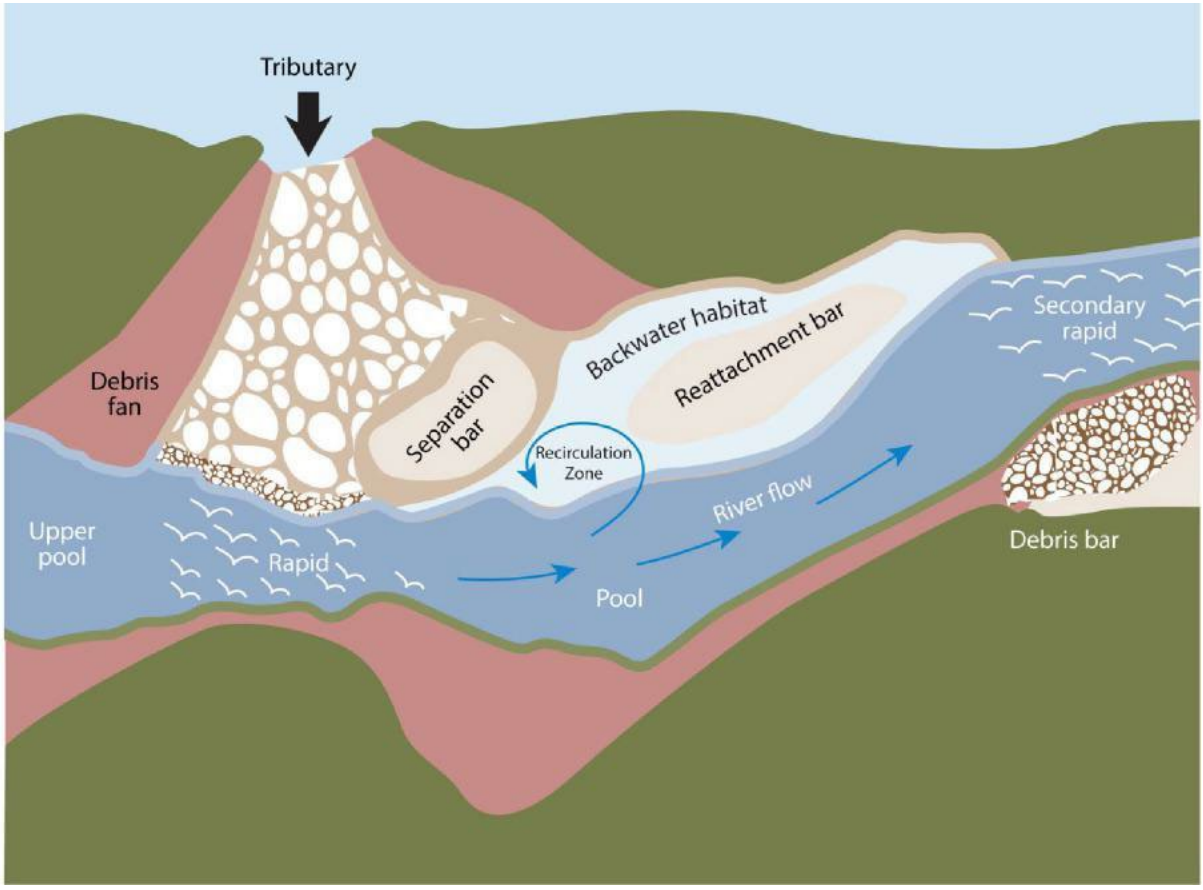
30 together contribute roughly 10 percent of the sand annually supplied by the Paria River (Griffiths and Topping 2017). Downstream from RM 30, the Marble Canyon lesser tributaries supply negligible amounts of sand (Griffiths and Topping 2017, Topping et al. 2021).

The amount of sand stored within the riverbed each year depends on the highly variable tributary supply, the frequency and duration of water released from the dam, and the amount of sand already deposited on the riverbed at the beginning of the year. Sand stored on the riverbed is the principal source for building sandbars during periods of high flow releases. Sediment transport is a function of, and increases with, the volume of water flowing in the river. It also depends on changes in the sediment size and supply associated with tributary floods and dam operations, as well as the distribution of shear stress[2] across the wetted channel.

The shear stress caused by flowing water can increase the amount of sediment in suspension and the amount that is available for transport. Sediment deposition occurs wherever there is more sediment influx than efflux, but is dependent on local hydraulics, such as eddies (see **TA 5.1.4**) and the topography of the riverbed (Grams et al. 2013). The greater the river's flow, the greater its velocity, shear stress, and sediment load.

Sediment storage on the riverbed depends on the spatial variability of the riverbed (such as variations of boulders, cobbles, bedrock, and vegetation), the depth to the riverbed, and the tributary sediment supply (Rubin et al. 2020). This sediment storage, in addition to storage within sandbars and along channel margins on the Colorado River, results from coupled flow, sediment transport, and storage within fan-eddy complexes (**Figure TA 5-1**)[3] that lead to the deposition of sediments.

TA 5.1.4 Geomorphic Features



The longitudinal profile of the Colorado River consists of long, flat pool reaches with intermixed short, steep rapids. The rapids in fan-eddy complexes are typically associated with boulder rich deposits formed by tributary debris flows,[4] and flash floods. Debris fans continue to be replenished and enlarged by debris flows triggered by slope failures into tributaries. The geologic conditions favorable for debris flows from side canyons vary greatly. Debris flows tend to be high-magnitude, short-duration events. Debris flows create and maintain the rapids, control the size and location of eddies, and serve as potential sources of sand to replenish Colorado River sandbars in Marble and Grand Canyons (Schmidt and Rubin 1995; Webb and Griffiths 2001).

The coarse sediments associated with debris-fan deposits can only be mobilized during elevated flows and do not constitute a significant contribution to sediment loads transported by the river. However, their dynamics are important with respect to their retention of fine sediments and the development of fan-eddy complexes (Reclamation 2016). Debris fans extending into the Colorado River obstruct the channel, making it narrower and raising the bed elevation, which forms rapids through the point of constriction and causes the downstream-directed current to become separated

[2] The force per unit area acting parallel to a surface that causes slippage.
[3] Areas along the river where a tributary's debris fan—a sloping deposit of poorly sorted sediment ranging in size from clays and silts to larger boulders—partially blocks the river flow, causing the formation of rapids and eddies (Schmidt and Rubin 1995). Fan-eddy complexes are the controlling geomorphic feature in the Colorado River for sediment deposition.
[4] A large mass flow of sediment caused by slope failures on tributary canyons.

from the riverbank (Webb and Griffiths 2001). Downstream of the constriction, the channel is typically wider, the main current reattaches to the riverbank, and some of the water is redirected upstream. This change in flow direction forms a zone of low-velocity recirculating water (an eddy) between the points of separation and reattachment and between the main channel and riverbank (Rubin et al. 1998). These conditions allow for sediment to become entrained within the recirculation zone, where lower-velocity flows enhance the potential for sediment deposition (Schmidt and Rubin 1995).

Figure TA 5-1
Diagram of the Fan-Eddy Complex on the Colorado River

Source: Web and Griffiths 2001

Sand is deposited throughout Glen, Marble, and Grand Canyons in bars (or patches) on the riverbed, in eddies, and on terrace sandbars. Nearly all sandbars in the Grand Canyon are associated with fan-eddy complexes. In general, these complexes generate consistent sandbar features, which include separation bars and reattachment bars, based on their specific locations within the recirculation zone (USGS 2011). They continuously exchange sand with the river. Thus, the sandbars commonly found along the banks of the Colorado River are generally dynamic and unstable.

The magnitude of deposition varies by site, depending on geomorphic conditions and vegetative cover; some sandbars are stabilized by vegetation (Mueller et al. 2018; Hazel et al. 2022). Sandbars

form a fundamental element of the river landscape and are important for vegetation, riparian habitat for fish and wildlife, cultural resources, and recreation (Reclamation 1995, 2024). They form the substrate for limited riparian vegetation in this arid environment. Low-elevation sandbars create zones of low-velocity aquatic habitat (i.e., backwaters) that may be utilized by juvenile native fishes for spawning and refuge (Van Steeter and Pitlick 1998; Rubin et al. 2002). These low-elevation sandbars have been documented to be the source of sand for wind transport that helps protect archaeological resources in certain areas (East et al. 2016; Collins et al. 2016; Sankey and Draut 2014; Sankey et al. 2023a, 2023b). In addition, beaches provide some of the only camping areas for whitewater river trips, a significant driver of economic activity in the region.

TA 5.1.5 Turbidity

Turbidity is known to increase in the study area during high flows when suspended sediment concentration increases. Clear water conditions exist most of the time in the study area, interrupted by temporary periods of low visual clarity after tributary flooding (Voichick and Topping 2014). During runoff events, turbidity often exceeds the maximum recording levels of optical turbidity probes of 1,000 to 2,000 formazin nephelometric units[5]. Optical measurements of turbidity can be correlated with streamflow or with suspended sediment concentration; however, these relationships should be used with caution because, in the Colorado River, a) physical sediment characteristics are highly variable over time and b) the upper limit of measurable turbidity on optical turbidity probes is reached (Voichick and Topping 2014).

High concentrations of fine suspended sediment can increase turbidity, an optical measurement of dissolved or suspended particles in water. The relationship between turbidity and suspended sediment concentration depends on the physical properties of sediment and changes under differing conditions and sediment sources. Although higher turbidity is generally viewed as undesirable for recreational activities, it more closely reflects pre-dam conditions of the river and may therefore benefit native fish (see **TA 8**). Turbidity in the Colorado River is a natural condition and is not considered further in this section.

TA 5.1.6 Study Area

The geographic scope that would be affected by the proposed alternatives extends from Lake Powell to the Southerly International Boundary with the United Mexican States. Lake Powell has sufficient dead storage capacity to trap most incoming sediments, with only a small amount reaching areas near Glen Canyon Dam. Surveys show Lake Powell has lost approximately 13 percent of its designed dead storage capacity (Root and Jones 2022), so sedimentation is not projected to impact dam safety, power generation, or the sediment concentration at Glen Canyon Dam during the analysis timeframe of this environmental impact statement (EIS).

HFEs would have significant impacts on geomorphology and sedimentation in Marble Canyon and Grand Canyon. Since most fine sediment is transported downstream, this material will ultimately be trapped behind Hoover Dam in Lake Mead.

[5] A measure of turbidity. These formazin nephelometric unit values indicate the water has more suspended sediment and light cannot penetrate easily.

Downstream of Hoover Dam, the Colorado River functions as a sediment-starved, clearwater system. The magnitude of releases from Hoover Dam influences sediment transport capacity but does not meaningfully alter sediment supply. Consequently, this reach is defined by stable, armored bed surfaces, simplified channel morphology, and limited sandbar formation. Sediment originates primarily from reworking of fine-grained material along channel margins and bank erosion associated with sparse depositional pockets. Vegetation encroachment along banks has increased in recent decades under stabilized baseflows, further constraining areas where sediment can accumulate or be remobilized.

The only significant sediment inputs downstream of Hoover Dam are large, infrequent events on the Bill Williams River and the Gila River, affecting the reaches from Parker Dam to Imperial Dam and from Imperial Dam to the Northerly International Boundary. Ongoing Reclamation dredging operations remove this sediment at and upstream of Imperial Dam as well as upstream of Morelos Diversion Dam to improve diversion capability and to efficiently convey water to downstream users, operations which will continue under the proposed alternatives.

TA 5.2 Environmental Consequences

TA 5.2.1 Methodology

All modeling used for this resource section was based on modeling performed by the United States Geological Survey (USGS) Grand Canyon Monitoring and Research Center (Grams et al. 2025; Salter et al. 2025), using a sand routing model (Wright et al. 2010) and a sandbar response model (Mueller and Grams 2021). Input hydrologies were developed using modeling results from the Colorado River Simulation System, a long-term planning tool operated by the Bureau of Reclamation to support decision making in the Colorado River Basin and implemented in RiverWare (Zagona et al. 2001). For additional information on Colorado River Simulation System results and assumptions, please see Appendix D of Reclamation (2016).

The initial conditions (bed thicknesses and bed grain-size distribution) for the sand routing model were based on Wright et al. (2010), using a spin-up period from September 1, 2002, to October 1, 2024, and sediment inputs and gage discharges downloaded from the USGS Grand Canyon Monitoring and Research Center website (USGS 2024). Because the initial conditions for future simulations are unknown, the following idealized initial conditions were selected based on a simulation of the sand routing model and the spin-up period: a bed thickness of 0.5 meter, a lognormal bed grain size distribution with a median bed grain size of 0.3 millimeter, and a geometric standard deviation of 1. Sediment inflow projections from the Paria and Little Colorado Rivers were also generated using the Wright et al. (2010) sand routing model. This sand routing model provides sediment budget by grain size, suspended sediment concentrations, and changes in bed texture over time. Each of the 400 hydrology traces were randomly assigned a trace of Paria River sediment year inputs for sediment years 1998 to 2024. A sediment year aligns with the seasonal cycle of sediment supply and river flow, rather than the calendar year. It runs from July 1 to June 30 the following year (Topping et al. 2000).

To generate final sand routing and sandbar volume simulations, the sand routing model was rerun for each trace, with new hourly hydrographs generated by a hydropower optimization model and the same Paria River traces as in the previous round of modeling. Changes to the sediment mass balance were minimal, and HFE release durations were not modified.

HFE release magnitude and duration were selected via iteration according to the sand mass balance. USGS Grand Canyon Monitoring and Research Center modelers redistributed monthly volumes if necessary and interfaced the monthly volumes with the sand routing model by generating synthetic 15-minute hydrographs.

The output of the sand routing model provided suspended sand concentration and median grain-size inputs for the Mueller and Grams (2021) sandbar model. This model predicts long-term changes in sandbar volume in the Colorado River through the Grand Canyon based on controlled releases from Glen Canyon Dam. The sandbar model was recalibrated to the 2002–2024 period based on the long-term monitoring program. The model was initialized using the January 1, 2025, volume, and each alternative was run for all 400 traces (see **Appendix F**, Approach to Hydrologic Uncertainty, for more information on the initial conditions).

Some modifications were made to the Mueller and Grams (2021) sandbar model for this Final EIS to use additional sandbars in the calibration dataset (a total of 25 sandbars that were separated into 12 within Marble Canyon and 13 within Grand Canyon); incorporate discharge-dependence into the erosion model, rather than assuming exponential erosion with an unchanging rate constant; and assume a constant sandbar area rather than a linear relationship between sandbar area and sandbar volume (Salter et al. 2025).

Two versions of the sandbar model were used to predict sandbar deposition: one for flow rates exceeding 8,000 cfs, the average daily discharge flow; and one for flow rates exceeding 25,000 cfs, the discharge at which sandbars will not be inundated during normal dam operations and will result in usable sandbars for recreational purposes (Salter et al. 2025). Except for modeled HFEs, the sandbar model did not include any sustained releases above 25,000 cfs over the calibration period.

This technical appendix uses modeled sand transport, sandbar volumes, and reservoir operations data for the Colorado River in Grand Canyon from the USGS Grand Canyon Monitoring and Research Center (Salter and Grams 2026).

Refer to **Section 3.2**, Analysis Methods, for additional information on Decision Making Under Deep Uncertainty (DMDU) and **Appendix E**, DMDU Overview and Approach, for an overview of how to interpret the DMDU conditional box plots, robustness heat maps, and vulnerability bar plots.

Impact Analysis Area

The impact analysis area used for the USGS Grand Canyon Monitoring and Research Center's sediment modeling data is the Colorado River from Glen Canyon Dam to Lake Mead, including sediment inputs from the Paria River and Little Colorado River tributaries. The analysis area for the sandbar model (quantitative model) is from Lees Ferry Gaging Station (RM 0) through Diamond Creek (RM 225). The extent of this model is limited by the availability of study sites in the

calibration dataset. However, it is expected that the finding for the reach between Lees Ferry and Diamond Creek is also representative of similar sandbars downstream to Separation Canyon (RM 240), the full-pool extent of Lake Mead.

With low Lake Mead elevations, the Colorado River will cut new paths through the mouth of the reservoir, resulting in sediment redistribution that forms new bars and alters the reservoir's delta. Finer particles may remain in suspension and travel further downstream in the reservoir before settling, increasing sediment concentration in the upper reaches of Lake Mead. Impacts on water surface elevations and consequently erosion and deposition patterns in the delta region of Lake Powell may also result. Sediment redistribution within the reservoirs is not evaluated in this EIS due to the absence of an applicable model.

The proposed alternatives may modify the magnitude, timing, or variability of releases from Hoover Dam relative to existing operations. Any such changes would affect sediment resources downstream by altering sediment transport capacity and the degree to which available fine sediment is mobilized or retained. However, because the downstream reach is sediment-starved and the alternatives would not introduce new sources of sediment, significantly modify sediment supply, or change channel morphology, any effects on geomorphology and sedimentation downstream of Hoover Dam are expected to be negligible. In all cases, sediment-related effects are expected to remain localized, reflecting the reach's supply-limited sediment regime.

Modeling Criteria and Assumptions

- For an HFE to be triggered, enough sand needs to be available in Marble Canyon (there must be a positive sand mass balance over the sediment accounting period), and enough water needs to be available in Lake Powell (as measured by the water level). Both the required amounts of sand and water depend on the selected HFE duration.
- Consistent with the 2024 Glen Canyon Dam Long-Term Experimental Management Plan (LTEMP) Supplemental EIS and Salter et al. (2025), HFE releases can only be implemented above a Lake Powell elevation of 3,500 feet, the elevation required for a release magnitude of 37,000 cfs.
- Reclamation's future operations will remain responsive to hydrology, system conditions, and applicable legal and operational requirements. Reclamation will continue to follow the 2016 Glen Canyon Dam LTEMP EIS and the 2024 LTEMP Supplemental EIS guidelines, which include the planning and implementation team process that helps assess monthly release volumes and Secretarial decision-making.
- Annual and monthly release volumes can limit the ability for an HFE release. HFE releases are offset by reducing releases from the rest of the water year, while ensuring no months go below LTEMP minimum releases in the process.
- Only sand deposited above flow rates of 25,000 cfs, which corresponds to the minimum water level that provides safety from flooding, is considered "usable" for recreational purposes.
- Sandbar deposition occurs most rapidly during the first 4 days of an HFE event, when the suspended sand concentration is largest, and the suspended sand is finest.
- Based on historical data, 60 hours is the minimum duration for an HFE to result in significant sandbar deposition.

- The transport capacity for sand during a 60-hour HFE event depends on the grain size of the accumulated sand. The average transport capacity for the 60-hour event is 294,000 metric tons, based on the analysis using the Wright et al. (2010) sand routing model.
- Sandbar erosion rates tend to be highest immediately after a flood (when bars have the most sediment available for erosion), then decrease with time (Grams et al. 2010). Steadier flows erode sandbars at a lower rate than fluctuating flows (Schmidt and Rubin 1995).
- Total discharge maximum ramp rates of 4,000 cfs per hour up and 2,500 cfs per hour down are consistent with the 2016 LTEMP EIS and 2024 LTEMP Supplemental EIS.
- Sandbar volume modeling uses the assumption that HFEs are implemented as often as possible.
- Most of the sand input from the Paria and Little Colorado Rivers occurs during the summer-fall thunderstorm season between July 1st and November 1st. A fall HFE would take full advantage of this by initiating an HFE prior to winter releases that could transport the sand downstream without the ability to aid in sandbar formation.
- During low water levels in Lake Powell, large winter releases are not a major concern. Snowpack accumulation is known prior to a possible spring HFE. This creates the option to prefer a spring HFE over a fall HFE during prolonged dry conditions, although fall HFE implementation is considered independent of a spring implementation. "Deferring," or choosing not to conduct an HFE, does not prioritize conducting an HFE during the next implementation window.
- If no HFE releases were implemented during the 1-year sediment accounting period, any positive sediment mass balance would be carried over into the next accounting period.

Impact Indicators

Issues related to geomorphology and sedimentation that are evaluated in this section are listed below.

1. Water Availability in Lake Powell
2. Sand Mass
3. HFE Frequency and Duration
4. Sandbar Volume
5. Sand Transport

TA 5.2.2 Issue 1: Water Availability

An HFE likely to enlarge sandbars requires enough water for a release rate of 37,000 cfs, generally considered the flow rate needed for significant deposition on certain sandbar types (Hazel et al. 2022). A 37,000 cfs release requires Lake Powell to be at or above 3,500 feet in April or November, when HFEs are typically scheduled. 3,500 feet also provides a 10-foot buffer above 3,490 feet – the elevation below which water can only be released through the river outlet works. As described in **Chapter 1**, **Section 1.8.4.1**, there are infrastructure concerns associated with the uncertainty of extended operations through the river outlet works as the sole means of sustained water releases from Glen Canyon Dam that could compromise the reliability and operational flexibility of Glen Canyon Dam and affect the ability to meet critical downstream water supply needs Alternatives

that more frequently result in water levels greater than this threshold are therefore preferable. It should be noted that there are challenges to conducting HFEs at a Lake Powell elevation of 3,500 feet. Historically, the lowest elevation at which an HFE has been implemented was 3,523 feet in April 2023, when a large snowpack resulted in predictions of high rates of spring/summer runoff. Fall HFEs have not been implemented when Lake Powell water levels were below 3,590 feet.

Since the models used an elevation of 3,500 feet as the lowest possible elevation at which HFEs could occur, it is likely that the modeling overestimates the number or frequency of HFEs and underestimates the impacts on sediment related resources in the Grand Canyon for some alternatives. **Table TA 5-1** below shows the percentage of modeled HFEs by alternative that were below the historical low of 3,523 feet, including a high of 18.5 percent under the Supply Driven Alternative (both Priority and Pro Rata approaches). Notably, the two alternatives resulting in the fewest modeled HFEs below 3,523 feet –Enhanced Coordination and Maximum Operational Flexibility – result in the best overall performance with respect to geomorphology and sediment out of all the alternatives, as described in the remainder of this section.

Figure TA 5-2 below depicts the ability of each alternative to maintain a Lake Powell pool elevation greater than 3,500 feet in November or April in the specified percent of years. The preferred minimum performance is shown in the purple highlighted row, which represents the percentage of futures that an alternative exceeds 3,500 feet in November or April in 100 percent of years. The 3,500-foot threshold was selected because it is undesirable to ever miss the opportunity to take advantage of other favorable conditions, such as large sediment loads from the Paria River.

Over the full modeling period, the Maximum Operational Flexibility Alternative is the most robust, as it met the preferred minimum performance in more than 91 percent of futures, followed by the Enhanced Coordination Alternative at 83 percent. The Representative Preferred Alternative meets the preferred minimum performance in 40 percent of futures. The Continued Current Strategies (CCS) Comparative Baseline, as well as Supply Driven (both Lower Basin Priority [LB Priority] and Lower Basin Pro Rata [LB Pro Rata] approaches) and Basic Coordination Alternatives, are less robust, with less than 30 percent of futures meeting the preferred minimum performance. The No Action Alternative is the least robust, with only 13 percent of futures meeting the preferred minimum performance. For all alternatives, fewer futures meet the preferred minimum performance over the full modeling period than in any subperiod. This reflects the increasing difficulty of sustaining a given level of performance over longer periods of time. Only a fraction of the futures meeting the preferred minimum performance in one subperiod also meet the preferred minimum performance in all subperiods, evidence of the interdecadal variability inherent in the ensemble of projected conditions.

Based on the planned length of this decision, it is important to compare robustness in the 2027-2039 modeling period. The Maximum Operational Flexibility (97 percent) and Enhanced Coordination (88 percent) are the most robust alternatives, followed by the Representative Preferred (60 percent). The No Action Alternative (19 percent) is the least robust, and the CCS Comparative Baseline (35 percent), Basic Coordination Alternative (36 percent), and the Supply Driven (both LB Priority and Pro Rata approaches) Alternative (46 percent) perform in the middle.

Table TA 5-1
Percentage of Modeled HFEs Above or Below the Historical Low Lake Powell Elevation (3,523 feet)

Alternative	Total number of HFEs (all years, all futures)[1]	Percent of all eligible timesteps with an HFE	Percentage of Modeled HFEs Above	Percentage of Modeled HFEs Below	Average number of HFEs/year Only Above	Average number of HFEs/year Above + Below
CCS Comparative Baseline	6,501	23.9%	85.3%	14.7%	0.41	0.48
No Action Alternative	6,478	23.9%	90.0%	12.0%	0.42	0.48
Basic Coordination Alternative	7,552	27.8%	87.2%	12.8%	0.48	0.56
Enhanced Coordination Alternative	7,897	28.9%	99.5%	0.5%	0.58	0.58
Maximum Operational Flexibility Alternative	8,846	35.5%	91.3%	8.6%	0.59	0.65
Supply Driven Alternative	7,438	27.3%	81.5%	18.5%	0.45	0.55
Representative Preferred Alternative	7,933	29.2%	86.4%	13.6%	0.50	0.58

[1] The total number of HFE eligible timesteps is 27,200 (April and November, all futures, all years)

Figure TA 5-2
Lake Powell Elevation Meeting Requirement for HFE: Robustness.
Percent of futures in which the November or April elevation exceeds 3,500 feet in the percent of years specified in each row

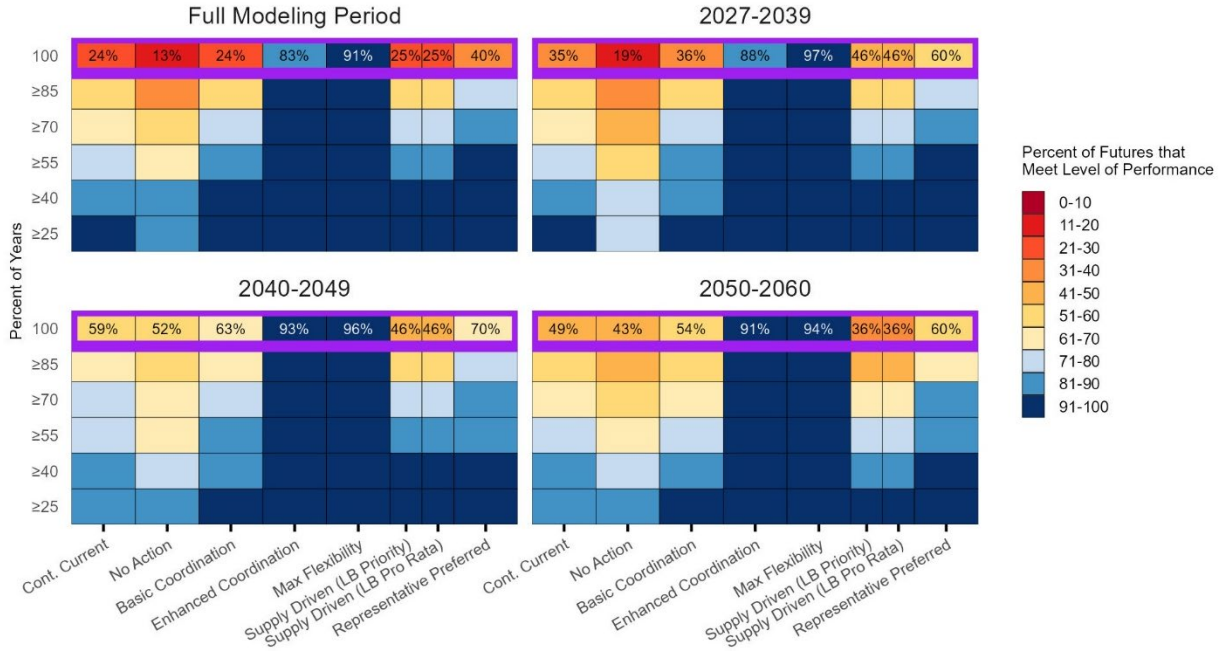


Figure TA 5-3 shows the same information as **Figure TA 5-2** but for an elevation threshold of 3,523 feet, the lowest Lake Powell elevation in the historic record. Once again, the Enhanced Coordination and Maximum Operational Flexibility Alternatives clearly outperform the other alternatives and the CCS Comparative Baseline, but the percentage of futures that meet the preferred minimum performance (26 percent and 21 percent, respectively) is substantially lower than in **Figure TA 5-2**, as an elevation of 3,500 feet is a less stringent threshold than 3,523 feet and therefore easier to achieve. In addition, whereas the Maximum Operational Flexibility Alternative is most robust for an elevation threshold of 3,500 feet (**Figure TA 5-2**), the Enhanced Coordination Alternative is most robust for an elevation threshold of 3,523 feet (**Figure TA 5-3**).

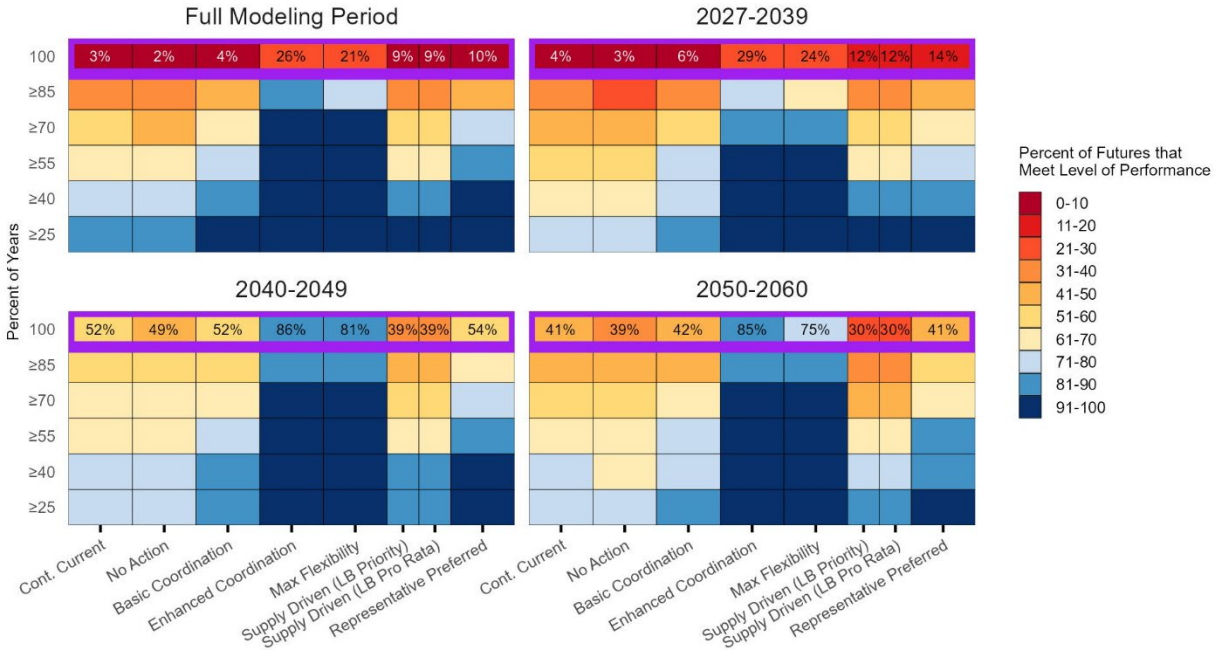
Based on the planned length of this decision, it is important to compare robustness in the 2027-2039 modeling period. As in the full modeling period, Enhanced Coordination (29 percent) and Maximum Operational Flexibility (24 percent) are the most robust alternatives. The No Action Alternative is the least robust (3 percent), followed closely by the CCS Comparative Baseline (4 percent) and the Basic Coordination Alternative (6 percent). The Supply Driven (both LB Priority and Pro Rata approaches) Alternative (12 percent) and the Representative Preferred Alternative (14 percent) perform in the middle over the first modeling period.

Figure TA 5-3
Lake Powell Elevation Above Lowest Observed in HFE Implementation: Robustness. Percent of futures in which the November or April elevation exceeds 3,523 feet in the percent of years specified in each row



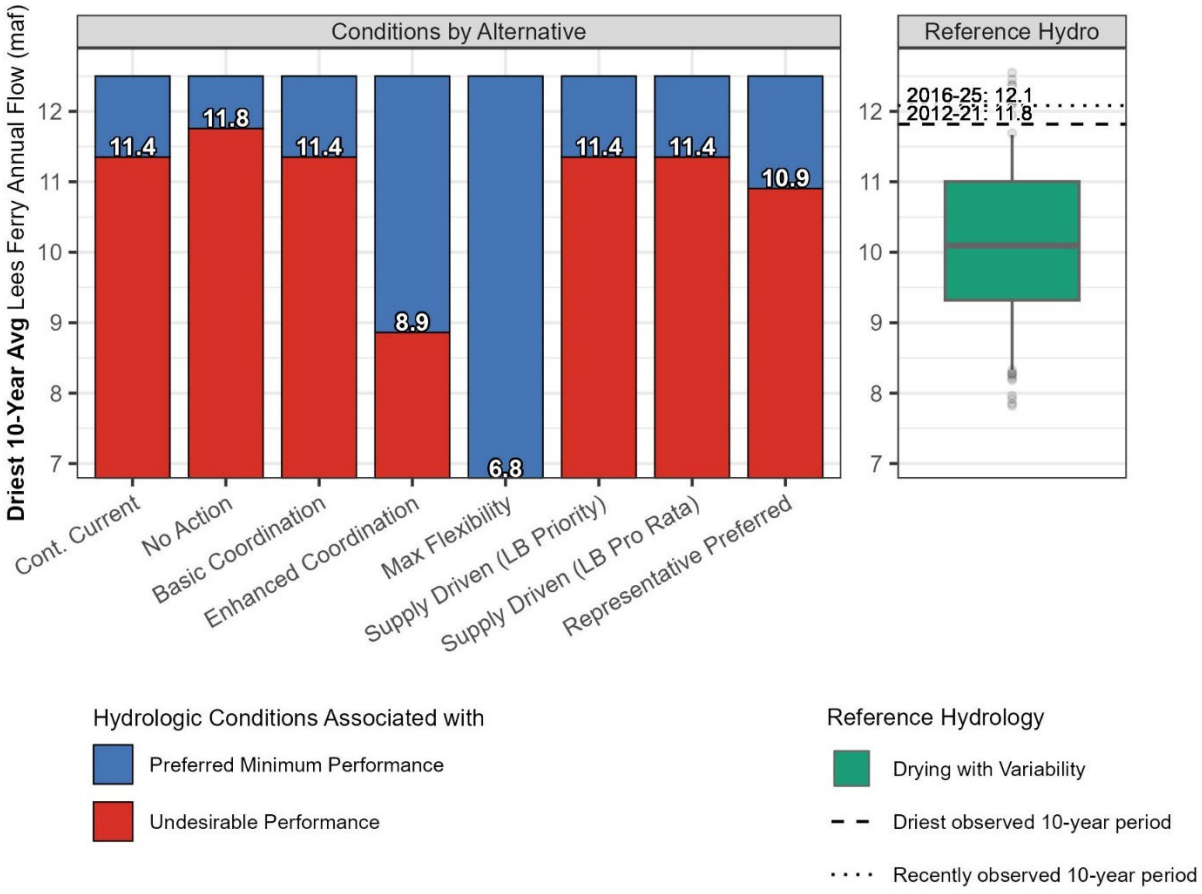


Figure TA 5-4 below shows what flow conditions are likely to cause the elevation of Lake Powell to fall below 3,500 feet in November and April in one or more sediment years. This definition of undesirable performance is based on the highlighted row in **Figure TA 5-2** above, which defined a future as successful when an alternative exceeds 3,500 feet in November or April in 100 percent of years.

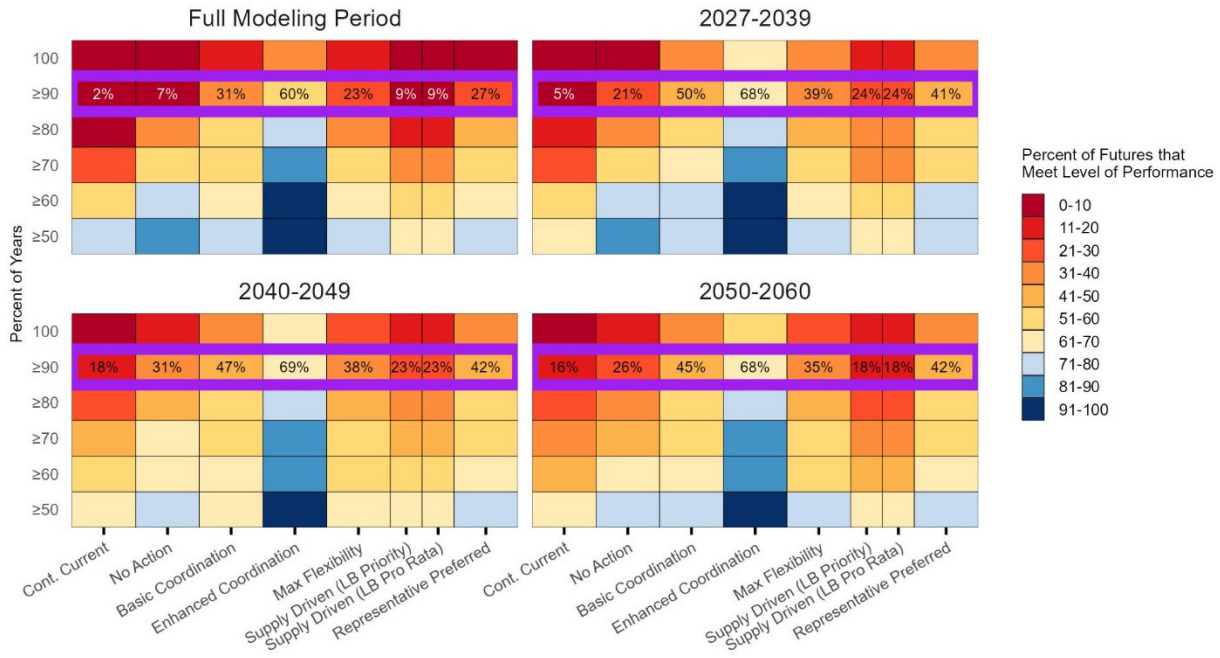
For this vulnerability analysis, the driest 10-year average Lees Ferry annual flow was determined to be best for predicting undesirable performance. The vulnerability threshold for each alternative is described and compared to the Drying with Variability ensemble using this streamflow summary statistic. The driest observed 10-year average flow from 2012–2021 (11.8 million acre-feet [maf]) and the average flow from 2016–2025 (12.1 maf) are also provided as dashed and dotted lines, respectively, for comparison (see **Chapter 3, Figure 3-4**, for more information on the selected reference hydrology).

Modeling results for the CCS Comparative Baseline indicate undesirable performance under futures whose driest 10-year average flow is 11.4 maf or lower. Modeling results for the No Action (11.8 percent), Basic Coordination (11.4 percent), and Supply Driven (both LB Priority and LB Pro Rata approaches) (11.4 percent) Alternatives are comparable to the CCS Comparative Baseline, where greater than 75 percent of reference hydrology Drying with Variability traces have 10-year average annual flows drier than these alternatives (see **Appendix F**, Approach to Hydrologic Uncertainty, for more information on the Drying with Variability ensemble). Enhanced Coordination Alternative

modeling results indicate undesirable performance when the driest 10-year average flow is 8.9 maf or lower, which occurs in less than 25 percent of the Drying with Variability traces. Modeling results for the Maximum Operational Flexibility Alternative, the best performing alternative in this case, indicate undesirable performance when the driest 10-year average flow is 6.8 maf or lower, which is notably lower than the driest observed 10-year average annual flow of 11.8 maf.

Figure TA 5-4
Lake Powell Elevation Meeting Requirement for HFE: Vulnerability. Conditions that could cause Lake Powell elevation below 3,500 feet in November and April in One or More Sediment Years

Modeling indicates that the Representative Preferred Alternative would likely be vulnerable to one or more occurrences of Lake Powell elevation falling below 3,500 feet in November and April under a 10-year average Lees Ferry annual flow of 10.9 maf. While these conditions have not yet been observed, absent additional action, this alternative is reasonably likely to be vulnerable in the next 10 years because these conditions occur in about 75 percent of the traces in the Drying with Variability Ensemble, which represents a drier future.



TA 5.2.3 Issue 2: Sand Mass

Sand in the Colorado River must be available to allow for downstream conveyance and sandbar deposition during an HFE release. Sand that accumulates in Marble Canyon but is transported

downstream outside HFE events does not result in sandbar formation. Sand available for sandbar building is generally supplied to the Colorado River in the late summer and early fall, the thunderstorm-induced flood season in the Paria and Little Colorado watersheds. While management under the proposed alternatives would not attempt to control the sediment generation in these tributaries, the alternatives would affect the timing and magnitude of Glen Canyon Dam releases and, therefore, the amount of sand transported outside HFE events.

Figure TA 5-5 below depicts the ability of each alternative to maintain a sediment year maximum monthly release from Glen Canyon Dam less than 900 thousand acre-feet (kaf) (approximately 15,000 cfs) in the specified percent of years. While average monthly flows must be lower than about 11,000 cfs to allow sediment accumulation under most initial conditions (bed conditions following a tributary sediment-supply event), monthly flows averaging greater than 15,000 cfs are likely to be erosive regardless of those initial conditions (Salter et al. 2025). Therefore, monthly outflows exceeding 900 kaf are considered erosive for accumulated sand. The preferred minimum performance is shown in the purple highlighted row, which represents the percentage of futures that an alternative maintains a sediment year maximum monthly release from Glen Canyon Dam less than 900 kaf in at least 90 percent of years.

Figure TA 5-5
Glen Canyon Dam Releases: Robustness.
Percent of futures in which the sediment year maximum monthly release is less than 900 kaf in the percent of years specified in each row

Over the full modeling period, the Enhanced Coordination Alternative is the most robust, meeting the preferred minimum performance in 60 percent of futures. The next best-performing alternatives are Basic Coordination at 31 percent, Representative Preferred Alternative at 27 percent, and Maximum Operational Flexibility at 23 percent. The No Action Alternative is the least robust, with

only 7 percent of futures meeting the preferred minimum performance. Under the CCS Comparative Baseline, as well as No Action and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives, less than 10 percent of simulated futures satisfy the preferred minimum performance.

Fewer futures meet the preferred minimum performance over the full modeling period than they do in any one of the subperiods, a reflection of the increasing difficulty of sustaining this performance level over a longer period and evidence of the interdecadal variability inherent in the ensemble of projected conditions.

Based on the planned length of this decision, it is important to compare robustness in the 2027-2039 modeling period. Enhanced Coordination (68 percent) and Basic Coordination (50 percent) are the most robust alternatives. The CCS Comparative Baseline (5 percent) is the least robust, followed by the No Action (21 percent) and Supply Driven (both LB Priority and Pro Rata approaches) (24 percent) Alternatives. The Maximum Operational Flexibility and the Representative Preferred Alternatives perform in the middle, meeting the preferred minimum performance in 39 percent and 41 percent of futures, respectively, over the 2027-2039 modeling period.

To a certain extent, release volumes are of reduced concern due to variability throughout the sediment year and flexibility in moving water under LTEMP. If the highest releases happen before most major Paria sediment deliveries in the late summer, sediment will remain in the riverbed for a fall HFE. Under current LTEMP operations, there is flexibility to reduce releases after sediment delivery and store water that can be released during an HFE. Because of those elements, it is anticipated that in most years with reservoir elevations above 3,500 feet and average monthly releases greater than 900 kaf per month, management flexibility will be allowed for the maximum preservation of sand mass.

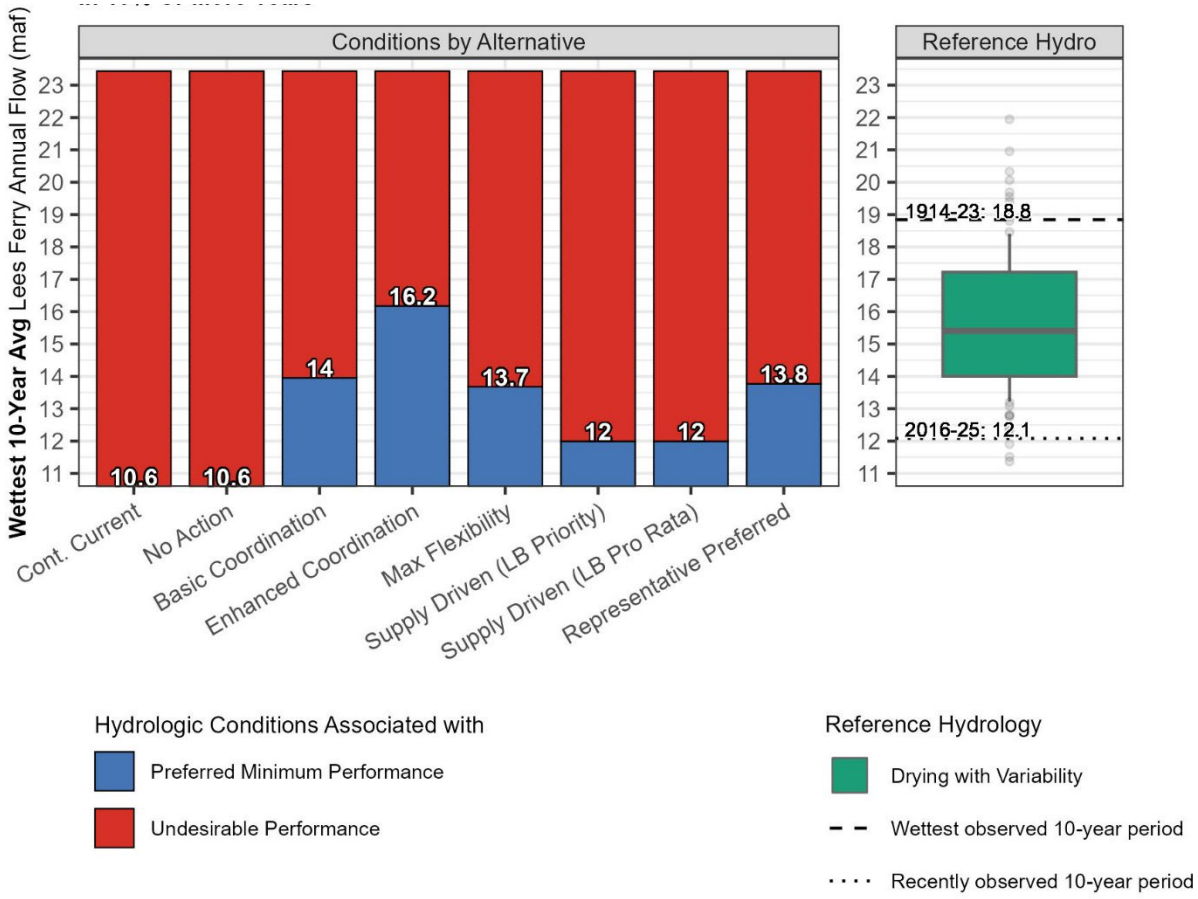


Figure TA 5-6 below shows what flow conditions are likely to cause the Glen Canyon Dam maximum monthly outflow to exceed 900 kaf in more than 10 percent of years. This definition of undesirable performance is based on the highlighted row in **Figure TA 5-5** above, which defined a future as successful when an alternative maintains a sediment year maximum monthly release from Glen Canyon Dam less than 900 kaf in at least 90 percent of years

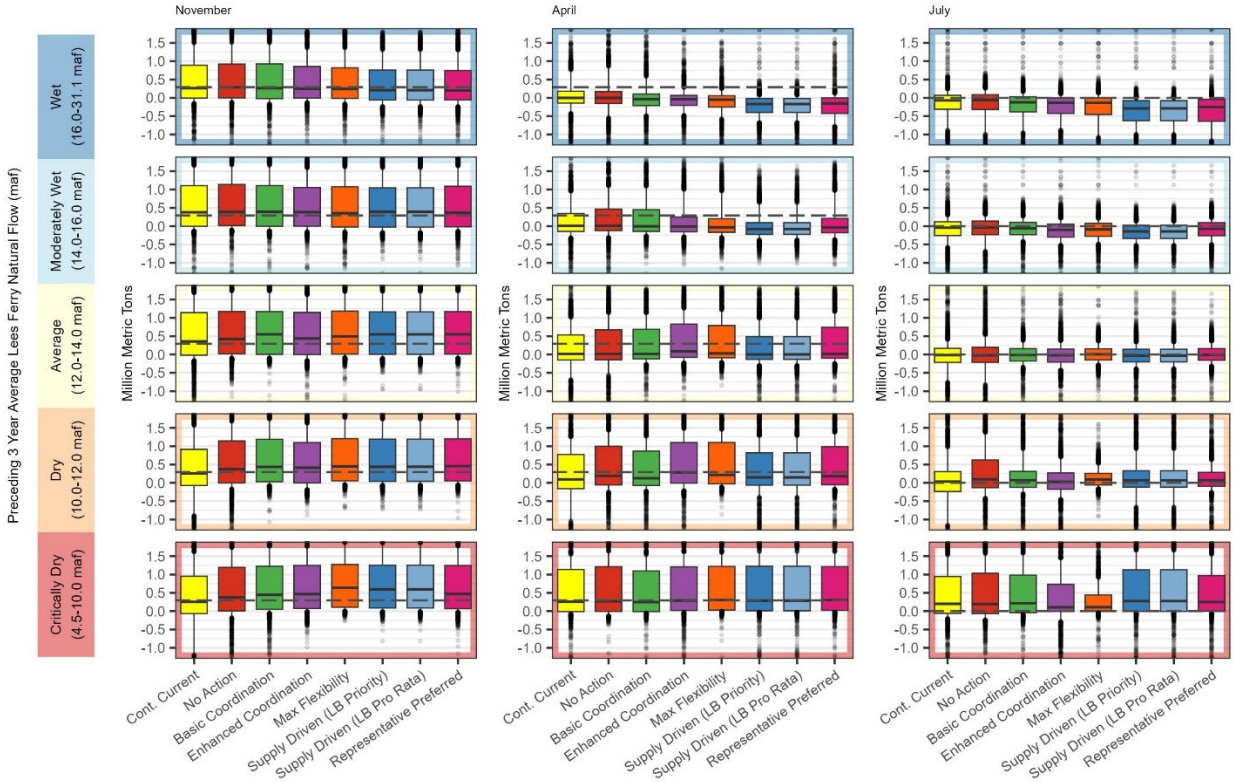
For this vulnerability analysis, the wettest 10-year average Lees Ferry annual flow was determined to be skillful at predicting undesirable performance. The vulnerability threshold for each alternative is described and compared to the Drying with Variability ensemble using this streamflow summary statistic. The wettest observed 10-year average flow from 1914–1923 (18.8 maf) and the average flow from 2016–2025 (12.1 maf) are also provided as dashed and dotted lines, respectively, for comparison.

Modeling results for the CCS Comparative Baseline and the No Action Alternative indicate undesirable performance under futures whose wettest 10-year average annual flow is 10.6 maf or higher, which is below the most recently observed 10-year average annual flow of 12.1 maf. Performance is almost as poor for the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), where undesirable performance occurs under futures whose wettest 10-year average flow is 12.0 maf or higher. Under Basic Coordination and Maximum Operational Flexibility

Alternatives, undesirable performance occurs when the wettest 10-year average flow is 14.0 and 13.7 maf or higher, respectively, which occurs in about 75 percent of the projected hydrology traces. Least vulnerable to projected conditions is the Enhanced Coordination Alternative, under which undesirable performance occurs when the wettest 10-year average flow is 16.2 maf or higher, occurring in less than 50 percent of the projected hydrology traces.

Figure TA 5-6
Glen Canyon Dam Releases: Vulnerability.
Conditions that could cause the maximum monthly outflow to exceed 900 kaf in more than 10 percent of years



The Representative Preferred Alternative is likely to be vulnerable if the wettest 10-year average Lees Ferry annual flow is 13.8 maf or higher. Compared to the historical periods shown in the Reference Hydrology panel, this flow has occurred before; though, this alternative may or may not be vulnerable in the next 10 years because different aspects of the panel conflict. Considering the Drying with Variability ensemble, about 75 percent of traces are greater than 13.8 maf, suggesting this alternative is reasonably likely to be vulnerable. However, the recently observed 10-year period (of 12.1 maf) is below 13.8 maf, suggesting that this alternative is unlikely to be vulnerable if the next 10 years are similar to or drier than the most recent 10 years.

All of the alternatives are vulnerable to historical conditions, of which the wettest 10-year period averaged 18.8 maf annually. Four of the alternatives (the CCS Comparative Baseline, No Action, and Supply Driven [both LB Priority and LB Pro Rata approaches] Alternatives) would have been vulnerable during the most recently observed 10-year period (2016-2025), which had an average flow of 12.1 maf.

Figure TA 5-7 shows the distribution of sand accumulation (in millions of metric tons) in Marble Canyon for three time periods: July 1 to November 1, July 1 to April 1, and July 1 to July 1 (the full sediment year, Topping et al. [2000]). Negative values indicate sand depletion. The distributions are further categorized according to five hydrologic conditions based on the average natural flow at Lees Ferry over the preceding 3-year period.

Figure TA 5-7
Marble Canyon Sand Accumulation or Depletion from (left) July 1 to November 1, (middle) July 1 to April 1, and (right) July 1 to July 1

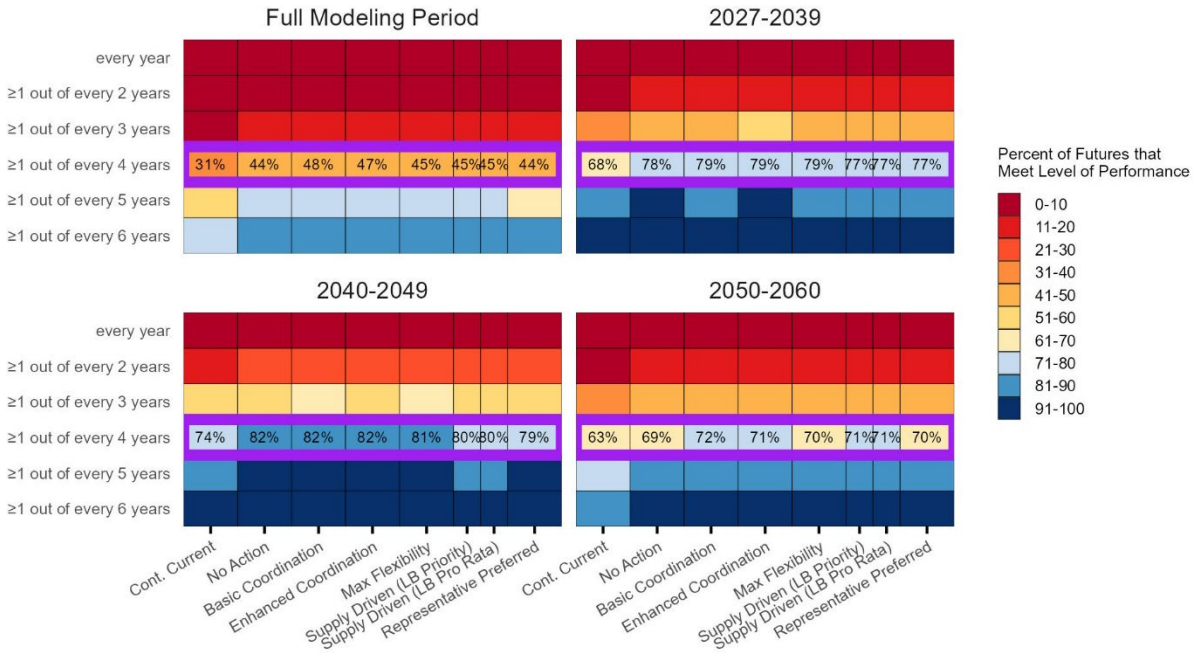
Interpretation of **Figure TA 5-7** depends on the three periods of interest. From July to November, it is preferable for sand accumulation to exceed 294,000 metric tons (indicated by a dashed line in the November column). Since 294,000 metric tons is the average transport capacity for an HFE event of 60 hours, the duration at which successful beach building occurs, sand accumulation exceeding this threshold allows for a fall HFE event (provided enough water is available in Lake Powell). If that is not possible, sand accumulation from July to April exceeding 294,000 metric tons (indicated by a dashed line in the April column) allows for a spring HFE event. In either case, it is preferable for annual sand accumulation from July to July to be near zero (indicated by a dashed line

in the July column), which suggests sand accumulated during the prior sediment year was subsequently depleted via an HFE event.

For all five hydrologic conditions, most sand accumulation in Marble Canyon occurs from July to November, the summer-fall thunderstorm season during which the Paria and Little Colorado Rivers are most active. Slightly less accumulation occurs for the wettest conditions, during which non-HFE releases are more likely to transport sand downstream, while slightly more accumulation occurs for the driest conditions.

In the Moderately Wet and Wet Flow Categories, conditions that would trigger an HFE release (i.e., Marble Canyon sand accumulation exceeding 294,000 metric tons) are more likely to occur in November. From November to April, larger than normal releases outside of HFE events are likely to contribute to sediment depletion, resulting in a median change in sand mass between July and April of close to zero. While very little change in sand mass occurs from April to July, indicating spring HFEs are uncommon during these conditions, slightly more depletion occurs on an annual basis under the Wet Flow Category.

In the Average and Dry Flow Categories, sand is also depleted between November and April, but the decrease is more gradual. As a result, sand accumulation exceeds 294,000 metric tons for a greater percentage of futures from July to April, allowing for spring HFE events. The gradual decrease in sand mass continues from April to July, so that on an annual basis (July 1 to July 1), there is little net change in sand mass, similar to the wettest two categories.



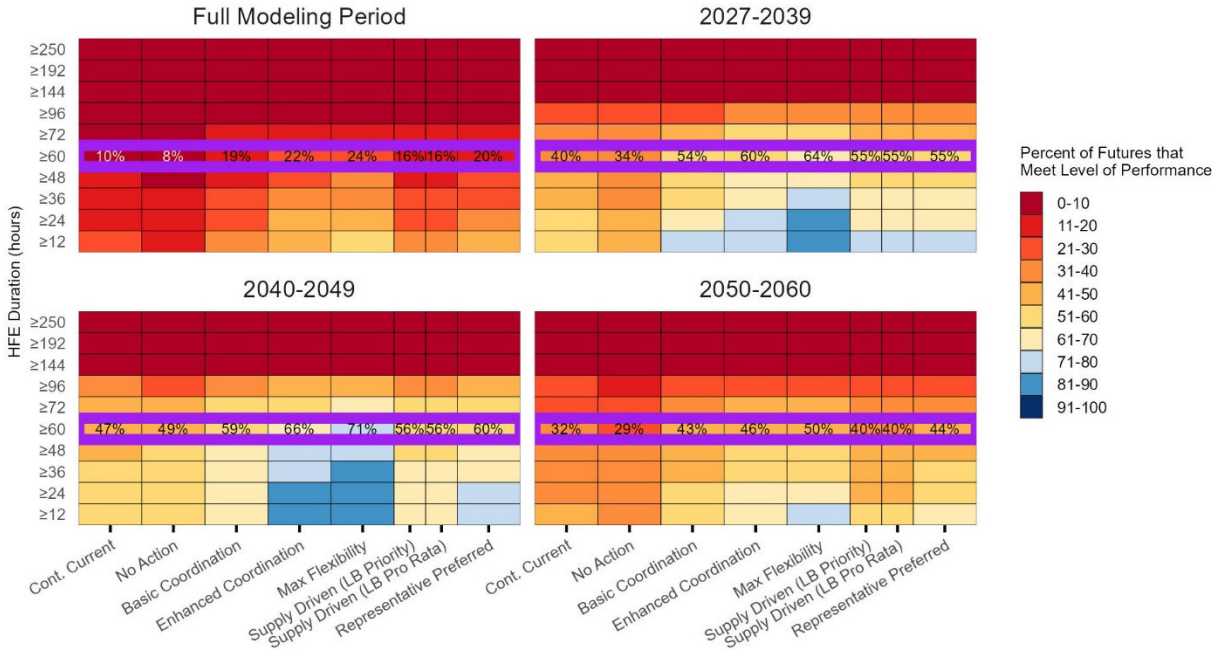
All six alternatives perform comparably across the four flow categories above. Only in the Critically Dry Flow Category does meaningful differentiation exist among performance. In general, there is little change in sand mass from both November to April and April to July, indicating HFE events are infrequent. However, on an annual basis, a smaller level of accumulation occurs for the Maximum Operational Flexibility and (somewhat) Enhanced Coordination Alternatives, suggesting they are slightly more conducive to HFE events during these conditions.

Figure TA 5-8 shows how often Marble Canyon sand mass exceeds 294,000 metric tons, the average transport capacity for a 60-hour HFE, in November or April. A 60-hour duration is required for successful beach building. The highlighted row shows the percentage of futures that meet this condition at least once every 4 years, the preferred minimum performance. As stated in the Methodology (see **TA 5.2.1**, Methodology), each future was randomly assigned a trace of Paria River sediment input (however, each future/sediment trace combination was kept the same across the alternatives).

Aside from the CCS Comparative Baseline, the other alternatives are similarly robust. The percentage of futures in which the November or April sand mass exceeds 294,000 metric tons at least once every 4 years in the other alternatives, ranges from 44 percent to 48 percent for the full modeling period. For the CCS Comparative Baseline, less than a third of the futures in the full modeling period meet the 294,000 metric ton threshold at least once every 4 years. As mentioned earlier for other figures, fewer futures meet the preferred minimum performance over the full modeling period than in any one of the subperiods, a reflection of the increasing difficulty of sustaining this performance level over a longer period and evidence of the interdecadal variability inherent in the ensemble of projected conditions.

Based on the planned length of this decision, it is important to note that, similar to the other action alternatives, the Representative Preferred Alternative meets the preferred minimum performance level in 77 percent of futures in the 2027-2039 modeling period.

Figure TA 5-8
Marble Canyon Sand Mass: Robustness.
Percent of futures in which the Marble Canyon sand mass exceeds 294,000 metric tons in November or April in the frequency of years specified in each row



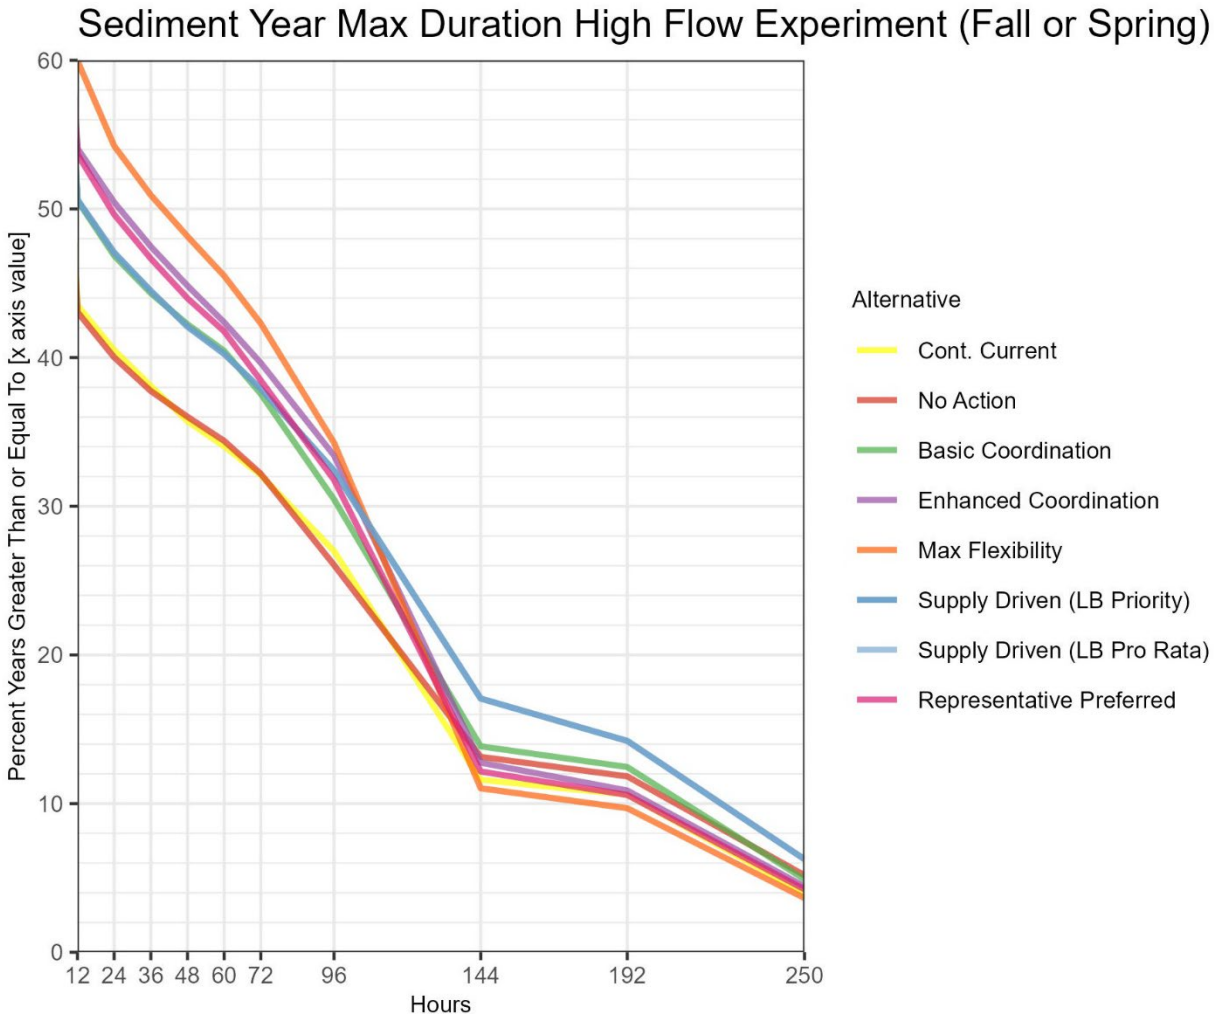
TA 5.2.4 Issue 3: HFE Frequency and Duration

Water availability in, and water releases from, Lake Powell can have an impact on HFE scheduling. Large non-HFE releases, such as the equalization flows implemented in 2011 to balance storage between Lake Powell and Lake Mead (Hazel et al. 2022), can reduce the sand mass in Marble Canyon available for an HFE without providing the benefit of increasing sandbar volumes further downstream (Grams et al. 2025; Topping et al. 2021; Salter et al. 2025). Since the alternatives propose different ways of operating Glen Canyon Dam, they have different impacts on water availability in Lake Powell, and consequently, the scheduling of HFE releases. Grams et al. (2025) noted that, except for the HFE implemented on March 26, 1996, the durations for all HFEs implemented have been between 60 and 96 hours.

Figure TA 5-9 shows the percentage of futures in which the annual HFE duration equals the number of hours specified in each row at least once every 4 years. Futures are considered preferable at a duration of 60 hours, the minimum duration associated with significant sandbar deposition. The highlighted row provides the percentage of futures that meet this criterion.

Figure TA 5-9
Annual HFE Duration: Robustness.
Percent of futures in which the annual HFE duration is the number of hours specified in each row at least once every 4 years

For the full modeling period, none of the alternatives satisfy the preferred minimum performance in more than 24 percent of futures. Fewer futures meet the preferred minimum performance over the full modeling period than in any one of the subperiods, a reflection of the increasing difficulty of sustaining this performance level over a longer period and evidence of the interdecadal variability inherent in the ensemble of projected conditions. For all periods, the action alternatives are similarly robust and perform better than the CCS Comparative Baseline and No Action Alternative, with the Maximum Operational Flexibility Alternative performing slightly better than the others. It is important to note the modeling does not imply an expected outcome, just that HFEs remain possible. HFE triggers and final HFE implementation would be a result of the LTEMP process.



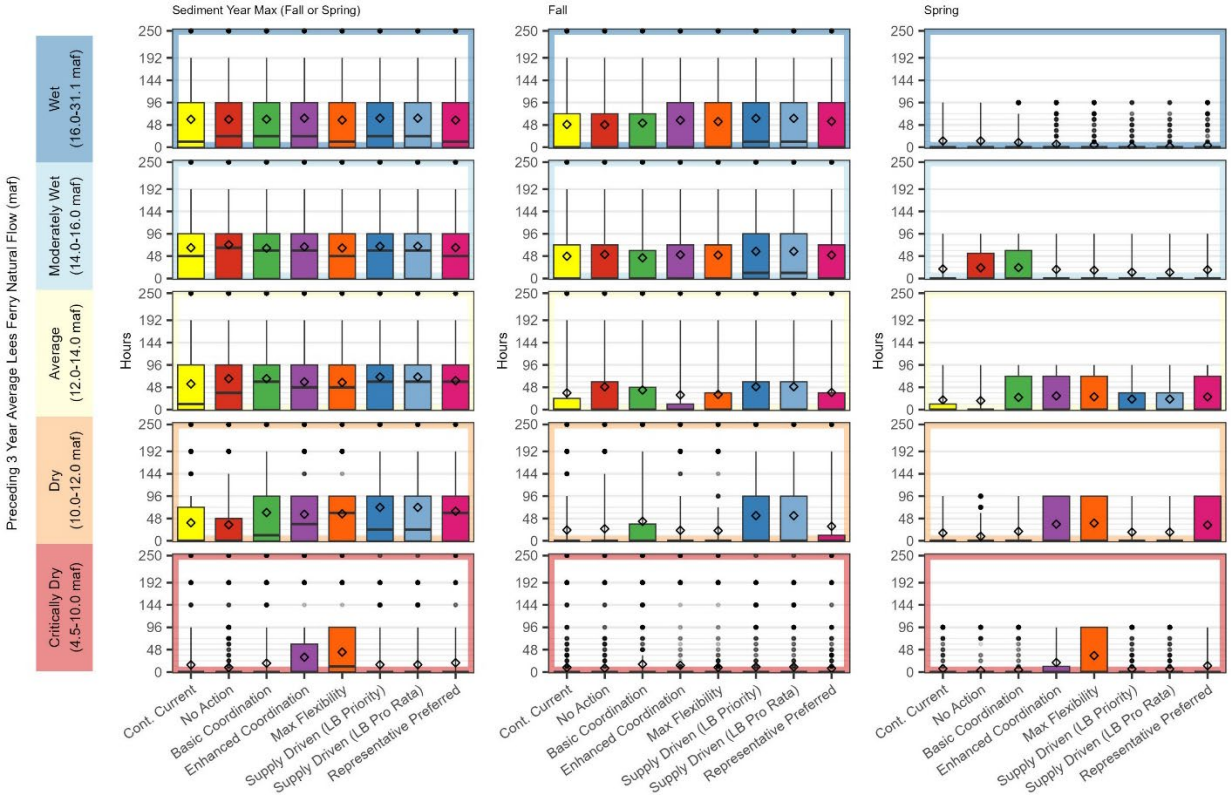
Based on the planned length of this decision, it is important to compare robustness in the 2027-2039 modeling period. The Representative Preferred Alternative meets the preferred minimum performance level in 55 percent of future which is the same as the Supply Driven Alternative (both LB Priority and Pro Rata approaches) and similar to the Basic Coordination Alternative (54 percent). The Maximum Operational Flexibility (64 percent) and Enhanced Coordination (60 percent) Alternatives are more robust. The No Action Alternative (34 percent) and CCS Comparative Baseline (40 percent) meet the preferred minimum performance least often in the first decade.

Figure TA 5-10 shows the frequency of HFE releases as a function of HFE duration, represented as the percentage of simulated years in which an HFE of a specified duration occurs. An HFE of 60 hours or longer occurring at least once every 4 years is the preferred minimum performance. While

Figure TA 5-10 does not directly address this indicator, it suggests the likelihood with which it is met.

For HFE releases lasting 12 to 96 hours, the Maximum Operational Flexibility, Enhanced Coordination, and Representative Preferred Alternatives perform the best, with 46, 43, and 42 percent of years having HFE releases greater than or equal to 60 hours, respectively. For HFE releases greater than or equal to 96 hours, the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) performs better than the other alternatives. Below 60 hours, the performance of the Basic Coordination Alternative is generally comparable to that of the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) and lower than the other action alternatives.

Figure TA 5-10
Frequency of HFE Releases as a Function of HFE Duration



The worst performance generally occurs under the CCS Comparative Baseline and the No Action Alternative. Their performance is comparable for HFE durations below 144 hours. For HFE durations above 144 hours, the No Action Alternative performs slightly better than the CCS

Comparative Baseline. However, excluding the HFE implemented on March 26, 1996, HFE durations above 144 hours have not been implemented (Grams et al. 2025).

While **Figure TA 5-10** indicates that, across all alternatives, 60-hour HFEs would occur in 36 to 46 percent of years simulated, **Figure TA 5-9** indicates 60-hour HFEs every 4 years would occur in only 10 to 25 percent of futures. This suggests that many more futures have HFEs concentrated over a small time period than futures in which HFEs are evenly spread out, another reflection of the importance of interdecadal hydrologic variability.

Figure TA 5-11 shows the distribution of HFE durations for the full sediment year (July 1 to July 1), fall, and spring. The distributions are further categorized according to five hydrologic conditions based on the average natural flow at Lees Ferry over the preceding 3-year period. As stated above, the preferred minimum performance is an HFE lasting 60 hours or longer at least once every 4 years. The Methodology (see **TA 5.2.1**) indicates that for an HFE to be scheduled, enough sand must be available in Marble Canyon, and enough water must be available in Lake Powell. If enough sand and water are available, longer HFE's could be scheduled. While **Figure TA 5-11** does not directly address this indicator, it provides some indication of the likelihood with which it is met.

Figure TA 5-11
Annual Duration of HFE Releases

The performance of alternatives in **Figure TA 5-11** varies by flow category. For the two wettest categories, the distribution of annual HFE durations over the full sediment year is comparable across all alternatives, with the majority of HFEs occurring in the fall. For the Average Flow

Category, HFE durations over the full sediment year are again comparable, but the timing of HFEs for the Basic Coordination, Enhanced Coordination, Maximum Operational Flexibility, and Representative Preferred Alternatives begins to shift from fall to spring. This trend continues for the two driest flow categories, with only the Enhanced Coordination and Maximum Operational Flexibility Alternatives resulting in HFEs of any significant duration in the Critically Dry Flow Category, typically occurring in the spring.

Notably, for all alternatives in all flow categories, the 75th percentile of HFE durations for the full sediment year is typically higher than it is in either fall or spring. This is due to the larger sample size of fall HFEs, whose high outliers serve to increase the 75th percentile for the full sediment year.

TA 5.2.5 Issue 4: Sandbar Volume

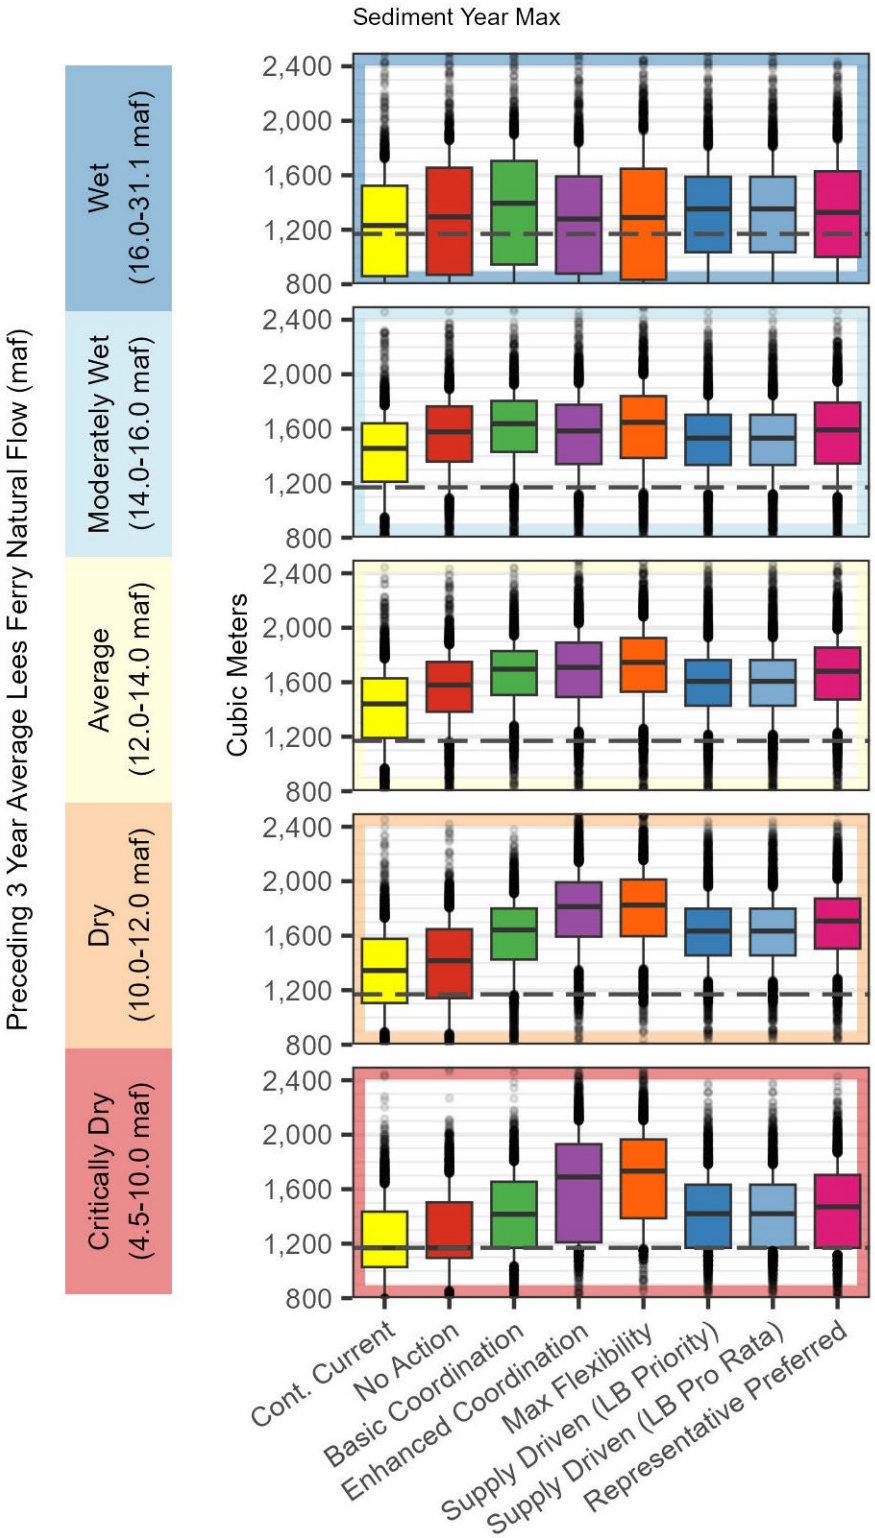
The sandbar volume above the water level during a 25,000 cfs flow condition, the threshold above which camping and recreational activities are considered safe, represents the volume of "usable" sand in the canyon. In general, larger sandbar volumes are preferable over smaller sandbar volumes.

Figure TA 5-12 shows distributions of "usable" sandbar volume, further categorized according to five hydrologic conditions based on the average natural flow at Lees Ferry over the preceding 3-year period. As the preferred minimum performance, sandbar volumes should exceed their volume at the start of the simulation period for at least 60 percent of modeled years. The average sandbar volume for the 25 sandbar monitoring sites at the start of the simulation period is 1169.512 cubic meters, indicated by a dashed horizontal line.

For all but the Wet Flow Category, all alternatives show sandbar growth in greater than 60 percent of years, with nearly all alternatives showing sandbar growth in greater than 75 percent of years. For the Wet Flow Category, the Basic Coordination, Supply Driven (both LB Priority and LB Pro Rata approaches), and Representative Preferred Alternatives show sandbar growth in greater than 60 percent of years, and 25th percentile sandbar volumes for all alternatives are lower than the initial condition (1169.512 cubic meters on average for the 25 sandbar monitoring sites). In general, sandbar growth increases as hydrologic conditions become drier. Differences in performance among the alternatives also increase as hydrologic conditions become drier, with the Enhanced Coordination and Maximum Operational Flexibility Alternatives clearly performing the best for the Critically Dry Flow Category.

Figure TA 5-13 shows the percentage of futures with *net* sandbar growth by comparing the maximum sandbar volume for each year with the volume at the start of each of four periods (2027–2039, 2040–2049, 2050–2060, and 2027–2060). Here again, the average sandbar volume for the 25 sandbar monitoring sites at the start of the full simulation period (2027) is 1169.512 cubic meters; initial sandbar volumes for subperiods depend on the hydrology trace. It is important to note that **Figure TA 5-13** does not show the percentage of years with year-over-year sandbar growth; if large increases in sandbar volume occur at the start of a period, it is very possible for sandbar volume to be lower than it was the year before and still be higher than it was at the start of the period. The figure reflects an alternative's ability to achieve long-term sandbar growth over scales of decades or more.

Figure TA 5-12
Sandbar volume above the water level associated with a flow rate of 25,000 cfs



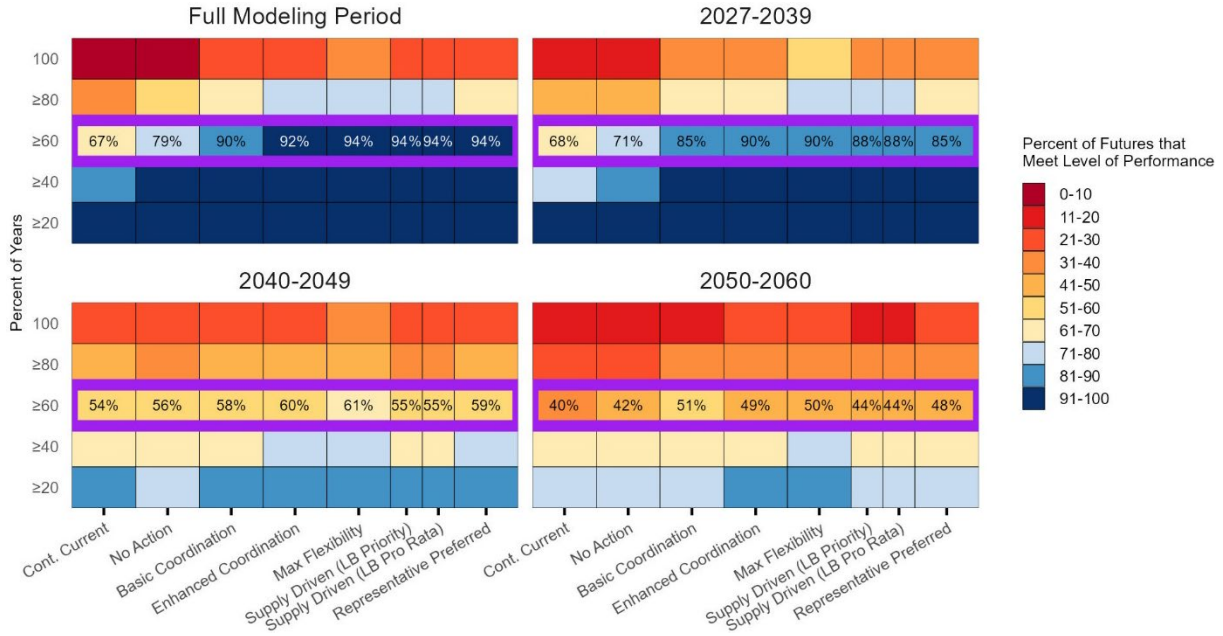


Figure TA 5-13
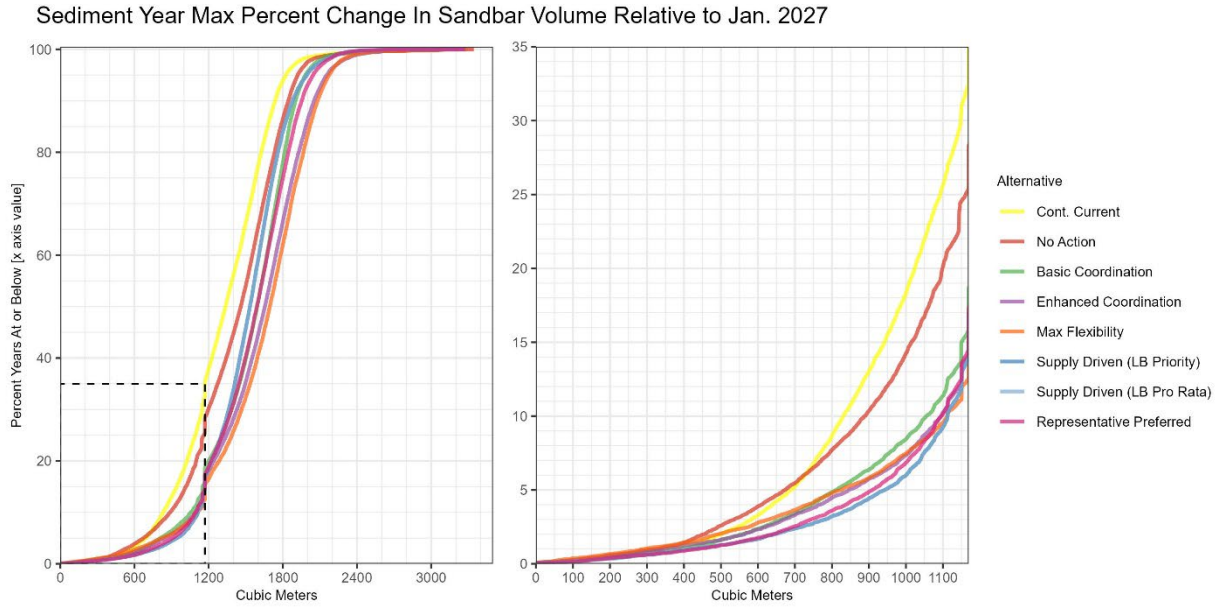
Long-Term Sandbar Growth: Robustness.
Percent of futures in which the weighted average sandbar volume of Grand Canyon and Marble canyon has increased relative to the start of each period in the percent of years specified in each row

A future is considered to satisfy the minimum preferred performance level if at least 60 percent of years within a given period have a sandbar volume that is larger than the sandbar volume at the start of the given period. The highlighted row provides the percentage of futures that meet this criterion.

Over the full modeling period, the Maximum Operational Flexibility, Enhanced Coordination, Supply Driven (both Priority and Pro Rata approaches), and Representative Preferred Alternatives are truly robust, meeting the minimum preferred performance level in over 90 percent of years. Though slightly less, the Basic Coordination Alternative is similarly robust, meeting the minimum preferred performance level in 90 percent of years. Performance level is lowest for the No Action Alternative and CCS Comparative Baseline, with the latter being the least robust. Most of the increase occurs in the first 13-year period, after which sandbar growth slows, possibly because of the larger sandbar volumes, and fewer opportunities for deposition, at the start of the other subperiods.



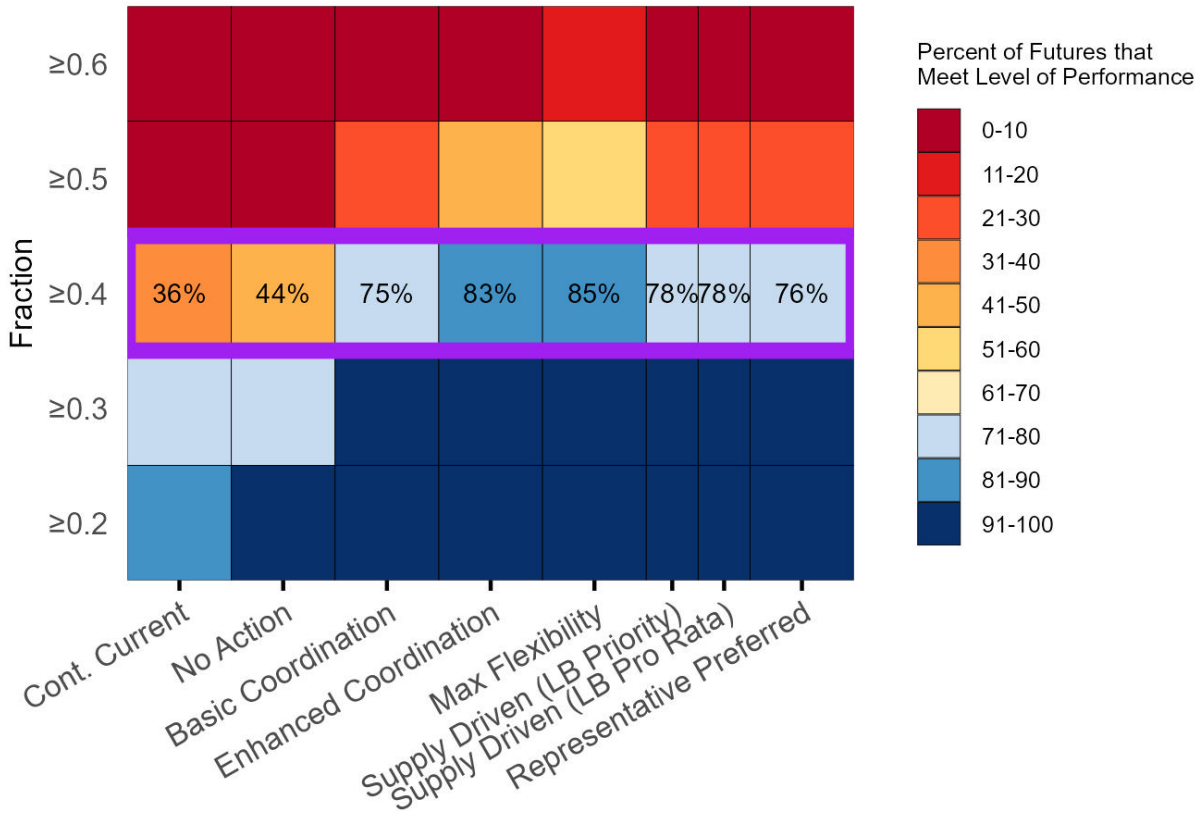
In general, a relatively high percentage of futures (at least 90 percent for all five action alternatives) meet the preferred minimum performance of more than 60 percent of years with net sandbar growth. This contrasts with figures such as **Figure TA 5-9**, where no more than 24 percent of futures meet the preferred minimum performance of 60-hour HFEs at least once every 4 years. The discrepancy is due to the definition of sandbar growth with respect to the *beginning* of a period, which allows for the possibility that years without an HFE might still meet this preferred minimum performance. In addition, each future is based on a single simulation and consequently subdivided into the three modeling subperiods. Consequently, the initial conditions for the 2040–2049 and 2050–2060 modeling periods depend on the simulation and differ for each future. The significant

increase in sandbar volume during the 2027–2039 modeling period could be partially attributed to the modeling assumption that HFEs are implemented as often as possible (see **TA 5.2.1**, Methodology).

Based on the planned length of this decision, it is important to note that, similar to the other action alternatives, the Representative Preferred Alternative meets the preferred minimum performance level in 85 percent of futures in the 2027-2039 modeling period. The CCS Comparative Baseline (68 percent) and No Action Alternative (71 percent) are less robust over the first modeling period.

Figure TA 5-14 shows the percentage of simulated years for which the maximum sandbar volume is less than or equal to a given value. A lower percentage of years for which sandbar volume is below a given value corresponds to a greater percentage of years for which sandbar volume is above that value. Therefore, curves with lower placement in the plot imply better performance for that alternative. The average sandbar volume for the 25 sandbar monitoring sites at the start of the full modeling period is 1169.512 cubic meters (see **TA 5.2.1**, Methodology).

Figure TA 5-14
Percentage of Years for which Maximum Sandbar Volume is at or below Given Values



With respect to the initial condition, the five action alternatives perform comparably, all resulting in average sandbar volumes smaller than 1169.512 cubic meters 13 to 15 percent of the time for the 25 sandbar monitoring locations. For very small sandbar volumes (less than 1000 cubic meters), the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) performs slightly better than the others. Performance under No Action lags behind, with performance for the CCS Comparative Baseline ranking last.

TA 5.2.6 Issue 5: Sand Transport

While sand can be transported downstream with flows well below 37,000 cfs, lower flows are not as conducive to sandbar formation and retention. The higher the fraction of sand transported during the larger flow events (above 37,000 cfs), the more sand that is available for sandbar formation (Hazel et al. 2022; Salter et al. 2025).

Figure TA 5-15 shows the percentage of futures in which the total sand mass transported by flow rates above 37,000 cfs (sandbar-forming flow rates) exceeds a given fraction over the 34-year simulation period. A future is considered to meet the minimum preferred performance level if the fraction of sand mass transported by sandbar-forming flow rates is at least 0.4 (40 percent of the sand transport). The highlighted row provides the percentage of futures that meet this criterion.

Figure TA 5-15
Sand Load Index: Robustness.
Percent of futures in which the sand mass transported when flows are above 37,000 cfs is at least the fraction specified in each row of the total sand mass transported over the 34-year modeling period

Under the best performing alternatives, the Maximum Operational Flexibility and Enhanced Coordination, 85 and 83 percent of simulated futures, respectively, meet the minimum preferred performance level, i.e., at least 40 percent of sand mass is transported by sandbar-forming flow rates in 85 and 83 percent of simulated futures, respectively. The next best performance occurs under the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), for which 78 percent of

futures meet the preferred minimum performance, followed by the similarly robust Representative Preferred and Basic Coordination Alternatives, for which 76 and 75 percent of futures meet the preferred minimum performance, respectively. Under both the No Action Alternative and the CCS Comparative Baseline, at least 40 percent of sand mass is transported by sandbar-forming flow rates in less than half of the simulated futures, with the CCS Comparative Baseline performing the worst of all alternatives.

TA 6. Water Quality

TA 6.1 Affected Environment

This section describes selected water quality constituents that could be affected by the alternatives. These water quality constituents of concern are:

- Salinity
- Temperature
- Harmful algal blooms and nutrients
- Dissolved oxygen
- Metals
- Perchlorate
- Per- and polyfluoroalkyl substances (PFAS)

Other water quality issues were considered but are not discussed here, as they were unlikely to be affected by the alternatives or lacked sufficient data for assessment.

TA 6.1.1 Salinity

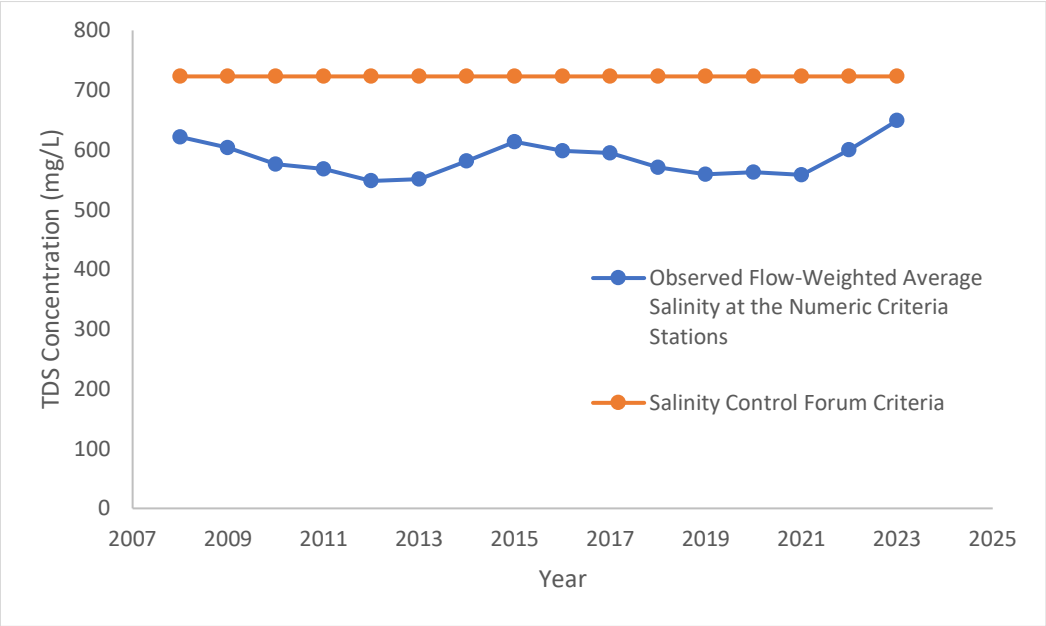
Historically, elevated salinity levels have been a concern for the Colorado River Basin (Basin), as higher salinity concentrations cause economic damage across agricultural, municipal, and industrial sectors in the United States (U.S.), and negatively impact municipal and agricultural users in the United Mexican States (Mexico; USGS 2021). To address these issues, in 1974 Congress enacted the Colorado River Basin Salinity Control Act, which directed the Secretary of the Interior to proceed with a program to enhance and protect the quality of water available in the Colorado River for use in the U.S. and Mexico. In 1975, the U.S. Environmental Protection Agency (EPA) approved water quality standards developed by the seven Basin States in response to the Federal Water Pollution Control Act of 1972. The standards included numeric criteria for three stations on the mainstem of the lower Colorado River (below Hoover Dam, below Parker Dam, and at Imperial Dam) and a Plan of Implementation to control salinity increases.

The Colorado River Basin Salinity Control Forum continues to review and make salinity criteria recommendations for the Colorado River every 3 years (Colorado River Basin Salinity Control Forum 2023). The water quality standards for salinity in the Colorado River were approved by the EPA and are reviewed every three years pursuant to Section 303(c)(1) of the Clean Water Act. **Table TA 6-1** shows the current salinity criteria for the Colorado River.

Table TA 6-1
Salinity Criteria for the Colorado River

Station	Flow-weighted average annual salinity (milligrams per liter [mg/L])
Below Hoover Dam	723
Below Parker Dam	747
At Imperial Dam	879

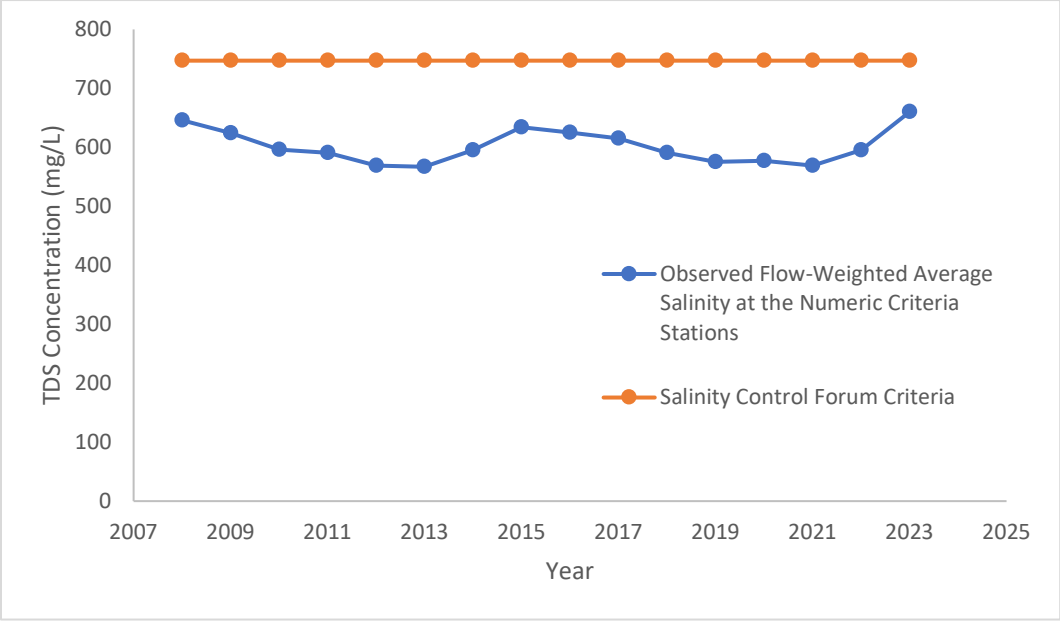
Source: Colorado River Basin Salinity Control Forum 2023



Salinity control is accomplished through multiple programs. The U.S. Department of Agriculture's Environmental Quality Incentives Program provides cost-share assistance to landowners who install salinity control measures (Reclamation 2022). Additionally, federal agencies, including the Bureau of Reclamation (Reclamation), the Bureau of Land Management, and the U.S. Department of Agriculture, pursue improvements on federal lands to reduce salinity loading to the Colorado River. Despite these efforts, salinity trends have plateaued since 2000, after decreasing throughout the twentieth century (Rumsey et al. 2021). Total dissolved solids[1] (TDS) loads increase during wet periods and decrease during dry periods, so increased regional aridification may be contributing to decreasing stream salinity through quicker surface runoff and lagged groundwater storage processes (Miller et al. 2024; Brooks et al. 2025). Conversely, increased aridification may increase concentrations, as 89 percent of TDS loads are derived from the baseflow fraction of streamflow, and declines in surface runoff are expected to outpace changes in baseflow contributions to streamflow (Rumsey et al. 2017).

Since the construction of Glen Canyon Dam, annual salinity concentration downstream of Glen Canyon Dam varies between 400 and 600 mg/L (Richards 2025). Within Lake Powell, reservoir stratification results in different salinity concentrations at different depths. Releases from lower elevations in Lake Powell through the river outlet works are generally more saline compared with releases from higher elevations through the penstocks of Glen Canyon Dam (Reclamation 2016). See **TA 6.1.2** for a more complete discussion of reservoir stratification.

In a review of sampling efforts from 2007–2023, Reclamation has not exceeded the salinity criteria for the Colorado River, which are described in **Table TA 6-1**. See **Figure TA 6-1**, **Figure TA 6-2**, and **Figure TA 6-3** for more information and historical salinity concentrations in the Lower Basin. Salinity concentrations are based on TDS concentrations and are used interchangeably in this discussion.



[1] Total dissolved solids are the combined content of all substances in a liquid volume and is related to salinity, which is the total concentration of all dissolved salts in water. The sum of constituents consists of calcium, magnesium, sodium, chloride, sulfate, the carbonate equivalent of alkalinity and, if measured, silica and potassium. The two terms are often used interchangeably in Colorado River salinity discussions.

TA 6.1.2 Temperature

Lake Powell is a monomictic[2] reservoir with strong thermal stratification through much of the spring, summer, and early fall; this means Lake Powell is arranged into layers with distinct temperatures and chemical characteristics. Generally, Lake Powell's epilimnion, or uppermost layer, ranges from 25 to 30 degrees Celsius (°C; 77 to 86 degrees Fahrenheit [°F]) in the summer, dropping to 6 to 10 °C (42.8 to 50 °F) in the winter (Deemer et al. 2023). Lake Powell's hypolimnion, or deeper layer, ranges from 6 to 9 °C (42.8 to 48.2 °F) year round. In the winter, the thermal stratification breaks down and Lake Powell experiences turnover where the different layers mix to create relatively uniform conditions throughout the water column (Reclamation 2016). Historically, complete mixing of the water column was rare; however, homogenous conditions have been observed more recently with lower reservoir elevations.

Since the early 2000s, lower water levels in Lake Powell have led to warm summer temperatures in the Colorado River below Glen Canyon Dam (Reclamation 2016). Temperatures in the Colorado River in the Grand Canyon are highly variable over space and time and are primarily controlled by the discharge and temperature released from Glen Canyon Dam and solar radiation dynamics along the river corridor (Mihalevich et al. 2020). As water moves farther away from Glen Canyon Dam, the influence of release volume and temperature on water temperature becomes less, and local meteorological conditions become more influential. During summer periods, increases in water temperatures downstream of Glen Canyon Dam are attributed to solar radiation and air temperatures (Dibble et al. 2021). The water in the Colorado River generally warms 1 °C (1.8 °F) for every 30 miles traveled downstream during warmer months of the year under specific discharge and

[2] Monomictic water bodies are those mix completely during one mixing period each year.

meteorological conditions. Some variation in lateral warming also occurs, with warmer temperatures along the shoreline and cooler water in the deep, fast-moving areas (Reclamation 2016).

Lake Mead is also monomictic. Lake Mead inflow temperatures are a function of Glen Canyon Dam discharges and downstream weather conditions (Reclamation 2016). Lake Mead's hypolimnion is around 12 °C (53.6 °F) year-round, and its epilimnion ranges from about 14 to 29 °C (57.2 to 84.2 °F) in the spring, summer, and early fall, dropping to about 13 to 15 °C (55.4 to 59 °F) in the winter (SNWA 2023). During the winter months, Lake Mead experiences turnover in about 50 percent of years. With lower reservoir elevations and increased air temperatures, water temperatures have been increasing, leading to warmer releases from Lake Mead. Further declines in reservoir elevation, coupled with rising air temperatures, may continue to lead to warmer releases from Lake Mead, though this depends on whether the lower Hoover Dam outlet is used (Hannoun et al. 2022).

TA 6.1.3 Harmful Algal Blooms and Nutrients

Nutrients, such as nitrogen and phosphorus, are essential for plant and animal growth and nourishment, but the overabundance of certain nutrients in water can harm human health, affect ecosystems, and impact recreational opportunities (USGS 2019; NPS 2025). Excess nutrients can cause eutrophication, where the accumulation of nutrients in a body of water results in the increased growth of microorganisms, such as algae. Algae can rapidly increase, leading to algal blooms, characterized by unsightly scum on the water surface, and producing toxins that pose serious health risks to humans and animals (NPS 2025). Consumption of dead algae by bacteria consumes dissolved oxygen and may deplete the oxygen in the water column, leading to fish kills (USGS 2019). For more details on the impacts of dissolved oxygen levels in the water column, see **TA 6.1.4**.

The most severe algal blooms are caused by cyanobacteria and have the potential for production of toxins that can threaten drinking water quality and harm human health (USGS 2019). Certain toxins, such as Microcystin-LR cylindrospermopsin, are associated with symptoms such as abdominal pain, headache, and vomiting, while the Anatoxin-a group toxin can lead to symptoms such as tingling, burning, numbness, drowsiness, and respiratory paralysis (EPA 2014). Algal blooms have led to water advisories at recreational sites within the planning area, such as the Glen Canyon National Recreation Area. When the National Park Service detected cyanotoxins at the Glen Canyon National Recreation Area, they recommended that boaters use caution and avoid unnecessary exposure to the reservoir for recreational activities such as fishing and boating (NPS 2025). See **TA 14.1.1**, Shoreline Public Use, **TA 14**, Recreation, for additional information on recreational activities.

Higher water temperature can elevate eutrophic conditions by stimulating nutrient release from lake sediments, increasing the rate of bacterial activity, and more easily converting nutrients into forms used by algae (Havens 2012; Wang et al. 2023). In Lake Mead in 2015, increased inflow temperature contributed to a harmful algal bloom caused by the freshwater cyanobacteria, *Microcystis*, which can produce toxins harmful to humans, pets, and wildlife (Reclamation 2016).

Releases from Glen Canyon Dam and downstream Colorado River waters are generally low in nutrients (for example, the Glen Canyon Dam phosphorus releases average 0.005 mg/L; Deemer et al. 2023). Tributary inflows (for example, Paria River and Little Colorado River) typically contain

higher levels of nutrients than the mainstem Colorado River (Reclamation 2016), but overall appear to contribute relatively little to overall nutrient concentrations.

In Lake Mead, water within Las Vegas Bay has the highest concentration of nutrients due to the discharges of highly treated wastewater from the Las Vegas metropolitan area. Wastewater is a persistent contributor of phosphorus, whereas stormwater with higher phosphorus contributions is an acute contributor but a minor source overall given the infrequency of storm events. Since phosphorus is a limiting nutrient in the Colorado River system, these contributions support algal growth (USGS 2012). Lowering reservoir levels could increase the concentration of nutrients and temperatures, especially in shallow areas, which could be more favorable for algal growth (Hannoun et al. 2022).

Lake Powell is a low nutrient, oligotrophic[3] waterbody. Preliminary analyses of long-term trends in limnological data reveal a directional change in several parameters in Lake Powell in recent decades (Deemer et al. 2023). These initial data analyses suggest an increase in surface phytoplankton biovolume (algal biomass) that may be paired with changes in community composition and could have cascading effects on ecosystem function and water quality management. For example, cyanobacteria genera across all sites have appeared to shift considerably from the beginning of monitoring (1993–1997) compared to recent years (2017–2021). These community shifts could translate into changes in algal toxin formation and/or altered edibility for aquatic grazers. Growing occurrences of harmful algal blooms in Lake Powell could mean critical changes to Lake Powell water quality with detrimental results to human use and aquatic life. In a mixed methods literature review of assessing risk for cyanobacteria and phytoplankton with changes in water level regime, cyanobacteria were significantly more likely to increase in response to decreases in water levels. The review also suggested that the prevalence of cyanobacteria increases when reservoir water levels decline, subsequently increasing the risk of cyanobacterial blooms in reservoirs undergoing more severe water level fluctuations and/or declines (Hoffman et al. 2025). See **TA 8.1.3***, Reaches*, in **TA 8**, Biological Resources – Fish and Other Aquatic Species, and **TA 14.1.1***, Shoreline Public Use*, in **TA 14**, Recreation, for additional information about harmful algal blooms' impacts on aquatic species and recreation.

TA 6.1.4 Dissolved Oxygen

Dissolved oxygen is a critical factor for fish health. Research on dissolved oxygen thresholds for both warmwater and coldwater fish species shows that salmonids are particularly vulnerable to low dissolved oxygen concentrations compared to warmwater species (Saari et al. 2018). Sustained dissolved oxygen levels below 3 mg/L can significantly reduce survival rates and feeding efficiency, whereas concentrations in the range of 6–9 mg/L are considered optimal for growth and survival across all life stages (EPA 1986).

Generally, Lake Powell dissolved oxygen concentrations are at their highest in the spring to early summer, when inflows are well-oxygenated and wind-induced mixing is high. Low dissolved oxygen concentrations move through the reservoir and closer to the dam during the summer into the fall because of organic matter decomposition and chemical reactions that consume oxygen. Dissolved

[3] Oligotrophic waterbodies are those with low concentrations of nutrients.

oxygen gradually increases in the winter because of the higher oxygen-carrying capacity of cold water and the natural mixing processes that occur during turnover. When water is discharged through the river outlet works, it becomes well-aerated and increases the dissolved oxygen levels in the tailwaters but only while the river outlet works are open.

Recently, dissolved oxygen levels in Lake Powell and the Glen Canyon Dam tailwaters[4] have been low compared with historical dissolved oxygen levels. This is due to a combination of low reservoir elevations and increasing reservoir age (Deemer et al. 2025). Low dissolved oxygen plumes occur in response to large sediment inputs; this is because suspended sediment creates high biological and chemical oxygen demand (that is, bacteria and other biota consuming oxygen, and chemical reactions consuming oxygen). Monsoonal activity, typically between July and September, can discharge particularly high organic matter loads from tributaries, leading to elevated oxygen demand within the reservoir. Large spring snowmelt inflows to Lake Powell can further drive down dissolved oxygen concentrations by resuspending deltaic sediments. Near the Colorado River inflow, approximately 45 meters (150 feet) of sediment has accumulated over the life of the reservoir. With lower storage conditions, the Colorado River has been carving away this sediment and creating a new path through its delta.

Low dissolved oxygen plumes can often extend the entire length of the reservoir, typically in the metalimnion due to the prevalence of interflows (Colorado River inflows denser than the surface water of Lake Powell entering the reservoir at a depth of neutral buoyancy). With lower storage conditions, penstock intakes draw from the metalimnion layer more frequently, causing low dissolved oxygen releases. The residence time in Lake Powell is also shorter for the low dissolved oxygen plumes under low lake elevations, extending the duration of low dissolved oxygen water being released from Glen Canyon Dam.

Dissolved oxygen levels below Glen Canyon Dam vary throughout the year, falling as low as 2.2 mg/L in the summer and rising as high as 9 to 10 mg/L in the spring (GCMRC 2025). This seasonal variation is due to changes in dissolved oxygen at the penstock level of Lake Powell during the year. The Colorado River dissolved oxygen increases approximately 1 mg/L between Glen Canyon Dam and Lees Ferry. This approximation can vary between negligible re-oxygenation and approximately 3 mg/L increases during very low oxygen releases during daylight hours (GCMRC 2025). Low dissolved oxygen conditions improve downstream of the Paria Riffle and Badger Rapids as the water is reaerated through whitewater action.

In Lake Mead, dissolved oxygen levels decrease in the bottom of Las Vegas Bay as a result of high decomposition of organic matter from the Las Vegas Wash. When there are greater nutrients and algae in surface water, generally more decomposition and low oxygen occur in bottom waters, assuming a stratified system. Monitoring is ongoing to determine the cause of decreased dissolved oxygen concentrations in isolated areas, but the driver is likely higher temperatures from inflows. Backwaters in embayments have little water exchange and tend to be shallower and warmer. These conditions increase the likelihood of algal blooms and issues with low dissolved oxygen conditions,

[4] Tailwater refers to waters located immediately below the dam. It is the reach of river immediately downstream of a reservoir that is heavily influenced by reservoir characteristics. Tailwaters are generally expected have water quality more similar to the reservoir compared to reaches further downstream.

or hypoxia[5] (Reclamation 2016). See **TA 10**, Terrestrial Wildlife Including Special Status Species, for information about algal blooms' effects on wildlife.

TA 6.1.5 Metals

The planning area contains sources of various metals, including selenium and mercury. Selenium and mercury are toxic to fish and wildlife and can accumulate in the food web (Walters et al. 2015).

Soluble hexavalent chromium has been detected in groundwater in two known locations in the Lower Basin: at the former McCulloch Manufacturing Plant in Lake Havasu City, Arizona, and at the Pacific Gas and Electric Compressor Station near Needles, California. Mitigation efforts and plume monitoring are ongoing. The latest groundwater monitoring data indicate that plume migration is not occurring (California Water Boards 2022). The landowner continues to monitor the chromium associated with the former McCulloch Manufacturing Plant at Lake Havasu and Holly Avenues. Based on the latest site investigations, the groundwater chromium plume extended approximately 3,000 feet long and about 600 feet wide from the former McCulloch facility. This remained within the vicinity of the former McCulloch facility, which is several thousand feet from the Colorado River (AZDEQ 2022). Pacific Gas and Electric Company removed soils from 15 locations on federal land and where contaminants could migrate to federal land from the Pacific Gas and Electric Compressor Station and continues to remediate groundwater (AZDEQ 2024).

Within the Basin, about three million gallons of water and sediment at the Gold King Mine near Silverton, Colorado were released into Cement Creek, a tributary of the Animas River (USGS 2018a). In addition to regular monitoring, additional U.S. Geological Survey (USGS) and EPA samples were taken to assess the quality of water quality data, and found detectable levels of heavy metals, such as antimony, arsenic, cadmium, and cobalt, in sediment and surface water samples (EPA 2017).

While there is a historical issue with heavy metals, these point sources are not a typical concern. Therefore, this was not considered further in the analysis.

TA 6.1.6 Perchlorate

Perchlorate is a chemical compound that targets the thyroid under acute exposure (that is, exposure under 14 days or less) and intermediate exposure (that is, exposure that is 15 to 364 days), particularly for iodide deficient individuals and during pregnancy (Agency for Toxic Substances and Disease Registry 2008). Within the planning area, perchlorate contamination was linked to a groundwater plume from the Kerr McGee Chemical Company in Henderson, Nevada. Since 2002, mitigation programs have successfully reduced perchlorate concentrations below applicable regulatory limits throughout the Lower Basin (Hannoun and Tietjen 2022, also cite EPA-815-F-20-002). Although a low-level, continuous release from the source area remains a concern, ongoing long-term monitoring programs enable adaptive management and ensure perchlorate is effectively managed under future operational scenarios.

[5] Low levels of dissolved oxygen that can have detrimental effects on the ecological and economic health of affected areas.

TA 6.1.7 PFAS

Adjacent to Lake Mead, PFAS was detected in the Las Vegas Wash. PFAS in the Las Vegas Wash likely entered via municipal wastewater effluents, of which the likely main source was residential wastewater. PFAS concentrations were relatively low for the small tributary associated with a smaller urban airport, so that airport is an unlikely significant PFAS source (Thompson n.d.). Generally, as reservoir elevations decrease, the dilution capacity of reservoirs like Lake Powell and Lake Mead would also decrease. Decreased dilution capacity from lower reservoir elevations could result in greater concentrations of pollutants of concern, such as PFAS.

TA 6.2 Environmental Consequences

TA 6.2.1 Methodology

The analysis methodology for water quality is based on a combination of Decision Making under Deep Uncertainty (DMDU); Colorado River Simulation System (CRSS); Grand Canyon Monitoring and Research Center Dissolved Oxygen & Temperature Models for Glen Canyon, Lees Ferry, and Grand Canyon; and qualitative analysis.

The CRSS model simulates Basin conditions decades into the future and can account for hydrological uncertainty. The CRSS model is a monthly time step model that produces reservoir elevations, dam releases, and salinity concentrations. The CRSS model does not consider potential decreases in calcium carbonate precipitation (that is, the mechanism by which Lake Powell reduces the downstream transport of salt on annual to decadal time scales) that might occur at lower reservoir elevations when residence time is lower. Using an equation developed by the USGS (USGS 2018b), which can be classified as a hybrid between a mechanistic and statistical model, salinity at Imperial Dam is calculated as a function of Hoover Dam salinity, Parker Dam releases, and diversions by Colorado River Indian Reservation and Palo Verde Irrigation District. Refer to **Appendix A**, CRSS Model Documentation, for more details on model documentation.

In this section, salinity is analyzed as it relates to the salinity criteria set by the Colorado River Salinity Control Forum. For information on salinity concentration and salinity related to the potential effects on resources in the International Border Region, see **Appendix N**, International Border Region of the Colorado River.

Impacts on water quality are described using conditional box plots and vulnerability bar plots based on CRSS model outputs, and Grand Canyon Monitoring and Research Center models. Refer to **Section 3.2**, Analysis Methods, for additional information on DMDU and **Appendix E**, DMDU Overview and Approach, for an overview of how interpret the DMDU conditional box plots, robustness heat maps, and vulnerability bar plots.

Decision Making Under Deep Uncertainty Modeling

To assess future alternatives and management strategies, a modeling analysis known as DMDU was applied to systematically evaluate potential system responses across a wide range of plausible futures. The analysis incorporated five alternative scenarios, which are the No Action, Basic Coordination, Enhanced Coordination, Maximum Operational Flexibility, and Supply Driven (Lower Basin

Priority [LB Priority] and Lower Basin Pro Rata [LB Pro Rata] approaches) Alternatives, representing various flow conditions and the continuation of the current flow management strategies from Lake Powell (Continued Current Strategies [CCS] Comparative Baseline). These alternative scenarios are designed to span a broad spectrum of uncertainty, allowing examination of impacts on resources under several alternatives and baseline conditions. By comparing outcomes across these alternative futures, DMDU quantifies water quality impacts compared to historic conditions, with data interpretation (for example, reservoir elevation and flow conditions by alternative). If an alternative achieves a robustness score of 90 percent or higher, it can be considered truly robust with respect to a particular resource. When the difference in robustness between alternatives exceeds 10 percent, one alternative can be considered more robust than another. If the difference is less than 10 percent, the alternatives are considered similarly robust. Models were considered based on a multiagency cooperation of resource impacts.

DMDU figures are presented to provide comprehensive and reliable information about potential system outcomes under each alternative, regardless of future uncertainties. By intentionally disconnecting the analysis from probabilistic interpretation, these figures focus attention on key resource concerns and improve our understanding of how each alternative performs across a range of hydrologic conditions and are presented to provide comprehensive and reliable information about potential system outcomes under each alternative, regardless of future uncertainties.

Robustness Heat Maps

Robustness heat maps evaluate how each alternative performs across a wide range of future scenarios over extended modeling periods, such as decades or the entire simulation horizon (2027–2060). Unlike conditional boxplots, which assess each year independently, heat maps aggregate results according to resource-specific definitions of "acceptability," using thresholds and frequencies to classify scenarios as successful or not. Each alternative is assigned a robustness score, indicating the percentage of futures where performance criteria are met, with higher scores reflecting greater robustness. The heat maps display multiple levels of performance, from the most challenging criteria at the top to the least stringent at the bottom, and use a highlighted row to emphasize key acceptability thresholds or significant comparison points. This color-coded format distills complex modeling results into an accessible, comparative framework, enabling readers to quickly compare alternatives, understand their relative robustness, and make informed decisions.

Vulnerability Bar Plots

Vulnerability bar plots display, for each alternative, the hydrologic conditions, based on a key Lees Ferry natural flow statistic, under which threshold outcomes are classified as preferred minimum performance (blue) or undesirable performance (red), such as during the worst 10-year drought. This visual division highlights the specific scenarios that lead to vulnerability, with larger blue regions indicating greater robustness. Accompanying boxplots provide context by relating these vulnerability thresholds to recent observations and a wide range of plausible future scenarios. The primary purpose of the vulnerability bar plot is to clarify the conditions under which an alternative is likely to fail and to determine whether those conditions fall within the range of what can reasonably be anticipated, thus informing decision-makers about each alternative's limits and resilience.

Grand Canyon Monitoring and Research Center Dissolved Oxygen and Temperature Models for Glen Canyon, Lees Ferry, and Grand Canyon

Dissolved Oxygen Model

Generalized linear mixed models were constructed to predict metalimnion dissolved oxygen content at the reservoir forebay (site name "Wahweap" LPCR0024). 176 water quality profiles were used from July, August, September, and October 1967–2023 to calculate the mean metalimnion dissolved oxygen concentration. Profiles were generally collected monthly at Wahweap, although some data gaps exist. Prior to 2010, water quality profiles were conducted by manually taking a reading every time one of the water quality parameters changed by a predetermined amount. After October 2010, a 4-Hertz profiler was used to collect measurements in continuous mode and bin data into 0.5-meter increments. The metalimnion depth in Lake Powell can vary widely, with deeper and more diffused metalimnions in years with large spring inflows. Dissolved oxygen concentrations were averaged between 7- and 50-meter, taking a broad definition of the metalimnion to encompass the order of magnitude differences observed in spring inflow volume (Deemer et al. 2025; Deemer et al. 2026).

Generalized linear mixed models were built to predict dissolved oxygen concentrations as a function of day of year, minimum reservoir elevation in that year, volume of spring inflow (calculated as total inflow from April to July), reservoir age (calculated in years since 1963), and 3 interaction terms: age by elevation, spring inflow by elevation, and age by spring inflow interaction with year as a random effect. Metalimnion water temperatures were positively correlated with the volume of the spring inflow (Pearson correlation = 0.61), so water temperature was not included in modeling efforts, given its weaker relationship to mean metalimnion dissolved oxygen concentration. At a yearly scale, the Pearson correlation between inflow and mean dissolved oxygen was −0.26, whereas the Pearson correlation between water temperature and mean dissolved oxygen was −0.19. Before modeling, all noninteractive predictors were standardized by subtracting the mean predictor value and dividing by the standard deviation of the predictor value. Interactions were then calculated as the product of the standardized predictors. Day of year was represented as the calendar day (183–304) standardized. The standardized calendar day was then squared for a second predictor term. Modeling was done in R 4.3.0 (R Core Team 2020) using the lmer function, and best models were selected based on Akaike information criterion values and a priori 2-stage buildup model selection strategy. All main effects were considered in the first stage, and any models within 5 Akaike information criterion of the best model were carried forward, and in the second stage all potential 2-way interactions among main effects selected in the first stage were considered as additions to the models identified in the first stage (Deemer et al. 2025; Deemer et al. 2026).

To test for monsoonal influence on reservoir dissolved oxygen concentrations, a proxy for local monsoon activity was developed using daily discharge data from July, August, and September from the Paria River near Kanab, Utah (gage 09381800); the Escalante River near Escalante, Utah (gage 09337500); Chinle Creek near Mexican Water, Arizona (gage 09379200); the San Rafael River near the Green River, Utah (gage 09328500); and the Dirty Devil River Above Poison Springs Wash near Hanksville, Utah (gage 09333500) from 1980 to 2023. The 43-year average monsoon (July to September) flow at these sites varied from 0.23 cubic meters per second at the Escalante to 2.59 cubic meters per second at the San Rafael. Flows were normalized from all gages to the average flow across all gages (1.39 cubic meters per second) by multiplying each daily discharge measurement by 1.39 and dividing by the site-specific long-term average. The mean normalized daily flow was then

calculated during July, August, and September across the 5 gages. The described generalized linear mixed modeling model selection strategy was repeated with this added monsoonal predictor using the subset of the data from 1980 forward (Deemer et al. 2025; Deemer et al. 2026).

Following the same procedure as for the reservoir forebay, generalized linear mixed models were constructed to predict metalimnion dissolved oxygen concentration at six additional sites within Lake Powell with at least 40 separate years of available profile data from at least 1 month spanning July to October. Five of the six sites were on the Colorado River arm, and one site was on the San Juan River arm of Lake Powell (Deemer et al. 2025; Deemer et al. 2026).

To support predictive modeling of dissolved oxygen in dam releases, six depth-specific models of monthly metalimnion dissolved in the reservoir forebay were constructed using the same model selection approach described earlier. Models were set up to predict dissolved oxygen in 10-meter depth bins starting 6 meters below the reservoir surface and extending down to 66-meters. Instead of predicting mean dissolved oxygen across the period, the models were set to predict the minimum monthly means, given concern over the minimum dissolved oxygen levels that may be released through the dam to the tailwater. The models can then be combined with reservoir elevation information and the associated depth of the penstock water release structures to predict the likelihood that dissolved oxygen concentrations will drop below threshold values each season. The probability of falling below a particular threshold was then determined from the cumulative probability distribution described by a predicted minimum and the estimated standard deviation associated with a model (that is, ignoring parameter uncertainty, a relatively small source of error; Deemer et al. 2025; Deemer et al. 2026).

Water Temperature Model

The Dibble et al. 2020 water temperature model, an equilibrium temperature model with empirically estimated parameters, was developed by fitting relationships to monthly average water temperature data collected from 1985 to 2015 at 44 gages along the Colorado, Gunnison, Green, Yampa, Duchesne, White, San Juan, and Animas rivers. Solar radiation and air temperature represent the primary components in the simplified heat budget that determines river temperature. The model also accounted for major tributaries (that is, mean annual flow greater than or equal to 10 percent of the mainstem river). To estimate model suitability, the model was first fit to data from odd years. Data from even years were used to calculate the root mean square error and overall bias of out-of-sample prediction aggregated by river segment and month of year. Then, the model was fit using all data, producing estimates with similar means but higher precision. The estimates were used to predict water temperatures for the current period (1985 to 2015) at a 1-river-kilometer resolution along 2,560 river-kilometer of river (Dibble 2020).

Future water temperature scenarios were determined by using air temperature predictions from phases 3 and 5 of the Coupled Model Intercomparison Project models to understand how air temperatures may change by mid-century (2040 to 2059) relative to 1950 to 1999. On average, air temperatures in the Basin are predicted to increase by 1.85 to 3.01 °C (35.3 to 37.4 °F) per month by mid-century, averaging approximately 2.6 °C (36.7 °F) on an annual basis. An annual air temperature increase of approximately 2.6 °C (36.7 °F) would reduce mean annual flow in the Basin by approximately 17 percent through greater evaporation, evapotranspiration, and sublimation, among others. Inputs into the model

considering climate only used predicted increases in monthly air temperature, combined with predicted declines in Colorado River flow. Inputs into the storage plus climate scenario used nonlinear regression (least squares) to predict reservoir release temperatures as a function of storage elevation by month, which permitted an assessment of the degree to which changes in reservoir storage affect riverine thermal regimes relative to warming alone. This analysis included data spanning 1965 to 2015 from five large storage reservoirs in the Basin (Fontenelle, Flaming Gorge, Navajo, Glen Canyon, and Hoover). The predicted water temperature associated with the lowest recorded storage elevation for each reservoir was used to predict potential warming of releases if storage was deemphasized. As such, the low storage adjustment represents predicted river temperature at the lowest storage after reservoirs initially filled relative to the base model (Dibble 2020).

The Eppeheimer et al., 2025 water temperature model includes the segment of the Colorado River flowing through Glen, Marble, and Grand canyons in Arizona that is bounded by Lake Powell and Lake Mead. Water from the upstream Lake Powell is released through Glen Canyon Dam and flows approximately 475 river-kilometers before entering Lake Mead. Riverine environmental conditions and aquatic communities change dramatically over its length. A dam tailwater segment is located in the first 25 river-kilometers downstream of Glen Canyon Dam and is characterized by clear water, abundant aquatic vegetation, and water temperatures almost entirely determined by reservoir release temperatures. Water temperature is measured every 15 minutes near the bottom of this river segment at the Lees Ferry gage (USGS gage: 09380000) near the location of Lee Ferry that demarcates the Upper and Lower Basins. Since 1973, the tailwater segment was characterized by three decades of very cold water temperatures (95 percent range of daily water temperatures: 7.6 to 11.3 °C [45.7 to 52.34 °F] at the Lees Ferry gage), followed by approximately two decades of cool water temperatures prior to 2022 (95 percent range of daily water temperatures: 8.1 to 14.3 °C [46.6 to 57.7 °F] at the Lees Ferry gage) and was managed as a Blue Ribbon rainbow trout fishery. Downstream from the tailwater segment and the Lees Ferry gage, the river becomes more turbid, aquatic vegetation becomes rare, and water temperatures gradually warm in the summer. Approximately 122 river-kilometers downstream from the Glen Canyon Dam, the Colorado River reaches its confluence with the Little Colorado River, a tributary that was once the only spawning site for humpback chub, and is currently a population center for humpback chub in Grand Canyon. Further downriver, the humpback chub population has increased dramatically over the last decade in a river segment approximately 200 river-kilometers in length. This river segment is frequently referred to as the western Grand Canyon and is approximately centered on the confluence of the Colorado River with Diamond Creek (approximately 386 river-kilometers downstream from Glen Canyon Dam). The two models separately estimate small-mouth bass propagule pressure from Lake Powell to the tail-water segment and the potential for smallmouth bass population growth based on Colorado River temperatures at the Lees Ferry gage, the Little Colorado River confluence, and the Diamond Creek confluence (Eppeheimer et al. 2025).

The model estimated smallmouth bass propagule pressure from Lake Powell by modeling rates of fish passage through Glen Canyon Dam which were assumed to be a function of (1) Lake Powell elevation, (2) predicted river temperatures by fitting and forecasting from a novel model of Glen Canyon Dam release temperatures combined with a previously published model of river warming below Glen Canyon Dam, and (3) estimated the probability of smallmouth bass asymptotic

population growth exceeding one under various scenarios based on predicted daily average water temperatures and a matrix model (Eppeheimer et al. 2025).

Glen Canyon Dam can release water through penstocks and river outlets. Typically, water is passed through the penstocks at a centerline elevation of 3,470 feet to generate hydropower; turbines likely cause high mortality but do not prevent successful fish passage. Water can also be released through the deeper river outlets (centerline of 3,370 feet). However, the river outlets do not generate hydropower, so their use is rare. Results presented here assume all water is passed through the penstocks until reservoir elevations are at or below 3,490 feet, at which point releases switch to river outlets to avoid damaging hydropower infrastructure. Both the smallmouth bass propagule pressure and smallmouth bass population growth models rely on Lake Powell elevations, which we estimated using a water resource operations model used by Basin managers. In the water resource operations model, changes in Lake Powell elevation are modelled monthly as a function of starting elevation, inflows, outflows, bank storage, and evaporative losses. A range of future conditions was considered using combinations of starting elevations at the beginning of a year, annual inflows, and annual outflows. We considered starting elevations ranging from 3,470 (18 percent of capacity) to 3,600 feet (50 percent of capacity). Inflows were based on resampling the past 23 years (2000–2022). Inflows during this period varied from 4 to 15 million acre-feet (maf) per year. In our analyses, we assumed one of two scenarios for annual outflows: (1) 7.48 maf per year outflows with monthly patterns derived from Reclamation's projections (these are the anticipated outflows for the near-term based on current water management agreements) and (2) a potential management scenario in which reservoir levels are held constant over the course of a year by matching monthly dam release volumes with monthly inflow volumes (this scenario will be referred to as "maintain elevation"). We also produced forecasts for 2025 using the 2025 calendar year projected Lake Powell starting elevation of 3,572 feet, 2025 predicted outflows as of October 2024, and 23 historic inflow traces (2000 to 2022) characterizing inflow variability (Eppeheimer et al. 2025).

Impact Analysis Area

The analysis area for water quality is the geographic and temporal scope introduced in **Section 3.2**. Due to the data available, analysis was limited to surface water quality.

While reduced water deliveries could have impacts on downstream municipal users, the analysis does not include an analysis of these impacts since the operations of municipal water providers fall outside of Reclamation's regulatory authority and are carried out independently by these third parties.

Assumptions

- There will be modifications in quantity, timing, temperature, and quality of water released from Glen Canyon Dam and Hoover Dam.

Impact Indicators

- Salinity
- Temperature
- Dissolved oxygen
- Reservoir elevation
- Dilution capacity

TA 6.2.2 Issue 1: How would reservoir storage, reservoir releases, and corresponding changes in river flows downstream of the reservoirs affect salinity?

Increased salinity concentrations from human activities pose a threat to drinking water, irrigation, agricultural production, municipal water supplies, and infrastructure. Reservoirs like Lake Powell and Lake Mead influence salinity by attenuating salinity transport downstream and possibly acting as a source or a sink (Deemer et al. 2020). Reservoirs also modulate the downstream transport of salinity (Deemer et al. 2020) by reducing the baseflow peaks in salinity and increasing the snowmelt troughs (Deemer et al. 2020; Moody and Mueller 1984). On an annual timescale or longer, reservoirs have been found to reduce salinity (for example, a 10 percent reduction in downstream TDS for Lake Powell, Deemer et al. 2020), although the extent to which this effect applies to other Basin reservoirs is unknown. Dam releases are typically from deeper in the water column and generally have elevated salinity concentrations relative to surface waters. As reservoir water levels drop, reservoir salinity can often increase (Zohary and Ostrovsky 2011).

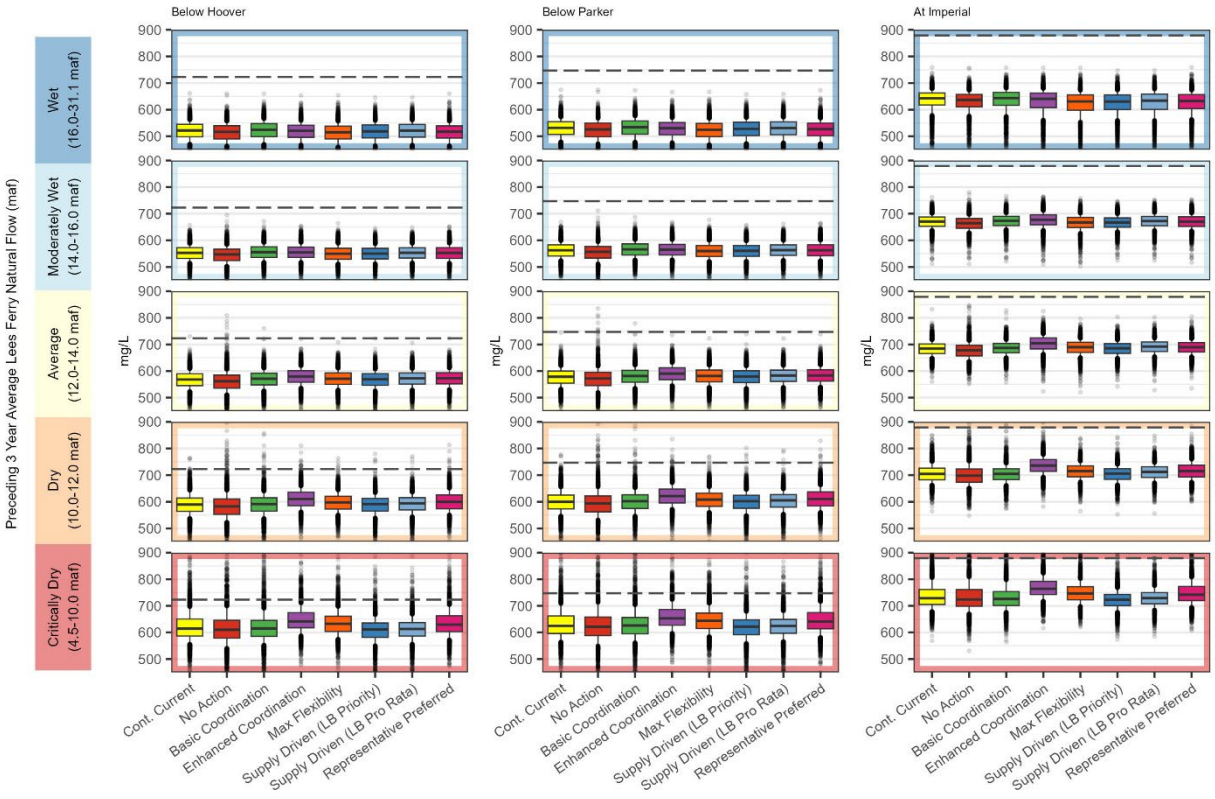

Figure TA 6-4 shows simulated salinity concentrations below Hoover Dam, below Parker Dam, and at Imperial Dam for each alternative using conditional boxplots. The box plots show how the alternatives perform under varying hydrologic conditions, defined by the preceding three-year average of Lees Ferry natural flow. The bottom and top of each box captures the 25th to 75th percentile of the modeled results, respectively. The lines extend to the 10th and 90th percentiles, and outliers are shown as dots. For comparison against the Colorado River Basin Salinity Control Forum's salinity water quality standards, the figure displays critical thresholds as a dashed line representing the salinity thresholds below Hoover Dam, below Parker Dam, and at Imperial Dam[6] (that is, 723 mg/L, 747 mg/L, and 879 mg/L, respectively).

Figure TA 6-4 also shows that below Hoover Dam, under the Average Flow Category only the No Action and Basic Coordination Alternatives exceed the critical salinity threshold, but a majority (90 percent or greater) of simulated futures does not exceed the critical salinity criteria. The highest median salinity concentrations occur in the Enhanced Coordination Alternative, with the greatest difference between alternatives in the Critically Dry Flow Category. Under the Dry Flow Category, all alternatives exceed the critical salinity threshold, but like under the Average Flow Category modeled conditions, a majority (90 percent or greater) of simulated futures does not exceed the salinity criteria. Further, under the Critically Dry Flow Category, more futures exceed the threshold, yet the majority of futures still remain below the critical salinity threshold. Overall, under all alternatives, the interquartile range (the middle half of the outputs, including the median) is narrow and does not exceed the salinity criteria under any of the hydrologic conditions. Therefore, a majority (90 percent or greater) of simulated futures do not exceed the salinity criteria in even the most challenging hydrologic conditions. The dynamics below Parker Dam and at Imperial Dam are similar to that below Hoover Dam where, under all alternatives and all locations, the distributions of annual flow-weight average salinity increases as conditions get drier but of which a majority of

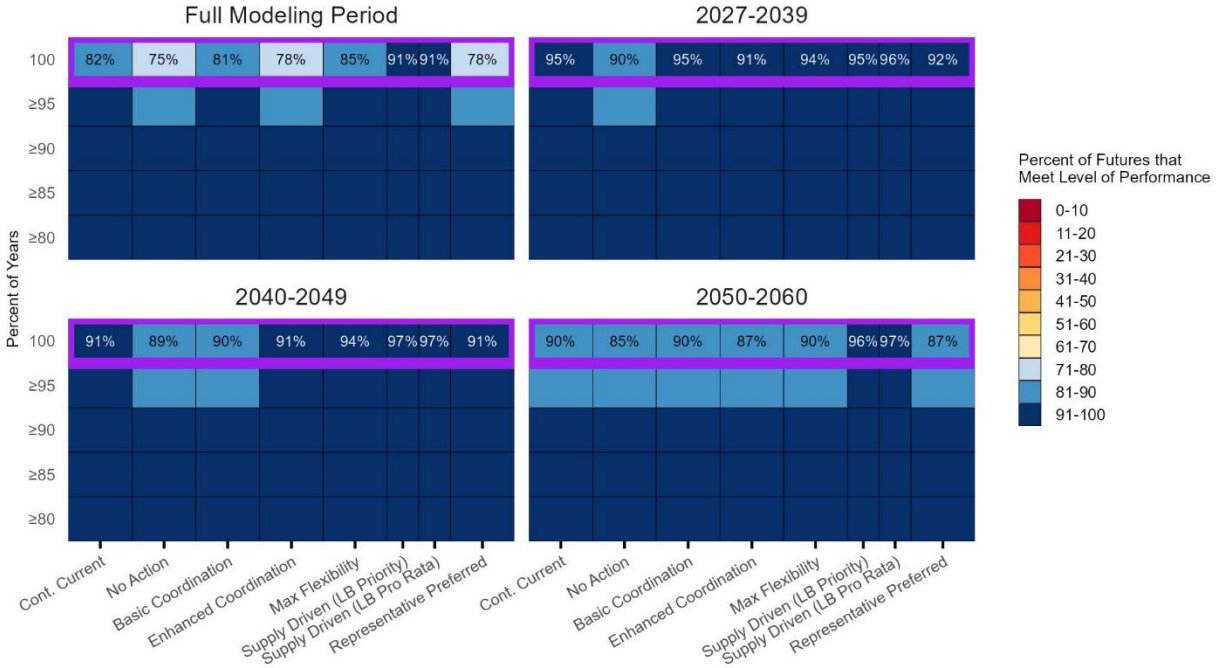
[6] The Colorado River Basin Salinity Control Forum does not have a water quality standard for Glen Canyon Dam; therefore, Glen Canyon Dam was not included in this analysis.

simulated futures does not exceed the critical salinity threshold. See **Table TA 6-2** at the end of this technical appendix for the upper extremes of the outputs shown in **Figure TA 6-4**.

Figure TA 6-4
Annual Flow-Weighted Average Salinity Concentrations

Note: Supply Driven Alternative (LB Priority approach) and Supply Driven Alternative (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

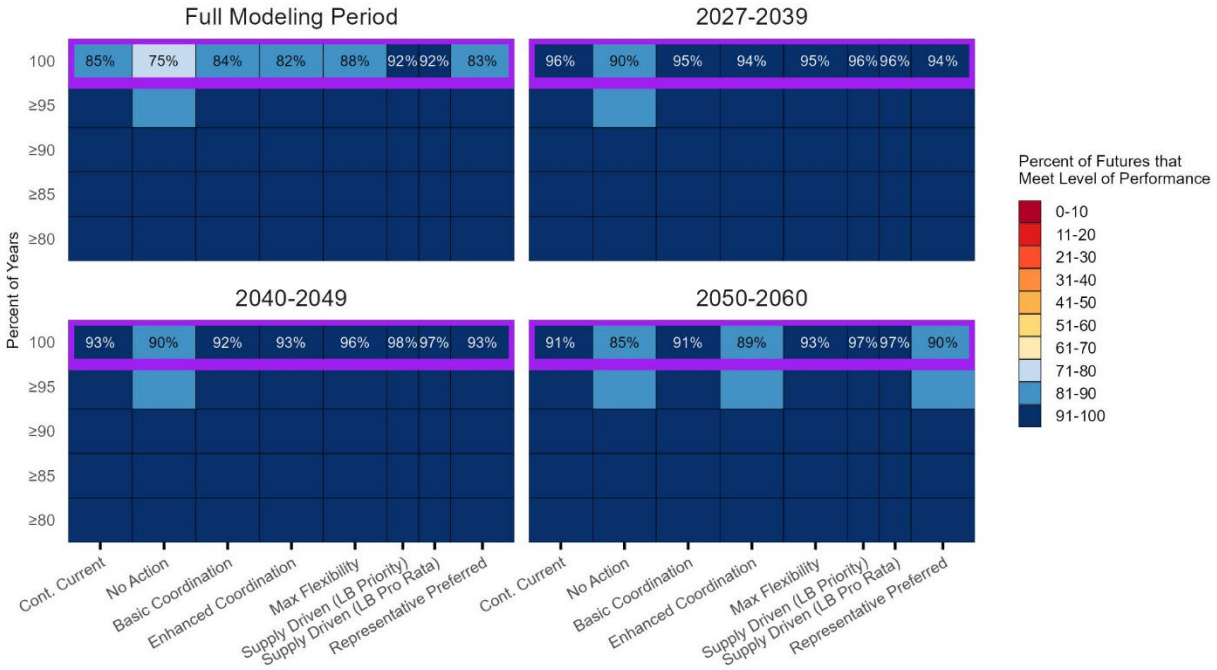
Under the Dry Flow Category, the Representative Preferred Alternative exhibits a median of 600 mg/L and a narrow interquartile range for salinity. Under the Critically Dry Flow Category, the Representative Preferred Alternative exhibits a median of 630 mg/L and a narrow interquartile range. These results are within the range analyzed across the other alternatives from the Draft EIS. The Representative Preferred Alternative falls below the critical salinity threshold under a majority of futures in the Critically Dry Flow Category.



In **Figure TA 6-5**, **Figure TA 6-6**, and **Figure TA 6-7**, the percent of futures in which the salinity concentration is less than 723 mg/L, 747 mg/L and 879 mg/L, respectively, are used to assess performance with respect to meeting the salinity criteria of the Colorado River Basin Salinity Control Forum. The highlighted rows in **Figure TA 6-5**, **Figure TA 6-6**, and **Figure TA 6-7**

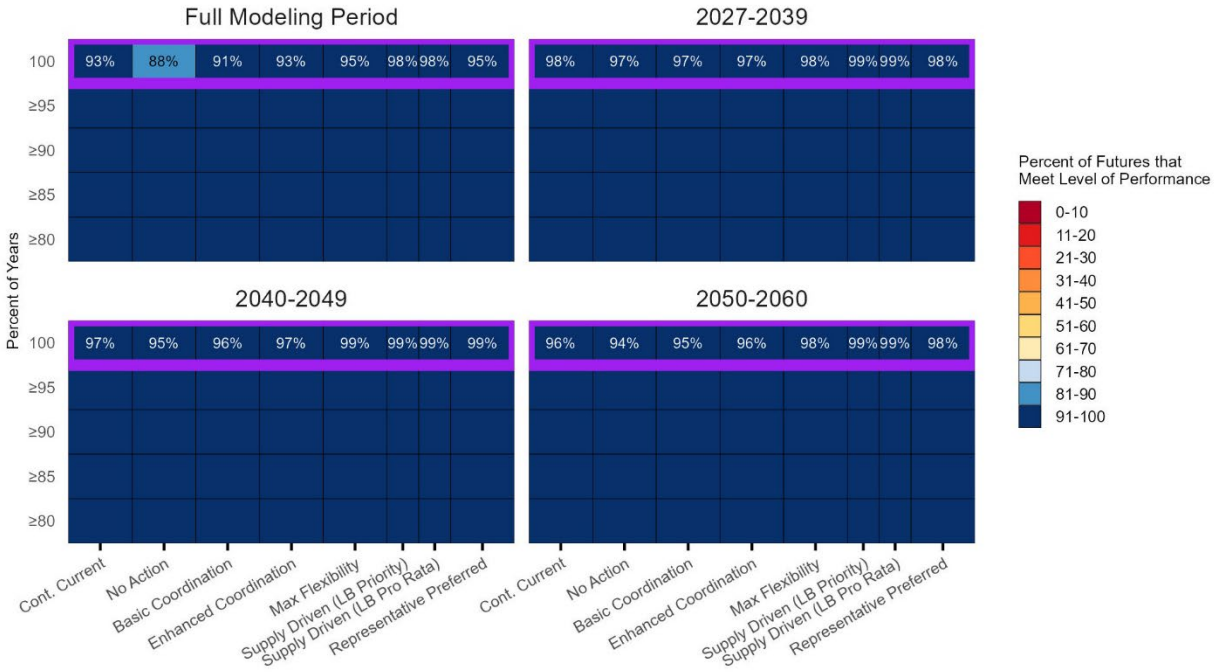
compare alternatives with respect to the salinity concentration in 100 percent of years to compare adherence to the salinity criteria. Lower rows represent lower percentages that are easier to achieve.

Over the first decadal period (that is, 2027 to 2039), **Figure TA 6-5** shows that all alternatives are truly robust, meeting the preferred level of performance in 90 percent of futures or greater. In the three subperiods, the alternatives meet the preferred minimum level of performance in greater percentages of futures because the preferred standard is easier to meet over shorter timespans than over the full 34 years. The Representative Preferred Alternative is less than 723 mg/L over 100 percent of years in 92 percent of modeled futures in the first decade.



It can be inferred that the annual flow-weighted salinity concentrations below Parker Dam and at Imperial Dam are correlated with those below Hoover Dam, as the median salinity values and interquartile ranges consistently increase as hydrologic conditions get drier and follow a similar pattern across all alternatives in **Figure TA 6-4**.

Figure TA 6-5
Salinity Below Hoover: Robustness.
Percent of futures in which the salinity concentration is less than 723 mg/L in the percent of years specified in each row



Note: Supply Driven Alternative (LB Priority approach) and Supply Driven Alternative (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

Figure TA 6-6
Salinity Below Parker: Robustness.
Percent of futures in which the salinity concentration is less than 747 mg/L in the percent of years specified in each row

Note: Supply Driven Alternative (LB Priority approach) and Supply Driven Alternative (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

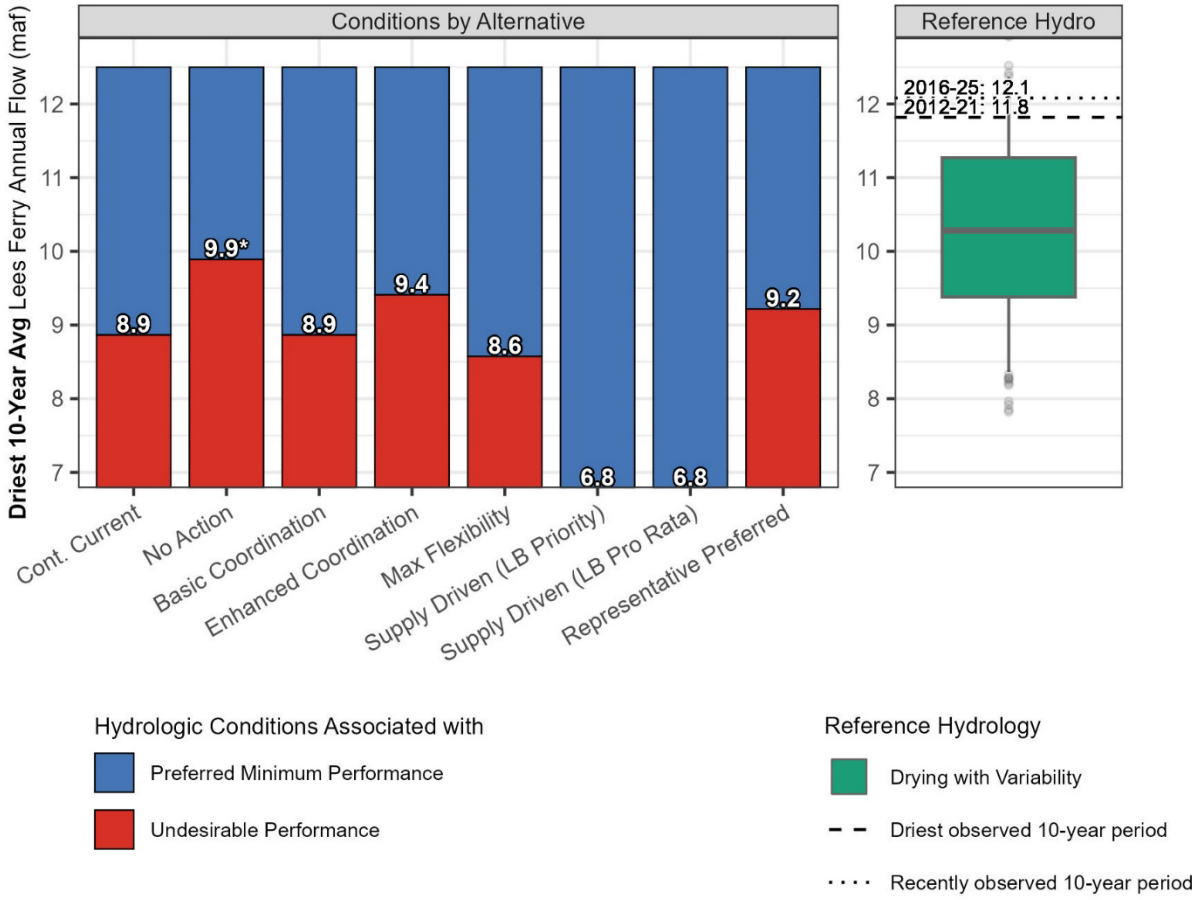


Figure TA 6-7
Salinity at Imperial: Robustness.
Percent of futures in which the salinity concentration is less than 879 mg/L in the percent of years specified in each row

Note: Supply Driven Alternative (LB Priority approach) and Supply Driven Alternative (LB Pro Rata approach) results differ primarily because of how the two shortage-distribution approaches interact with the modeled assumptions governing the storage and delivery of conserved water (see **Appendix B**, Modeling Assumptions: Lake Powell and Lake Mead Storage and Delivery of Conserved Water).

Since the salinity below Parker Dam and at Imperial Dam correlates closely with the simulated salinity concentrations below Hoover Dam, a vulnerability analysis was completed for salinity below Hoover Dam to represent all three sites. **Figure TA 6-8** highlights the preferred minimum performance level of salinity below Hoover Dam above 723 mg/L in one or more years to capture the conditions that would cause a failure to meet the salinity criteria. To identify hydrologic conditions that could cause undesirable performance, the incidence of annual flow-weighted average salinity concentration below Hoover Dam in at least 1 year over the 34-year modeling period was analyzed. The distribution of driest 10-year average volumes in the reference hydrology was identified as a good predictor of undesirable performance. The reference hydrologic panel shows the range of driest 10-year average flows represented in a reference hydrology along with the most recent and driest observed 10-year periods. The Representative Preferred Alternative is likely to be vulnerable if the driest 10-year average Lees Ferry annual flow is 9.2 maf or less. Compared to the historical periods shown in the reference hydrologic panel, this flow has occurred before. Compared to the Drying with Variability Ensemble that represents potential future hydrologic conditions, less than 25 percent of the traces have a 10-year period drier than the vulnerability threshold for the Representative Preferred Alternative.

Figure TA 6-8
Salinity at Hoover: Vulnerability.
Conditions that Could Cause Salinity Below Hoover Above 723 mg/L in 1 or More Years.

Note: Results of vulnerability analyses are based on dividing data into two categories and identifying hydrologic conditions that skillfully predict which category a future belongs in. The primary calculation is based on ensuring a high level of skill in predicting futures that meet preferred minimum performance (blue portion) and then confirming that the predictions of futures belonging in the undesirable performance category (red portion) are also skillful. The No Action Alternative has lower skill in predicting the undesirable performance category due to frequent and large dead pool-related delivery reductions, which result in a weaker relationship between natural flow at Lees Ferry and flow weighted salinity concentrations below Hoover. There is the same level of confidence for all alternatives in predicting when they will meet preferred minimum performance.

If the future includes a 10-year average flow of 11.8 maf or lower, modeling results do not indicate undesirable performance for all alternatives; over 75 percent of the reference hydrology include averages this low or lower. Further, the hydrologic conditions associated with undesirable performance for the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches) (a 10-year drought averaging 6.8 maf or lower), are drier than any conditions in the observed record or the reference hydrologic ensemble, in which the lowest 10-year drought averaged 7.8 maf, so these alternatives have low vulnerability. The CCS Comparative Baseline, and the No Action, Basic

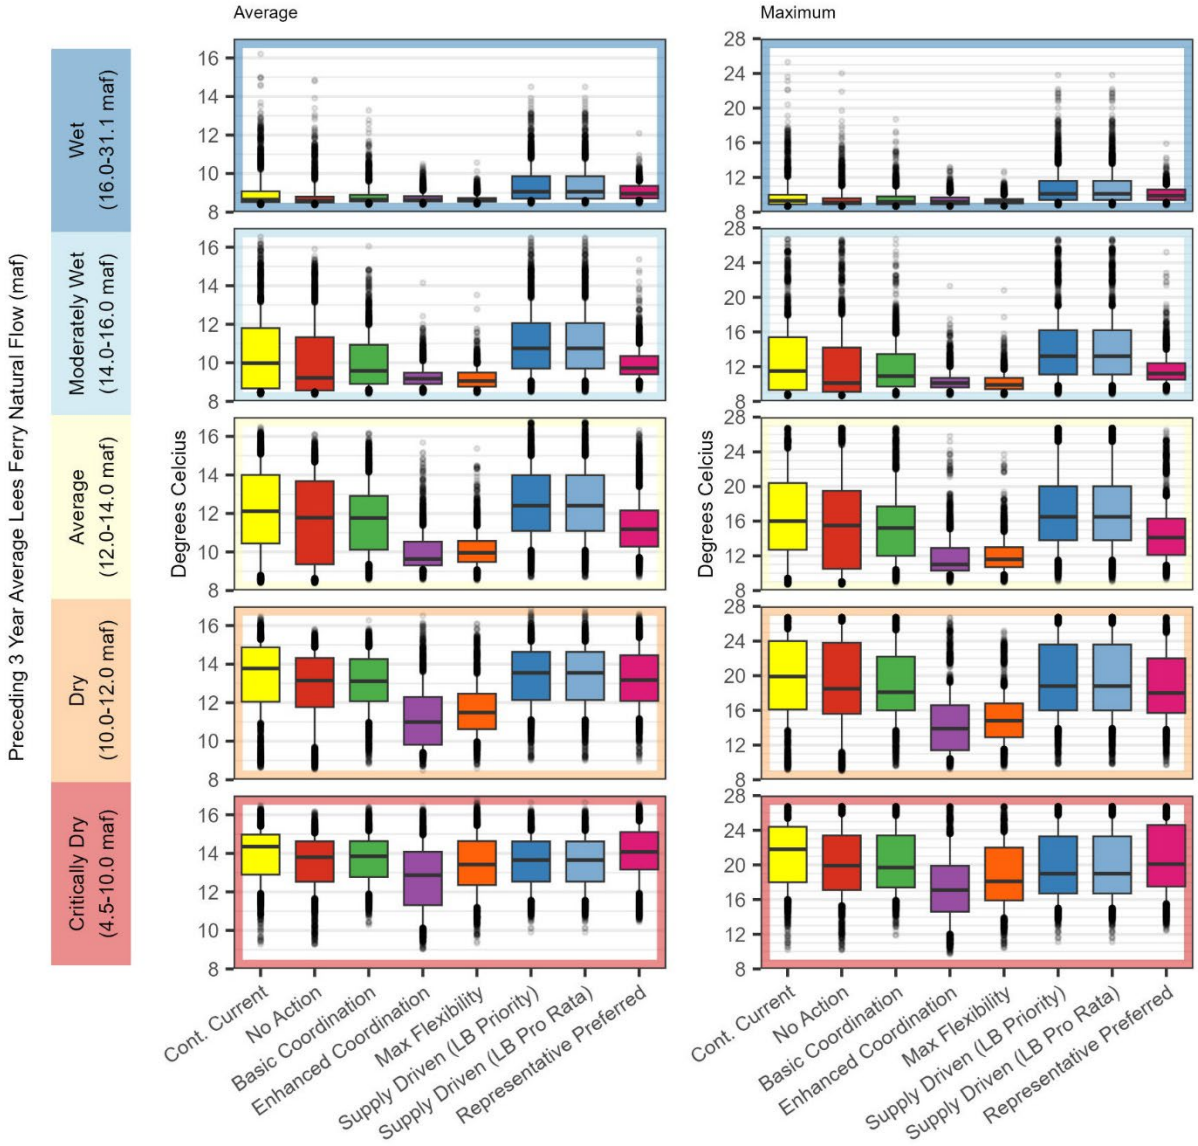
Coordination, Enhanced Coordination, Maximum Operational Flexibility, and Representative Preferred Alternatives are vulnerable to undesirable performance for simulated salinity under a relatively wide range of conditions compared to the least vulnerable alternatives. However, for all alternatives, except the No Action Alternative, more than 75 percent of the traces in the reference hydrology are wetter than these values, so the vulnerability is low. Therefore, no significant negative impacts on salinity were associated with any of the alternatives.

Analysis key takeaways:

- Under the Average Flow Category, the maximum simulated annual flow-weighted salinity concentrations under the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives exceed the salinity threshold below Hoover Dam in less than 10 percent of simulated futures.
- Simulated annual flow-weighted salinity concentrations are greatest under the Critically Dry Flow Category under all alternatives due to the lowest reservoir elevations associated with these hydrologic conditions. Under the Critically Dry Flow Category, simulated average flow-weighted average salinity concentration upper extremes exceed the salinity thresholds at all sites under all alternatives. Under all alternatives, a majority (90 percent or greater) of simulated futures do not exceed the salinity criteria in even the most challenging hydrologic conditions.
- Considering the robustness of simulated salinity results, compared with the other alternatives, simulated futures under the No Action Alternative exceed the salinity threshold below Hoover Dam under the greatest percentage of futures over the full modeling period. However, under all alternatives, a majority of simulated futures do not exceed the salinity criteria established by the Colorado River Basin Salinity Control Forum below Hoover Dam, below Parker Dam, or at Imperial Dam.
- Salinity for releases below Parker Dam and at Imperial Dam are highly correlated with releases below Hoover Dam.
- In a vulnerability analysis of conditions that could cause salinity concentrations below Hoover Dam to exceed 723 mg/L in one or more years, the hydrologic conditions associated with undesirable performance are drier than the median reference hydrologic conditions (that is, a 10-year drought averaging 10.3 maf or lower). Further, the hydrologic conditions associated with undesirable performance for the Supply Driven Alternative (both LB Priority and LB Pro Rata approaches [a 10-year drought averaging 6.8 maf or lower]) are drier than any conditions in the observed record or reference hydrologic ensemble so these alternatives have low vulnerability. The Representative Preferred Alternative is likely to be vulnerable if the driest 10-year average Lees Ferry annual flow is 9.2 maf or less. Compared to the historical periods shown in the reference hydrologic panel, this flow has occurred before.

TA 6.2.3 Issue 2: How would reservoir storage, reservoir releases, and corresponding changes in river flows downstream of the reservoirs affect water temperature?

Water temperature strongly influences biological and chemical processes. For example, the temperature of dam releases affects fish population dynamics in downstream river segments, and elevated reservoir temperatures can lead to harmful algal blooms.



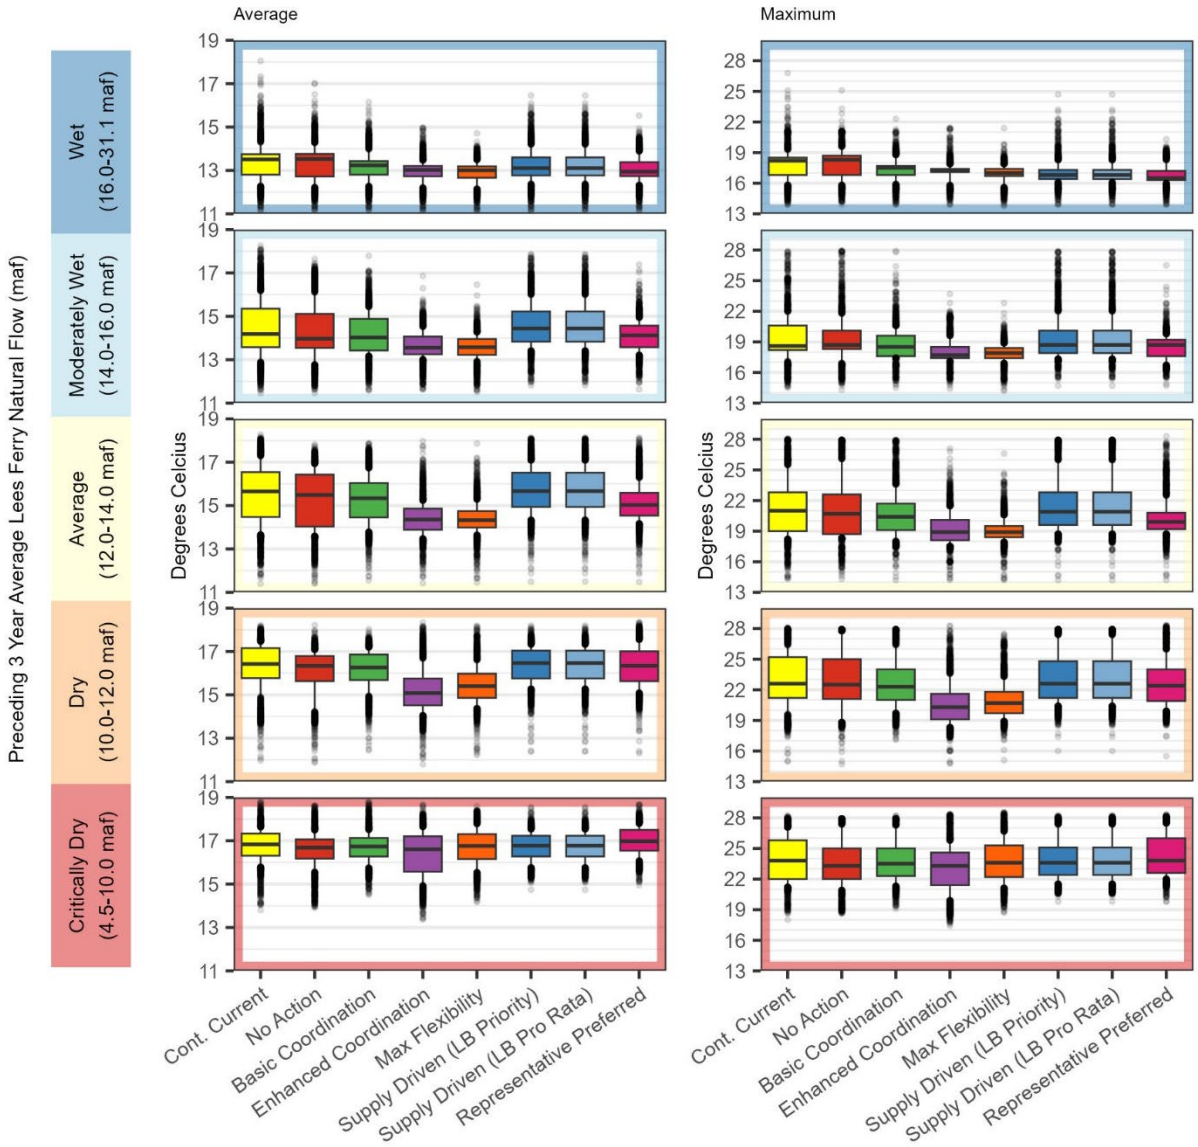
Sections **TA 8.2.3** and **TA 8.2.5**, in **TA 8**, Biological Resources – Fish and Other Aquatic Species, describe the impacts of temperature on fish and other aquatic species at temperature thresholds of 12 °C, 16 °C, and 20 °C (53.6 °F, 60.8 °F, and 68 °F). Exceeding 12 °C (53.6 °F) creates thermal conditions that support mainstream humpback chub growth, which is a desirable response, but exceeding 16 °C (60.8 °F) improves smallmouth bass reproduction at Lees Ferry, which is an undesirable response). For trout species, exceeding the 20 °C (68 °F) threshold reduces rainbow trout survival (exceeding is an undesirable response). According to the life histories of rainbow trout and native Grand Canyon fishes, temperatures above 20 °C (68 °F) are likely to decrease rainbow trout survival while creating conditions more favorable for the growth of native fish and smallmouth bass. Additionally, warmer water temperatures may increase the competitive advantage for brown trout, as this species is more tolerant of elevated temperatures.

Figure TA 6-9 shows simulated Colorado River temperature at Lees Ferry under different hydrologic conditions by looking at the preceding 3-year average of Lees Ferry natural flows. In the Average Flow Category, the median and interquartile ranges for simulated annual average of daily temperatures fall below 12 °C (53.6 °F) for the Enhanced Coordination and Maximum Operational Flexibility Alternatives. Under the Representative Preferred Alternative, the 75th percentile is 12.2 °C (54 °F) with a relatively narrow interquartile range. Under all other alternatives, the interquartile range is large, and exceeds 12 °C (53.6 °F); furthermore, under the CCS Comparative Baseline and Supply Driven Alternative (both LB Priority and LB Pro Rata approaches), the 50th percentile exceeds 12 °C (53.6 °F).

Under the driest hydrologic conditions (Dry Flow Category and Critically Dry Flow Category) at Lees Ferry, the Enhanced Coordination and Maximum Operational Flexibility Alternatives have the lowest median values for the annual average of daily temperatures and the annual maximum temperature. The Enhanced Coordination Alternative also has the largest interquartile range under the Critically Dry Flow Category.

Under the Critically Dry Flow Category, under all alternatives, the majority of the average temperatures are greater than 12 °C (53.6 °F). The Enhanced Coordination Alternative has the lowest median and interquartile range. The variability of the maximum values for Colorado River temperature at Lees Ferry is similar to that of the average Colorado River temperature at Lees Ferry. The CCS Comparative Baseline has the highest annual maximum median temperature among all alternatives.

Figure TA 6-9
Average* and Maximum Colorado River Temperature at Lees Ferry**



*Average temperature refers to the annual average of daily temperatures.
**Maximum temperature refers to the annual maximum of daily temperature.

Under the Dry Flow Category, the Representative Preferred Alternative exhibits a median annual average of daily temperatures of 13.2 °C (55.8 °F) with a large interquartile range. Further, under the Critically Dry Flow Category, the Representative Preferred Alternative exhibits a median annual average of daily temperatures of 14.1 °C (57.4 °F) with a similarly large interquartile range. These results are within the range analyzed across the other alternatives from the Draft EIS. The 50th percentile of the Preliminary Proposed Preferred Alternative is greater than 12 °C (53.6 °F) in the Critically Dry Flow Category.

As shown in **Figure TA 6-10**, simulated Colorado River temperature at Pearce Ferry trends similarly to Lees Ferry under all alternatives and hydrologic categories. The Enhanced Coordination and Maximum Operational Flexibility Alternatives have the lowest median values for the annual average of daily temperatures and the annual maximum temperature under the Dry Flow Category.

Figure TA 6-10
Average* and Maximum Colorado River Temperature at Pearce Ferry**

*Average temperature refers to the annual average of daily temperatures.
**Maximum temperature refers to the annual maximum of daily temperature.

As shown in **Figure TA 8-9** in **TA 8.2.3**, **TA 8**, Biological Resources – Fish and Other Aquatic Resources, each temperature threshold for fish species was assessed based on the number of days in

which modeled traces exceed the threshold compared to different flow regimes. For drier conditions (that is, the Dry Flow Category and Critically Dry Flow Category), simulated temperatures have higher medians and smaller interquartile ranges than the other hydrologic conditions. Under the driest conditions (that is, the Critically Dry Flow Category), temperatures are expected to exceed 12 °C (53.6 °F) at a higher probability and frequency across all alternatives, with the Enhanced Coordination Alternative having the greatest interquartile range of 124.5 to 220 days.

TA 8.2.3, in **TA 8**, Biological Resources – Fish and Other Aquatic Resources, **Figure TA 8-10** shows the percent of futures in which water temperature does not exceed 20 °C (68 °F), which is the temperature threshold that reduces rainbow trout survival, in one or more days in the modeling period. The 20 °C (68 °F) threshold was analyzed as this is the temperature likely to decrease rainbow trout and native Grand Canyon fishes' survival based on life histories of both fish. The Enhanced Coordination Alternative meets the preferred minimum performance for fish (that is, not exceeding 20 °C [68 °F] in one or more days out of the first decadal period [that is, 2027-2039]) in 62 percent of simulated futures. The Enhanced Coordination Alternative has the greatest number of simulated futures that maintains cooler water temperatures at Lees Ferry, which is beneficial for rainbow trout and limits smallmouth bass reproduction, but these temperatures also inhibit native fish growth and reproduction. Alternatives with larger simulated river flows and higher Lake Powell elevations generally maintain cooler water temperatures in more simulated futures than alternatives with lower simulated river flows and Lake Powell elevations. However, during extended droughts, every alternative has a greater number of simulated futures with undesirable temperature increases, affecting fish habitat and species composition. See **TA 8.2.3** and **TA 8.2.5**, **TA 8**, Biological Resources – Fish and Other Aquatic Species, for more detailed information on changes in water temperature from Glen Canyon Dam downstream through the Grand Canyon to Pearce Ferry and impacts on sportfish, native Grand Canyon fishes, and nonnative predatory fish.

TA 14.2.2, in **TA 14**, Recreation, describes the impact of temperature on recreation, particularly impacts on sportfish populations. Water temperatures exceeding 20 °C (68 °F) can cause thermal stress and mortality of rainbow trout while creating conditions more favorable for the growth of nonnative fish and smallmouth bass. Additionally, warmer water temperatures may increase the competitive advantage for brown trout, as this species is more tolerant of elevated temperatures. Over the full modeling period, the Enhanced Coordination Alternative has the greatest number of simulated futures that maintain cooler water temperatures at Lees Ferry, which is beneficial for sportfish, like rainbow trout, and limits smallmouth bass reproduction. See **TA 14.2.2**, in **TA 14**, Recreation, for more detailed information on temperature impacts on recreation associated with sportfish populations.

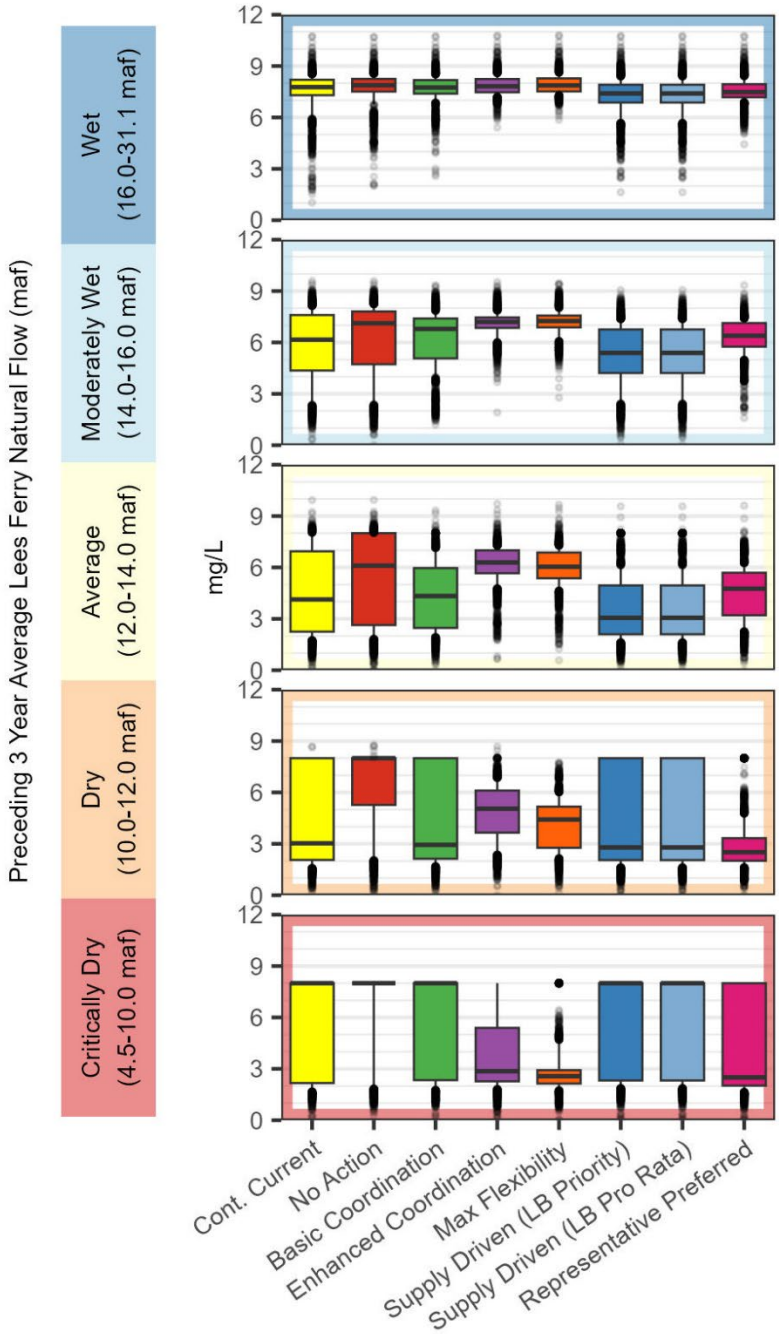
Analysis key takeaways:

- In the Average Flow Category, the Enhanced Coordination and Maximum Operational Flexibility Alternatives have lower median simulated annual average and maximum daily temperatures, with a narrower interquartile range, compared with other alternatives at both Lees Ferry and Pearce Ferry.
- Under Dry and Critically Dry Flow Categories, the Enhanced Coordination Alternative have the lowest median values for simulated annual average of daily temperatures and maximum

temperatures. Additionally, the interquartile ranges increases across all alternatives, indicating more variability in annual average of daily temperatures and maximum temperatures as flow conditions become drier.

- The Enhanced Coordination Alternative has the greatest number of simulated futures that maintained cooler water temperatures at both Lees Ferry and Pearce Ferry, which is beneficial for rainbow trout and limits smallmouth bass reproduction, but these temperatures also inhibit native fish growth and reproduction.

TA 6.2.4 Issue 3: How would reservoir storage, reservoir releases, and corresponding changes in river flows downstream of the reservoirs affect dissolved oxygen?



Dissolved oxygen dynamics can be affected by reservoir drawdowns through several pathways, including remobilization of deposited sediment as water levels change. Lower reservoir elevations may result in plumes of low dissolved oxygen from resuspended sediment at the penstock elevation. Thus, the effects of reservoir storage will likely vary based on inflow conditions, with an increased potential for greater variability between annual minimum and maximum concentrations (Deemer et al. 2025). As older reservoirs like Lake Powell experience lower elevations, there is greater metalimnion dissolved oxygen consumption, with larger spring snowmelt inflows furthering dissolved oxygen declines (Deemer et al. 2025). Dissolved oxygen is also affected by certain operations. For example, as reservoir levels decrease below 3,490 feet at Lake Powell, use of the river outlet works is triggered, which leads to high dissolved oxygen concentrations downstream of the Glen Canyon Dam due to aeration as water passes through the river outlet works (Vernieu 2010).

Figure TA 6-11 displays the response of minimum annual dissolved oxygen concentrations released from Glen Canyon Dam to different hydrologic conditions under the alternatives by looking at the preceding 3-year average of Lees Ferry natural flows.

Under the Average Flow Category modeled conditions, the 50th percentile of minimum annual dissolved oxygen concentration released from Glen Canyon Dam is lowest (that is, around 3 to 5 mg/L) for CCS Baseline and the Basic Coordination and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives; the interquartile range is relatively wide compared with most of the other alternatives. The 50th percentile is highest and the interquartile range is most narrow for the Enhanced Coordination and Maximum Operational Flexibility Alternatives compared with the other alternatives. The 50th percentile is similar to that of the Enhanced Coordination and Maximum Operational Flexibility Alternatives for the No Action Alternative, but the interquartile range is largest.

Analysis of minimum annual dissolved oxygen concentrations under various hydrologic scenarios shows that, in wetter years (that is, the Wet Flow Category), median dissolved oxygen levels are similar across all alternatives, generally falling between 7 and 8 mg/L (see **Figure TA 6-11**).

Figure TA 6-11
Minimum Annual Dissolved Oxygen Concentration Released from Glen Canyon Dam*

*8 mg/L is used as a conservative minimum when Lake Powell's elevation drops below 3,490 feet and dam operations use the river outlet works to pass water through the dam (Deemer et al. 2025). Under the Basic Coordination and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives, and the CCS Comparative Baseline, the median, upper quartile, and maximum values are 8 mg/L in the Critically Dry Flow Category; therefore, the upper quartile is collapsed to a single point that is the same value as the median. Under the No Action Alternative, the maximum, the upper quartile, median, and lower quartile values are 8 mg/L in the Critically Dry Flow Category; therefore, the box is collapsed to a single point and represented as a single horizontal line.

Under the Dry Flow Category modeled conditions, the 50th percentile value of the minimum annual dissolved oxygen concentration released from Glen Canyon Dam decreases under all alternatives and the interquartile range increases for all alternatives except the No Action Alternative. Under the Critically Dry Flow Category modeled conditions, the 50th percentile for the CCS Baseline, and the No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives is 8 mg/L, since 8 mg/L is used as a conservative minimum when Lake Powell's elevation drops below 3,490 feet and dam operations use the river outlet works to pass water through Glen Canyon Dam (Deemer et al. 2025). However, given the large lower interquartile ranges, it is difficult to predict how each of these alternatives may respond. Under the Critically Dry Flow Category modeled conditions, the 50th percentile is lower and the interquartile range is narrower for the Enhanced Coordination and Maximum Operational Flexibility Alternatives, since Lake Powell's elevation stays above 3,490 feet in a majority of simulated futures, thus dam operations does not use the river outlet works in a majority of simulated futures (see **Figure TA 3-6** in **TA 3.2.1**, **TA 3**, Hydrologic Resources).

Under the Dry Flow Category, the Representative Preferred Alternative exhibits a median minimum annual dissolved oxygen concentration of 2.5 mg/L and a narrow interquartile range. Under the Critically Dry Flow Category, the Representative Preferred Alternative still exhibits a median of 2.5 mg/L but a large interquartile range for minimum annual dissolved oxygen concentration. These results are within the range analyzed across the other alternatives from the Final EIS.

In **Figure TA 6-12**, the minimum annual dissolved oxygen concentration of Glen Canyon Dam releases in at least 90 percent of years is used to assess performance because it captures the lowest annual dissolved oxygen concentration within a year. The row with the minimum dissolved oxygen concentrations greater than 2 mg/L is highlighted, as this is considered hypoxia in most streams and rivers (Blaszczak et al. 2023). Over the first decadal period (that is, 2027-2039), the Enhanced Coordination and Maximum Operational Flexibility Alternatives are the most robust, meeting the preferred level of performance in 82 percent and 76 percent of futures, respectively. The CCS Comparative Baseline and No Action Alternative meet it in 29 percent and 48 percent of futures, respectively. The Basic Coordination is similarly robust to the CCS Comparative Baseline, meeting the preferred level of performance in 38 percent of futures. The Supply Driven (both LB Priority and LB Pro Rata approaches), and Representative Preferred Alternatives are similarly robust to the No Action Alternative, meeting the preferred level of performance in 46 percent and 49 percent of futures, respectively. The first decadal period begins with relatively low reservoir elevations, which results in poorer first-decade performance.

When Lake Powell's elevation drops below 3,490 feet, dam operations will use the river outlet works to pass water through the dam. To capture this change to dam operations and aeration of water through the river outlet works, the Grand Canyon Monitoring and Research Center Dissolved Oxygen Model (Deemer et al. 2025) uses 8 mg/L as a conservative minimum. This 8 mg/L assumption can be seen in **Figure TA 6-11** and **Figure TA 6-12** under the Critically Dry Flow Category, where reservoir elevations fall below 3,490 feet under the No Action, Basic Coordination, Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives, and the CCS Comparative Baseline. While dissolved oxygen would increase because releases from the river outlet works would effectively aerate Glen Canyon Dam releases, this assumption does not capture the infrastructure concerns

associated with the uncertainty of extended operations through the river outlet works as the sole means of sustained water releases from Glen Canyon Dam that could compromise the reliability and operational flexibility of Glen Canyon Dam and affect the ability to meet critical downstream water supply needs, as described in **Chapter 1**, **Section 1.8.4.1.** Further, as described in **Chapter 2**, Reclamation maintains the authority to modify operations to protect Glen Canyon Dam infrastructure. Therefore, due to the limitation of long-term use of the river outlet works, a minimum annual dissolved oxygen concentration greater than 2 mg/L and elevations below 3,490 feet at Lake Powell were considered, as shown in **Figure TA 6-13**. Under these assumptions, the Enhanced Coordination and Maximum Operational Flexibility Alternatives are the most robust, meeting the preferred level of performance in 79 percent and 76 percent of futures, respectively, for the first decadal period (that is, 2027-2039). Similar to analyzing minimum dissolved oxygen concentrations alone, the simulated minimum dissolved oxygen concentrations are greater than 2 mg/L and elevations above 3,490 feet at Lake Powell in the fewest number of futures under the CCS Comparative Baseline, and Basic Coordination Alternative. The No Action, Supply Driven (both LB Priority and LB Pro Rata approaches), and Representative Preferred Alternatives meet the preferred level of performance in 20 percent, 34 percent, and 44 percent of futures, respectively.

Figure TA 6-12
Dissolved Oxygen Concentration in Glen Canyon Dam Releases: Robustness. Percent of futures in which the minimum annual dissolved oxygen concentration is greater than the value specified in each row in at least 90 percent of years

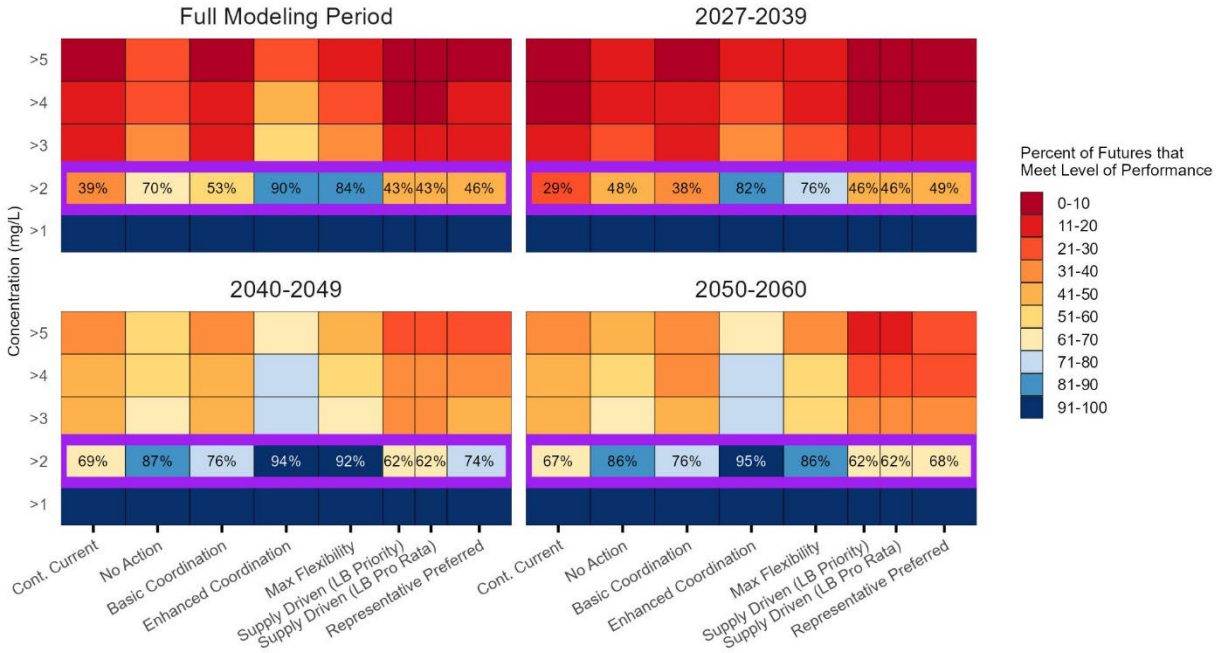


Figure TA 6-13
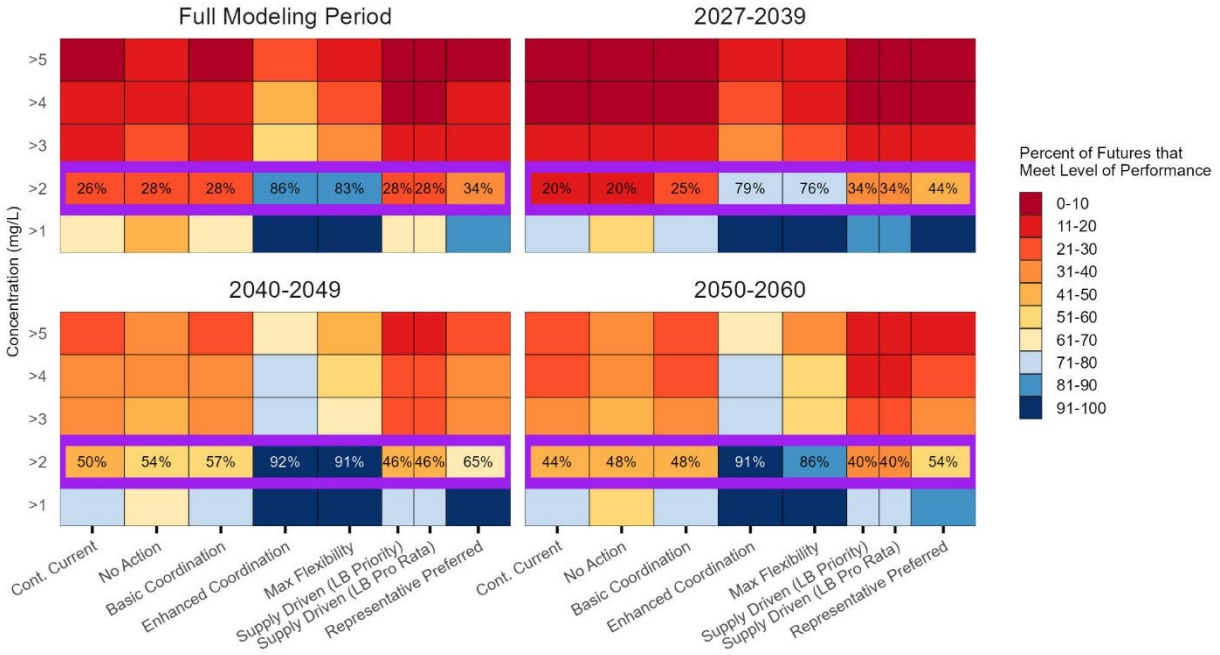
Lake Powell 3,490 and Dissolved Oxygen Concentration: Robustness. Percent of futures in which Lake Powell elevation stays above 3,490 feet and the minimum annual dissolved oxygen concentration is greater than the value specified in each row in at least 90 percent of years



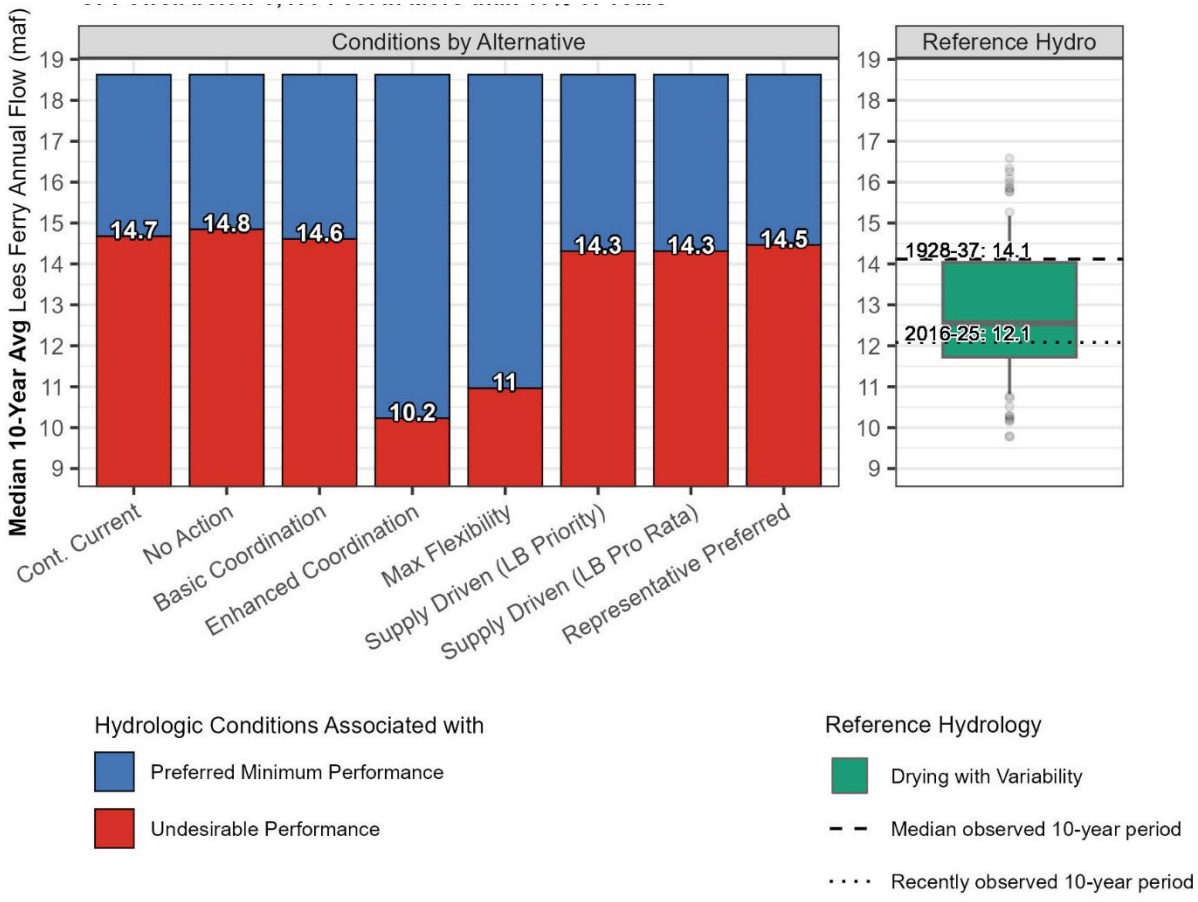


Figure TA 6-14 highlights the preferred minimum performance level of minimum annual dissolved oxygen concentrations released from Glen Canyon Dam less than 2 mg/L or Lake Powell elevation below 3,490 feet, because 2 mg/L is considered hypoxia in most streams and rivers (Blaszczak et al. 2023) and there is a limitation to long-term use of the river outlet works at Lake Powell elevations below 3,490 feet. To identify hydrologic conditions that could cause undesirable performance, the incidence of minimum dissolved oxygen less than 2 mg/L or Lake Powell elevation below 3,490 feet in more than 10 percent of years over the 34-year modeling period was analyzed.

The median 10-year average Lees Ferry natural flow was identified as a good predictor of undesirable performance. The reference hydrologic panel shows the range of median 10-year average flows represented in a reference hydrology along with the median and most recently observed 10-year periods.

If a future includes a 10-year average flow of 14.1 maf or lower, the CCS Baseline and the No Action, Basic Coordination, Supply Driven (both LB Priority and LB Pro Rata approaches), and Representative Preferred Alternatives indicate undesirable performance. About 75 percent of the reference hydrologic traces include averages this low or lower. Therefore, the hydrologic conditions associated with undesirable performance for these alternatives fall within a majority of hydrologic conditions that have already been observed.

As shown on **Figure TA 6-14**, the Enhanced Coordination Alternative would be vulnerable if the median 10-year-average Lees Ferry flow was 10.2 maf or drier, and the Maximum Operational Flexibility Alternatives would be vulnerable if the median 10-year-average Lees Ferry flow was 11 maf or drier. These conditions are drier than 90 percent of the traces in the Drying with Variability Ensemble and below recently observed 10-year-average flow; therefore, these alternatives have low vulnerability.

Figure TA 6-14
Lake Powell 3,490 and Dissolved Oxygen Concentration: Vulnerability. Conditions that Could Cause Dissolved Oxygen Concentration Less than 2 mg/L or Powell below 3,490 Feet in More than 10 percent of Years.

The Representative Preferred Alternative is likely to be vulnerable if the median 10-year-average Lees Ferry flow is 14.5 maf or less. Compared to the historical periods shown in the reference hydrologic panel, this flow has occurred before. Compared to the Drying with Variability Ensemble that represents potential future hydrologic conditions, more than 75 percent of the traces have a 10-year period drier than the vulnerability threshold for the Representative Preferred Alternative.

TA 8.2.3, in **TA 8**, Biological Resources – Fish and Other Aquatic Resources, describes dissolved oxygen impacts on fish. The section also presents dissolved oxygen concentration thresholds of less than 3 mg/L, which can lead to reduced survival and feeding efficiencies, and of 6–9 mg/L, which are optimal for growth and survival at all life stages. Analysis of simulated minimum annual dissolved oxygen concentrations under various hydrologic scenarios shows that, in the Wet Flow Category, the median dissolved levels are similar across all alternatives, generally falling between 7 and 8 mg/L (see **Figure TA 6-11**). However, as shown on **Figure TA 6-13**, Lake Powell elevations stay above 3,490 feet and the simulated minimum annual dissolved oxygen concentration is greater than 3 mg/L in at least 90 percent of the years in a majority of futures under the Enhanced Coordination Alternative; this occurs under the other alternatives in less than 50 percent of futures, which is critical for survival and feeding efficiencies of fish. See **TA 8.2.3**, in **TA 8**, Biological Resources – Fish and Other Aquatic Resources, for more information on the impact of dissolved oxygen on fish.

Analysis key takeaways:

- Under the Wet Flow Category, the alternatives have similar simulated median dissolved oxygen at Lees Ferry. Under drier conditions, the Enhanced Coordination and Maximum Operational Flexibility Alternatives generally have higher simulated minimum annual dissolved oxygen concentrations than the other alternatives when considering futures in which Lake Powell elevations stay above 3,490 feet.
- By controlling for elevation at Lake Powell below 3,490 feet, the effect of bypass tube releases on dissolved oxygen concentrations is not captured, the Enhanced Coordination and Maximum Operational Flexibility Alternatives are the only alternatives under which simulated minimum dissolved oxygen concentrations are greater than 2 mg/L in a majority of futures (greater than 50 percent) for the full modeling period. The simulated minimum dissolved oxygen concentrations are greater than 2 mg/L in the fewest number of futures under the CCS Comparative Baseline, Basic Coordination and the Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives across the full modeling period.
- CCS Comparative Baseline, No Action, Basic Coordination, and Supply Driven Alternatives are vulnerable, the 10-year average Lees Ferry natural flows associated with their undesirable performance have already been observed. The Enhanced Coordination and Maximum Operational Flexibility Alternatives are less vulnerable, with less the driest 10 percent in the Drying with Variability Ensemble below these alternatives' threshold for undesirable performance.
- Under the Critically Dry Flow Category, Lake Powell elevations stay above 3,490 feet and the simulated minimum annual dissolved oxygen concentration is greater than 3 mg/L in at least 90 percent of the years in a majority of futures under the Enhanced Coordination Alternative; this occurs under the other alternatives in less than 50 percent of futures, which is critical for survival and feeding efficiencies of fish. See **TA 8.2.3**, in **TA 8**, Biological Resources – Fish and Other Aquatic Resources, for more information on the effect of dissolved oxygen on fish.

TA 6.2.5 Issue 4: How would reservoir storage, reservoir releases, and corresponding changes in river flows downstream of the reservoirs affect harmful algal blooms and nutrients?

Cyanobacteria blooms can alter physical and chemical water quality properties, threaten aquatic species, and release toxins into water bodies, leading to health effects for recreationists and affecting water supplies. As reservoir water levels decline, the risk of cyanobacterial blooms in reservoirs increases with more severe water level fluctuations and/or declines (Hoffman et al. 2025). However, examples also exist of no marked water quality responses to long-term water level drawdown, including Lake Mead. For example, Lake Mead reservoir has experienced dramatic multiyear reductions in water level with no apparent effects on nutrient or chlorophyll-*a* concentrations (Hannoun and Tietjen 2022). Additionally, contrary to the hypothesis that cyanobacteria would have increased throughout the reservoir, phytoplankton communicated structure remains largely stable, except for shallow areas where increases in temperature or phosphorus levels were observed (van der Nagel et al. 2025)

In **TA 3**, Hydrologic Resources, **Figure TA 3-6** shows that the water year (WY) minimum values for each alternative are similar in wetter hydrology. However, in the Average Flow Category, the Maximum Operational Flexibility and Enhanced Coordination Alternatives exhibit less variability and greater median WY minimum than the other alternatives.

Additionally, **Figure TA 3-6**, Water Year Minimum and End of Water Year Elevations and Storage Volumes of Lake Powell, in **TA 3**, Hydrologic Resources, indicates that in the Critically Dry Flow Category, the median WY minimum Lake Powell elevations are lowest amongst the CCS Comparative Baseline and the No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives. The median WY minimum Lake Powell elevations are highest in the Enhanced Coordination and Maximum Operational Flexibility Alternatives and third highest under the Representative Preferred Alternative. The Enhanced Coordination Alternative is the only alternative under which the median WY minimum Lake Powell elevation is above 3,500 feet. Based on the latest literature review on the impact of lake levels on cyanobacteria and these simulated WY minimums, the CCS Comparative Baseline, and the No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives would have an increased risk for cyanobacterial blooms associated with declining reservoir elevations.

In considering severe water level fluctuations as a marker of increased risk for cyanobacterial blooms in reservoirs, **Figure TA 9-7**, Robustness Heat Map showing Lake Powell maximum Annual Surface Elevation Variability in any 10-year Period, in **TA 9**, Vegetation Including Special Status Species, shows that the Enhanced Coordination and Maximum Flexibility Alternatives have the greatest number of simulated futures in which the maximum annual change in water surface elevation is less than 31.45 feet in 4 years or more out of 10 years during the first decadal period (that is, 2027-2039) compared with the other alternatives. Less severe water level fluctuations are associated with a lower risk of cyanobacterial blooms, which could indicate a decreased risk under the Enhanced Coordination Alternative compared with the other alternatives.

Key analysis takeaways:

- The CCS Comparative Baseline, and the No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives would pose an increased risk of cyanobacterial blooms due to the lower simulated Lake Powell elevations. These increased risks would be greatest under the Critically Dry Flow Category associated with lower reservoir elevations.
- The Enhanced Coordination Alternative has the greatest number of simulated futures in which the maximum annual change in water surface elevation was less than 31.45 feet in 4 years or more out of 10 years during the full modeling period. This could decrease the risk of cyanobacterial blooms associated with severe water level fluctuations under the Enhanced Coordination Alternative compared with the other alternatives.

TA 6.2.6 Issue 5: How would reservoir storage and reservoir releases affect reservoir dilution capacity?

Generally, as reservoir elevations decrease, the dilution capacity of reservoirs like Lake Powell and Lake Mead would also decrease. Decreased dilution capacity from lower reservoir elevations could result in greater concentrations of pollutants of concern, such as PFAS. Therefore, the impacts of reservoir elevations on pollutants, such as PFAS, could be greater in the alternatives with the lowest median WY minimum reservoir elevations (see **Figure TA 3-6**, End of Water Year and Water Year Minimum Elevation and Storage Volumes of Lake Powell, in **TA 3**, Hydrologic Resources), including the CCS Comparative Baseline, and the No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives. Quantifiable water quality impacts related to dilution capacity are not available at the time of this environmental impact statement. However, it is unlikely that any of the reservoir elevations of the alternatives would substantially reduce the dilution capacity and increase the concentration of pollutants of concern.

Key Analysis Takeaways:

- Given the current data and modeling capabilities, the impacts of the alternatives on pollutants of concern could not be quantitatively assessed. The impact of decreased dilution capacity associated with lower reservoir elevations on pollutants of concern, such as PFAS, would be greatest under alternatives with the lowest median WY minimum reservoir elevations, including the CCS Comparative Baseline, and the No Action, Basic Coordination, and Supply Driven (both LB Priority and LB Pro Rata approaches) Alternatives. However, this impact would likely be negligible since it is unlikely that any of the reservoir elevations in the alternatives would significantly reduce dilution capacity or increase the concentration of pollutants of concern.

TA 6.2.7 Summary Comparison of Alternatives

Under the Average Flow Category, the maximum simulated annual flow-weighted salinity concentrations under the CCS Comparative Baseline and the No Action and Basic Coordination Alternatives exceed the salinity threshold below Hoover Dam in one or more simulations. Simulated annual flow-weighted salinity concentrations are greatest under the Critically Dry Flow Category for all alternatives due to the low reservoir elevations associated with these hydrologic conditions.

Under the Critically Dry Flow Category, simulated average flow-weighted average salinity concentration upper extremes exceed the salinity thresholds at all sites under all alternatives. Under all alternatives, a majority (90 percent or greater) of simulated futures does not exceed the salinity criteria in even the most challenging hydrologic conditions. Therefore, no significant negative impacts on salinity are associated with any of the alternatives.

Considering the robustness of simulated salinity results, compared with the other alternatives, simulated futures under the No Action Alternative exceeds the salinity threshold below Hoover Dam under the greatest percentage of futures over the first decadal period (that is, 2027-2039). However, under all alternatives, a majority of simulated futures does not exceed the salinity criteria established by the Colorado River Basin Salinity Control Forum below Hoover Dam, below Parker Dam, or at Imperial Dam. Salinity for releases below Parker Dam and at Imperial Dam are highly correlated with releases below Hoover Dam.

In a vulnerability analysis of conditions that could cause salinity concentrations below Hoover Dam to exceed 723 mg/L, the hydrologic conditions (a 10-year drought average) associated with undesirable performance for the each of the alternatives are drier than any conditions in the observed record or 50 percent of the traces in the Drying with Variability Ensemble, so the alternatives have low vulnerability.
